## Conflicts

The parser produced for an input grammar may contain states in which conflicts occur. The conflicts occur because the grammar is not LALR(1). An ambiguous grammar always contains at least one LALR(1) conflict. The *yacc* utility shall resolve all conflicts, using either default rules or user-specified precedence rules.

Conflicts are either shift/reduce conflicts or reduce/reduce conflicts. A shift/reduce conflict is where, for a given state and lookahead symbol, both a shift action and a reduce action are possible. A reduce/reduce conflict is where, for a given state and lookahead symbol, reductions by two different rules are possible.

The rules below describe how to specify what actions to take when a conflict occurs. Not all shift/reduce conflicts can be successfully resolved this way because the conflict may be due to something other than ambiguity, so incautious use of these facilities can cause the language accepted by the parser to be much different from that which was intended. The description file shall contain sufficient information to understand the cause of the conflict. Where ambiguity is the reason either the default or explicit rules should be adequate to produce a working parser.

The declared precedences and associativities (see **Declarations Section** (on page 1066)) are used to resolve parsing conflicts as follows:

1. A precedence and associativity is associated with each grammar rule; it is the precedence and associativity of the last token or literal in the body of the rule. If the **%prec** keyword is used, it overrides this default. Some grammar rules might not have both precedence and associativity.
2. If there is a shift/reduce conflict, and both the grammar rule and the input symbol have precedence and associativity associated with them, then the conflict is resolved in favor of the action (shift or reduce) associated with the higher precedence. If the precedences are the same, then the associativity is used; left associative implies reduce, right associative implies shift, and non-associative implies an error in the string being parsed.
3. When there is a shift/reduce conflict that cannot be resolved by rule 2, the shift is done. Conflicts resolved this way are counted in the diagnostic output described in **Error Handling**.
4. When there is a reduce/reduce conflict, a reduction is done by the grammar rule that occurs earlier in the input sequence. Conflicts resolved this way are counted in the diagnostic output described in **Error Handling**.

Conflicts resolved by precedence or associativity shall not be counted in the shift/reduce and reduce/reduce conflicts reported by *yacc* on either standard error or in the description file.

## Error Handling

The token **error** shall be reserved for error handling. The name **error** can be used in grammar rules. It indicates places where the parser can recover from a syntax error. The default value of **error** shall be 256. Its value can be changed using a **%token** declaration. The lexical analyzer should not return the value of **error**.

The parser shall detect a syntax error when it is in a state where the action associated with the lookahead symbol is **error**. A semantic action can cause the parser to initiate error handling by executing the macro YYERROR. When YYERROR is executed, the semantic action passes control back to the parser. YYERROR cannot be used outside of semantic actions.

When the parser detects a syntax error, it normally calls *yyerror()* with the character string "syntax error" as its argument. The call shall not be made if the parser is still recovering

41325 from a previous error when the error is detected. The parser is considered to be recovering from  
 41326 a previous error until the parser has shifted over at least three normal input symbols since the  
 41327 last error was detected or a semantic action has executed the macro *yterror*. The parser shall not  
 41328 call *yterror*() when YYERROR is executed.

41329 The macro function YYRECOVERING shall return 1 if a syntax error has been detected and the  
 41330 parser has not yet fully recovered from it. Otherwise, zero shall be returned.

41331 When a syntax error is detected by the parser, the parser shall check if a previous syntax error  
 41332 has been detected. If a previous error was detected, and if no normal input symbols have been  
 41333 shifted since the preceding error was detected, the parser checks if the lookahead symbol is an  
 41334 endmarker (see **Interface to the Lexical Analyzer**). If it is, the parser shall return with a non-  
 41335 zero value. Otherwise, the lookahead symbol shall be discarded and normal parsing shall  
 41336 resume.

41337 When YYERROR is executed or when the parser detects a syntax error and no previous error has  
 41338 been detected, or at least one normal input symbol has been shifted since the previous error was  
 41339 detected, the parser shall pop back one state at a time until the parse stack is empty or the  
 41340 current state allows a shift over **error**. If the parser empties the parse stack, it shall return with a  
 41341 non-zero value. Otherwise, it shall shift over **error** and then resume normal parsing. If the parser  
 41342 reads a lookahead symbol before the error was detected, that symbol shall still be the lookahead  
 41343 symbol when parsing is resumed.

41344 The macro *yterror* in a semantic action shall cause the parser to act as if it has fully recovered  
 41345 from any previous errors. The macro *yyclearin* shall cause the parser to discard the current  
 41346 lookahead token. If the current lookahead token has not yet been read, *yyclearin* shall have no  
 41347 effect.

41348 The macro YYACCEPT shall cause the parser to return with the value zero. The macro  
 41349 YYABORT shall cause the parser to return with a non-zero value.

#### 41350 **Interface to the Lexical Analyzer**

41351 The *yylex*() function is an integer-valued function that returns a *token number* representing the  
 41352 kind of token read. If there is a value associated with the token returned by *yylex*() (see the  
 41353 discussion of *tag* above), it shall be assigned to the external variable *yylval*.

41354 If the parser and *yylex*() do not agree on these token numbers, reliable communication between  
 41355 them cannot occur. For (single-byte character) literals, the token is simply the numeric value of  
 41356 the character in the current character set. The numbers for other tokens can either be chosen by  
 41357 *yacc*, or chosen by the user. In either case, the **#define** construct of C is used to allow *yylex*() to  
 41358 return these numbers symbolically. The **#define** statements are put into the code file, and the  
 41359 header file if that file is requested. The set of characters permitted by *yacc* in an identifier is larger  
 41360 than that permitted by C. Token names found to contain such characters shall not be included in  
 41361 the **#define** declarations.

41362 If the token numbers are chosen by *yacc*, the tokens other than literals shall be assigned numbers  
 41363 greater than 256, although no order is implied. A token can be explicitly assigned a number by  
 41364 following its first appearance in the declarations section with a number. Names and literals not  
 41365 defined this way retain their default definition. All token numbers assigned by *yacc* shall be  
 41366 unique and distinct from the token numbers used for literals and user-assigned tokens. If  
 41367 duplicate token numbers cause conflicts in parser generation, *yacc* shall report an error;  
 41368 otherwise, it is unspecified whether the token assignment is accepted or an error is reported.

41369 The end of the input is marked by a special token called the *endmarker*, which has a token  
 41370 number that is zero or negative. (These values are invalid for any other token.) All lexical  
 41371 analyzers shall return zero or negative as a token number upon reaching the end of their input. If

the tokens up to, but excluding, the endmarker form a structure that matches the start symbol, the parser shall accept the input. If the endmarker is seen in any other context, it shall be considered an error.

### 41375 **Completing the Program**

In addition to *yyparse()* and *yylex()*, the functions *yyerror()* and *main()* are required to make a complete program. The application can supply *main()* and *yyerror()*, or those routines can be obtained from the *yacc* library.

### 41379 **Yacc Library**

The following functions shall appear only in the *yacc* library accessible through the **-ly** operand to *c99*; they can therefore be redefined by a conforming application:

#### 41382 **int main(void)**

This function shall call *yyparse()* and exit with an unspecified value. Other actions within this function are unspecified.

#### 41385 **int yyerror(const char \*s)**

This function shall write the NUL-terminated argument to standard error, followed by a `<newline>`.

The order of the **-ly** and **-ll** operands given to *c99* is significant; the application shall either provide its own *main()* function or ensure that **-ly** precedes **-ll**.

### 41390 **Debugging the Parser**

The parser generated by *yacc* shall have diagnostic facilities in it that can be optionally enabled at either compile time or at runtime (if enabled at compile time). The compilation of the runtime debugging code is under the control of *YYDEBUG*, a preprocessor symbol. If *YYDEBUG* has a non-zero value, the debugging code shall be included. If its value is zero, the code shall not be included.

In parsers where the debugging code has been included, the external **int yydebug** can be used to turn debugging on (with a non-zero value) and off (zero value) at runtime. The initial value of *yydebug* shall be zero.

When **-t** is specified, the code file shall be built such that, if *YYDEBUG* is not already defined at compilation time (using the *c99 -D YYDEBUG* option, for example), *YYDEBUG* shall be set explicitly to 1. When **-t** is not specified, the code file shall be built such that, if *YYDEBUG* is not already defined, it shall be set explicitly to zero.

The format of the debugging output is unspecified but includes at least enough information to determine the shift and reduce actions, and the input symbols. It also provides information about error recovery.

### 41406 **Algorithms**

The parser constructed by *yacc* implements an LALR(1) parsing algorithm as documented in the literature. It is unspecified whether the parser is table-driven or direct-coded.

A parser generated by *yacc* shall never request an input symbol from *yylex()* while in a state where the only actions other than the error action are reductions by a single rule.

The literature of parsing theory defines these concepts.

**Limits**

The *yacc* utility may have several internal tables. The minimum maximums for these tables are shown in the following table. The exact meaning of these values is implementation-defined. The implementation shall define the relationship between these values and between them and any error messages that the implementation may generate should it run out of space for any internal structure. An implementation may combine groups of these resources into a single pool as long as the total available to the user does not fall below the sum of the sizes specified by this section.

**Table 4-22** Internal Limits in *yacc*

| Limit      | Minimum Maximum | Description                                                                                                                                                                                                                                               |
|------------|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| {NTERMS}   | 126             | Number of tokens.                                                                                                                                                                                                                                         |
| {NNONTERM} | 200             | Number of non-terminals.                                                                                                                                                                                                                                  |
| {NPROD}    | 300             | Number of rules.                                                                                                                                                                                                                                          |
| {NSTATES}  | 600             | Number of states.                                                                                                                                                                                                                                         |
| {MEMSIZE}  | 5 200           | Length of rules. The total length, in names (tokens and non-terminals), of all the rules of the grammar. The left-hand side is counted for each rule, even if it is not explicitly repeated, as specified in <b>Grammar Rules in yacc</b> (on page 1068). |
| {ACTSIZE}  | 4 000           | Number of actions. “Actions” here (and in the description file) refer to parser actions (shift, reduce, and so on) not to semantic actions defined in <b>Grammar Rules in yacc</b> (on page 1068).                                                        |

**EXIT STATUS**

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

**CONSEQUENCES OF ERRORS**

If any errors are encountered, the run is aborted and *yacc* exits with a non-zero status. Partial code files and header files may be produced. The summary information in the description file shall always be produced if the **-v** flag is present.

**APPLICATION USAGE**

Historical implementations experience name conflicts on the names **yacc.tmp**, **yacc.acts**, **yacc.debug**, **y.tab.c**, **y.tab.h**, and **y.output** if more than one copy of *yacc* is running in a single directory at one time. The **-b** option was added to overcome this problem. The related problem of allowing multiple *yacc* parsers to be placed in the same file was addressed by adding a **-p** option to override the previously hard-coded **yy** variable prefix.

The description of the **-p** option specifies the minimal set of function and variable names that cause conflict when multiple parsers are linked together. **YYSTYPE** does not need to be changed. Instead, the programmer can use **-b** to give the header files for different parsers different names, and then the file with the **yylex()** for a given parser can include the header for that parser. Names such as **yyclearerr** do not need to be changed because they are used only in the actions; they do not have linkage. It is possible that an implementation has other names, either internal ones for implementing things such as **yyclearerr**, or providing non-standard features that it wants to change with **-p**.

Unary operators that are the same token as a binary operator in general need their precedence adjusted. This is handled by the **%prec** advisory symbol associated with the particular grammar rule defining that unary operator. (See **Grammar Rules in yacc** (on page 1068).) Applications are not required to use this operator for unary operators, but the grammars that do not require it are rare.

#### 41464 EXAMPLES

Access to the *yacc* library is obtained with library search operands to *c99*. To use the *yacc* library *main()*:

```
41467 c99 y.tab.c -l y
```

Both the *lex* library and the *yacc* library contain *main()*. To access the *yacc* *main()*:

```
41469 c99 y.tab.c lex.yy.c -l y -l l
```

This ensures that the *yacc* library is searched first, so that its *main()* is used.

The historical *yacc* libraries have contained two simple functions that are normally coded by the application programmer. These functions are similar to the following code:

```
41473 #include <locale.h>
41474 int main(void)
41475 {
41476 extern int yyparse();
41477 setlocale(LC_ALL, "");
41478 /* If the following parser is one created by lex, the
41479 application must be careful to ensure that LC_CTYPE
41480 and LC_COLLATE are set to the POSIX locale. */
41481 (void) yyparse();
41482 return (0);
41483 }
41484 #include <stdio.h>
41485 int yyerror(const char *msg)
41486 {
41487 (void) fprintf(stderr, "%s\n", msg);
41488 return (0);
41489 }
```

#### 41490 RATIONALE

The references in **Referenced Documents** (on page xxxi) may be helpful in constructing the parser generator. The referenced DeRemer and Pennello article (along with the works it references) describes a technique to generate parsers that conform to this volume of IEEE Std 1003.1-2001. Work in this area continues to be done, so implementors should consult current literature before doing any new implementations. The original Knuth article is the theoretical basis for this kind of parser, but the tables it generates are impractically large for reasonable grammars and should not be used. The “equivalent to” wording is intentional to assure that the best tables that are LALR(1) can be generated.

There has been confusion between the class of grammars, the algorithms needed to generate parsers, and the algorithms needed to parse the languages. They are all reasonably orthogonal. In particular, a parser generator that accepts the full range of LR(1) grammars need not generate a table any more complex than one that accepts SLR(1) (a relatively weak class of LR grammars) for a grammar that happens to be SLR(1). Such an implementation need not recognize the case, either; table compression can yield the SLR(1) table (or one even smaller than that) without

41505 recognizing that the grammar is SLR(1). The speed of an LR(1) parser for any class is dependent  
 41506 more upon the table representation and compression (or the code generation if a direct parser is  
 41507 generated) than upon the class of grammar that the table generator handles.

41508 The speed of the parser generator is somewhat dependent upon the class of grammar it handles.  
 41509 However, the original Knuth article algorithms for constructing LR parsers were judged by its  
 41510 author to be impractically slow at that time. Although full LR is more complex than LALR(1), as  
 41511 computer speeds and algorithms improve, the difference (in terms of acceptable wall-clock  
 41512 execution time) is becoming less significant.

41513 Potential authors are cautioned that the referenced DeRemer and Pennello article previously  
 41514 cited identifies a bug (an over-simplification of the computation of LALR(1) lookahead sets) in  
 41515 some of the LALR(1) algorithm statements that preceded it to publication. They should take the  
 41516 time to seek out that paper, as well as current relevant work, particularly Aho's.

41517 The **-b** option was added to provide a portable method for permitting yacc to work on multiple  
 41518 separate parsers in the same directory. If a directory contains more than one yacc grammar, and  
 41519 both grammars are constructed at the same time (by, for example, a parallel *make* program),  
 41520 conflict results. While the solution is not historical practice, it corrects a known deficiency in  
 41521 historical implementations. Corresponding changes were made to all sections that referenced  
 41522 the filenames **y.tab.c** (now "the code file"), **y.tab.h** (now "the header file"), and **y.output** (now  
 41523 "the description file").

41524 The grammar for yacc input is based on System V documentation. The textual description shows  
 41525 there that the ' ; ' is required at the end of the rule. The grammar and the implementation do not  
 41526 require this. (The use of **C\_IDENTIFIER** causes a reduce to occur in the right place.)

41527 Also, in that implementation, the constructs such as **%token** can be terminated by a semicolon,  
 41528 but this is not permitted by the grammar. The keywords such as **%token** can also appear in  
 41529 uppercase, which is again not discussed. In most places where '**%**' is used, '**\**' can be  
 41530 substituted, and there are alternate spellings for some of the symbols (for example, **%LEFT** can  
 41531 be "**%<**" or even "**\<**").

41532 Historically, **<tag>** can contain any characters except '**>**', including white space, in the  
 41533 implementation. However, since the *tag* must reference an ISO C standard union member, in  
 41534 practice conforming implementations need to support only the set of characters for ISO C  
 41535 standard identifiers in this context.

41536 Some historical implementations are known to accept actions that are terminated by a period.  
 41537 Historical implementations often allow '**\$**' in names. A conforming implementation does not  
 41538 need to support either of these behaviors.

41539 Deciding when to use **%prec** illustrates the difficulty in specifying the behavior of yacc. There  
 41540 may be situations in which the *grammar* is not, strictly speaking, in error, and yet yacc cannot  
 41541 interpret it unambiguously. The resolution of ambiguities in the grammar can in many instances  
 41542 be resolved by providing additional information, such as using **%type** or **%union** declarations. It  
 41543 is often easier and it usually yields a smaller parser to take this alternative when it is  
 41544 appropriate.

41545 The size and execution time of a program produced without the runtime debugging code is  
 41546 usually smaller and slightly faster in historical implementations.

41547 Statistics messages from several historical implementations include the following types of  
 41548 information:

41549 *n*/512 terminals, *n*/300 non-terminals  
 41550 *n*/600 grammar rules, *n*/1500 states  
 41551 *n* shift/reduce, *n* reduce/reduce conflicts reported

41552  $n/350$  working sets used  
 41553 Memory: states, etc.  $n/15\,000$ , parser  $n/15\,000$   
 41554  $n/600$  distinct lookahead sets  
 41555  $n$  extra closures  
 41556  $n$  shift entries,  $n$  exceptions  
 41557  $n$  goto entries  
 41558  $n$  entries saved by goto default  
 41559 Optimizer space used: input  $n/15\,000$ , output  $n/15\,000$   
 41560  $n$  table entries,  $n$  zero  
 41561 Maximum spread:  $n$ , Maximum offset:  $n$

41562 The report of internal tables in the description file is left implementation-defined because all  
 41563 aspects of these limits are also implementation-defined. Some implementations may use  
 41564 dynamic allocation techniques and have no specific limit values to report.

41565 The format of the **y.output** file is not given because specification of the format was not seen to  
 41566 enhance applications portability. The listing is primarily intended to help human users  
 41567 understand and debug the parser; use of **y.output** by a conforming application script would be  
 41568 unusual. Furthermore, implementations have not produced consistent output and no popular  
 41569 format was apparent. The format selected by the implementation should be human-readable, in  
 41570 addition to the requirement that it be a text file.

41571 Standard error reports are not specifically described because they are seldom of use to  
 41572 conforming applications and there was no reason to restrict implementations.

41573 Some implementations recognize " $=\{$ " as equivalent to ' $\{$ ' because it appears in historical  
 41574 documentation. This construction was recognized and documented as obsolete as long ago as  
 41575 1978, in the referenced *Yacc: Yet Another Compiler-Compiler*. This volume of IEEE Std 1003.1-2001  
 41576 chose to leave it as obsolete and omit it.

41577 Multi-byte characters should be recognized by the lexical analyzer and returned as tokens. They  
 41578 should not be returned as multi-byte character literals. The token **error** that is used for error  
 41579 recovery is normally assigned the value 256 in the historical implementation. Thus, the token  
 41580 value 256, which is used in many multi-byte character sets, is not available for use as the value  
 41581 of a user-defined token.

41582 **FUTURE DIRECTIONS**  
 41583 None.

41586 **CHANGE HISTORY**  
 41587 First released in Issue 2.

41588 **Issue 5**  
 41589 The FUTURE DIRECTIONS section is added.

41590 **Issue 6**  
 41591 This utility is marked as part of the C-Language Development Utilities option.  
 41592 Minor changes have been added to align with the IEEE P1003.2b draft standard.  
 41593 The normative text is reworded to avoid use of the term “must” for application requirements.  
 41594 IEEE PASC Interpretation 1003.2 #177 is applied, changing the comment on **RCURL** from the }%  
 41595 token to the %}.

41596 **NAME**

41597           zcat — expand and concatenate data

41598 **SYNOPSIS**41599 xSI       zcat [*file...*]

41600

41601 **DESCRIPTION**

41602       The *zcat* utility shall write to standard output the uncompressed form of files that have been  
 41603       compressed using the *compress* utility. It is the equivalent of *uncompress -c*. Input files are not  
 41604       affected.

41605 **OPTIONS**

41606       None.

41607 **OPERANDS**

41608       The following operand shall be supported:

41609       *file*           The pathname of a file previously processed by the *compress* utility. If *file* already  
 41610       has the *.Z* suffix specified, it is used as submitted. Otherwise, the *.Z* suffix is  
 41611       appended to the filename prior to processing.

41612 **STDIN**41613       The standard input shall be used only if no *file* operands are specified, or if a *file* operand is *'-'*.41614 **INPUT FILES**41615       Input files shall be compressed files that are in the format produced by the *compress* utility.41616 **ENVIRONMENT VARIABLES**41617       The following environment variables shall affect the execution of *zcat*:

41618       *LANG*           Provide a default value for the internationalization variables that are unset or null.  
 41619       (See the Base Definitions volume of IEEE Std 1003.1-2001, Section 8.2,  
 41620       Internationalization Variables for the precedence of internationalization variables  
 41621       used to determine the values of locale categories.)

41622       *LC\_ALL*       If set to a non-empty string value, override the values of all the other  
 41623       internationalization variables.

41624       *LC\_CTYPE*   Determine the locale for the interpretation of sequences of bytes of text data as  
 41625       characters (for example, single-byte as opposed to multi-byte characters in  
 41626       arguments).

41627       *LC\_MESSAGES* Determine the locale that should be used to affect the format and contents of  
 41628       diagnostic messages written to standard error.  
 41629

41630       *NLSPATH*   Determine the location of message catalogs for the processing of *LC\_MESSAGES*.

41631 **ASYNCHRONOUS EVENTS**

41632       Default.

41633 **STDOUT**

41634       The compressed files given as input shall be written on standard output in their uncompressed  
 41635       form.

41636 **STDERR**

41637       The standard error shall be used only for diagnostic messages.

41638 **OUTPUT FILES**

41639           None.

41640 **EXTENDED DESCRIPTION**

41641           None.

41642 **EXIT STATUS**

41643           The following exit values shall be returned:

41644           0   Successful completion.

41645           &gt;0  An error occurred.

41646 **CONSEQUENCES OF ERRORS**

41647           Default.

41648 **APPLICATION USAGE**

41649           None.

41650 **EXAMPLES**

41651           None.

41652 **RATIONALE**

41653           None.

41654 **FUTURE DIRECTIONS**

41655           None.

41656 **SEE ALSO**41657           *compress, uncompress*41658 **CHANGE HISTORY**

41659           First released in Issue 4.

## Abstract

This standard is simultaneously ISO/IEC 9945:2002, IEEE Std 1003.1-2001, and forms the core of the Single UNIX Specification, Version 3.

The IEEE Std 1003.1, 2003 Edition includes IEEE Std 1003.1-2001/Cor 1-2002 incorporated into IEEE Std 1003.1-2001 (base document). The Corrigendum addresses problems discovered since the approval of IEEE Std 1003.1-2001. These changes are mainly due to resolving integration issues raised by the merger of the base documents that were incorporated into IEEE Std 1003.1-2001, which is the single common revision to IEEE Std 1003.1<sup>™</sup>-1996, IEEE Std 1003.2<sup>™</sup>-1992, ISO/IEC 9945-1:1996, ISO/IEC 9945-2:1993, and the Base Specifications of The Open Group Single UNIX<sup>®</sup> Specification, Version 2.

This standard defines a standard operating system interface and environment, including a command interpreter (or “shell”), and common utility programs to support applications portability at the source code level. This standard is intended to be used by both applications developers and system implementors and comprises four major components (each in an associated volume):

- General terms, concepts, and interfaces common to all volumes of this standard, including utility conventions and C-language header definitions, are included in the Base Definitions volume.
- Definitions for system service functions and subroutines, language-specific system services for the C programming language, function issues, including portability, error handling, and error recovery, are included in the System Interfaces volume.
- Definitions for a standard source code-level interface to command interpretation services (a “shell”) and common utility programs for application programs are included in the Shell and Utilities volume.
- Extended rationale that did not fit well into the rest of the document structure, which contains historical information concerning the contents of this standard and why features were included or discarded by the standard developers, is included in the Rationale (Informative) volume.

The following areas are outside the scope of this standard:

- Graphics interfaces
- Database management system interfaces
- Record I/O considerations
- Object or binary code portability
- System configuration and resource availability

This standard describes the external characteristics and facilities that are of importance to applications developers, rather than the internal construction techniques employed to achieve these capabilities. Special emphasis is placed on those functions and facilities that are needed in a wide variety of commercial applications.

## Keywords

application program interface (API), argument, asynchronous, basic regular expression (BRE), batch job, batch system, built-in utility, byte, child, command language interpreter, CPU, extended regular expression (ERE), FIFO, file access control mechanism, input/output (I/O), job control, network, portable operating system interface (POSIX<sup>®</sup>), parent, shell, stream, string, synchronous, system, thread, X/Open System Interface (XSI)

Portions of this standard are derived with permission from copyrighted material owned by Hewlett-Packard Company, International Business Machines Corporation, Novell Inc., The Open Software Foundation, and Sun Microsystems, Inc.

#### Permissions

Authorization to photocopy portions of this standard for internal or personal use is granted provided that the appropriate fee is paid to the Copyright Clearance Center or the equivalent body outside of the U.S. Permission to make multiple copies for educational purposes in the U.S. requires agreement and a license fee to be paid to the Copyright Clearance Center.

Beyond these provisions, permission to reproduce all or any part of this standard must be with the consent of both copyright holders and may be subject to a license fee. Both copyright holders will need to be satisfied that the other has granted permission. Requests to the copyright holders should be sent by email to [austin-group-permissions@opengroup.org](mailto:austin-group-permissions@opengroup.org).

#### Feedback

This standard has been prepared by the Austin Group. Feedback relating to the material contained in this standard may be submitted using the Austin Group web site at <http://www.opengroup.org/austin/defectform.html>.

## IEEE

IEEE Standards documents are developed within the IEEE Societies and the Standards Coordinating Committees of the IEEE Standards Association (IEEE-SA) Standards Board. The IEEE develops its standards through a consensus development process, approved by the American National Standards Institute, which brings together volunteers representing varied viewpoints and interests to achieve the final product. Volunteers are not necessarily members of the Institute and serve without compensation. While the IEEE administers the process and establishes rules to promote fairness in the consensus development process, the IEEE does not independently evaluate, test, or verify the accuracy of any of the information contained in its standards.

Use of an IEEE Standard is wholly voluntary. The IEEE disclaims liability for any personal injury, property, or other damage, of any nature whatsoever, whether special, indirect, consequential, or compensatory, directly or indirectly resulting from the publication, use of, or reliance upon this, or any other IEEE Standard document.

**The IEEE does not warrant or represent the accuracy or content of the material contained herein, and expressly disclaims any express or implied warranty, including any implied warranty of merchantability or fitness for a specific purpose, or that the use of the material contained herein is free from patent infringement. IEEE Standards documents are supplied “AS IS”.**

The existence of an IEEE Standard does not imply that there are no other ways to produce, test, measure, purchase, market, or provide other goods and services related to the scope of the IEEE Standard. Furthermore, the viewpoint expressed at the time a standard is approved and issued is subject to change brought about through developments in the state of the art and comments received from users of the standard. Every IEEE Standard is subjected to review at least every five years for revision or reaffirmation. When a document is more than five years old and has not been reaffirmed, it is reasonable to conclude that its contents, although still of some value, do not wholly reflect the present state of the art. Users are cautioned to check to determine that they have the latest edition of any IEEE Standard.

In publishing and making this document available, the IEEE is not suggesting or rendering professional or other services for, or on behalf of, any person or entity. Nor is the IEEE undertaking to perform any duty owed by any other person or entity to another. Any person utilizing this, and any other IEEE Standards document, should rely upon the advice of a competent professional in determining the exercise of reasonable care in any given circumstances.

Interpretations: Occasionally questions may arise regarding the meaning of portions of standards as they relate to specific applications. When the need for interpretations is brought to the attention of the IEEE, the Institute will initiate action to prepare appropriate responses. Since IEEE Standards represent a consensus of concerned interests, it is important to ensure that any interpretation has also received the concurrence of a balance of interests. For this reason, IEEE and the members of its societies and Standards Coordinating Committees are not able to provide an instant response to interpretation requests except in those cases where the matter has previously received formal consideration.

Comments for revision of IEEE Standards are welcome from any interested party, regardless of membership affiliation with the IEEE.<sup>1</sup> Suggestions for changes in documents should be in the form of a proposed change of text, together with appropriate supporting comments. Comments on standards and requests for interpretations should be addressed to:

Secretary, IEEE-SA Standards Board, 445 Hoes Lane, P.O. Box 1331, Piscataway, NJ 08855-1331, U.S.A.

Attention is called to the possibility that implementation of this standard may require use of subject matter covered by patent rights. By publication of this standard, no position is taken with respect to the existence or validity of any patent rights in connection therewith. The IEEE shall not be responsible for identifying patents for which a license may be required by an IEEE Standard or for conducting inquiries into the legal validity or scope of those patents that are brought to its attention.

A patent holder has filed a statement of assurance that it will grant licenses under these rights without compensation or under reasonable rates and non-discriminatory, reasonable terms and conditions to all applicants desiring to obtain such licenses. The IEEE makes no representation as to the reasonableness of rates and/or terms and conditions of the license agreements offered by patent holders. Further information may be obtained from the IEEE Standards Department.

Authorization to photocopy portions of any individual standard for internal or personal use is granted in the U.S. by the Institute of Electrical and Electronics Engineers, Inc., provided that the appropriate fee is paid to the Copyright Clearance Center.<sup>2</sup> Permission to photocopy portions of any individual standard for educational classroom use can also be obtained through the Copyright Clearance Center. To arrange for payment of the licensing fee, please contact:

Copyright Clearance Center, Customer Service, 222 Rosewood Drive, Danvers, MA 01923, U.S.A., Tel.: +1 978 750 8400

Amendments, corrigenda, and interpretations for this standard, or information about the IEEE standards development process, may be found at <http://standards.ieee.org>.

Full catalog and ordering information on all IEEE publications is available from the IEEE Online Catalog & Store at <http://shop.ieee.org/store>.

1. For this standard, please send comments via the Austin Group as requested on page iii.

2. Please refer to the special provisions for this standard on page iii concerning permissions from both copyright holders and arrangements to cover photocopying and reproduction across the world, as well as by commercial organizations wishing to license the material for use in product documentation.

## The Open Group

The Open Group, a vendor and technology-neutral consortium, is committed to delivering greater business efficiency by bringing together buyers and suppliers of information technology to lower the time, cost, and risks associated with integrating new technology across the enterprise.

The Open Group's mission is to offer all organizations concerned with open information infrastructures a forum to share knowledge, integrate open initiatives, and certify approved products and processes in a manner in which they continue to trust our impartiality.

In the global eCommerce world of today, no single economic entity can achieve independence while still ensuring interoperability. The assurance that products will interoperate with each other across differing systems and platforms is essential to the success of eCommerce and business workflow. The Open Group, with its proven testing and certification program, is the international guarantor of interoperability in the new century.

The Open Group provides opportunities to exchange information and shape the future of IT. The Open Group's members include some of the largest and most influential organizations in the world. The flexible structure of The Open Groups membership allows for almost any organization, no matter what their size, to join and have a voice in shaping the future of the IT world.

More information is available on The Open Group web site at <http://www.opengroup.org>.

The Open Group has over 15 years' experience in developing and operating certification programs and has extensive experience developing and facilitating industry adoption of test suites used to validate conformance to an open standard or specification. The Open Group portfolio of test suites includes the *Westwood* family of tests for this standard and the associated certification program for Version 3 of the Single UNIX Specification, as well tests for CDE, CORBA, Motif, Linux, LDAP, POSIX.1, POSIX.2, POSIX Realtime, Sockets, UNIX, XPG4, XNFS, XTI, and X11. The Open Group test tools are essential for proper development and maintenance of standards-based products, ensuring conformance of products to industry-standard APIs, applications portability, and interoperability. In-depth testing identifies defects at the earliest possible point in the development cycle, saving costs in development and quality assurance.

More information is available at <http://www.opengroup.org/testing>.

The Open Group publishes a wide range of technical documentation, the main part of which is focused on development of Technical and Product Standards and Guides, but which also includes white papers, technical studies, branding and testing documentation, and business titles. Full details and a catalog are available at <http://www.opengroup.org/pubs>.

As with all *live* documents, Technical Standards and Specifications require revision to align with new developments and associated international standards. To distinguish between revised specifications which are fully backwards compatible and those which are not:

- A new *Version* indicates there is no change to the definitive information contained in the previous publication of that title, but additions/extensions are included. As such, it *replaces* the previous publication.
- A new *Issue* indicates there is substantive change to the definitive information contained in the previous publication of that title, and there may also be additions/extensions. As such, both previous and new documents are maintained as current publications.

Readers should note that Corrigenda may apply to any publication. Corrigenda information is published at <http://www.opengroup.org/corrigenda>.

Full catalog and ordering information on all Open Group publications is available at <http://www.opengroup.org/pubs>.

| B.3.1           | Examples for Spawn.....                                   | 206        |
| <b>Part</b>     | <b>C Shell and Utilities.....</b>                         | <b>217</b> |
| <b>Appendix</b> | <b>C Rationale for Shell and Utilities .....</b>          | <b>219</b> |
| C.1             | Introduction .....                                        | 219        |
| C.1.1           | Scope.....                                                | 219        |
| C.1.2           | Conformance .....                                         | 219        |
| C.1.3           | Normative References .....                                | 219        |
| C.1.4           | Change History .....                                      | 219        |
| C.1.5           | Terminology .....                                         | 220        |
| C.1.6           | Definitions.....                                          | 220        |
| C.1.7           | Relationship to Other Documents.....                      | 220        |
| C.1.7.1         | System Interfaces.....                                    | 220        |
| C.1.7.2         | Concepts Derived from the ISO C Standard.....             | 221        |

|          |                                                                       |     |
|----------|-----------------------------------------------------------------------|-----|
| C.1.8    | Portability .....                                                     | 221 |
| C.1.8.1  | Codes .....                                                           | 221 |
| C.1.9    | Utility Limits .....                                                  | 222 |
| C.1.10   | Grammar Conventions .....                                             | 225 |
| C.1.11   | Utility Description Defaults .....                                    | 225 |
| C.1.12   | Considerations for Utilities in Support of Files of Arbitrary Size .. | 228 |
| C.1.13   | Built-In Utilities .....                                              | 229 |
| C.2      | Shell Command Language .....                                          | 231 |
| C.2.1    | Shell Introduction .....                                              | 231 |
| C.2.2    | Quoting .....                                                         | 231 |
| C.2.2.1  | Escape Character (Backslash) .....                                    | 231 |
| C.2.2.2  | Single-Quotes .....                                                   | 231 |
| C.2.2.3  | Double-Quotes .....                                                   | 231 |
| C.2.3    | Token Recognition .....                                               | 233 |
| C.2.3.1  | Alias Substitution .....                                              | 233 |
| C.2.4    | Reserved Words .....                                                  | 234 |
| C.2.5    | Parameters and Variables .....                                        | 234 |
| C.2.5.1  | Positional Parameters .....                                           | 234 |
| C.2.5.2  | Special Parameters .....                                              | 234 |
| C.2.5.3  | Shell Variables .....                                                 | 235 |
| C.2.6    | Word Expansions .....                                                 | 237 |
| C.2.6.1  | Tilde Expansion .....                                                 | 237 |
| C.2.6.2  | Parameter Expansion .....                                             | 238 |
| C.2.6.3  | Command Substitution .....                                            | 239 |
| C.2.6.4  | Arithmetic Expansion .....                                            | 240 |
| C.2.6.5  | Field Splitting .....                                                 | 241 |
| C.2.6.6  | Pathname Expansion .....                                              | 242 |
| C.2.6.7  | Quote Removal .....                                                   | 242 |
| C.2.7    | Redirection .....                                                     | 242 |
| C.2.7.1  | Redirecting Input .....                                               | 243 |
| C.2.7.2  | Redirecting Output .....                                              | 243 |
| C.2.7.3  | Appending Redirected Output .....                                     | 243 |
| C.2.7.4  | Here-Document .....                                                   | 243 |
| C.2.7.5  | Duplicating an Input File Descriptor .....                            | 243 |
| C.2.7.6  | Duplicating an Output File Descriptor .....                           | 243 |
| C.2.7.7  | Open File Descriptors for Reading and Writing .....                   | 244 |
| C.2.8    | Exit Status and Errors .....                                          | 244 |
| C.2.8.1  | Consequences of Shell Errors .....                                    | 244 |
| C.2.8.2  | Exit Status for Commands .....                                        | 244 |
| C.2.9    | Shell Commands .....                                                  | 244 |
| C.2.9.1  | Simple Commands .....                                                 | 245 |
| C.2.9.2  | Pipelines .....                                                       | 247 |
| C.2.9.3  | Lists .....                                                           | 247 |
| C.2.9.4  | Compound Commands .....                                               | 249 |
| C.2.9.5  | Function Definition Command .....                                     | 250 |
| C.2.10   | Shell Grammar .....                                                   | 251 |
| C.2.10.1 | Shell Grammar Lexical Conventions .....                               | 252 |
| C.2.10.2 | Shell Grammar Rules .....                                             | 252 |

|                 |                                                          |            |
|-----------------|----------------------------------------------------------|------------|
| C.2.11          | Signals and Error Handling .....                         | 253        |
| C.2.12          | Shell Execution Environment .....                        | 253        |
| C.2.13          | Pattern Matching Notation .....                          | 253        |
| C.2.13.1        | Patterns Matching a Single Character .....               | 253        |
| C.2.13.2        | Patterns Matching Multiple Characters .....              | 254        |
| C.2.13.3        | Patterns Used for Filename Expansion .....               | 254        |
| C.2.14          | Special Built-In Utilities .....                         | 255        |
| C.3             | Batch Environment Services and Utilities .....           | 255        |
| C.3.1           | Batch General Concepts .....                             | 258        |
| C.3.2           | Batch Services .....                                     | 260        |

# Foreword

## Structure of the Standard

This standard was originally developed by the Austin Group, a joint working group of members of the IEEE, members of The Open Group, and members of ISO/IEC Joint Technical Committee 1, as one of the four volumes of IEEE Std 1003.1-2001. The standard was approved by ISO and IEC and published in four parts, correlating to the original volumes.

A mapping of the parts to the volumes is shown below:

| <b>ISO/IEC 9945<br/>Part</b> | <b>IEEE Std 1003.1<br/>Volume</b> | <b>Description</b>                                                                                                                                                                                                                           |
|------------------------------|-----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 9945-1                       | Base Definitions                  | Includes general terms, concepts, and interfaces common to all parts of ISO/IEC 9945, including utility conventions and C-language header definitions.                                                                                       |
| 9945-2                       | System Interfaces                 | Includes definitions for system service functions and subroutines, language-specific system services for the C programming language, function issues, including portability, error handling, and error recovery.                             |
| 9945-3                       | Shell and Utilities               | Includes definitions for a standard source code-level interface to command interpretation services (a “shell”) and common utility programs for application programs.                                                                         |
| 9945-4                       | Rationale                         | Includes extended rationale that did not fit well into the rest of the document structure, containing historical information concerning the contents of ISO/IEC 9945 and why features were included or discarded by the standard developers. |

All four parts comprise the entire standard, and are intended to be used together to accommodate significant internal referencing among them. POSIX-conforming systems are required to support all four parts.

# Introduction

**Note:** This introduction is not part of IEEE Std 1003.1-2001, Standard for Information Technology — Portable Operating System Interface (POSIX).

This standard has been jointly developed by the IEEE and The Open Group. It is simultaneously an IEEE Standard, an ISO/IEC Standard, and an Open Group Technical Standard.

## **The Austin Group**

This standard was developed, and is maintained, by a joint working group of members of the IEEE Portable Applications Standards Committee, members of The Open Group, and members of ISO/IEC Joint Technical Committee 1. This joint working group is known as the Austin Group.<sup>3</sup> The Austin Group arose out of discussions amongst the parties which started in early 1998, leading to an initial meeting and formation of the group in September 1998. The purpose of the Austin Group has been to revise, combine, and update the following standards: ISO/IEC 9945-1, ISO/IEC 9945-2, IEEE Std 1003.1, IEEE Std 1003.2, and the Base Specifications of The Open Group Single UNIX Specification.

After two initial meetings, an agreement was signed in July 1999 between The Open Group and the Institute of Electrical and Electronics Engineers (IEEE), Inc., to formalize the project with the first draft of the revised specifications being made available at the same time. Under this agreement, The Open Group and IEEE agreed to share joint copyright of the resulting work. The Open Group has provided the chair and secretariat for the Austin Group.

The base document for the revision was The Open Group's Base volumes of its Single UNIX Specification, Version 2. These were selected since they were a superset of the existing POSIX.1 and POSIX.2 specifications and had some organizational aspects that would benefit the audience for the new revision.

The approach to specification development has been one of “write once, adopt everywhere”, with the deliverables being a set of specifications that carry the IEEE POSIX designation, The Open Group's Technical Standard designation, and an ISO/IEC designation. This set of specifications forms the core of the Single UNIX Specification, Version 3.

This unique development has combined both the industry-led efforts and the formal standardization activities into a single initiative, and included a wide spectrum of participants. The Austin Group continues as the maintenance body for this document.

Anyone wishing to participate in the Austin Group should contact the chair with their request. There are no fees for participation or membership. You may participate as an observer or as a contributor. You do not have to attend face-to-face meetings to participate; electronic participation is most welcome. For more information on the Austin Group and how to participate, see <http://www.opengroup.org/austin>.

---

3. The Austin Group is named after the location of the inaugural meeting held at the IBM facility in Austin, Texas in September 1998.

### Background

The developers of this standard represent a cross section of hardware manufacturers, vendors of operating systems and other software development tools, software designers, consultants, academics, authors, applications programmers, and others.

Conceptually, this standard describes a set of fundamental services needed for the efficient construction of application programs. Access to these services has been provided by defining an interface, using the C programming language, a command interpreter, and common utility programs that establish standard semantics and syntax. Since this interface enables application writers to write portable applications—it was developed with that goal in mind—it has been designated POSIX,<sup>4</sup> an acronym for Portable Operating System Interface.

Although originated to refer to the original IEEE Std 1003.1-1988, the name POSIX more correctly refers to a *family* of related standards: IEEE Std 1003.*n* and the parts of ISO/IEC 9945. In earlier editions of the IEEE standard, the term POSIX was used as a synonym for IEEE Std 1003.1-1988. A preferred term, POSIX.1, emerged. This maintained the advantages of readability of the symbol “POSIX” without being ambiguous with the POSIX family of standards.

### Audience

The intended audience for this standard is all persons concerned with an industry-wide standard operating system based on the UNIX system. This includes at least four groups of people:

1. Persons buying hardware and software systems
2. Persons managing companies that are deciding on future corporate computing directions
3. Persons implementing operating systems, and especially
4. Persons developing applications where portability is an objective

### Purpose

Several principles guided the development of this standard:

- Application-Oriented

The basic goal was to promote portability of application programs across UNIX system environments by developing a clear, consistent, and unambiguous standard for the interface specification of a portable operating system based on the UNIX system documentation. This standard codifies the common, existing definition of the UNIX system.

- Interface, Not Implementation

This standard defines an interface, not an implementation. No distinction is made between library functions and system calls; both are referred to as functions. No details of the implementation of any function are given (although historical practice is sometimes indicated in the RATIONALE section). Symbolic names are given for constants (such as signals and error numbers) rather than numbers.

---

4. The name POSIX was suggested by Richard Stallman. It is expected to be pronounced *pahz-icks*, as in *positive*, not *poh-six*, or other variations. The pronunciation has been published in an attempt to promulgate a standardized way of referring to a standard operating system interface.

- Source, Not Object, Portability

This standard has been written so that a program written and translated for execution on one conforming implementation may also be translated for execution on another conforming implementation. This standard does not guarantee that executable (object or binary) code will execute under a different conforming implementation than that for which it was translated, even if the underlying hardware is identical.

- The C Language

The system interfaces and header definitions are written in terms of the standard C language as specified in the ISO C standard.

- No Superuser, No System Administration

There was no intention to specify all aspects of an operating system. System administration facilities and functions are excluded from this standard, and functions usable only by the superuser have not been included. Still, an implementation of the standard interface may also implement features not in this standard. This standard is also not concerned with hardware constraints or system maintenance.

- Minimal Interface, Minimally Defined

In keeping with the historical design principles of the UNIX system, the mandatory core facilities of this standard have been kept as minimal as possible. Additional capabilities have been added as optional extensions.

- Broadly Implementable

The developers of this standard endeavored to make all specified functions implementable across a wide range of existing and potential systems, including:

1. All of the current major systems that are ultimately derived from the original UNIX system code (Version 7 or later)
2. Compatible systems that are not derived from the original UNIX system code
3. Emulations hosted on entirely different operating systems
4. Networked systems
5. Distributed systems
6. Systems running on a broad range of hardware

No direct references to this goal appear in this standard, but some results of it are mentioned in the Rationale (Informative) volume.

- Minimal Changes to Historical Implementations

When the original version of IEEE Std 1003.1 was published, there were no known historical implementations that did not have to change. However, there was a broad consensus on a set of functions, types, definitions, and concepts that formed an interface that was common to most historical implementations.

The adoption of the 1988 and 1990 IEEE system interface standards, the 1992 IEEE shell and utilities standard, the various Open Group (formerly X/Open) specifications, and the subsequent revisions and addenda to all of them have consolidated this consensus, and this revision reflects the significantly increased level of consensus arrived at since the original versions. The earlier standards and their modifications specified a number of areas where consensus had not been reached before, and these are now reflected in this revision. The authors of the original versions tried, as much as possible, to follow the principles below

when creating new specifications:

1. By standardizing an interface like one in an historical implementation; for example, directories
2. By specifying an interface that is readily implementable in terms of, and backwards-compatible with, historical implementations, such as the extended *tar* format defined in the *pax* utility
3. By specifying an interface that, when added to an historical implementation, will not conflict with it; for example, the *sigaction()* function

This revision tries to minimize the number of changes required to implementations which conform to the earlier versions of the approved standards to bring them into conformance with the current standard. Specifically, the scope of this work excluded doing any “new” work, but rather collecting into a single document what had been spread across a number of documents, and presenting it in what had been proven in practice to be a more effective way. Some changes to prior conforming implementations were unavoidable, primarily as a consequence of resolving conflicts found in prior revisions, or which became apparent when bringing the various pieces together.

However, since it references the 1999 version of the ISO C standard, and no longer supports “Common Usage C”, there are a number of unavoidable changes. Applications portability is similarly affected.

This standard is specifically not a codification of a particular vendor’s product.

It should be noted that implementations will have different kinds of extensions. Some will reflect “historical usage” and will be preserved for execution of pre-existing applications. These functions should be considered “obsolescent” and the standard functions used for new applications. Some extensions will represent functions beyond the scope of this standard. These need to be used with careful management to be able to adapt to future extensions of this standard and/or port to implementations that provide these services in a different manner.

- Minimal Changes to Existing Application Code

A goal of this standard was to minimize additional work for the developers of applications. However, because every known historical implementation will have to change at least slightly to conform, some applications will have to change.

### **This Standard**

This standard defines the Portable Operating System Interface (POSIX) requirements and consists of the following volumes:

- Base Definitions
- Shell and Utilities
- System Interfaces
- Rationale (Informative) (this volume)

**This Volume**

This volume is being published to assist in the process of review. It contains historical information concerning the contents of this standard and why features were included or discarded by the standard developers. It also contains notes of interest to application programmers on recommended programming practices, emphasizing the consequences of some aspects of this standard that may not be immediately apparent.

This volume is organized in parallel to the normative volumes of this standard, with a separate part for each of the three normative volumes.

Within this volume, the following terms are used:

**base standard**

The portions of this standard that are not optional, equivalent to the definitions of *classic* POSIX.1 and POSIX.2.

**POSIX.0**

Although this term is not used in the normative text of this standard, it is used in this volume to refer to IEEE Std 1003.0-1995.

**POSIX.1b**

Although this term is not used in the normative text of this standard, it is used in this volume to refer to the elements of the POSIX Realtime Extension amendment. (This was earlier referred to as POSIX.4 during the standard development process.)

**POSIX.1c**

Although this term is not used in the normative text of this standard, it is used in this volume to refer to the POSIX Threads Extension amendment. (This was earlier referred to as POSIX.4a during the standard development process.)

**standard developers**

The individuals and companies in the development organizations responsible for this standard: the IEEE P1003.1 working groups, The Open Group Base working group, advised by the hundreds of individual technical experts who balloted the draft standards within the Austin Group, and the member bodies and technical experts of ISO/IEC JTC 1/SC22/WG15.

**XSI extension**

The portions of this standard addressing the extension added for support of the Single UNIX Specification.

# *Participants*

IEEE Std 1003.1-2001 was prepared by the Austin Group, sponsored by the Portable Applications Standards Committee of the IEEE Computer Society, The Open Group, and ISO/SC22 WG15.

## **The Austin Group**

At the time of approval, the membership of the Austin Group was as follows:

**Andrew Josey**, Chair

**Donald W. Cragun**, Organizational Representative, IEEE PASC

**Nicholas Stoughton**, Organizational Representative, ISO/SC22 WG15

**Mark Brown**, Organizational Representative, The Open Group

**Cathy Hughes**, Technical Editor

## **Austin Group Technical Reviewers**

**The Open Group**

When The Open Group approved the Base Specifications, Issue 6 on 12 September 2001, the membership of The Open Group Base Working Group was as follows:

**Andrew Josey**, Chair

**Finnbarr P. Murphy**, Vice-Chair

**Mark Brown**, Austin Group Liaison

**Cathy Hughes**, Technical Editor

**Base Working Group Members**

Bouazza Bachar

Mark Brown

Dave Butenhof

Donald W. Cragun

Larry Dwyer

Joanna Farley

Andrew Gollan

Karen D. Gordon

Gary Miller

Finnbarr P. Murphy

Frank Prindle

Andrew K. Roach

Curtis Royster Jr.

Nicholas Stoughton

Kenjiro Tsuji

## IEEE

When the IEEE Standards Board approved IEEE Std 1003.1-2001 on 6 December 2001, the membership of the committees was as follows:

### Portable Applications Standards Committee (PASC)

**Lowell G. Johnson**, Chair  
**Joseph M. Gwinn**, Vice-Chair  
**Jay Ashford**, Functional Chair  
**Andrew Josey**, Functional Chair  
**Curtis Royster Jr.**, Functional Chair  
**Nicholas Stoughton**, Secretary

### Balloting Committee

The following members of the balloting committee voted on IEEE Std 1003.1-2001. Balloters may have voted for approval, disapproval, or abstention:

|                            |                    |                      |
|----------------------------|--------------------|----------------------|
| Harold C. Adams            | Steven A. Haaser   | Frank Prindle        |
| Pierre-Jean Arcos          | Charles E. Hammons | Francois Riche       |
| Jay Ashford                | Chris J. Harding   | John D. Riley        |
| Theodore P. Baker          | Barry Hedquist     | Andrew K. Roach      |
| Robert Barned              | Vincent E. Henley  | Helmut Roth          |
| David J. Blackwood         | Karl Heubaum       | Jaideep Roy          |
| Shirley Bockstahler-Brandt | Niklas Holsti      | Curtis Royster Jr.   |
| James Bottomley            | Thomas Hosmer      | Stephen C. Schwarm   |
| Mark Brown                 | Jim D. Isaak       | Richard Seibel       |
| Eric W. Burger             | Lowell G. Johnson  | David L. Shroads Jr. |
| Alan Burns                 | Michael B. Jones   | W. Olin Sibert       |
| Dave Butenhof              | Andrew Josey       | Keld Jorn Simonsen   |
| Keith Chow                 | Michael J. Karels  | Nicholas Stoughton   |
| Donald W. Cragun           | Steven Kramer      | Donn S. Terry        |
| Juan Antonio De La Puente  | Thomas M. Kurihara | Mark-Rene Uchida     |
| Ming De Zhou               | C. Douglass Locke  | Scott A. Valcourt    |
| Steven J. Dovich           | Roger J. Martin    | Michael W. Vannier   |
| Richard P. Draves          | Craig H. Meyer     | Frederick N. Webb    |
| Philip H. Enslow           | Finnbarr P. Murphy | Paul A.T. Wolfgang   |
| Michael Gonzalez           | John Napier        | Oren Yuen            |
| Karen D. Gordon            | Peter E. Obermayer | Janusz Zalewski      |
| Joseph M. Gwinn            | James T. Oblinger  |                      |

The following organizational representative voted on this standard:

**Andrew Josey**, X/Open Company Ltd.

### IEEE-SA Standards Board

When the IEEE-SA Standards Board approved IEEE Std 1003.1-2001 on 6 December 2001, it had the following membership:

**Donald N. Heirman**, Chair

**James T. Carlo**, Vice-Chair

**Judith Gorman**, Secretary

Satish K. Aggarwal

Mark D. Bowman

Gary R. Engmann

Harold E. Epstein

H. Landis Floyd

Jay Forster\*

Howard M. Frazier

Ruben D. Garzon

James H. Gurney

Richard J. Holleman

Lowell G. Johnson

Robert J. Kennelly

Joseph L. Koepfinger\*

Peter H. Lips

L. Bruce McClung

Daleep C. Mohla

James W. Moore

Robert F. Munzner

Ronald C. Petersen

Gerald H. Peterson

John B. Posey

Gary S. Robinson

Akio Tojo

Donald W. Zipse

Also included are the following non-voting IEEE-SA Standards Board liaisons:

**Alan Cookson**, NIST Representative

**Donald R. Volzka**, TAB Representative

**Yvette Ho Sang**, **Don Messina**, **Savoula Amanatidis**, IEEE Project Editors

---

\* Member Emeritus

IEEE Std 1003.1-2001/Cor 1-2002 was prepared by the Austin Group, sponsored by the Portable Applications Standards Committee of the IEEE Computer Society, The Open Group, and ISO/IEC JTC 1/SC22/WG15.

### **The Austin Group**

At the time of approval, the membership of the Austin Group was as follows:

**Andrew Josey**, Chair

**Donald W. Cragun**, Organizational Representative, IEEE PASC

**Nicholas Stoughton**, Organizational Representative, ISO/IEC JTC 1/SC22/WG15

**Mark Brown**, Organizational Representative, The Open Group

**Cathy Fox**, Technical Editor

### **Austin Group Technical Reviewers**

## IEEE-SA Standards Board

When the IEEE-SA Standards Board approved IEEE Std 1003.1-2001 / Cor 1-2002 on 11 December 2002, the membership was as follows:

**James T. Carlo**, Chair

**James H. Gurney**, Vice-Chair

**Judith Gorman**, Secretary

Sid Bennett

H. Stephen Berger

Clyde R. Camp

Richard DeBlasio

Harold E. Epstein

Julian Forster\*

Howard M. Frazier

Toshio Fukuda

Arnold M. Greenspan

Raymond Hapeman

Donald M. Heirman

Richard H. Hulett

Lowell G. Johnson

Joseph L. Koepfinger\*

Peter H. Lips

Nader Mehravari

Daleep C. Mohla

William J. Moylan

Malcolm V. Thaden

Geoffrey O. Thompson

Howard L. Wolfman

Don Wright

Also included are the following non-voting IEEE-SA Standards Board liaisons:

**Alan Cookson**, NIST Representative

**Satish K. Aggarwal**, NRC Representative

**Savoula Amanatidis**, IEEE Standards Managing Editor

# *Trademarks*

The following information is given for the convenience of users of this standard and does not constitute endorsement of these products by The Open Group or the IEEE. There may be other products mentioned in the text that might be covered by trademark protection and readers are advised to verify them independently.

1003.1<sup>™</sup> is a trademark of the Institute of Electrical and Electronic Engineers, Inc.

AIX<sup>®</sup> is a registered trademark of IBM Corporation.

AT&T<sup>®</sup> is a registered trademark of AT&T in the U.S.A. and other countries.

BSD<sup>™</sup> is a trademark of the University of California, Berkeley, U.S.A.

Hewlett-Packard<sup>®</sup>, HP<sup>®</sup>, and HP-UX<sup>®</sup> are registered trademarks of Hewlett-Packard Company.

IBM<sup>®</sup> is a registered trademark of International Business Machines Corporation.

The Open Group and Boundaryless Information Flow are trademarks and UNIX is a registered trademark of The Open Group in the United States and other countries. All other trademarks are the property of their respective owners.

POSIX<sup>®</sup> is a registered trademark of the Institute of Electrical and Electronic Engineers, Inc.

Sun<sup>®</sup> and Sun Microsystems<sup>®</sup> are registered trademarks of Sun Microsystems, Inc.

/usr/group<sup>®</sup> is a registered trademark of UniForum, the International Network of UNIX System Users.

# *Acknowledgements*

The contributions of the following organizations to the development of IEEE Std 1003.1-2001 are gratefully acknowledged:

- AT&T for permission to reproduce portions of its copyrighted System V Interface Definition (SVID) and material from the UNIX System V Release 2.0 documentation.
- The SC22 WG14 Committees.

This standard was prepared by the Austin Group, a joint working group of the IEEE, The Open Group, and ISO SC22 WG15.

# Rationale for Base Definitions

## A.1 Introduction

### A.1.1 Scope

IEEE Std 1003.1-2001 is one of a family of standards known as POSIX. The family of standards extends to many topics; IEEE Std 1003.1-2001 is known as POSIX.1 and consists of both operating system interfaces and shell and utilities. IEEE Std 1003.1-2001 is technically identical to The Open Group Base Specifications, Issue 6, which comprise the core volumes of the Single UNIX Specification, Version 3.

#### Scope of IEEE Std 1003.1-2001

The (paraphrased) goals of this development were to produce a single common revision to the overlapping POSIX.1 and POSIX.2 standards, and the Single UNIX Specification, Version 2. As such, the scope of the revision includes the scopes of the original documents merged.

Since the revision includes merging the Base volumes of the Single UNIX Specification, many features that were previously not “adopted” into earlier revisions of POSIX.1 and POSIX.2 are now included in IEEE Std 1003.1-2001. In most cases, these additions are part of the XSI extension; in other cases the standard developers decided that now was the time to migrate these to the base standard.

The Single UNIX Specification programming environment provides a broad-based functional set of interfaces to support the porting of existing UNIX applications and the development of new applications. The environment also supports a rich set of tools for application development.

The majority of the obsolescent material from the existing POSIX.1 and POSIX.2 standards, and material marked LEGACY from The Open Group’s Base specifications, has been removed in this revision. New members of the Legacy Option Group have been added, reflecting the advance in understanding of what is required.

The following IEEE standards have been added to the base documents in this revision:

- IEEE Std 1003.1d-1999
- IEEE Std 1003.1j-2000
- IEEE Std 1003.1q-2000
- IEEE P1003.1a draft standard
- IEEE Std 1003.2d-1994
- IEEE P1003.2b draft standard
- Selected parts of IEEE Std 1003.1g-2000

Only selected parts of IEEE Std 1003.1g-2000 were included. This was because there is much duplication between the XNS, Issue 5.2 specification (another base document) and the material from IEEE Std 1003.1g-2000, the former document being aligned with the latest networking specifications for IPv6. Only the following sections of IEEE Std 1003.1g-2000 were considered for inclusion:

- General terms related to sockets (Section 2.2.2)
- Socket concepts (Sections 5.1 through 5.3 inclusive)
- The `pselect()` function (Sections 6.2.2.1 and 6.2.3)
- The `<sys/select.h>` header (Section 6.2)

The following were requirements on IEEE Std 1003.1-2001:

- Backward-compatibility

It was agreed that there should be no breakage of functionality in the existing base documents. This requirement was tempered by changes introduced due to interpretations and corrigenda on the base documents, and any changes introduced in the ISO/IEC 9899:1999 standard (C Language).

- Architecture and n-bit neutral

The common standard should not make any implicit assumptions about the system architecture or size of data types; for example, previously some 32-bit implicit assumptions had crept into the standards.

- Extensibility

It should be possible to extend the common standard without breaking backwards-compatibility. For example, the name space should be reserved and structured to avoid duplication of names between the standard and extensions to it.

## POSIX.1 and the ISO C Standard

Previous revisions of POSIX.1 built upon the ISO C standard by reference only. This revision takes a different approach.

The standard developers believed it essential for a programmer to have a single complete reference place, but recognized that deference to the formal standard had to be addressed for the duplicate interface definitions between the ISO C standard and the Single UNIX Specification.

It was agreed that where an interface has a version in the ISO C standard, the DESCRIPTION section should describe the relationship to the ISO C standard and markings should be added as appropriate to show where the ISO C standard has been extended in the text.

A block of text was added to the start of each affected reference page stating whether the page is aligned with the ISO C standard or extended. Each page was parsed for additions beyond the ISO C standard (that is, including both POSIX and UNIX extensions), and these extensions are marked as CX extensions (for C Extensions).

## FIPS Requirements

The Federal Information Processing Standards (FIPS) are a series of U.S. government procurement standards managed and maintained on behalf of the U.S. Department of Commerce by the National Institute of Standards and Technology (NIST).

The following restrictions have been made in this version of IEEE Std 1003.1 in order to align with FIPS 151-2 requirements:

- The implementation supports `_POSIX_CHOWN_RESTRICTED`.
- The limit `{NGROUPS_MAX}` is now greater than or equal to 8.
- The implementation supports the setting of the group ID of a file (when it is created) to that of the parent directory.

- The implementation supports `_POSIX_SAVED_IDS`.
- The implementation supports `_POSIX_VDISABLE`.
- The implementation supports `_POSIX_JOB_CONTROL`.
- The implementation supports `_POSIX_NO_TRUNC`.
- The `read()` function returns the number of bytes read when interrupted by a signal and does not return `-1`.
- The `write()` function returns the number of bytes written when interrupted by a signal and does not return `-1`.
- In the environment for the login shell, the environment variables `LOGNAME` and `HOME` are defined and have the properties described in IEEE Std 1003.1-2001.
- The value of `{CHILD_MAX}` is now greater than or equal to 25.
- The value of `{OPEN_MAX}` is now greater than or equal to 20.
- The implementation supports the functionality associated with the symbols `CS7`, `CS8`, `CSTOPB`, `PARODD`, and `PARENB` defined in `<termios.h>`.

### A.1.2 Conformance

See Section A.2 (on page 9).

### A.1.3 Normative References

There is no additional rationale provided for this section.

### A.1.4 Terminology

The meanings specified in IEEE Std 1003.1-2001 for the words *shall*, *should*, and *may* are mandated by ISO/IEC directives.

In the Rationale (Informative) volume of IEEE Std 1003.1-2001, the words *shall*, *should*, and *may* are sometimes used to illustrate similar usages in IEEE Std 1003.1-2001. However, the rationale itself does not specify anything regarding implementations or applications.

#### conformance document

As a practical matter, the conformance document is effectively part of the system documentation. Conformance documents are distinguished by IEEE Std 1003.1-2001 so that they can be referred to distinctly.

#### implementation-defined

This definition is analogous to that of the ISO C standard and, together with “undefined” and “unspecified”, provides a range of specification of freedom allowed to the interface implementor.

#### may

The use of *may* has been limited as much as possible, due both to confusion stemming from its ordinary English meaning and to objections regarding the desirability of having as few options as possible and those as clearly specified as possible.

The usage of *can* and *may* were selected to contrast optional application behavior (can) against optional implementation behavior (may).

**shall**

Declarative sentences are sometimes used in IEEE Std 1003.1-2001 as if they included the word *shall*, and facilities thus specified are no less required. For example, the two statements:

1. The *foo()* function shall return zero.
2. The *foo()* function returns zero.

are meant to be exactly equivalent.

**should**

In IEEE Std 1003.1-2001, the word *should* does not usually apply to the implementation, but rather to the application. Thus, the important words regarding implementations are *shall*, which indicates requirements, and *may*, which indicates options.

**obsolescent**

The term “obsolescent” means “do not use this feature in new applications”. The obsolescence concept is not an ideal solution, but was used as a method of increasing consensus: many more objections would be heard from the user community if some of these historical features were suddenly withdrawn without the grace period obsolescence implies. The phrase “may be considered for withdrawal in future revisions” implies that the result of that consideration might in fact keep those features indefinitely if the predominance of applications do not migrate away from them quickly.

**legacy**

The term “legacy” was added for compatibility with the Single UNIX Specification. It means “this feature is historic and optional; do not use this feature in new applications. There are alternative interfaces that are more suitable.”. It is used exclusively for XSI extensions, and includes facilities that were mandatory in previous versions of the base document but are optional in this revision. This is a way to “sunset” the usage of certain functions. Application writers should not rely on the existence of these facilities in new applications, but should follow the migration path detailed in the APPLICATION USAGE sections of the relevant pages.

The terms “legacy” and “obsolescent” are different: a feature marked LEGACY is not recommended for new work and need not be present on an implementation (if the XSI Legacy Option Group is not supported). A feature noted as obsolescent is supported by all implementations, but may be removed in a future revision; new applications should not use these features.

**system documentation**

The system documentation should normally describe the whole of the implementation, including any extensions provided by the implementation. Such documents normally contain information at least as detailed as the specifications in IEEE Std 1003.1-2001. Few requirements are made on the system documentation, but the term is needed to avoid a dangling pointer where the conformance document is permitted to point to the system documentation.

**undefined**

See *implementation-defined*.

**unspecified**

See *implementation-defined*.

The definitions for “unspecified” and “undefined” appear nearly identical at first examination, but are not. The term “unspecified” means that a conforming application may deal with the unspecified behavior, and it should not care what the outcome is. The term

“undefined” says that a conforming application should not do it because no definition is provided for what it does (and implicitly it would care what the outcome was if it tried it). It is important to remember, however, that if the syntax permits the statement at all, it must have some outcome in a real implementation.

Thus, the terms “undefined” and “unspecified” apply to the way the application should think about the feature. In terms of the implementation, it is always “defined”—there is always some result, even if it is an error. The implementation is free to choose the behavior it prefers.

This also implies that an implementation, or another standard, could specify or define the result in a useful fashion. The terms apply to IEEE Std 1003.1-2001 specifically.

The term “implementation-defined” implies requirements for documentation that are not required for “undefined” (or “unspecified”). Where there is no need for a conforming program to know the definition, the term “undefined” is used, even though “implementation-defined” could also have been used in this context. There could be a fourth term, specifying “this standard does not say what this does; it is acceptable to define it in an implementation, but it does not need to be documented”, and undefined would then be used very rarely for the few things for which any definition is not useful. In particular, implementation-defined is used where it is believed that certain classes of application will need to know such details to determine whether the application can be successfully ported to the implementation. Such applications are not always strictly portable, but nevertheless are common and useful; often the requirements met by the application cannot be met without dealing with the issues implied by “implementation-defined”.

In many places IEEE Std 1003.1-2001 is silent about the behavior of some possible construct. For example, a variable may be defined for a specified range of values and behaviors are described for those values; nothing is said about what happens if the variable has any other value. That kind of silence can imply an error in the standard, but it may also imply that the standard was intentionally silent and that any behavior is permitted. There is a natural tendency to infer that if the standard is silent, a behavior is prohibited. That is not the intent. Silence is intended to be equivalent to the term “unspecified”.

The term “application” is not defined in IEEE Std 1003.1-2001; it is assumed to be a part of general computer science terminology.

Three terms used within IEEE Std 1003.1-2001 overlap in meaning: “macro”, “symbolic name”, and “symbolic constant”.

#### **macro**

This usually describes a C preprocessor symbol, the result of the **#define** operator, with or without an argument. It may also be used to describe similar mechanisms in editors and text processors.

#### **symbolic name**

This can also refer to a C preprocessor symbol (without arguments), but is also used to refer to the names for characters in character sets. In addition, it is sometimes used to refer to host names and even filenames.

#### **symbolic constant**

This also refers to a C preprocessor symbol (also without arguments).

In most cases, the difference in semantic content is negligible to nonexistent. Readers should not attempt to read any meaning into the various usages of these terms.

### A.1.5 Portability

To aid the identification of options within IEEE Std 1003.1-2001, a notation consisting of margin codes and shading is used. This is based on the notation used in previous revisions of The Open Group's Base specifications.

The benefit of this approach is a reduction in the number of *if* statements within the running text, that makes the text easier to read, and also an identification to the programmer that they need to ensure that their target platforms support the underlying options. For example, if functionality is marked with THR in the margin, it will be available on all systems supporting the Threads option, but may not be available on some others.

#### A.1.5.1 Codes

This section includes codes for options defined in the Base Definitions volume of IEEE Std 1003.1-2001, Section 2.1.6, Options, and the following additional codes for other purposes:

**CX** This margin code is used to denote extensions beyond the ISO C standard. For interfaces that are duplicated between IEEE Std 1003.1-2001 and the ISO C standard, a CX introduction block describes the nature of the duplication, with any extensions appropriately CX marked and shaded.

Where an interface is added to an ISO C standard header, within the header the interface has an appropriate margin marker and shading (for example, CX, XSI, TSF, and so on) and the same marking appears on the reference page in the SYNOPSIS section. This enables a programmer to easily identify that the interface is extending an ISO C standard header.

**MX** This margin code is used to denote IEC 60559:1989 standard floating-point extensions.

**OB** This margin code is used to denote obsolescent behavior and thus flag a possible future applications portability warning.

**OH** The Single UNIX Specification has historically tried to reduce the number of headers an application has had to include when using a particular interface. Sometimes this was fewer than the base standard, and hence a notation is used to flag which headers are optional if you are using a system supporting the XSI extension.

**XSI** This code is used to denote interfaces and facilities within interfaces only required on systems supporting the XSI extension. This is introduced to support the Single UNIX Specification.

**XSR** This code is used to denote interfaces and facilities within interfaces only required on systems supporting STREAMS. This is introduced to support the Single UNIX Specification, although it is defined in a way so that it can stand alone from the XSI notation.

#### A.1.5.2 Margin Code Notation

Since some features may depend on one or more options, or require more than one option, a notation is used. Where a feature requires support of a single option, a single margin code will occur in the margin. If it depends on two options and both are required, then the codes will appear with a <space> separator. If either of two options are required, then a logical OR is denoted using the ' | ' symbol. If more than two codes are used, a special notation is used.

## A.2 Conformance

The terms “profile” and “profiling” are used throughout this section.

A profile of a standard or standards is a codified set of option selections, such that by being conformant to a profile, particular classes of users are specifically supported.

These conformance definitions are descended from those in the ISO POSIX-1: 1996 standard, but with changes for the following:

- The addition of profiling options, allowing larger profiles of options such as the XSI extension used by the Single UNIX Specification. In effect, it has profiled itself (that is, created a self-profile).
- The addition of a definition of subprofiling considerations, to allow smaller profiles of options.
- The addition of a hierarchy of super-options for XSI; these were formerly known as “Feature Groups” in the System Interfaces and Headers, Issue 5 specification.
- Options from the ISO POSIX-2: 1993 standard are also now included, as IEEE Std 1003.1-2001 merges the functionality from it.

### A.2.1 Implementation Conformance

These definitions allow application developers to know what to depend on in an implementation.

There is no definition of a “strictly conforming implementation”; that would be an implementation that provides *only* those facilities specified by POSIX.1 with no extensions whatsoever. This is because no actual operating system implementation can exist without system administration and initialization facilities that are beyond the scope of POSIX.1.

#### A.2.1.1 Requirements

The word “support” is used in certain instances, rather than “provide”, in order to allow an implementation that has no resident software development facilities, but that supports the execution of a *Strictly Conforming POSIX.1 Application*, to be a *conforming implementation*.

#### A.2.1.2 Documentation

The conformance documentation is required to use the same numbering scheme as POSIX.1 for purposes of cross-referencing. All options that an implementation chooses are reflected in **<limits.h>** and **<unistd.h>**.

Note that the use of “may” in terms of where conformance documents record where implementations may vary, implies that it is not required to describe those features identified as undefined or unspecified.

Other aspects of systems must be evaluated by purchasers for suitability. Many systems incorporate buffering facilities, maintaining updated data in volatile storage and transferring such updates to non-volatile storage asynchronously. Various exception conditions, such as a power failure or a system crash, can cause this data to be lost. The data may be associated with a file that is still open, with one that has been closed, with a directory, or with any other internal system data structures associated with permanent storage. This data can be lost, in whole or part, so that only careful inspection of file contents could determine that an update did not occur.

Also, interrelated file activities, where multiple files and/or directories are updated, or where space is allocated or released in the file system structures, can leave inconsistencies in the relationship between data in the various files and directories, or in the file system itself. Such inconsistencies can break applications that expect updates to occur in a specific sequence, so that updates in one place correspond with related updates in another place.

For example, if a user creates a file, places information in the file, and then records this action in another file, a system or power failure at this point followed by restart may result in a state in which the record of the action is permanently recorded, but the file created (or some of its information) has been lost. The consequences of this to the user may be undesirable. For a user on such a system, the only safe action may be to require the system administrator to have a policy that requires, after any system or power failure, that the entire file system must be restored from the most recent backup copy (causing all intervening work to be lost).

The characteristics of each implementation will vary in this respect and may or may not meet the requirements of a given application or user. Enforcement of such requirements is beyond the scope of POSIX.1. It is up to the purchaser to determine what facilities are provided in an implementation that affect the exposure to possible data or sequence loss, and also what underlying implementation techniques and/or facilities are provided that reduce or limit such loss or its consequences.

#### A.2.1.3 *POSIX Conformance*

This really means conformance to the base standard; however, since this revision includes the core material of the Single UNIX Specification, the standard developers decided that it was appropriate to segment the conformance requirements into two, the former for the base standard, and the latter for the Single UNIX Specification.

Within POSIX.1 there are some symbolic constants that, if defined, indicate that a certain option is enabled. Other symbolic constants exist in POSIX.1 for other reasons.

As part of the revision some alignment has occurred of the options with the FIPS 151-2 profile on the POSIX.1-1990 standard. The following options from the POSIX.1-1990 standard are now mandatory:

- `_POSIX_JOB_CONTROL`
- `_POSIX_SAVED_IDS`
- `_POSIX_VDISABLE`

A POSIX-conformant system may support the XSI extensions of the Single UNIX Specification. This was intentional since the standard developers intend them to be upwards-compatible, so that a system conforming to the Single UNIX Specification can also conform to the base standard at the same time.

#### A.2.1.4 *XSI Conformance*

This section is added since the revision merges in the base volumes of the Single UNIX Specification.

XSI conformance can be thought of as a profile, selecting certain options from IEEE Std 1003.1-2001.

### A.2.1.5 Option Groups

The concept of “Option Groups” is introduced to IEEE Std 1003.1-2001 to allow collections of related functions or options to be grouped together. This has been used as follows: the “XSI Option Groups” have been created to allow super-options, collections of underlying options and related functions, to be collectively supported by XSI-conforming systems. These reflect the “Feature Groups” from the System Interfaces and Headers, Issue 5 specification.

The standard developers considered the matter of subprofiling and decided it was better to include an enabling mechanism rather than detailed normative requirements. A set of subprofiling options was developed and included later in this volume of IEEE Std 1003.1-2001 as an informative illustration.

### Subprofiling Considerations

The goal of not simultaneously fixing maximums and minimums was to allow implementations of the base standard or standards to support multiple profiles without conflict.

The following summarizes the rules for the limit types:

| Limit Type       | Fixed Value                          | Minimum Acceptable Value                            | Maximum Acceptable Value                            |
|------------------|--------------------------------------|-----------------------------------------------------|-----------------------------------------------------|
| Standard Profile | $X_s$<br>$X_p == X_s$<br>(No change) | $Y_s$<br>$Y_p \geq Y_s$<br>(May increase the limit) | $Z_s$<br>$Z_p \leq Z_s$<br>(May decrease the limit) |

The intent is that ranges specified by limits in profiles be entirely contained within the corresponding ranges of the base standard or standards being profiled, and that the unlimited end of a range in a base standard must remain unlimited in any profile of that standard.

Thus, the fixed `_POSIX_*` limits are constants and must not be changed by a profile. The variable counterparts (typically without the leading `_POSIX_`) can be changed but still remain semantically the same; that is, they still allow implementation values to vary as long as they meet the requirements for that value (be it a minimum or maximum).

Where a profile does not provide a feature upon which a limit is based, the limit is not relevant. Applications written to that profile should be written to operate independently of the value of the limit.

An example which has previously allowed implementations to support both the base standard and two other profiles in a compatible manner follows:

```
Base standard (POSIX.1-1996): _POSIX_CHILD_MAX 6
Base standard: CHILD_MAX minimum maximum _POSIX_CHILD_MAX
FIPS profile/SUSv2 CHILD_MAX 25 (minimum maximum)
```

Another example:

```
Base standard (POSIX.1-1996): _POSIX_NGROUPS_MAX 0
Base standard: NGROUPS_MAX minimum maximum _POSIX_NGROUP_MAX
FIPS profile/SUSv2 NGROUPS_MAX 8
```

A profile may lower a minimum maximum below the equivalent `_POSIX` value:

```
Base standard: _POSIX_foo_MAX Z
Base standard: foo_MAX _POSIX_foo_MAX
profile standard : foo_MAX X (X can be less than, equal to,
or greater than _POSIX_foo_MAX)
```

381 In this case an implementation conforming to the profile may not conform to the base standard,  
382 but an implementation to the base standard will conform to the profile.

#### 383 A.2.1.6 Options

384 The final subsections within *Implementation Conformance* list the core options within  
385 IEEE Std 1003.1-2001. This includes both options for the System Interfaces volume of  
386 IEEE Std 1003.1-2001 and the Shell and Utilities volume of IEEE Std 1003.1-2001.

### 387 A.2.2 Application Conformance

388 These definitions guide users or adaptors of applications in determining on which  
389 implementations an application will run and how much adaptation would be required to make  
390 it run on others. These definitions are modeled after related ones in the ISO C standard.

391 POSIX.1 occasionally uses the expressions “portable application” or “conforming application”.  
392 As they are used, these are synonyms for any of these terms. The differences between the classes  
393 of application conformance relate to the requirements for other standards, the options supported  
394 (such as the XSI extension) or, in the case of the Conforming POSIX.1 Application Using  
395 Extensions, to implementation extensions. When one of the less explicit expressions is used, it  
396 should be apparent from the context of the discussion which of the more explicit names is  
397 appropriate

#### 398 A.2.2.1 Strictly Conforming POSIX Application

399 This definition is analogous to that of an ISO C standard “conforming program”.

400 The major difference between a Strictly Conforming POSIX Application and an ISO C standard  
401 strictly conforming program is that the latter is not allowed to use features of POSIX that are not  
402 in the ISO C standard.

#### 403 A.2.2.2 Conforming POSIX Application

404 Examples of <National Bodies> include ANSI, BSI, and AFNOR.

#### 405 A.2.2.3 Conforming POSIX Application Using Extensions

406 Due to possible requirements for configuration or implementation characteristics in excess of the  
407 specifications in <limits.h> or related to the hardware (such as array size or file space), not every  
408 Conforming POSIX Application Using Extensions will run on every conforming  
409 implementation.

#### 410 A.2.2.4 Strictly Conforming XSI Application

411 This is intended to be upwards-compatible with the definition of a Strictly Conforming POSIX  
412 Application, with the addition of the facilities and functionality included in the XSI extension.

#### 413 A.2.2.5 Conforming XSI Application Using Extensions

414 Such applications may use extensions beyond the facilities defined by IEEE Std 1003.1-2001  
415 including the XSI extension, but need to document the additional requirements.

### A.2.3 Language-Dependent Services for the C Programming Language

POSIX.1 is, for historical reasons, both a specification of an operating system interface, shell and utilities, and a C binding for that specification. Efforts had been previously undertaken to generate a language-independent specification; however, that had failed, and the fact that the ISO C standard is the *de facto* primary language on POSIX and the UNIX system makes this a necessary and workable situation.

### A.2.4 Other Language-Related Specifications

There is no additional rationale provided for this section.

## A.3 Definitions

The definitions in this section are stated so that they can be used as exact substitutes for the terms in text. They should not contain requirements or cross-references to sections within IEEE Std 1003.1-2001; that is accomplished by using an informative note. In addition, the term should not be included in its own definition. Where requirements or descriptions need to be addressed but cannot be included in the definitions, due to not meeting the above criteria, these occur in the General Concepts chapter.

In this revision, the definitions have been reworked extensively to meet style requirements and to include terms from the base documents (see the Scope).

Many of these definitions are necessarily circular, and some of the terms (such as “process”) are variants of basic computing science terms that are inherently hard to define. Where some definitions are more conceptual and contain requirements, these appear in the General Concepts chapter. Those listed in this section appear in an alphabetical glossary format of terms.

Some definitions must allow extension to cover terms or facilities that are not explicitly mentioned in IEEE Std 1003.1-2001. For example, the definition of “Extended Security Controls” permits implementations beyond those defined in IEEE Std 1003.1-2001.

Some terms in the following list of notes do not appear in IEEE Std 1003.1-2001; these are marked suffixed with an asterisk (\*). Many of them have been specifically excluded from IEEE Std 1003.1-2001 because they concern system administration, implementation, or other issues that are not specific to the programming interface. Those are marked with a reason, such as “implementation-defined”.

### Appropriate Privileges

One of the fundamental security problems with many historical UNIX systems has been that the privilege mechanism is monolithic—a user has either no privileges or *all* privileges. Thus, a successful “trojan horse” attack on a privileged process defeats all security provisions. Therefore, POSIX.1 allows more granular privilege mechanisms to be defined. For many historical implementations of the UNIX system, the presence of the term “appropriate privileges” in POSIX.1 may be understood as a synonym for “superuser” (UID 0). However, other systems have emerged where this is not the case and each discrete controllable action has *appropriate privileges* associated with it. Because this mechanism is implementation-defined, it must be described in the conformance document. Although that description affects several parts of POSIX.1 where the term “appropriate privilege” is used, because the term “implementation-defined” only appears here, the description of the entire mechanism and its effects on these other sections belongs in this equivalent section of the conformance document. This is especially convenient for implementations with a single mechanism that applies in all areas, since it only needs to be described once.

**Byte**

The restriction that a byte is now exactly eight bits was a conscious decision by the standard developers. It came about due to a combination of factors, primarily the use of the type `int8_t` within the networking functions and the alignment with the ISO / IEC 9899: 1999 standard, where the `intN_t` types are now defined.

According to the ISO / IEC 9899: 1999 standard:

- The `[u]intN_t` types must be two's complement with no padding bits and no illegal values.
- All types (apart from bit fields, which are not relevant here) must occupy an integral number of bytes.
- If a type with width  $W$  occupies  $B$  bytes with  $C$  bits per byte ( $C$  is the value of `{CHAR_BIT}`), then it has  $P$  padding bits where  $P+W=B*C$ .
- Therefore, for `int8_t`  $P=0$ ,  $W=8$ . Since  $B \geq 1$ ,  $C \geq 8$ , the only solution is  $B=1$ ,  $C=8$ .

The standard developers also felt that this was not an undue restriction for the current state-of-the-art for this version of IEEE Std 1003.1, but recognize that if industry trends continue, a wider character type may be required in the future.

**Character**

The term “character” is used to mean a sequence of one or more bytes representing a single graphic symbol. The deviation in the exact text of the ISO C standard definition for “byte” meets the intent of the rationale of the ISO C standard also clears up the ambiguity raised by the term “basic execution character set”. The octet-minimum requirement is a reflection of the `{CHAR_BIT}` value.

**Clock Tick**

The ISO C standard defines a similar interval for use by the `clock()` function. There is no requirement that these intervals be the same. In historical implementations these intervals are different.

**Command**

The terms “command” and “utility” are related but have distinct meanings. Command is defined as “a directive to a shell to perform a specific task”. The directive can be in the form of a single utility name (for example, `ls`), or the directive can take the form of a compound command (for example, `"ls | grep name | pr"`). A utility is a program that can be called by name from a shell. Issuing only the name of the utility to a shell is the equivalent of a one-word command. A utility may be invoked as a separate program that executes in a different process than the command language interpreter, or it may be implemented as a part of the command language interpreter. For example, the `echo` command (the directive to perform a specific task) may be implemented such that the `echo` utility (the logic that performs the task of echoing) is in a separate program; therefore, it is executed in a process that is different from the command language interpreter. Conversely, the logic that performs the `echo` utility could be built into the command language interpreter; therefore, it could execute in the same process as the command language interpreter.

The terms “tool” and “application” can be thought of as being synonymous with “utility” from the perspective of the operating system kernel. Tools, applications, and utilities historically have run, typically, in processes above the kernel level. Tools and utilities historically have been a part of the operating system non-kernel code and have performed system-related functions, such as listing directory contents, checking file systems, repairing file systems, or extracting system

status information. Applications have not generally been a part of the operating system, and they perform non-system-related functions, such as word processing, architectural design, mechanical design, workstation publishing, or financial analysis. Utilities have most frequently been provided by the operating system distributor, applications by third-party software distributors, or by the users themselves. Nevertheless, IEEE Std 1003.1-2001 does not differentiate between tools, utilities, and applications when it comes to receiving services from the system, a shell, or the standard utilities. (For example, the *xargs* utility invokes another utility; it would be of fairly limited usefulness if the users could not run their own applications in place of the standard utilities.) Utilities are not applications in the sense that they are not themselves subject to the restrictions of IEEE Std 1003.1-2001 or any other standard—there is no requirement for *grep*, *stty*, or any of the utilities defined here to be any of the classes of conforming applications.

### Column Positions

In most 1-byte character sets, such as ASCII, the concept of column positions is identical to character positions and to bytes. Therefore, it has been historically acceptable for some implementations to describe line folding or tab stops or table column alignment in terms of bytes or character positions. Other character sets pose complications, as they can have internal representations longer than one octet and they can have display characters that have different widths on the terminal screen or printer.

In IEEE Std 1003.1-2001 the term “column positions” has been defined to mean character—not byte—positions in input files (such as “column position 7 of the FORTRAN input”). Output files describe the column position in terms of the display width of the narrowest printable character in the character set, adjusted to fit the characteristics of the output device. It is very possible that *n* column positions will not be able to hold *n* characters in some character sets, unless all of those characters are of the narrowest width. It is assumed that the implementation is aware of the width of the various characters, deriving this information from the value of *LC\_CTYPE*, and thus can determine how many column positions to allot for each character in those utilities where it is important.

The term “column position” was used instead of the more natural “column” because the latter is frequently used in the different contexts of columns of figures, columns of table values, and so on. Wherever confusion might result, these latter types of columns are referred to as “text columns”.

### Controlling Terminal

The question of which of possibly several special files referring to the terminal is meant is not addressed in POSIX.1. The filename */dev/tty* is a synonym for the controlling terminal associated with a process.

### Device Number\*

The concept is handled in *stat()* as *ID of device*.

**Direct I/O**

Historically, direct I/O refers to the system bypassing intermediate buffering, but may be extended to cover implementation-defined optimizations.

**Directory**

The format of the directory file is implementation-defined and differs radically between System V and 4.3 BSD. However, routines (derived from 4.3 BSD) for accessing directories and certain constraints on the format of the information returned by those routines are described in the `<dirent.h>` header.

**Directory Entry**

Throughout IEEE Std 1003.1-2001, the term “link” is used (about the `link()` function, for example) in describing the objects that point to files from directories.

**Display**

The Shell and Utilities volume of IEEE Std 1003.1-2001 assigns precise requirements for the terms “display” and “write”. Some historical systems have chosen to implement certain utilities without using the traditional file descriptor model. For example, the *vi* editor might employ direct screen memory updates on a personal computer, rather than a `write()` system call. An instance of user prompting might appear in a dialog box, rather than with standard error. When the Shell and Utilities volume of IEEE Std 1003.1-2001 uses the term “display”, the method of outputting to the terminal is unspecified; many historical implementations use *termcap* or *terminfo*, but this is not a requirement. The term “write” is used when the Shell and Utilities volume of IEEE Std 1003.1-2001 mandates that a file descriptor be used and that the output can be redirected. However, it is assumed that when the writing is directly to the terminal (it has not been redirected elsewhere), there is no practical way for a user or test suite to determine whether a file descriptor is being used. Therefore, the use of a file descriptor is mandated only for the redirection case and the implementation is free to use any method when the output is not redirected. The verb *write* is used almost exclusively, with the very few exceptions of those utilities where output redirection need not be supported: *tabs*, *talk*, *tput*, and *vi*.

**Dot**

The symbolic name *dot* is carefully used in POSIX.1 to distinguish the working directory filename from a period or a decimal point.

**Dot-Dot**

Historical implementations permit the use of these filenames without their special meanings. Such use precludes any meaningful use of these filenames by a Conforming POSIX.1 Application. Therefore, such use is considered an extension, the use of which makes an implementation non-conforming; see also Section A.4.11 (on page 37).

**Epoch**

Historically, the origin of UNIX system time was referred to as “00:00:00 GMT, January 1, 1970”. Greenwich Mean Time is actually not a term acknowledged by the international standards community; therefore, this term, “Epoch”, is used to abbreviate the reference to the actual standard, Coordinated Universal Time.

**FIFO Special File**

See **Pipe** (on page 24).

**File**

It is permissible for an implementation-defined file type to be non-readable or non-writable.

**File Classes**

These classes correspond to the historical sets of permission bits. The classes are general to allow implementations flexibility in expanding the access mechanism for more stringent security environments. Note that a process is in one and only one class, so there is no ambiguity.

**Filename**

At the present time, the primary responsibility for truncating filenames containing multi-byte characters must reside with the application. Some industry groups involved in internationalization believe that in the future the responsibility must reside with the kernel. For the moment, a clearer understanding of the implications of making the kernel responsible for truncation of multi-byte filenames is needed.

Character-level truncation was not adopted because there is no support in POSIX.1 that advises how the kernel distinguishes between single and multi-byte characters. Until that time, it must be incumbent upon application writers to determine where multi-byte characters must be truncated.

**File System**

Historically, the meaning of this term has been overloaded with two meanings: that of the complete file hierarchy, and that of a mountable subset of that hierarchy; that is, a mounted file system. POSIX.1 uses the term “file system” in the second sense, except that it is limited to the scope of a process (and a process’ root directory). This usage also clarifies the domain in which a file serial number is unique.

**Graphic Character**

This definition is made available for those definitions (in particular, *TZ*) which must exclude control characters.

**Group Database**

See **User Database** (on page 32).

**Group File\***

Implementation-defined; see **User Database** (on page 32).

**Historical Implementations\***

This refers to previously existing implementations of programming interfaces and operating systems that are related to the interface specified by POSIX.1.

**Hosted Implementation\***

This refers to a POSIX.1 implementation that is accomplished through interfaces from the POSIX.1 services to some alternate form of operating system kernel services. Note that the line between a hosted implementation and a native implementation is blurred, since most implementations will provide some services directly from the kernel and others through some indirect path. (For example, *fopen()* might use *open()*; or *mkfifo()* might use *mknod()*.) There is no necessary relationship between the type of implementation and its correctness, performance, and/or reliability.

**Implementation\***

This term is generally used instead of its synonym, “system”, to emphasize the consequences of decisions to be made by system implementors. Perhaps if no options or extensions to POSIX.1 were allowed, this usage would not have occurred.

The term “specific implementation” is sometimes used as a synonym for “implementation”. This should not be interpreted too narrowly; both terms can represent a relatively broad group of systems. For example, a hardware vendor could market a very wide selection of systems that all used the same instruction set, with some systems desktop models and others large multi-user minicomputers. This wide range would probably share a common POSIX.1 operating system, allowing an application compiled for one to be used on any of the others; this is a [*specific*] *implementation*. However, such a wide range of machines probably has some differences between the models. Some may have different clock rates, different file systems, different resource limits, different network connections, and so on, depending on their sizes or intended usages. Even on two identical machines, the system administrators may configure them differently. Each of these different systems is known by the term “a specific instance of a specific implementation”. This term is only used in the portions of POSIX.1 dealing with runtime queries: *sysconf()* and *pathconf()*.

**Incomplete Pathname\***

Absolute pathname has been adequately defined.

**Job Control**

In order to understand the job control facilities in POSIX.1 it is useful to understand how they are used by a job control-cognizant shell to create the user interface effect of job control.

While the job control facilities supplied by POSIX.1 can, in theory, support different types of interactive job control interfaces supplied by different types of shells, there was historically one particular interface that was most common when the standard was originally developed (provided by BSD C Shell).

This discussion describes that interface as a means of illustrating how the POSIX.1 job control facilities can be used.

Job control allows users to selectively stop (suspend) the execution of processes and continue (resume) their execution at a later point. The user typically employs this facility via the interactive interface jointly supplied by the terminal I/O driver and a command interpreter (shell).

The user can launch jobs (command pipelines) in either the foreground or background. When launched in the foreground, the shell waits for the job to complete before prompting for additional commands. When launched in the background, the shell does not wait, but immediately prompts for new commands.

If the user launches a job in the foreground and subsequently regrets this, the user can type the suspend character (typically set to <control>-Z), which causes the foreground job to stop and the shell to begin prompting for new commands. The stopped job can be continued by the user (via special shell commands) either as a foreground job or as a background job. Background jobs can also be moved into the foreground via shell commands.

If a background job attempts to access the login terminal (controlling terminal), it is stopped by the terminal driver and the shell is notified, which, in turn, notifies the user. (Terminal access includes *read()* and certain terminal control functions, and conditionally includes *write()*.) The user can continue the stopped job in the foreground, thus allowing the terminal access to succeed in an orderly fashion. After the terminal access succeeds, the user can optionally move the job into the background via the suspend character and shell commands.

#### *Implementing Job Control Shells*

The interactive interface described previously can be accomplished using the POSIX.1 job control facilities in the following way.

The key feature necessary to provide job control is a way to group processes into jobs. This grouping is necessary in order to direct signals to a single job and also to identify which job is in the foreground. (There is at most one job that is in the foreground on any controlling terminal at a time.)

The concept of process groups is used to provide this grouping. The shell places each job in a separate process group via the *setpgid()* function. To do this, the *setpgid()* function is invoked by the shell for each process in the job. It is actually useful to invoke *setpgid()* twice for each process: once in the child process, after calling *fork()* to create the process, but before calling one of the *exec* family of functions to begin execution of the program, and once in the parent shell process, after calling *fork()* to create the child. The redundant invocation avoids a race condition by ensuring that the child process is placed into the new process group before either the parent or the child relies on this being the case. The process group ID for the job is selected by the shell to be equal to the process ID of one of the processes in the job. Some shells choose to make one process in the job be the parent of the other processes in the job (if any). Other shells (for example, the C Shell) choose to make themselves the parent of all processes in the pipeline (job). In order to support this latter case, the *setpgid()* function accepts a process group ID parameter since the correct process group ID cannot be inherited from the shell. The shell itself is considered to be a job and is the sole process in its own process group.

The shell also controls which job is currently in the foreground. A foreground and background job differ in two ways: the shell waits for a foreground command to complete (or stop) before continuing to read new commands, and the terminal I/O driver inhibits terminal access by background jobs (causing the processes to stop). Thus, the shell must work cooperatively with the terminal I/O driver and have a common understanding of which job is currently in the foreground. It is the user who decides which command should be currently in the foreground, and the user informs the shell via shell commands. The shell, in turn, informs the terminal I/O driver via the *tcsetpgrp()* function. This indicates to the terminal I/O driver the process group ID

of the foreground process group (job). When the current foreground job either stops or terminates, the shell places itself in the foreground via *tcsetpgrp()* before prompting for additional commands. Note that when a job is created the new process group begins as a background process group. It requires an explicit act of the shell via *tcsetpgrp()* to move a process group (job) into the foreground.

When a process in a job stops or terminates, its parent (for example, the shell) receives synchronous notification by calling the *waitpid()* function with the WUNTRACED flag set. Asynchronous notification is also provided when the parent establishes a signal handler for SIGCHLD and does not specify the SA\_NOCLDSTOP flag. Usually all processes in a job stop as a unit since the terminal I/O driver always sends job control stop signals to all processes in the process group.

To continue a stopped job, the shell sends the SIGCONT signal to the process group of the job. In addition, if the job is being continued in the foreground, the shell invokes *tcsetpgrp()* to place the job in the foreground before sending SIGCONT. Otherwise, the shell leaves itself in the foreground and reads additional commands.

There is additional flexibility in the POSIX.1 job control facilities that allows deviations from the typical interface. Clearing the TOSTOP terminal flag allows background jobs to perform *write()* functions without stopping. The same effect can be achieved on a per-process basis by having a process set the signal action for SIGTTOU to SIG\_IGN.

Note that the terms “job” and “process group” can be used interchangeably. A login session that is not using the job control facilities can be thought of as a large collection of processes that are all in the same job (process group). Such a login session may have a partial distinction between foreground and background processes; that is, the shell may choose to wait for some processes before continuing to read new commands and may not wait for other processes. However, the terminal I/O driver will consider all these processes to be in the foreground since they are all members of the same process group.

In addition to the basic job control operations already mentioned, a job control-cognizant shell needs to perform the following actions.

When a foreground (not background) job stops, the shell must sample and remember the current terminal settings so that it can restore them later when it continues the stopped job in the foreground (via the *tcgetattr()* and *tcsetattr()* functions).

Because a shell itself can be spawned from a shell, it must take special action to ensure that subshells interact well with their parent shells.

A subshell can be spawned to perform an interactive function (prompting the terminal for commands) or a non-interactive function (reading commands from a file). When operating non-interactively, the job control shell will refrain from performing the job control-specific actions described above. It will behave as a shell that does not support job control. For example, all jobs will be left in the same process group as the shell, which itself remains in the process group established for it by its parent. This allows the shell and its children to be treated as a single job by a parent shell, and they can be affected as a unit by terminal keyboard signals.

An interactive subshell can be spawned from another job control-cognizant shell in either the foreground or background. (For example, from the C Shell, the user can execute the command, *csh &.*) Before the subshell activates job control by calling *setpgid()* to place itself in its own process group and *tcsetpgrp()* to place its new process group in the foreground, it needs to ensure that it has already been placed in the foreground by its parent. (Otherwise, there could be multiple job control shells that simultaneously attempt to control mediation of the terminal.) To determine this, the shell retrieves its own process group via *getpgrp()* and the process group of the current foreground job via *tcgetpgrp()*. If these are not equal, the shell sends SIGTTIN to

its own process group, causing itself to stop. When continued later by its parent, the shell repeats the process group check. When the process groups finally match, the shell is in the foreground and it can proceed to take control. After this point, the shell ignores all the job control stop signals so that it does not inadvertently stop itself.

#### *Implementing Job Control Applications*

Most applications do not need to be aware of job control signals and operations; the intuitively correct behavior happens by default. However, sometimes an application can inadvertently interfere with normal job control processing, or an application may choose to overtly effect job control in cooperation with normal shell procedures.

An application can inadvertently subvert job control processing by “blindly” altering the handling of signals. A common application error is to learn how many signals the system supports and to ignore or catch them all. Such an application makes the assumption that it does not know what this signal is, but knows the right handling action for it. The system may initialize the handling of job control stop signals so that they are being ignored. This allows shells that do not support job control to inherit and propagate these settings and hence to be immune to stop signals. A job control shell will set the handling to the default action and propagate this, allowing processes to stop. In doing so, the job control shell is taking responsibility for restarting the stopped applications. If an application wishes to catch the stop signals itself, it should first determine their inherited handling states. If a stop signal is being ignored, the application should continue to ignore it. This is directly analogous to the recommended handling of SIGINT described in the referenced UNIX Programmer’s Manual.

If an application is reading the terminal and has disabled the interpretation of special characters (by clearing the ISIG flag), the terminal I/O driver will not send SIGTSTP when the suspend character is typed. Such an application can simulate the effect of the suspend character by recognizing it and sending SIGTSTP to its process group as the terminal driver would have done. Note that the signal is sent to the process group, not just to the application itself; this ensures that other processes in the job also stop. (Note also that other processes in the job could be children, siblings, or even ancestors.) Applications should not assume that the suspend character is <control>-Z (or any particular value); they should retrieve the current setting at startup.

#### *Implementing Job Control Systems*

The intent in adding 4.2 BSD-style job control functionality was to adopt the necessary 4.2 BSD programmatic interface with only minimal changes to resolve syntactic or semantic conflicts with System V or to close recognized security holes. The goal was to maximize the ease of providing both conforming implementations and Conforming POSIX.1 Applications.

It is only useful for a process to be affected by job control signals if it is the descendant of a job control shell. Otherwise, there will be nothing that continues the stopped process.

POSIX.1 does not specify how controlling terminal access is affected by a user logging out (that is, by a controlling process terminating). 4.2 BSD uses the *vhangup()* function to prevent any access to the controlling terminal through file descriptors opened prior to logout. System V does not prevent controlling terminal access through file descriptors opened prior to logout (except for the case of the special file, */dev/tty*). Some implementations choose to make processes immune from job control after logout (that is, such processes are always treated as if in the foreground); other implementations continue to enforce foreground/background checks after logout. Therefore, a Conforming POSIX.1 Application should not attempt to access the controlling terminal after logout since such access is unreliable. If an implementation chooses to deny access to a controlling terminal after its controlling process exits, POSIX.1 requires a certain type of behavior (see **Controlling Terminal** (on page 15)).

**796 Kernel\***

797 See **System Call\*** (on page 30).

**798 Library Routine\***

799 See **System Call\*** (on page 30).

**800 Logical Device\***

801 Implementation-defined.

**802 Map**

803 The definition of map is included to clarify the usage of mapped pages in the description of the  
804 behavior of process memory locking.

**805 Memory-Resident**

806 The term “memory-resident” is historically understood to mean that the so-called resident  
807 pages are actually present in the physical memory of the computer system and are immune from  
808 swapping, paging, copy-on-write faults, and so on. This is the actual intent of  
809 IEEE Std 1003.1-2001 in the process memory locking section for implementations where this is  
810 logical. But for some implementations—primarily mainframes—actually locking pages into  
811 primary storage is not advantageous to other system objectives, such as maximizing throughput.  
812 For such implementations, memory locking is a “hint” to the implementation that the  
813 application wishes to avoid situations that would cause long latencies in accessing memory.  
814 Furthermore, there are other implementation-defined issues with minimizing memory access  
815 latencies that “memory residency” does not address—such as MMU reload faults. The definition  
816 attempts to accommodate various implementations while allowing conforming applications to  
817 specify to the implementation that they want or need the best memory access times that the  
818 implementation can provide.

**819 Memory Object\***

820 The term “memory object” usually implies shared memory. If the object is the same as a  
821 filename in the file system name space of the implementation, it is expected that the data written  
822 into the memory object be preserved on disk. A memory object may also apply to a physical  
823 device on an implementation. In this case, writes to the memory object are sent to the controller  
824 for the device and reads result in control registers being returned.

**825 Mount Point\***

826 The directory on which a “mounted file system” is mounted. This term, like *mount()* and  
827 *umount()*, was not included because it was implementation-defined.

**828 Mounted File System\***

829 See **File System** (on page 17).

**Name**

There are no explicit limits in IEEE Std 1003.1-2001 on the sizes of names, words (see the definition of word in the Base Definitions volume of IEEE Std 1003.1-2001), lines, or other objects. However, other implicit limits do apply: shell script lines produced by many of the standard utilities cannot exceed {LINE\_MAX} and the sum of exported variables comes under the {ARG\_MAX} limit. Historical shells dynamically allocate memory for names and words and parse incoming lines a character at a time. Lines cannot have an arbitrary {LINE\_MAX} limit because of historical practice, such as makefiles, where *make* removes the <newline>s associated with the commands for a target and presents the shell with one very long line. The text on INPUT FILES in the Shell and Utilities volume of IEEE Std 1003.1-2001, Section 1.11, Utility Description Defaults does allow a shell to run out of memory, but it cannot have arbitrary programming limits.

**Native Implementation\***

This refers to an implementation of POSIX.1 that interfaces directly to an operating system kernel; see also *hosted implementation*. A similar concept is a native UNIX system, which would be a kernel derived from one of the original UNIX system products.

**Nice Value**

This definition is not intended to suggest that all processes in a system have priorities that are comparable. Scheduling policy extensions, such as adding realtime priorities, make the notion of a single underlying priority for all scheduling policies problematic. Some implementations may implement the features related to *nice* to affect all processes on the system, others to affect just the general time-sharing activities implied by IEEE Std 1003.1-2001, and others may have no effect at all. Because of the use of “implementation-defined” in *nice* and *renice*, a wide range of implementation strategies is possible.

**Open File Description**

An “open file description”, as it is currently named, describes how a file is being accessed. What is currently called a “file descriptor” is actually just an identifier or “handle”; it does not actually describe anything.

The following alternate names were discussed:

- For “open file description”:  
“open instance”, “file access description”, “open file information”, and “file access information”.
- For “file descriptor”:  
“file handle”, “file number” (cf., *fileno()*). Some historical implementations use the term “file table entry”.

**Orphaned Process Group**

Historical implementations have a concept of an orphaned process, which is a process whose parent process has exited. When job control is in use, it is necessary to prevent processes from being stopped in response to interactions with the terminal after they no longer are controlled by a job control-cognizant program. Because signals generated by the terminal are sent to a process group and not to individual processes, and because a signal may be provoked by a process that is not orphaned, but sent to another process that is orphaned, it is necessary to define an orphaned process group. The definition assumes that a process group will be manipulated as a group and that the job control-cognizant process controlling the group is outside of the group

and is the parent of at least one process in the group (so that state changes may be reported via `waitpid()`). Therefore, a group is considered to be controlled as long as at least one process in the group has a parent that is outside of the process group, but within the session.

This definition of orphaned process groups ensures that a session leader's process group is always considered to be orphaned, and thus it is prevented from stopping in response to terminal signals.

## **Page**

The term “page” is defined to support the description of the behavior of memory mapping for shared memory and memory mapped files, and the description of the behavior of process memory locking. It is not intended to imply that shared memory/file mapping and memory locking are applicable only to “paged” architectures. For the purposes of IEEE Std 1003.1-2001, whatever the granularity on which an architecture supports mapping or locking, this is considered to be a “page”. If an architecture cannot support the memory mapping or locking functions specified by IEEE Std 1003.1-2001 on any granularity, then these options will not be implemented on the architecture.

## **Passwd File\***

Implementation-defined; see **User Database** (on page 32).

## **Parent Directory**

There may be more than one directory entry pointing to a given directory in some implementations. The wording here identifies that exactly one of those is the parent directory. In pathname resolution, dot-dot is identified as the way that the unique directory is identified. (That is, the parent directory is the one to which dot-dot points.) In the case of a remote file system, if the same file system is mounted several times, it would appear as if they were distinct file systems (with interesting synchronization properties).

## **Pipe**

It proved convenient to define a pipe as a special case of a FIFO, even though historically the latter was not introduced until System III and does not exist at all in 4.3 BSD.

## **Portable Filename Character Set**

The encoding of this character set is not specified—specifically, ASCII is not required. But the implementation must provide a unique character code for each of the printable graphics specified by POSIX.1; see also Section A.4.6 (on page 34).

Situations where characters beyond the portable filename character set (or historically ASCII or the ISO/IEC 646:1991 standard) would be used (in a context where the portable filename character set or the ISO/IEC 646:1991 standard is required by POSIX.1) are expected to be common. Although such a situation renders the use technically non-compliant, mutual agreement among the users of an extended character set will make such use portable between those users. Such a mutual agreement could be formalized as an optional extension to POSIX.1. (Making it required would eliminate too many possible systems, as even those systems using the ISO/IEC 646:1991 standard as a base character set extend their character sets for Western Europe and the rest of the world in different ways.)

Nothing in POSIX.1 is intended to preclude the use of extended characters where interchange is not required or where mutual agreement is obtained. It has been suggested that in several places “should” be used instead of “shall”. Because (in the worst case) use of any character beyond the

portable filename character set would render the program or data not portable to all possible systems, no extensions are permitted in this context.

### Regular File

POSIX.1 does not intend to preclude the addition of structuring data (for example, record lengths) in the file, as long as such data is not visible to an application that uses the features described in POSIX.1.

### Root Directory

This definition permits the operation of *chroot()*, even though that function is not in POSIX.1; see also Section A.4.5 (on page 33).

### Root File System\*

Implementation-defined.

### Root of a File System\*

Implementation-defined; see **Mount Point\*** (on page 22).

### Signal

The definition implies a double meaning for the term. Although a signal is an event, common usage implies that a signal is an identifier of the class of event.

### Superuser\*

This concept, with great historical significance to UNIX system users, has been replaced with the notion of appropriate privileges.

### Supplementary Group ID

The POSIX.1-1990 standard is inconsistent in its treatment of supplementary groups. The definition of supplementary group ID explicitly permits the effective group ID to be included in the set, but wording in the description of the *setuid()* and *setgid()* functions states: “Any supplementary group IDs of the calling process remain unchanged by these function calls”. In the case of *setgid()* this contradicts that definition. In addition, some felt that the unspecified behavior in the definition of supplementary group IDs adds unnecessary portability problems. The standard developers considered several solutions to this problem:

1. Reword the description of *setgid()* to permit it to change the supplementary group IDs to reflect the new effective group ID. A problem with this is that it adds more “may”s to the wording and does not address the portability problems of this optional behavior.
2. Mandate the inclusion of the effective group ID in the supplementary set (giving {NGROUPS\_MAX} a minimum value of 1). This is the behavior of 4.4 BSD. In that system, the effective group ID is the first element of the array of supplementary group IDs (there is no separate copy stored, and changes to the effective group ID are made only in the supplementary group set). By convention, the initial value of the effective group ID is duplicated elsewhere in the array so that the initial value is not lost when executing a set-group-ID program.
3. Change the definition of supplementary group ID to exclude the effective group ID and specify that the effective group ID does not change the set of supplementary group IDs. This is the behavior of 4.2 BSD, 4.3 BSD, and System V Release 4.

4. Change the definition of supplementary group ID to exclude the effective group ID, and require that *getgroups()* return the union of the effective group ID and the supplementary group IDs.
5. Change the definition of {NGROUPS\_MAX} to be one more than the number of supplementary group IDs, so it continues to be the number of values returned by *getgroups()* and existing applications continue to work. This alternative is effectively the same as the second (and might actually have the same implementation).

The standard developers decided to permit either 2 or 3. The effective group ID is orthogonal to the set of supplementary group IDs, and it is implementation-defined whether *getgroups()* returns this. If the effective group ID is returned with the set of supplementary group IDs, then all changes to the effective group ID affect the supplementary group set returned by *getgroups()*. It is permissible to eliminate duplicates from the list returned by *getgroups()*. However, if a group ID is contained in the set of supplementary group IDs, setting the group ID to that value and then to a different value should not remove that value from the supplementary group IDs.

The definition of supplementary group IDs has been changed to not include the effective group ID. This simplifies permanent rationale and makes the relevant functions easier to understand. The *getgroups()* function has been modified so that it can, on an implementation-defined basis, return the effective group ID. By making this change, functions that modify the effective group ID do not need to discuss adding to the supplementary group list; the only view into the supplementary group list that the application writer has is through the *getgroups()* function.

## Symbolic Link

Many implementations associate no attributes, including ownership with symbolic links. Security experts encouraged consideration for defining these attributes as optional. Consideration was given to changing *utime()* to allow modification of the times for a symbolic link, or as an alternative adding an *lutime()* interface. Modifications to *chown()* were also considered: allow changing symbolic link ownership or alternatively adding *lchown()*. As a result of alignment with the Single UNIX Specification, the *lchown()* function is included as part of the XSI extension and XSI-conformant systems may support an owner and a group associated with a symbolic link. There was no consensus to define further attributes for symbolic links, and for systems not supporting the XSI extension only the file type bits in the *st\_mode* member and the *st\_size* member of the **stat** structure are required to be applicable to symbolic links.

Historical implementations were followed when determining which interfaces should apply to symbolic links. Interfaces that historically followed symbolic links include *chmod()*, *link()*, and *utime()*. Interfaces that historically do not follow symbolic links include *chown()*, *lstat()*, *readlink()*, *rename()*, *remove()*, *rmdir()*, and *unlink()*. IEEE Std 1003.1-2001 deviates from historical practice only in the case of *chown()*. Because there is no requirement for systems not supporting the XSI extension that there is an association of ownership with symbolic links, there was no interface in the base standard to change ownership. In addition, other implementations of symbolic links have modified *chown()* to follow symbolic links.

In the case of symbolic links, IEEE Std 1003.1-2001 states that a trailing slash is considered to be the final component of a pathname rather than the pathname component that preceded it. This is the behavior of historical implementations. For example, for */a/b* and */a/b/*, if */a/b* is a symbolic link to a directory, then */a/b* refers to the symbolic link, and */a/b/* is the same as */a/b/.*, which is the directory to which the symbolic link points.

For multi-level security purposes, it is possible to have the link read mode govern permission for the *readlink()* function. It is also possible that the read permissions of the directory containing the link be used for this purpose. Implementations may choose to use either of these methods; however, this is not current practice and neither method is specified.

Several reasons were advanced for requiring that when a symbolic link is used as the source argument to the *link()* function, the resulting link will apply to the file named by the contents of the symbolic link rather than to the symbolic link itself. This is the case in historical implementations. This action was preferred, as it supported the traditional idea of persistence with respect to the target of a hard link. This decision is appropriate in light of a previous decision not to require association of attributes with symbolic links, thereby allowing implementations which do not use inodes. Opposition centered on the lack of symmetry on the part of the *link()* and *unlink()* function pair with respect to symbolic links.

Because a symbolic link and its referenced object coexist in the file system name space, confusion can arise in distinguishing between the link itself and the referenced object. Historically, utilities and system calls have adopted their own link following conventions in a somewhat *ad hoc* fashion. Rules for a uniform approach are outlined here, although historical practice has been adhered to as much as was possible. To promote consistent system use, user-written utilities are encouraged to follow these same rules.

Symbolic links are handled either by operating on the link itself, or by operating on the object referenced by the link. In the latter case, an application or system call is said to “follow” the link. Symbolic links may reference other symbolic links, in which case links are dereferenced until an object that is not a symbolic link is found, a symbolic link that references a file that does not exist is found, or a loop is detected. (Current implementations do not detect loops, but have a limit on the number of symbolic links that they will dereference before declaring it an error.)

There are four domains for which default symbolic link policy is established in a system. In almost all cases, there are utility options that override this default behavior. The four domains are as follows:

1. Symbolic links specified to system calls that take filename arguments
2. Symbolic links specified as command line filename arguments to utilities that are not performing a traversal of a file hierarchy
3. Symbolic links referencing files not of type directory, specified to utilities that are performing a traversal of a file hierarchy
4. Symbolic links referencing files of type directory, specified to utilities that are performing a traversal of a file hierarchy

#### *First Domain*

The first domain is considered in earlier rationale.

#### *Second Domain*

The reason this category is restricted to utilities that are not traversing the file hierarchy is that some standard utilities take an option that specifies a hierarchical traversal, but by default operate on the arguments themselves. Generally, users specifying the option for a file hierarchy traversal wish to operate on a single, physical hierarchy, and therefore symbolic links, which may reference files outside of the hierarchy, are ignored. For example, *chown owner file* is a different operation from the same command with the **-R** option specified. In this example, the behavior of the command *chown owner file* is described here, while the behavior of the command *chown -R owner file* is described in the third and fourth domains.

The general rule is that the utilities in this category follow symbolic links named as arguments.

Exceptions in the second domain are:

- The *mv* and *rm* utilities do not follow symbolic links named as arguments, but respectively attempt to rename or delete them.

- The *ls* utility is also an exception to this rule. For compatibility with historical systems, when the **-R** option is not specified, the *ls* utility follows symbolic links named as arguments if the **-L** option is specified or if the **-F**, **-d**, or **-l** options are not specified. (If the **-L** option is specified, *ls* always follows symbolic links; it is the only utility where the **-L** option affects its behavior even though a tree walk is not being performed.)

All other standard utilities, when not traversing a file hierarchy, always follow symbolic links named as arguments.

Historical practice is that the **-h** option is specified if standard utilities are to act upon symbolic links instead of upon their targets. Examples of commands that have historically had a **-h** option for this purpose are the *chgrp*, *chown*, *file*, and *test* utilities.

### Third Domain

The third domain is symbolic links, referencing files not of type directory, specified to utilities that are performing a traversal of a file hierarchy. (This includes symbolic links specified as command line filename arguments or encountered during the traversal.)

The intention of the Shell and Utilities volume of IEEE Std 1003.1-2001 is that the operation that the utility is performing is applied to the symbolic link itself, if that operation is applicable to symbolic links. The reason that the operation is not required is that symbolic links in some implementations do not have such attributes as a file owner, and therefore the *chown* operation would be meaningless. If symbolic links on the system have an owner, it is the intention that the utility *chown* cause the owner of the symbolic link to change. If symbolic links do not have an owner, the symbolic link should be ignored. Specifically, by default, no change should be made to the file referenced by the symbolic link.

### Fourth Domain

The fourth domain is symbolic links referencing files of type directory, specified to utilities that are performing a traversal of a file hierarchy. (This includes symbolic links specified as command line filename arguments or encountered during the traversal.)

Most standard utilities do not, by default, indirect into the file hierarchy referenced by the symbolic link. (The Shell and Utilities volume of IEEE Std 1003.1-2001 uses the informal term “physical walk” to describe this case. The case where the utility does indirect through the symbolic link is termed a “logical walk”.)

There are three reasons for the default to be a physical walk:

1. With very few exceptions, a physical walk has been the historical default on UNIX systems supporting symbolic links. Because some utilities (that is, *rm*) must default to a physical walk, regardless, changing historical practice in this regard would be confusing to users and needlessly incompatible.
2. For systems where symbolic links have the historical file attributes (that is, *owner*, *group*, *mode*), defaulting to a logical traversal would require the addition of a new option to the commands to modify the attributes of the link itself. This is painful and more complex than the alternatives.
3. There is a security issue with defaulting to a logical walk. Historically, the command *chown -R user file* has been safe for the superuser because *setuid* and *setgid* bits were lost when the ownership of the file was changed. If the walk were logical, changing ownership would no longer be safe because a user might have inserted a symbolic link pointing to any file in the tree. Again, this would necessitate the addition of an option to the commands doing hierarchy traversal to not indirect through the symbolic links, and historical scripts doing recursive walks would instantly become security problems. While this is mostly an

1096 issue for system administrators, it is preferable to not have different defaults for different  
1097 classes of users.

1098 However, the standard developers agreed to leave it unspecified to achieve consensus.

1099 As consistently as possible, users may cause standard utilities performing a file hierarchy  
1100 traversal to follow any symbolic links named on the command line, regardless of the type of file  
1101 they reference, by specifying the **-H** (for half logical) option. This option is intended to make the  
1102 command line name space look like the logical name space.

1103 As consistently as possible, users may cause standard utilities performing a file hierarchy  
1104 traversal to follow any symbolic links named on the command line as well as any symbolic links  
1105 encountered during the traversal, regardless of the type of file they reference, by specifying the  
1106 **-L** (for logical) option. This option is intended to make the entire name space look like the  
1107 logical name space.

1108 For consistency, implementors are encouraged to use the **-P** (for “physical”) flag to specify the  
1109 physical walk in utilities that do logical walks by default for whatever reason. The only standard  
1110 utilities that require the **-P** option are *cd* and *pwd*; see the note below.

1111 When one or more of the **-H**, **-L**, and **-P** flags can be specified, the last one specified determines  
1112 the behavior of the utility. This permits users to alias commands so that the default behavior is a  
1113 logical walk and then override that behavior on the command line.

#### 1114 *Exceptions in the Third and Fourth Domains*

1115 The *ls* and *rm* utilities are exceptions to these rules. The *rm* utility never follows symbolic links  
1116 and does not support the **-H**, **-L**, or **-P** options. Some historical versions of *ls* always followed  
1117 symbolic links given on the command line whether the **-L** option was specified or not. Historical  
1118 versions of *ls* did not support the **-H** option. In IEEE Std 1003.1-2001, unless one of the **-H** or **-L**  
1119 options is specified, the *ls* utility only follows symbolic links to directories that are given as  
1120 operands. The *ls* utility does not support the **-P** option.

1121 The Shell and Utilities volume of IEEE Std 1003.1-2001 requires that the standard utilities *ls*, *find*,  
1122 and *pax* detect infinite loops when doing logical walks; that is, a directory, or more commonly a  
1123 symbolic link, that refers to an ancestor in the current file hierarchy. If the file system itself is  
1124 corrupted, causing the infinite loop, it may be impossible to recover. Because *find* and *ls* are often  
1125 used in system administration and security applications, they should attempt to recover and  
1126 continue as best as they can. The *pax* utility should terminate because the archive it was creating  
1127 is by definition corrupted. Other, less vital, utilities should probably simply terminate as well.  
1128 Implementations are strongly encouraged to detect infinite loops in all utilities.

1129 Historical practice is shown in Table A-1 (on page 30). The heading **SVID3** stands for the Third  
1130 Edition of the System V Interface Definition.

1131 Historically, several shells have had built-in versions of the *pwd* utility. In some of these shells,  
1132 *pwd* reported the physical path, and in others, the logical path. Implementations of the shell  
1133 corresponding to IEEE Std 1003.1-2001 must report the logical path by default. Earlier versions of  
1134 IEEE Std 1003.1-2001 did not require the *pwd* utility to be a built-in utility. Now that *pwd* is  
1135 required to set an environment variable in the current shell execution environment, it must be a  
1136 built-in utility.

1137 The *cd* command is required, by default, to treat the filename dot-dot logically. Implementors are  
1138 required to support the **-P** flag in *cd* so that users can have their current environment handled  
1139 physically. In 4.3 BSD, *chgrp* during tree traversal changed the group of the symbolic link, not  
1140 the target. Symbolic links in 4.4 BSD do not have *owner*, *group*, *mode*, or other standard UNIX  
1141 system file attributes.

| <i>tar</i>   |                | <b>-h</b> | <b>-h</b>      |           | Follow symlinks.                        |
| <i>test</i>  | <b>-h</b>      |           | <b>-h</b>      | <b>-h</b> | Affect the symlink.                     |

1176

**Synchronously-Generated Signal**

1177

1178

Those signals that may be generated synchronously include SIGABRT, SIGBUS, SIGILL, SIGFPE, SIGPIPE, and SIGSEGV.

1179

1180

Any signal sent via the *raise()* function or a *kill()* function targeting the current process is also considered synchronous.

1181

**System Call\***

1182

1183

The distinction between a “system call” and a “library routine” is an implementation detail that may differ between implementations and has thus been excluded from POSIX.1.

1184

See “Interface, Not Implementation” in **Introduction** (on page xiii).

**System Reboot**

A “system reboot” is an event initiated by an unspecified circumstance that causes all processes (other than special system processes) to be terminated in an implementation-defined manner, after which any changes to the state and contents of files created or written to by a Conforming POSIX.1 Application prior to the event are implementation-defined.

**Synchronized I/O Data (and File) Integrity Completion**

These terms specify that for synchronized read operations, pending writes must be successfully completed before the read operation can complete. This is motivated by two circumstances. Firstly, when synchronizing processes can access the same file, but not share common buffers (such as for a remote file system), this requirement permits the reading process to guarantee that it can read data written remotely. Secondly, having data written synchronously is insufficient to guarantee the order with respect to a subsequent write by a reading process, and thus this extra read semantic is necessary.

**Text File**

The term “text file” does not prevent the inclusion of control or other non-printable characters (other than NUL). Therefore, standard utilities that list text files as inputs or outputs are either able to process the special characters or they explicitly describe their limitations within their individual descriptions. The definition of “text file” has caused controversy. The only difference between text and binary files is that text files have lines of less than {LINE\_MAX} bytes, with no NUL characters, each terminated by a <newline>. The definition allows a file with a single <newline>, but not a totally empty file, to be called a text file. If a file ends with an incomplete line it is not strictly a text file by this definition. The <newline> referred to in IEEE Std 1003.1-2001 is not some generic line separator, but a single character; files created on systems where they use multiple characters for ends of lines are not portable to all conforming systems without some translation process unspecified by IEEE Std 1003.1-2001.

**Thread**

IEEE Std 1003.1-2001 defines a thread to be a flow of control within a process. Each thread has a minimal amount of private state; most of the state associated with a process is shared among all of the threads in the process. While most multi-thread extensions to POSIX have taken this approach, others have made different decisions.

**Note:** The choice to put threads within a process does not constrain implementations to implement threads in that manner. However, all functions have to behave as though threads share the indicated state information with the process from which they were created.

Threads need to share resources in order to cooperate. Memory has to be widely shared between threads in order for the threads to cooperate at a fine level of granularity. Threads keep data structures and the locks protecting those data structures in shared memory. For a data structure to be usefully shared between threads, such structures should not refer to any data that can only be interpreted meaningfully by a single thread. Thus, any system resources that might be referred to in data structures need to be shared between all threads. File descriptors, pathnames, and pointers to stack variables are all things that programmers want to share between their threads. Thus, the file descriptor table, the root directory, the current working directory, and the address space have to be shared.

Library implementations are possible as long as the effective behavior is as if system services invoked by one thread do not suspend other threads. This may be difficult for some library implementations on systems that do not provide asynchronous facilities.

1230 See Section B.2.9 (on page 150) for additional rationale.

### 1231 **Thread ID**

1232 See Section B.2.9.2 (on page 166) for additional rationale.

### 1233 **Thread-Safe Function**

1234 All functions required by IEEE Std 1003.1-2001 need to be thread-safe; see Section A.4.16 (on  
1235 page 40) and Section B.2.9.1 (on page 163) for additional rationale.

### 1236 **User Database**

1237 There are no references in IEEE Std 1003.1-2001 to a “passwd file” or a “group file”, and there is  
1238 no requirement that the *group* or *passwd* databases be kept in files containing editable text. Many  
1239 large timesharing systems use *passwd* databases that are hashed for speed. Certain security  
1240 classifications prohibit certain information in the *passwd* database from being publicly readable.

1241 The term “encoded” is used instead of “encrypted” in order to avoid the implementation  
1242 connotations (such as reversibility or use of a particular algorithm) of the latter term.

1243 The *getgrent()*, *setgrent()*, *endgrent()*, *getpwent()*, *setpwent()*, and *endpwent()* functions are not  
1244 included as part of the base standard because they provide a linear database search capability  
1245 that is not generally useful (the *getpwuid()*, *getpwnam()*, *getgrgid()*, and *getgrnam()* functions are  
1246 provided for keyed lookup) and because in certain distributed systems, especially those with  
1247 different authentication domains, it may not be possible or desirable to provide an application  
1248 with the ability to browse the system databases indiscriminately. They are provided on XSI-  
1249 conformant systems due to their historical usage by many existing applications.

1250 A change from historical implementations is that the structures used by these functions have  
1251 fields of the types **gid\_t** and **uid\_t**, which are required to be defined in the **<sys/types.h>** header.  
1252 IEEE Std 1003.1-2001 requires implementations to ensure that these types are defined by  
1253 inclusion of **<grp.h>** and **<pwd.h>**, respectively, without imposing any name space pollution or  
1254 errors from redefinition of types.

1255 IEEE Std 1003.1-2001 is silent about the content of the strings containing user or group names.  
1256 These could be digit strings. IEEE Std 1003.1-2001 is also silent as to whether such digit strings  
1257 bear any relationship to the corresponding (numeric) user or group ID.

### 1258 **Database Access**

1259 The thread-safe versions of the user and group database access functions return values in user-  
1260 supplied buffers instead of possibly using static data areas that may be overwritten by each call.

### 1261 **Virtual Processor\***

1262 The term “virtual processor” was chosen as a neutral term describing all kernel-level  
1263 schedulable entities, such as processes, Mach tasks, or lightweight processes. Implementing  
1264 threads using multiple processes as virtual processors, or implementing multiplexed threads  
1265 above a virtual processor layer, should be possible, provided some mechanism has also been  
1266 implemented for sharing state between processes or virtual processors. Many systems may also  
1267 wish to provide implementations of threads on systems providing “shared processes” or  
1268 “variable-weight processes”. It was felt that exposing such implementation details would  
1269 severely limit the type of systems upon which the threads interface could be supported and  
1270 prevent certain types of valid implementations. It was also determined that a virtual processor  
1271 interface was out of the scope of the Rationale (Informative) volume of IEEE Std 1003.1-2001.

1272 **XSI**

1273 This is introduced to allow IEEE Std 1003.1-2001 to be adopted as an IEEE standard and an Open  
 1274 Group Technical Standard, serving both the POSIX and the Single UNIX Specification in a core  
 1275 set of volumes.

1276 The term “XSI” has been used for 10 years in connection with the XPG series and the first and  
 1277 second versions of the base volumes of the Single UNIX Specification. The XSI margin code was  
 1278 introduced to denote the extended or more restrictive semantics beyond POSIX that are  
 1279 applicable to UNIX systems.

1280 **A.4 General Concepts**1281 **A.4.1 Concurrent Execution**

1282 There is no additional rationale provided for this section.

1283 **A.4.2 Directory Protection**

1284 There is no additional rationale provided for this section.

1285 **A.4.3 Extended Security Controls**

1286 Allowing an implementation to define extended security controls enables the use of  
 1287 IEEE Std 1003.1-2001 in environments that require different or more rigorous security than that  
 1288 provided in POSIX.1. Extensions are allowed in two areas: privilege and file access permissions.  
 1289 The semantics of these areas have been defined to permit extensions with reasonable, but not  
 1290 exact, compatibility with all existing practices. For example, the elimination of the superuser  
 1291 definition precludes identifying a process as privileged or not by virtue of its effective user ID.

1292 **A.4.4 File Access Permissions**

1293 A process should not try to anticipate the result of an attempt to access data by *a priori* use of  
 1294 these rules. Rather, it should make the attempt to access data and examine the return value (and  
 1295 possibly *errno* as well), or use *access()*. An implementation may include other security  
 1296 mechanisms in addition to those specified in POSIX.1, and an access attempt may fail because of  
 1297 those additional mechanisms, even though it would succeed according to the rules given in this  
 1298 section. (For example, the user’s security level might be lower than that of the object of the access  
 1299 attempt.) The supplementary group IDs provide another reason for a process to not attempt to  
 1300 anticipate the result of an access attempt.

1301 **A.4.5 File Hierarchy**

1302 Though the file hierarchy is commonly regarded to be a tree, POSIX.1 does not define it as such  
 1303 for three reasons:

- 1304 1. Links may join branches.
- 1305 2. In some network implementations, there may be no single absolute root directory; see  
 1306 *pathname resolution*.
- 1307 3. With symbolic links, the file system need not be a tree or even a directed acyclic graph.

1308 **A.4.6 Filenames**

1309 Historically, certain filenames have been reserved. This list includes **core**, **/etc/passwd**, and so  
 1310 on. Conforming applications should avoid these.

1311 Most historical implementations prohibit case folding in filenames; that is, treating uppercase  
 1312 and lowercase alphabetic characters as identical. However, some consider case folding desirable:

- 1313 • For user convenience
- 1314 • For ease-of-implementation of the POSIX.1 interface as a hosted system on some popular  
 1315 operating systems

1316 Variants, such as maintaining case distinctions in filenames, but ignoring them in comparisons,  
 1317 have been suggested. Methods of allowing escaped characters of the case opposite the default  
 1318 have been proposed.

1319 Many reasons have been expressed for not allowing case folding, including:

- 1320 • No solid evidence has been produced as to whether case-sensitivity or case-insensitivity is  
 1321 more convenient for users.
- 1322 • Making case-insensitivity a POSIX.1 implementation option would be worse than either  
 1323 having it or not having it, because:
  - 1324 — More confusion would be caused among users.
  - 1325 — Application developers would have to account for both cases in their code.
  - 1326 — POSIX.1 implementors would still have other problems with native file systems, such as  
 1327 short or otherwise constrained filenames or pathnames, and the lack of hierarchical  
 1328 directory structure.
- 1329 • Case folding is not easily defined in many European languages, both because many of them  
 1330 use characters outside the US ASCII alphabetic set, and because:
  - 1331 — In Spanish, the digraph "ll" is considered to be a single letter, the capitalized form of  
 1332 which may be either "Ll" or "LL", depending on context.
  - 1333 — In French, the capitalized form of a letter with an accent may or may not retain the accent,  
 1334 depending on the country in which it is written.
  - 1335 — In German, the sharp ess may be represented as a single character resembling a Greek  
 1336 beta (ß) in lowercase, but as the digraph "SS" in uppercase.
  - 1337 — In Greek, there are several lowercase forms of some letters; the one to use depends on its  
 1338 position in the word. Arabic has similar rules.
- 1339 • Many East Asian languages, including Japanese, Chinese, and Korean, do not distinguish  
 1340 case and are sometimes encoded in character sets that use more than one byte per character.
- 1341 • Multiple character codes may be used on the same machine simultaneously. There are  
 1342 several ISO character sets for European alphabets. In Japan, several Japanese character codes  
 1343 are commonly used together, sometimes even in filenames; this is evidently also the case in  
 1344 China. To handle case insensitivity, the kernel would have to at least be able to distinguish  
 1345 for which character sets the concept made sense.
- 1346 • The file system implementation historically deals only with bytes, not with characters, except  
 1347 for slash and the null byte.
- 1348 • The purpose of POSIX.1 is to standardize the common, existing definition, not to change it.  
 1349 Mandating case-insensitivity would make all historical implementations non-standard.

- Not only the interface, but also application programs would need to change, counter to the purpose of having minimal changes to existing application code.
- At least one of the original developers of the UNIX system has expressed objection in the strongest terms to either requiring case-insensitivity or making it an option, mostly on the basis that POSIX.1 should not hinder portability of application programs across related implementations in order to allow compatibility with unrelated operating systems.

Two proposals were entertained regarding case folding in filenames:

1. Remove all wording that previously permitted case folding.

Rationale Case folding is inconsistent with portable filename character set definition and filename definition (all characters except slash and null). No known implementations allowing all characters except slash and null also do case folding.

2. Change “though this practice is not recommended:” to “although this practice is strongly discouraged.”

Rationale If case folding must be included in POSIX.1, the wording should be stronger to discourage the practice.

The consensus selected the first proposal. Otherwise, a conforming application would have to assume that case folding would occur when it was not wanted, but that it would not occur when it was wanted.

#### A.4.7 File Times Update

This section reflects the actions of historical implementations. The times are not updated immediately, but are only marked for update by the functions. An implementation may update these times immediately.

The accuracy of the time update values is intentionally left unspecified so that systems can control the bandwidth of a possible covert channel.

The wording was carefully chosen to make it clear that there is no requirement that the conformance document contain information that might incidentally affect file update times. Any function that performs pathname resolution might update several *st\_atime* fields. Functions such as *getpwnam()* and *getgrnam()* might update the *st\_atime* field of some specific file or files. It is intended that these are not required to be documented in the conformance document, but they should appear in the system documentation.

#### A.4.8 Host and Network Byte Order

There is no additional rationale provided for this section.

#### A.4.9 Measurement of Execution Time

The methods used to measure the execution time of processes and threads, and the precision of these measurements, may vary considerably depending on the software architecture of the implementation, and on the underlying hardware. Implementations can also make tradeoffs between the scheduling overhead and the precision of the execution time measurements. IEEE Std 1003.1-2001 does not impose any requirement on the accuracy of the execution time; it instead specifies that the measurement mechanism and its precision are implementation-defined.

#### 1391 **A.4.10 Memory Synchronization**

1392 In older multi-processors, access to memory by the processors was strictly multiplexed. This  
 1393 meant that a processor executing program code interrogates or modifies memory in the order  
 1394 specified by the code and that all the memory operation of all the processors in the system  
 1395 appear to happen in some global order, though the operation histories of different processors are  
 1396 interleaved arbitrarily. The memory operations of such machines are said to be sequentially  
 1397 consistent. In this environment, threads can synchronize using ordinary memory operations. For  
 1398 example, a producer thread and a consumer thread can synchronize access to a circular data  
 1399 buffer as follows:

```

1400 int rdptr = 0;
1401 int wrptr = 0;
1402 data_t buf[BUFSIZE];

1403 Thread 1:
1404 while (work_to_do) {
1405 int next;

1406 buf[wrptr] = produce();
1407 next = (wrptr + 1) % BUFSIZE;
1408 while (rdptr == next)
1409 ;
1410 wrptr = next;
1411 }

1412 Thread 2:
1413 while (work_to_do) {
1414 while (rdptr == wrptr)
1415 ;
1416 consume(buf[rdptr]);
1417 rdptr = (rdptr + 1) % BUFSIZE;
1418 }

```

1419 In modern multi-processors, these conditions are relaxed to achieve greater performance. If one  
 1420 processor stores values in location A and then location B, then other processors loading data  
 1421 from location B and then location A may see the new value of B but the old value of A. The  
 1422 memory operations of such machines are said to be weakly ordered. On these machines, the  
 1423 circular buffer technique shown in the example will fail because the consumer may see the new  
 1424 value of *wrptr* but the old value of the data in the buffer. In such machines, synchronization can  
 1425 only be achieved through the use of special instructions that enforce an order on memory  
 1426 operations. Most high-level language compilers only generate ordinary memory operations to  
 1427 take advantage of the increased performance. They usually cannot determine when memory  
 1428 operation order is important and generate the special ordering instructions. Instead, they rely on  
 1429 the programmer to use synchronization primitives correctly to ensure that modifications to a  
 1430 location in memory are ordered with respect to modifications and/or access to the same location  
 1431 in other threads. Access to read-only data need not be synchronized. The resulting program is  
 1432 said to be data race-free.

1433 Synchronization is still important even when accessing a single primitive variable (for example,  
 1434 an integer). On machines where the integer may not be aligned to the bus data width or be larger  
 1435 than the data width, a single memory load may require multiple memory cycles. This means  
 1436 that it may be possible for some parts of the integer to have an old value while other parts have a  
 1437 newer value. On some processor architectures this cannot happen, but portable programs cannot  
 1438 rely on this.

In summary, a portable multi-threaded program, or a multi-process program that shares writable memory between processes, has to use the synchronization primitives to synchronize data access. It cannot rely on modifications to memory being observed by other threads in the order written in the application or even on modification of a single variable being seen atomically.

Conforming applications may only use the functions listed to synchronize threads of control with respect to memory access. There are many other candidates for functions that might also be used. Examples are: signal sending and reception, or pipe writing and reading. In general, any function that allows one thread of control to wait for an action caused by another thread of control is a candidate. IEEE Std 1003.1-2001 does not require these additional functions to synchronize memory access since this would imply the following:

- All these functions would have to be recognized by advanced compilation systems so that memory operations and calls to these functions are not reordered by optimization.
- All these functions would potentially have to have memory synchronization instructions added, depending on the particular machine.
- The additional functions complicate the model of how memory is synchronized and make automatic data race detection techniques impractical.

Formal definitions of the memory model were rejected as unreadable by the vast majority of programmers. In addition, most of the formal work in the literature has concentrated on the memory as provided by the hardware as opposed to the application programmer through the compiler and runtime system. It was believed that a simple statement intuitive to most programmers would be most effective. IEEE Std 1003.1-2001 defines functions that can be used to synchronize access to memory, but it leaves open exactly how one relates those functions to the semantics of each function as specified elsewhere in IEEE Std 1003.1-2001. IEEE Std 1003.1-2001 also does not make a formal specification of the partial ordering in time that the functions can impose, as that is implied in the description of the semantics of each function. It simply states that the programmer has to ensure that modifications do not occur “simultaneously” with other access to a memory location.

IEEE Std 1003.1-2001/Cor 1-2002, item XBD/TC1/D6/4 is applied, adding a new paragraph beneath the table of functions: “The *pthread\_once()* function shall synchronize memory for the first call in each thread for a given **pthread\_once\_t** object.”.

#### A.4.11 Pathname Resolution

It is necessary to differentiate between the definition of pathname and the concept of pathname resolution with respect to the handling of trailing slashes. By specifying the behavior here, it is not possible to provide an implementation that is conforming but extends all interfaces that handle pathnames to also handle strings that are not legal pathnames (because they have trailing slashes).

Pathnames that end with one or more trailing slash characters must refer to directory paths. Previous versions of IEEE Std 1003.1-2001 were not specific about the distinction between trailing slashes on files and directories, and both were permitted.

Two types of implementation have been prevalent; those that ignored trailing slash characters on all pathnames regardless, and those that permitted them only on existing directories.

IEEE Std 1003.1-2001 requires that a pathname with a trailing slash character be treated as if it had a trailing “/ . ” everywhere.

Note that this change does not break any conforming applications; since there were two different types of implementation, no application could have portably depended on either

behavior. This change does however require some implementations to be altered to remain compliant. Substantial discussion over a three-year period has shown that the benefits to application developers outweighs the disadvantages for some vendors.

On a historical note, some early applications automatically appended a `'/'` to every path. Rather than fix the applications, the system implementation was modified to accept this behavior by ignoring any trailing slash.

Each directory has exactly one parent directory which is represented by the name **dot-dot** in the first directory. No other directory, regardless of linkages established by symbolic links, is considered the parent directory by IEEE Std 1003.1-2001.

There are two general categories of interfaces involving pathname resolution: those that follow the symbolic link, and those that do not. There are several exceptions to this rule; for example, `open(path, O_CREAT|O_EXCL)` will fail when `path` names a symbolic link. However, in all other situations, the `open()` function will follow the link.

What the filename **dot-dot** refers to relative to the root directory is implementation-defined. In Version 7 it refers to the root directory itself; this is the behavior mentioned in IEEE Std 1003.1-2001. In some networked systems the construction `../hostname/` is used to refer to the root directory of another host, and POSIX.1 permits this behavior.

Other networked systems use the construct `//hostname` for the same purpose; that is, a double initial slash is used. There is a potential problem with existing applications that create full pathnames by taking a trunk and a relative pathname and making them into a single string separated by `'/'`, because they can accidentally create networked pathnames when the trunk is `'/'`. This practice is not prohibited because such applications can be made to conform by simply changing to use `"/"` as a separator instead of `'/'`:

- If the trunk is `'/'`, the full pathname will begin with `"/"` (the initial `'/'` and the separator `"/"`). This is the same as `'/'`, which is what is desired. (This is the general case of making a relative pathname into an absolute one by prefixing with `"/"` instead of `'/'`.)
- If the trunk is `"/A"`, the result is `"/A/..."`; since non-leading sequences of two or more slashes are treated as a single slash, this is equivalent to the desired `"/A/..."`.
- If the trunk is `"//A"`, the implementation-defined semantics will apply. (The multiple slash rule would apply.)

Application developers should avoid generating pathnames that start with `"/"`. Implementations are strongly encouraged to avoid using this special interpretation since a number of applications currently do not follow this practice and may inadvertently generate `"//..."`.

The term “root directory” is only defined in POSIX.1 relative to the process. In some implementations, there may be no absolute root directory. The initialization of the root directory of a process is implementation-defined.

1522 **A.4.12 Process ID Reuse**

1523 There is no additional rationale provided for this section.

1524 **A.4.13 Scheduling Policy**

1525 There is no additional rationale provided for this section.

1526 **A.4.14 Seconds Since the Epoch**

1527 Coordinated Universal Time (UTC) includes leap seconds. However, in POSIX time (seconds  
 1528 since the Epoch), leap seconds are ignored (not applied) to provide an easy and compatible  
 1529 method of computing time differences. Broken-down POSIX time is therefore not necessarily  
 1530 UTC, despite its appearance.

1531 As of September 2000, 24 leap seconds had been added to UTC since the Epoch, 1 January, 1970.  
 1532 Historically, one leap second is added every 15 months on average, so this offset can be expected  
 1533 to grow steadily with time.

1534 Most systems' notion of "time" is that of a continuously increasing value, so this value should  
 1535 increase even during leap seconds. However, not only do most systems not keep track of leap  
 1536 seconds, but most systems are probably not synchronized to any standard time reference.  
 1537 Therefore, it is inappropriate to require that a time represented as seconds since the Epoch  
 1538 precisely represent the number of seconds between the referenced time and the Epoch.

1539 It is sufficient to require that applications be allowed to treat this time as if it represented the  
 1540 number of seconds between the referenced time and the Epoch. It is the responsibility of the  
 1541 vendor of the system, and the administrator of the system, to ensure that this value represents  
 1542 the number of seconds between the referenced time and the Epoch as closely as necessary for the  
 1543 application being run on that system.

1544 It is important that the interpretation of time names and seconds since the Epoch values be  
 1545 consistent across conforming systems; that is, it is important that all conforming systems  
 1546 interpret "536 457 599 seconds since the Epoch" as 59 seconds, 59 minutes, 23 hours 31 December  
 1547 1986, regardless of the accuracy of the system's idea of the current time. The expression is given  
 1548 to ensure a consistent interpretation, not to attempt to specify the calendar. The relationship  
 1549 between *tm\_yday* and the day of week, day of month, and month is in accordance with the  
 1550 Gregorian calendar, and so is not specified in POSIX.1.

1551 Consistent interpretation of seconds since the Epoch can be critical to certain types of distributed  
 1552 applications that rely on such timestamps to synchronize events. The accrual of leap seconds in  
 1553 a time standard is not predictable. The number of leap seconds since the Epoch will likely  
 1554 increase. POSIX.1 is more concerned about the synchronization of time between applications of  
 1555 astronomically short duration.

1556 Note that *tm\_yday* is zero-based, not one-based, so the day number in the example above is 364.  
 1557 Note also that the division is an integer division (discarding remainder) as in the C language.

1558 Note also that the meaning of *gmtime()*, *localtime()*, and *mktime()* is specified in terms of this  
 1559 expression. However, the ISO C standard computes *tm\_yday* from *tm\_mday*, *tm\_mon*, and  
 1560 *tm\_year* in *mktime()*. Because it is stated as a (bidirectional) relationship, not a function, and  
 1561 because the conversion between month-day-year and day-of-year dates is presumed well known  
 1562 and is also a relationship, this is not a problem.

1563 Implementations that implement **time\_t** as a signed 32-bit integer will overflow in 2038. The  
 1564 data size for **time\_t** is as per the ISO C standard definition, which is implementation-defined.

1565 See also **Epoch** (on page 17).

1566 The topic of whether seconds since the Epoch should account for leap seconds has been debated  
1567 on a number of occasions, and each time consensus was reached (with acknowledged dissent  
1568 each time) that the majority of users are best served by treating all days identically. (That is, the  
1569 majority of applications were judged to assume a single length—as measured in seconds since  
1570 the Epoch—for all days. Thus, leap seconds are not applied to seconds since the Epoch.) Those  
1571 applications which do care about leap seconds can determine how to handle them in whatever  
1572 way those applications feel is best. This was particularly emphasized because there was  
1573 disagreement about what the best way of handling leap seconds might be. It is a practical  
1574 impossibility to mandate that a conforming implementation must have a fixed relationship to  
1575 any particular official clock (consider isolated systems, or systems performing “reruns” by  
1576 setting the clock to some arbitrary time).

1577 Note that as a practical consequence of this, the length of a second as measured by some external  
1578 standard is not specified. This unspecified second is nominally equal to an International System  
1579 (SI) second in duration. Applications must be matched to a system that provides the particular  
1580 handling of external time in the way required by the application.

#### 1581 **A.4.15 Semaphore**

1582 There is no additional rationale provided for this section.

#### 1583 **A.4.16 Thread-Safety**

1584 Where the interface of a function required by IEEE Std 1003.1-2001 precludes thread-safety, an  
1585 alternate thread-safe form is provided. The names of these thread-safe forms are the same as the  
1586 non-thread-safe forms with the addition of the suffix “\_r”. The suffix “\_r” is historical, where  
1587 the ‘r’ stood for “reentrant”.

1588 In some cases, thread-safety is provided by restricting the arguments to an existing function.

1589 See also Section B.2.9.1 (on page 163).

#### 1590 **A.4.17 Tracing**

1591 Refer to Section B.2.11 (on page 179).

#### 1592 **A.4.18 Treatment of Error Conditions for Mathematical Functions**

1593 There is no additional rationale provided for this section.

#### 1594 **A.4.19 Treatment of NaN Arguments for Mathematical Functions**

1595 There is no additional rationale provided for this section.

#### 1596 **A.4.20 Utility**

1597 There is no additional rationale provided for this section.

1598 **A.4.21 Variable Assignment**

1599 There is no additional rationale provided for this section.

1600 **A.5 File Format Notation**

1601 The notation for spaces allows some flexibility for application output. Note that an empty  
 1602 character position in *format* represents one or more <blank>s on the output (not *white space*,  
 1603 which can include <newline>s). Therefore, another utility that reads that output as its input  
 1604 must be prepared to parse the data using *scanf()*, *awk*, and so on. The 'Δ' character is used when  
 1605 exactly one <space> is output.

1606 The treatment of integers and spaces is different from the *printf()* function in that they can be  
 1607 surrounded with <blank>s. This was done so that, given a format such as:

1608 `"%d\n", <foo>`1609 the implementation could use a *printf()* call such as:1610 `printf("%6d\n", foo);`1611 and still conform. This notation is thus somewhat like *scanf()* in addition to *printf()*.

1612 The *printf()* function was chosen as a model because most of the standard developers were  
 1613 familiar with it. One difference from the C function *printf()* is that the l and h conversion  
 1614 specifier characters are not used. As expressed by the Shell and Utilities volume of  
 1615 IEEE Std 1003.1-2001, there is no differentiation between decimal values for type **int**, type **long**,  
 1616 or type **short**. The conversion specifications %d or %i should be interpreted as an arbitrary  
 1617 length sequence of digits. Also, no distinction is made between single precision and double  
 1618 precision numbers (**float** or **double** in C). These are simply referred to as floating-point numbers.

1619 Many of the output descriptions in the Shell and Utilities volume of IEEE Std 1003.1-2001 use the  
 1620 term “line”, such as:

1621 `"%s", <input line>`

1622 Since the definition of *line* includes the trailing <newline> already, there is no need to include a  
 1623 '\n' in the format; a double <newline> would otherwise result.

1624 **A.6 Character Set**1625 **A.6.1 Portable Character Set**

1626 The portable character set is listed in full so there is no dependency on the ISO/IEC 646:1991  
 1627 standard (or historically ASCII) encoded character set, although the set is identical to the  
 1628 characters defined in the International Reference version of the ISO/IEC 646:1991 standard.

1629 IEEE Std 1003.1-2001 poses no requirement that multiple character sets or codesets be supported,  
 1630 leaving this as a marketing differentiation for implementors. Although multiple charmap files  
 1631 are supported, it is the responsibility of the implementation to provide the file(s); if only one is  
 1632 provided, only that one will be accessible using the *localedef -f* option.

1633 The statement about invariance in codesets for the portable character set is worded to avoid  
 1634 precluding implementations where multiple incompatible codesets are available (for instance,  
 1635 ASCII and EBCDIC). The standard utilities cannot be expected to produce predictable results if  
 1636 they access portable characters that vary on the same implementation.

Not all character sets need include the portable character set, but each locale must include it. For example, a Japanese-based locale might be supported by a mixture of character sets: JIS X 0201 Roman (a Japanese version of the ISO/IEC 646:1991 standard), JIS X 0208, and JIS X 0201 Katakana. Not all of these character sets include the portable characters, but at least one does (JIS X 0201 Roman).

## A.6.2 Character Encoding

Encoding mechanisms based on single shifts, such as the EUC encoding used in some Asian and other countries, can be supported via the current charmap mechanism. With single-shift encoding, each character is preceded by a shift code (SS2 or SS3). A complete EUC code, consisting of the portable character set (G0) and up to three additional character sets (G1, G2, G3), can be described using the current charmap mechanism; the encoding for each character in additional character sets G2 and G3 must then include their single-shift code. Other mechanisms to support locales based on encoding mechanisms such as locking shift are not addressed by this volume of IEEE Std 1003.1-2001.

## A.6.3 C Language Wide-Character Codes

There is no additional rationale provided for this section.

## A.6.4 Character Set Description File

IEEE PASC Interpretation 1003.2 #196 is applied, removing three lines of text dealing with ranges of symbolic names using position constant values which had been erroneously included in the final IEEE P1003.2b draft standard.

### A.6.4.1 State-Dependent Character Encodings

A requirement was considered that would force utilities to eliminate any redundant locking shifts, but this was left as a quality of implementation issue.

This change satisfies the following requirement from the ISO POSIX-2:1993 standard, Annex H.1:

*The support of state-dependent (shift encoding) character sets should be addressed fully. See descriptions of these in the Base Definitions volume of IEEE Std 1003.1-2001, Section 6.2, Character Encoding. If such character encodings are supported, it is expected that this will impact the Base Definitions volume of IEEE Std 1003.1-2001, Section 6.2, Character Encoding, the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 7, Locale, the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 9, Regular Expressions, and the comm, cut, diff, grep, head, join, paste, and tail utilities.*

The character set description file provides:

- The capability to describe character set attributes (such as collation order or character classes) independent of character set encoding, and using only the characters in the portable character set. This makes it possible to create generic *localedef* source files for all codesets that share the portable character set (such as the ISO 8859 family or IBM Extended ASCII).
- Standardized symbolic names for all characters in the portable character set, making it possible to refer to any such character regardless of encoding.

Implementations are free to choose their own symbolic names, as long as the names identified by the Base Definitions volume of IEEE Std 1003.1-2001 are also defined; this provides support for already existing “character names”.

1679 The names selected for the members of the portable character set follow the  
 1680 ISO/IEC 8859-1:1998 standard and the ISO/IEC 10646-1:2000 standard. However, several  
 1681 commonly used UNIX system names occur as synonyms in the list:

- 1682 • The historical UNIX system names are used for control characters.
- 1683 • The word “slash” is given in addition to “solidus”.
- 1684 • The word “backslash” is given in addition to “reverse-solidus”.
- 1685 • The word “hyphen” is given in addition to “hyphen-minus”.
- 1686 • The word “period” is given in addition to “full-stop”.
- 1687 • For digits, the word “digit” is eliminated.
- 1688 • For letters, the words “Latin Capital Letter” and “Latin Small Letter” are eliminated.
- 1689 • The words “left brace” and “right brace” are given in addition to “left-curly-bracket” and  
 1690 “right-curly-bracket”.
- 1691 • The names of the digits are preferred over the numbers to avoid possible confusion between  
 1692 ‘0’ and ‘O’, and between ‘1’ and ‘l’ (one and the letter ell).

1693 The names for the control characters in the Base Definitions volume of IEEE Std 1003.1-2001,  
 1694 Chapter 6, Character Set were taken from the ISO/IEC 4873:1991 standard.

1695 The charmap file was introduced to resolve problems with the portability of, especially, *localedef*  
 1696 sources. IEEE Std 1003.1-2001 assumes that the portable character set is constant across all  
 1697 locales, but does not prohibit implementations from supporting two incompatible codings, such  
 1698 as both ASCII and EBCDIC. Such dual-support implementations should have all charmaps and  
 1699 *localedef* sources encoded using one portable character set, in effect cross-compiling for the other  
 1700 environment. Naturally, charmaps (and *localedef* sources) are only portable without  
 1701 transformation between systems using the same encodings for the portable character set. They  
 1702 can, however, be transformed between two sets using only a subset of the actual characters (the  
 1703 portable character set). However, the particular coded character set used for an application or an  
 1704 implementation does not necessarily imply different characteristics or collation; on the contrary,  
 1705 these attributes should in many cases be identical, regardless of codeset. The charmap provides  
 1706 the capability to define a common locale definition for multiple codesets (the same *localedef*  
 1707 source can be used for codesets with different extended characters; the ability in the charmap to  
 1708 define empty names allows for characters missing in certain codesets).

1709 The **<escape\_char>** declaration was added at the request of the international community to ease  
 1710 the creation of portable charmap files on terminals not implementing the default backslash  
 1711 escape. The **<comment\_char>** declaration was added at the request of the international  
 1712 community to eliminate the potential confusion between the number sign and the pound sign.

1713 The octal number notation with no leading zero required was selected to match those of *awk* and  
 1714 *tr* and is consistent with that used by *localedef*. To avoid confusion between an octal constant  
 1715 and the back-references used in *localedef* source, the octal, hexadecimal, and decimal constants  
 1716 must contain at least two digits. As single-digit constants are relatively rare, this should not  
 1717 impose any significant hardship. Provision is made for more digits to account for systems in  
 1718 which the byte size is larger than 8 bits. For example, a Unicode (ISO/IEC 10646-1:2000  
 1719 standard) system that has defined 16-bit bytes may require six octal, four hexadecimal, and five  
 1720 decimal digits.

1721 The decimal notation is supported because some newer international standards define character  
 1722 values in decimal, rather than in the old column/row notation.

The charmap identifies the coded character sets supported by an implementation. At least one charmap must be provided, but no implementation is required to provide more than one. Likewise, implementations can allow users to generate new charmaps (for instance, for a new version of the ISO 8859 family of coded character sets), but does not have to do so. If users are allowed to create new charmaps, the system documentation describes the rules that apply (for instance, “only coded character sets that are supersets of the ISO/IEC 646:1991 standard IRV, no multi-byte characters”).

This addition of the **WIDTH** specification satisfies the following requirement from the ISO POSIX-2:1993 standard, Annex H.1:

- (9) *The definition of column position relies on the implementation’s knowledge of the integral width of the characters. The charmap or LC\_CTYPE locale definitions should be enhanced to allow application specification of these widths.*

The character “width” information was first considered for inclusion under *LC\_CTYPE* but was moved because it is more closely associated with the information in the charmap than information in the locale source (cultural conventions information). Concerns were raised that formalizing this type of information is moving the locale source definition from the codeset-independent entity that it was designed to be to a repository of codeset-specific information. A similar issue occurred with the *<code\_set\_name>*, *<mb\_cur\_max>*, and *<mb\_cur\_min>* information, which was resolved to reside in the charmap definition.

The width definition was added to the IEEE P1003.2b draft standard with the intent that the *wcswidth()* and/or *wcwidth()* functions (currently specified in the System Interfaces volume of IEEE Std 1003.1-2001) be the mechanism to retrieve the character width information.

## A.7 Locale

### A.7.1 General

The description of locales is based on work performed in the UniForum Technical Committee, Subcommittee on Internationalization. Wherever appropriate, keywords are taken from the ISO C standard or the X/Open Portability Guide.

The value used to specify a locale with environment variables is the name specified as the *name* operand to the *localedef* utility when the locale was created. This provides a verifiable method to create and invoke a locale.

The “object” definitions need not be portable, as long as “source” definitions are. Strictly speaking, source definitions are portable only between implementations using the same character set(s). Such source definitions, if they use symbolic names only, easily can be ported between systems using different codesets, as long as the characters in the portable character set (see the Base Definitions volume of IEEE Std 1003.1-2001, Section 6.1, Portable Character Set) have common values between the codesets; this is frequently the case in historical implementations. Of source, this requires that the symbolic names used for characters outside the portable character set be identical between character sets. The definition of symbolic names for characters is outside the scope of IEEE Std 1003.1-2001, but is certainly within the scope of other standards organizations.

Applications can select the desired locale by invoking the *setlocale()* function (or equivalent) with the appropriate value. If the function is invoked with an empty string, the value of the corresponding environment variable is used. If the environment variable is not set or is set to the empty string, the implementation sets the appropriate environment as defined in the Base

1767 Definitions volume of IEEE Std 1003.1-2001, Chapter 8, Environment Variables.

## 1768 **A.7.2 POSIX Locale**

1769 The POSIX locale is equal to the C locale. To avoid being classified as a C-language function, the  
1770 name has been changed to the POSIX locale; the environment variable value can be either  
1771 "POSIX" or, for historical reasons, "C".

1772 The POSIX definitions mirror the historical UNIX system behavior.

1773 The use of symbolic names for characters in the tables does not imply that the POSIX locale must  
1774 be described using symbolic character names, but merely that it may be advantageous to do so.

## 1775 **A.7.3 Locale Definition**

1776 The decision to separate the file format from the *localedef* utility description was only partially  
1777 editorial. Implementations may provide other interfaces than *localedef*. Requirements on “the  
1778 utility”, mostly concerning error messages, are described in this way because they are meant to  
1779 affect the other interfaces implementations may provide as well as *localedef*.

1780 The text about POSIX2\_LOCALEDEF does not mean that internationalization is optional; only  
1781 that the functionality of the *localedef* utility is. REs, for instance, must still be able to recognize,  
1782 for example, character class expressions such as "[[:alpha:]]". A possible analogy is with  
1783 an applications development environment; while all conforming implementations must be  
1784 capable of executing applications, not all need to have the development environment installed.  
1785 The assumption is that the capability to modify the behavior of utilities (and applications) via  
1786 locale settings must be supported. If the *localedef* utility is not present, then the only choice is to  
1787 select an existing (presumably implementation-documented) locale. An implementation could,  
1788 for example, choose to support only the POSIX locale, which would in effect limit the amount of  
1789 changes from historical implementations quite drastically. The *localedef* utility is still required,  
1790 but would always terminate with an exit code indicating that no locale could be created.  
1791 Supported locales must be documented using the syntax defined in this chapter. (This ensures  
1792 that users can accurately determine what capabilities are provided. If the implementation  
1793 decides to provide additional capabilities to the ones in this chapter, that is already provided  
1794 for.)

1795 If the option is present (that is, locales can be created), then the *localedef* utility must be capable  
1796 of creating locales based on the syntax and rules defined in this chapter. This does not mean that  
1797 the implementation cannot also provide alternate means for creating locales.

1798 The octal, decimal, and hexadecimal notations are the same employed by the charmap facility  
1799 (see the Base Definitions volume of IEEE Std 1003.1-2001, Section 6.4, Character Set Description  
1800 File). To avoid confusion between an octal constant and a back-reference, the octal, hexadecimal,  
1801 and decimal constants must contain at least two digits. As single-digit constants are relatively  
1802 rare, this should not impose any significant hardship. Provision is made for more digits to  
1803 account for systems in which the byte size is larger than 8 bits. For example, a Unicode (see the  
1804 ISO/IEC 10646-1:2000 standard) system that has defined 16-bit bytes may require six octal, four  
1805 hexadecimal, and five decimal digits. As with the charmap file, multi-byte characters are  
1806 described in the locale definition file using “big-endian” notation for reasons of portability.  
1807 There is no requirement that the internal representation in the computer memory be in this same  
1808 order.

1809 One of the guidelines used for the development of this volume of IEEE Std 1003.1-2001 is that  
1810 characters outside the invariant part of the ISO/IEC 646:1991 standard should not be used in  
1811 portable specifications. The backslash character is not in the invariant part; the number sign is,  
1812 but with multiple representations: as a number sign, and as a pound sign. As far as general

usage of these symbols, they are covered by the “grandfather clause”, but for newly defined interfaces, the WG15 POSIX working group has requested that POSIX provide alternate representations. Consequently, while the default escape character remains the backslash and the default comment character is the number sign, implementations are required to recognize alternative representations, identified in the applicable source file via the `<escape_char>` and `<comment_char>` keywords.

#### A.7.3.1 *LC\_CTYPE*

The *LC\_CTYPE* category is primarily used to define the encoding-independent aspects of a character set, such as character classification. In addition, certain encoding-dependent characteristics are also defined for an application via the *LC\_CTYPE* category. IEEE Std 1003.1-2001 does not mandate that the encoding used in the locale is the same as the one used by the application because an implementation may decide that it is advantageous to define locales in a system-wide encoding rather than having multiple, logically identical locales in different encodings, and to convert from the application encoding to the system-wide encoding on usage. Other implementations could require encoding-dependent locales.

In either case, the *LC\_CTYPE* attributes that are directly dependent on the encoding, such as `<mb_cur_max>` and the display width of characters, are not user-specifiable in a locale source and are consequently not defined as keywords.

Implementations may define additional keywords or extend the *LC\_CTYPE* mechanism to allow application-defined keywords.

The text “The ellipsis specification shall only be valid within a single encoded character set” is present because it is possible to have a locale supported by multiple character encodings, as explained in the rationale for the Base Definitions volume of IEEE Std 1003.1-2001, Section 6.1, Portable Character Set. An example given there is of a possible Japanese-based locale supported by a mixture of the character sets JIS X 0201 Roman, JIS X 0208, and JIS X 0201 Katakana. Attempting to express a range of characters across these sets is not logical and the implementation is free to reject such attempts.

As the *LC\_CTYPE* character classes are based on the ISO C standard character class definition, the category does not support multi-character elements. For instance, the German character `<sharp-s>` is traditionally classified as a lowercase letter. There is no corresponding uppercase letter; in proper capitalization of German text, the `<sharp-s>` will be replaced by “SS”; that is, by two characters. This kind of conversion is outside the scope of the **toupper** and **tolower** keywords.

Where IEEE Std 1003.1-2001 specifies that only certain characters can be specified, as for the keywords **digit** and **xdigit**, the specified characters must be from the portable character set, as shown. As an example, only the Arabic digits 0 through 9 are acceptable as digits.

The character classes **digit**, **xdigit**, **lower**, **upper**, and **space** have a set of automatically included characters. These only need to be specified if the character values (that is, encoding) differs from the implementation default values. It is not possible to define a locale without these automatically included characters unless some implementation extension is used to prevent their inclusion. Such a definition would not be a proper superset of the C locale, and thus, it might not be possible for the standard utilities to be implemented as programs conforming to the ISO C standard.

The definition of character class **digit** requires that only ten characters—the ones defining digits—can be specified; alternate digits (for example, Hindi or Kanji) cannot be specified here. However, the encoding may vary if an implementation supports more than one encoding.

The definition of character class **xdigit** requires that the characters included in character class **digit** are included here also and allows for different symbols for the hexadecimal digits 10 through 15.

The inclusion of the **charclass** keyword satisfies the following requirement from the ISO POSIX-2: 1993 standard, Annex H.1:

(3) *The LC\_CTYPE (2.5.2.1) locale definition should be enhanced to allow user-specified additional character classes, similar in concept to the ISO C standard Multibyte Support Extension (MSE) iswctype() function.*

This keyword was previously included in The Open Group specifications and is now mandated in the Shell and Utilities volume of IEEE Std 1003.1-2001.

The symbolic constant {CHARCLASS\_NAME\_MAX} was also adopted from The Open Group specifications. Applications portability is enhanced by the use of symbolic constants.

#### A.7.3.2 LC\_COLLATE

The rules governing collation depend to some extent on the use. At least five different levels of increasingly complex collation rules can be distinguished:

1. *Byte/machine code order:* This is the historical collation order in the UNIX system and many proprietary operating systems. Collation is here performed character by character, without any regard to context. The primary virtue is that it usually is quite fast and also completely deterministic; it works well when the native machine collation sequence matches the user expectations.
2. *Character order:* On this level, collation is also performed character by character, without regard to context. The order between characters is, however, not determined by the code values, but on the expectations by the user of the “correct” order between characters. In addition, such a (simple) collation order can specify that certain characters collate equally (for example, uppercase and lowercase letters).
3. *String ordering:* On this level, entire strings are compared based on relatively straightforward rules. Several “passes” may be required to determine the order between two strings. Characters may be ignored in some passes, but not in others; the strings may be compared in different directions; and simple string substitutions may be performed before strings are compared. This level is best described as “dictionary” ordering; it is based on the spelling, not the pronunciation, or meaning, of the words.
4. *Text search ordering:* This is a further refinement of the previous level, best described as “telephone book ordering”; some common homonyms (words spelled differently but with the same pronunciation) are collated together; numbers are collated as if they were spelled out, and so on.
5. *Semantic-level ordering:* Words and strings are collated based on their meaning; entire words (such as “the”) are eliminated; the ordering is not deterministic. This usually requires special software and is highly dependent on the intended use.

While the historical collation order formally is at level 1, for the English language it corresponds roughly to elements at level 2. The user expects to see the output from the *ls* utility sorted very much as it would be in a dictionary. While telephone book ordering would be an optimal goal for standard collation, this was ruled out as the order would be language-dependent. Furthermore, a requirement was that the order must be determined solely from the text string and the collation rules; no external information (for example, “pronunciation dictionaries”) could be required.

1904 As a result, the goal for the collation support is at level 3. This also matches the requirements for  
 1905 the Canadian collation order, as well as other, known collation requirements for alphabetic  
 1906 scripts. It specifically rules out collation based on pronunciation rules or based on semantic  
 1907 analysis of the text.

1908 The syntax for the *LC\_COLLATE* category source meets the requirements for level 3 and has  
 1909 been verified to produce the correct result with examples based on French, Canadian, and  
 1910 Danish collation order. Because it supports multi-character collating elements, it is also capable  
 1911 of supporting collation in codesets where a character is expressed using non-spacing characters  
 1912 followed by the base character (such as the ISO/IEC 6937: 1994 standard).

1913 The directives that can be specified in an operand to the **order\_start** keyword are based on the  
 1914 requirements specified in several proposed standards and in customary use. The following is a  
 1915 rephrasing of rules defined for “lexical ordering in English and French” by the Canadian  
 1916 Standards Association (the text in square brackets is rephrased):

- 1917 • Once special characters [punctuation] have been removed from original strings, the ordering  
 1918 is determined by scanning forwards (left to right) [disregarding case and diacriticals].
- 1919 • In case of equivalence, special characters are once again removed from original strings and  
 1920 the ordering is determined by scanning backwards (starting from the rightmost character of  
 1921 the string and back), character by character [disregarding case but considering diacriticals].
- 1922 • In case of repeated equivalence, special characters are removed again from original strings  
 1923 and the ordering is determined by scanning forwards, character by character [considering  
 1924 both case and diacriticals].
- 1925 • If there is still an ordering equivalence after the first three rules have been applied, then only  
 1926 special characters and the position they occupy in the string are considered to determine  
 1927 ordering. The string that has a special character in the lowest position comes first. If two  
 1928 strings have a special character in the same position, the character [with the lowest collation  
 1929 value] comes first. In case of equality, the other special characters are considered until there  
 1930 is a difference or until all special characters have been exhausted.

1931 It is estimated that this part of IEEE Std 1003.1-2001 covers the requirements for all European  
 1932 languages, and no particular problems are anticipated with Slavic or Middle East character sets.

1933 The Far East (particularly Japanese/Chinese) collations are often based on contextual  
 1934 information and pronunciation rules (the same ideogram can have different meanings and  
 1935 different pronunciations). Such collation, in general, falls outside the desired goal of  
 1936 IEEE Std 1003.1-2001. There are, however, several other collation rules (stroke/radical or “most  
 1937 common pronunciation”) that can be supported with the mechanism described here.

1938 The character order is defined by the order in which characters and elements are specified  
 1939 between the **order\_start** and **order\_end** keywords. Weights assigned to the characters and  
 1940 elements define the collation sequence; in the absence of weights, the character order is also the  
 1941 collation sequence.

1942 The **position** keyword provides the capability to consider, in a compare, the relative position of  
 1943 characters not subject to **IGNORE**. As an example, consider the two strings "o-ring" and  
 1944 "or-ing". Assuming the hyphen is subject to **IGNORE** on the first pass, the two strings  
 1945 compare equal, and the position of the hyphen is immaterial. On second pass, all characters  
 1946 except the hyphen are subject to **IGNORE**, and in the normal case the two strings would again  
 1947 compare equal. By taking position into account, the first collates before the second.

1948 A.7.3.3 *LC\_MONETARY*

1949 The currency symbol does not appear in *LC\_MONETARY* because it is not defined in the C locale  
 1950 of the ISO C standard.

1951 The ISO C standard limits the size of decimal points and thousands delimiters to single-byte  
 1952 values. In locales based on multi-byte coded character sets, this cannot be enforced;  
 1953 IEEE Std 1003.1-2001 does not prohibit such characters, but makes the behavior unspecified (in  
 1954 the text “In contexts where other standards ...”).

1955 The grouping specification is based on, but not identical to, the ISO C standard. The `-1` indicates  
 1956 that no further grouping is performed; the equivalent of `{CHAR_MAX}` in the ISO C standard.

1957 The text “the value is not available in the locale” is taken from the ISO C standard and is used  
 1958 instead of the “unspecified” text in early proposals. There is no implication that omitting these  
 1959 keywords or assigning them values of “ ” or `-1` produces unspecified results; such omissions or  
 1960 assignments eliminate the effects described for the keyword or produce zero-length strings, as  
 1961 appropriate.

1962 The locale definition is an extension of the ISO C standard *localeconv()* specification. In  
 1963 particular, rules on how **currency\_symbol** is treated are extended to also cover **int\_curr\_symbol**,  
 1964 and **p\_set\_by\_space** and **n\_sep\_by\_space** have been augmented with the value 2, which places  
 1965 a <space> between the sign and the symbol (if they are adjacent; otherwise, it should be treated  
 1966 as a 0). The following table shows the result of various combinations:

|                          |                        | <b>p_sep_by_space</b> |           |          |
|--------------------------|------------------------|-----------------------|-----------|----------|
|                          |                        | <b>2</b>              | <b>1</b>  | <b>0</b> |
| <b>p_cs_precedes = 1</b> | <b>p_sign_posn = 0</b> | (\$1.25)              | (\$ 1.25) | (\$1.25) |
|                          | <b>p_sign_posn = 1</b> | + \$1.25              | +\$ 1.25  | +\$1.25  |
|                          | <b>p_sign_posn = 2</b> | \$1.25 +              | \$ 1.25+  | \$1.25+  |
|                          | <b>p_sign_posn = 3</b> | + \$1.25              | +\$ 1.25  | +\$1.25  |
|                          | <b>p_sign_posn = 4</b> | \$ +1.25              | \$+ 1.25  | +\$1.25  |
| <b>p_cs_precedes = 0</b> | <b>p_sign_posn = 0</b> | (1.25 \$)             | (1.25 \$) | (1.25\$) |
|                          | <b>p_sign_posn = 1</b> | +1.25 \$              | +1.25 \$  | +1.25\$  |
|                          | <b>p_sign_posn = 2</b> | 1.25\$ +              | 1.25 \$+  | 1.25\$+  |
|                          | <b>p_sign_posn = 3</b> | 1.25+ \$              | 1.25 +\$  | 1.25+\$  |
|                          | <b>p_sign_posn = 4</b> | 1.25\$ +              | 1.25 \$+  | 1.25\$+  |

1979 The following is an example of the interpretation of the **mon\_grouping** keyword. Assuming that  
 1980 the value to be formatted is 123456789 and the **mon\_thousands\_sep** is ‘ ’, then the following  
 1981 table shows the result. The third column shows the equivalent string in the ISO C standard that  
 1982 would be used by the *localeconv()* function to accommodate this grouping.

| <b>mon_grouping</b> | <b>Formatted Value</b> | <b>ISO C String</b> |
|---------------------|------------------------|---------------------|
| 3;-1                | 123456'789             | "\3\177"            |
| 3                   | 123'456'789            | "\3"                |
| 3;2;-1              | 1234'56'789            | "\3\2\177"          |
| 3;2                 | 12'34'56'789           | "\3\2"              |
| -1                  | 123456789              | "\177"              |

1989 In these examples, the octal value of `{CHAR_MAX}` is 177.

1990 IEEE Std 1003.1-2001 / Cor 1-2002, item XBD / TC1 / D6 / 6 adds a correction that permits the Euro  
 1991 currency symbol and addresses extensibility. The correction is stated using the term “should”  
 1992 intentionally, in order to make this a recommendation rather than a restriction on  
 1993 implementations. This allows for flexibility in implementations on how they handle future

|      |                                                                                                                                   |  |
|------|-----------------------------------------------------------------------------------------------------------------------------------|--|
| 1994 | currency symbol additions.                                                                                                        |  |
| 1995 | IEEE Std 1003.1-2001 / Cor 1-2002, tem XBD/TC1/D6/5 is applied, adding the <b>int[np]*</b> values                                 |  |
| 1996 | to the POSIX locale definition of <i>LC_MONETARY</i> .                                                                            |  |
| 1997 | <b>A.7.3.4</b> <i>LC_NUMERIC</i>                                                                                                  |  |
| 1998 | See the rationale for <i>LC_MONETARY</i> for a description of the behavior of grouping.                                           |  |
| 1999 | <b>A.7.3.5</b> <i>LC_TIME</i>                                                                                                     |  |
| 2000 | Although certain of the conversion specifications in the POSIX locale (such as the name of the                                    |  |
| 2001 | month) are shown with initial capital letters, this need not be the case in other locales. Programs                               |  |
| 2002 | using these conversion specifications may need to adjust the capitalization if the output is going                                |  |
| 2003 | to be used at the beginning of a sentence.                                                                                        |  |
| 2004 | The <i>LC_TIME</i> descriptions of <b>abday</b> , <b>day</b> , <b>mon</b> , and <b>abmon</b> imply a Gregorian style calendar (7- |  |
| 2005 | day weeks, 12-month years, leap years, and so on). Formatting time strings for other types of                                     |  |
| 2006 | calendars is outside the scope of IEEE Std 1003.1-2001.                                                                           |  |
| 2007 | While the ISO 8601:2000 standard numbers the weekdays starting with Monday, historical                                            |  |
| 2008 | practice is to use the Sunday as the first day. Rather than change the order and introduce                                        |  |
| 2009 | potential confusion, the days must be specified beginning with Sunday; previous references to                                     |  |
| 2010 | “first day” have been removed. Note also that the Shell and Utilities volume of                                                   |  |
| 2011 | IEEE Std 1003.1-2001 <i>date</i> utility supports numbering compliant with the ISO 8601:2000                                      |  |
| 2012 | standard.                                                                                                                         |  |
| 2013 | As specified under <i>date</i> in the Shell and Utilities volume of IEEE Std 1003.1-2001 and <i>strftime()</i> in                 |  |
| 2014 | the System Interfaces volume of IEEE Std 1003.1-2001, the conversion specifications                                               |  |
| 2015 | corresponding to the optional keywords consist of a modifier followed by a traditional                                            |  |
| 2016 | conversion specification (for instance, %Ex). If the optional keywords are not supported by the                                   |  |
| 2017 | implementation or are unspecified for the current locale, these modified conversion                                               |  |
| 2018 | specifications are treated as the traditional conversion specifications. For example, assume the                                  |  |
| 2019 | following keywords:                                                                                                               |  |
| 2020 | <code>alt_digits</code> "0th"; "1st"; "2nd"; "3rd"; "4th"; "5th"; \                                                               |  |
| 2021 | "6th"; "7th"; "8th"; "9th"; "10th"                                                                                                |  |
| 2022 | <code>d_fmt</code> "The %Od day of %B in %Y"                                                                                      |  |
| 2023 | On July 4th 1776, the %x conversion specifications would result in "The 4th day of July                                           |  |
| 2024 | in 1776", while on July 14th 1789 it would result in "The 14 day of July in 1789". It                                             |  |
| 2025 | can be noted that the above example is for illustrative purposes only; the %O modifier is                                         |  |
| 2026 | primarily intended to provide for Kanji or Hindi digits in <i>date</i> formats.                                                   |  |
| 2027 | The following is an example for Japan that supports the current plus last three Emperors and                                      |  |
| 2028 | reverts to Western style numbering for years prior to the Meiji era. The example also allows for                                  |  |
| 2029 | the custom of using a special name for the first year of an era instead of using 1. (The examples                                 |  |
| 2030 | substitute romaji where kanji should be used.)                                                                                    |  |

2031 era\_d\_fmt "%EY%mgatsu%dnichi (%a)"

2032 era "+:2:1990/01/01:+\*:Heisei:%EC%Eynen";\  
 2033 "+:1:1989/01/08:1989/12/31:Heisei:%ECgannen";\  
 2034 "+:2:1927/01/01:1989/01/07:Shouwa:%EC%Eynen";\  
 2035 "+:1:1926/12/25:1926/12/31:Shouwa:%ECgannen";\  
 2036 "+:2:1913/01/01:1926/12/24:Taishou:%EC%Eynen";\  
 2037 "+:1:1912/07/30:1912/12/31:Taishou:%ECgannen";\  
 2038 "+:2:1869/01/01:1912/07/29:Meiji:%EC%Eynen";\  
 2039 "+:1:1868/09/08:1868/12/31:Meiji:%ECgannen";\  
 2040 "-:1868:1868/09/07:-\*::%Ey"

2041 Assuming that the current date is September 21, 1991, a request to *date* or *strftime()* would yield  
 2042 the following results:

2043 %Ec - Heisei3nen9gatsu21nichi (Sat) 14:39:26  
 2044 %EC - Heisei  
 2045 %Ex - Heisei3nen9gatsu21nichi (Sat)  
 2046 %Ey - 3  
 2047 %EY - Heisei3nen

2048 Example era definitions for the Republic of China:

2049 era "+:2:1913/01/01:+\*:ChungHwaMingGuo:%EC%EyNen";\  
 2050 "+:1:1912/1/1:1912/12/31:ChungHwaMingGuo:%ECYuenNen";\  
 2051 "+:1:1911/12/31:-\*:MingChien:%EC%EyNen"

2052 Example definitions for the Christian Era:

2053 era "+:1:0001/01/01:+\*:AD:%EC %Ey";\  
 2054 "+:1:-0001/12/31:-\*:BC:%Ey %EC"

#### 2055 A.7.3.6 LC\_MESSAGES

2056 The **yesstr** and **nostr** locale keywords and the YESSTR and NOSTR *langinfo* items were formerly  
 2057 used to match user affirmative and negative responses. In IEEE Std 1003.1-2001, the **yesexpr**,  
 2058 **noexpr**, YESEXPR, and NOEXPR extended regular expressions have replaced them.  
 2059 Applications should use the general locale-based messaging facilities to issue prompting  
 2060 messages which include sample desired responses.

### 2061 A.7.4 Locale Definition Grammar

2062 There is no additional rationale provided for this section.

#### 2063 A.7.4.1 Locale Lexical Conventions

2064 There is no additional rationale provided for this section.

#### 2065 A.7.4.2 Locale Grammar

2066 There is no additional rationale provided for this section.

## 2067 A.7.5 Locale Definition Example

2068 The following is an example of a locale definition file that could be used as input to the *localedef*  
 2069 utility. It assumes that the utility is executed with the **-f** option, naming a charmap file with (at  
 2070 least) the following content:

```

2071 CHARMAP
2072 <space> \x20
2073 <dollar> \x24
2074 <A> \101
2075 <a> \141
2076 <A-acute> \346
2077 <a-acute> \365
2078 <A-grave> \300
2079 <a-grave> \366
2080 \142
2081 <C> \103
2082 <c> \143
2083 <c-cedilla> \347
2084 <d> \x64
2085 <H> \110
2086 <h> \150
2087 <eszet> \xb7
2088 <s> \x73
2089 <z> \x7a
2090 END CHARMAP

```

2091 It should not be taken as complete or to represent any actual locale, but only to illustrate the  
 2092 syntax.

```

2093 #
2094 LC_CTYPE
2095 lower <a>;;<c>;<c-cedilla>;<d>;...;<z>
2096 upper A;B;C;Ç;...;Z
2097 space \x20;\x09;\x0a;\x0b;\x0c;\x0d
2098 blank \040;\011
2099 toupper (<a>,<A>);(b,B);(c,C);(ç,Ç);(d,D);(z,Z)
2100 END LC_CTYPE
2101 #
2102 LC_COLLATE
2103 #
2104 # The following example of collation is based on
2105 # Canadian standard Z243.4.1-1998, "Canadian Alphanumeric
2106 # Ordering Standard for Character Sets of CSA Z234.4 Standard".
2107 # (Other parts of this example locale definition file do not
2108 # purport to relate to Canada, or to any other real culture.)
2109 # The proposed standard defines a 4-weight collation, such that
2110 # in the first pass, characters are compared without regard to
2111 # case or accents; in the second pass, backwards-compare without
2112 # regard to case; in the third pass, forwards-compare without
2113 # regard to diacriticals. In the 3 first passes, non-alphabetic
2114 # characters are ignored; in the fourth pass, only special
2115 # characters are considered, such that "The string that has a
2116 # special character in the lowest position comes first. If two

```

```

2117 # strings have a special character in the same position, the
2118 # collation value of the special character determines ordering.
2119 #
2120 # Only a subset of the character set is used here; mostly to
2121 # illustrate the set-up.
2122 #
2123 collating-symbol <NULL>
2124 collating-symbol <LOW_VALUE>
2125 collating-symbol <LOWER-CASE>
2126 collating-symbol <SUBSCRIPT-LOWER>
2127 collating-symbol <SUPERSCRIPT-LOWER>
2128 collating-symbol <UPPER-CASE>
2129 collating-symbol <NO-ACCENT>

## 2241 **A.8 Environment Variables**

### 2242 **A.8.1 Environment Variable Definition**

2243 The variable *environ* is not intended to be declared in any header, but rather to be declared by the  
 2244 user for accessing the array of strings that is the environment. This is the traditional usage of the  
 2245 symbol. Putting it into a header could break some programs that use the symbol for their own  
 2246 purposes.

2247 The decision to restrict conforming systems to the use of digits, uppercase letters, and  
 2248 underscores for environment variable names allows applications to use lowercase letters in their  
 2249 environment variable names without conflicting with any conforming system.

2250 In addition to the obvious conflict with the shell syntax for positional parameter substitution,  
 2251 some historical applications (including some shells) exclude names with leading digits from the  
 2252 environment.

### 2253 **A.8.2 Internationalization Variables**

2254 The text about locale implies that any utilities written in standard C and conforming to  
 2255 IEEE Std 1003.1-2001 must issue the following call:

```
2256 setlocale(LC_ALL, "")
```

2257 If this were omitted, the ISO C standard specifies that the C locale would be used.

2258 If any of the environment variables are invalid, it makes sense to default to an implementation-  
 2259 defined, consistent locale environment. It is more confusing for a user to have partial settings  
 2260 occur in case of a mistake. All utilities would then behave in one language/cultural  
 2261 environment. Furthermore, it provides a way of forcing the whole environment to be the  
 2262 implementation-defined default. Disastrous results could occur if a pipeline of utilities partially  
 2263 uses the environment variables in different ways. In this case, it would be appropriate for  
 2264 utilities that use *LANG* and related variables to exit with an error if any of the variables are

invalid. For example, users typing individual commands at a terminal might want *date* to work if *LC\_MONETARY* is invalid as long as *LC\_TIME* is valid. Since these are conflicting reasonable alternatives, IEEE Std 1003.1-2001 leaves the results unspecified if the locale environment variables would not produce a complete locale matching the specification of the user.

The locale settings of individual categories cannot be truly independent and still guarantee correct results. For example, when collating two strings, characters must first be extracted from each string (governed by *LC\_CTYPE*) before being mapped to collating elements (governed by *LC\_COLLATE*) for comparison. That is, if *LC\_CTYPE* is causing parsing according to the rules of a large, multi-byte code set (potentially returning 20 000 or more distinct character codeset values), but *LC\_COLLATE* is set to handle only an 8-bit codeset with 256 distinct characters, meaningful results are obviously impossible.

The *LC\_MESSAGES* variable affects the language of messages generated by the standard utilities.

The description of the environment variable names starting with the characters “LC\_” acknowledges the fact that the interfaces presented may be extended as new international functionality is required. In the ISO C standard, names preceded by “LC\_” are reserved in the name space for future categories.

To avoid name clashes, new categories and environment variables are divided into two classifications: “implementation-independent” and “implementation-defined”.

Implementation-independent names will have the following format:

*LC\_NAME*

where *NAME* is the name of the new category and environment variable. Capital letters must be used for implementation-independent names.

Implementation-defined names must be in lowercase letters, as below:

*LC\_name*

### A.8.3 Other Environment Variables

#### COLUMNS, LINES

The default values for the number of column positions, *COLUMNS*, and screen height, *LINES*, are unspecified because historical implementations use different methods to determine values corresponding to the size of the screen in which the utility is run. This size is typically known to the implementation through the value of *TERM*, or by more elaborate methods such as extensions to the *stty* utility or knowledge of how the user is dynamically resizing windows on a bit-mapped display terminal. Users should not need to set these variables in the environment unless there is a specific reason to override the default behavior of the implementation, such as to display data in an area arbitrarily smaller than the terminal or window. Values for these variables that are not decimal integers greater than zero are implicitly undefined values; it is unnecessary to enumerate all of the possible values outside of the acceptable set.

**LOGNAME**

In most implementations, the value of such a variable is easily forged, so security-critical applications should rely on other means of determining user identity. *LOGNAME* is required to be constructed from the portable filename character set for reasons of interchange. No diagnostic condition is specified for violating this rule, and no requirement for enforcement exists. The intent of the requirement is that if extended characters are used, the “guarantee” of portability implied by a standard is void.

**PATH**

Many historical implementations of the Bourne shell do not interpret a trailing colon to represent the current working directory and are thus non-conforming. The C Shell and the KornShell conform to IEEE Std 1003.1-2001 on this point. The usual name of dot may also be used to refer to the current working directory.

Many implementations historically have used a default value of */bin* and */usr/bin* for the *PATH* variable. IEEE Std 1003.1-2001 does not mandate this default path be identical to that retrieved from *getconf \_CS\_PATH* because it is likely that the standardized utilities may be provided in another directory separate from the directories used by some historical applications.

**SHELL**

The *SHELL* variable names the preferred shell of the user; it is a guide to applications. There is no direct requirement that that shell conform to IEEE Std 1003.1-2001; that decision should rest with the user. It is the intention of the standard developers that alternative shells be permitted, if the user chooses to develop or acquire one. An operating system that builds its shell into the “kernel” in such a manner that alternative shells would be impossible does not conform to the spirit of IEEE Std 1003.1-2001.

**TZ**

The quoted form of the timezone variable allows timezone names of the form UTC+1 (or any name that contains the character plus (+)), the character minus (−), or digits), which may be appropriate for countries that do not have an official timezone name. It would be coded as <UTC+1>+1<UTC+2>, which would cause *std* to have a value of UTC+1 and *dst* a value of UTC+2, each with a length of 5 characters. This does not appear to conflict with any existing usage. The characters ‘<’ and ‘>’ were chosen for quoting because they are easier to parse visually than a quoting character that does not provide some sense of bracketing (and in a string like this, such bracketing is helpful). They were also chosen because they do not need special treatment when assigning to the *TZ* variable. Users are often confused by embedding quotes in a string. Because ‘<’ and ‘>’ are meaningful to the shell, the whole string would have to be quoted, but that is easily explained. (Parentheses would have presented the same problems.) Although the ‘>’ symbol could have been permitted in the string by either escaping it or doubling it, it seemed of little value to require that. This could be provided as an extension if there was a need. Timezone names of this new form lead to a requirement that the value of {\_POSIX\_TZNAME\_MAX} change from 3 to 6.

Since the *TZ* environment variable is usually inherited by all applications started by a user after the value of the *TZ* environment variable is changed and since many applications run using the C or POSIX locale, using characters that are not in the portable character set in the *std* and *dst* fields could cause unexpected results.

The format of the *TZ* environment variable is changed in Issue 6 to allow for the quoted form, as defined in previous versions of the ISO POSIX-1 standard.

2347 IEEE Std 1003.1-2001/Cor 1-2002, item XBD/TC1/D6/7 is applied, adding the *ctime\_r()* and  
 2348 *localtime\_r()* functions to the list of functions that use the TZ environment variable.

## 2349 **A.9 Regular Expressions**

2350 Rather than repeating the description of REs for each utility supporting REs, the standard  
 2351 developers preferred a common, comprehensive description of regular expressions in one place.  
 2352 The most common behavior is described here, and exceptions or extensions to this are  
 2353 documented for the respective utilities, as appropriate.

2354 The BRE corresponds to the *ed* or historical *grep* type, and the ERE corresponds to the historical  
 2355 *egrep* type (now *grep -E*).

2356 The text is based on the *ed* description and substantially modified, primarily to aid developers  
 2357 and others in the understanding of the capabilities and limitations of REs. Much of this was  
 2358 influenced by internationalization requirements.

2359 It should be noted that the definitions in this section do not cover the *tr* utility; the *tr* syntax does  
 2360 not employ REs.

2361 The specification of REs is particularly important to internationalization because pattern  
 2362 matching operations are very basic operations in business and other operations. The syntax and  
 2363 rules of REs are intended to be as intuitive as possible to make them easy to understand and use.  
 2364 The historical rules and behavior do not provide that capability to non-English language users,  
 2365 and do not provide the necessary support for commonly used characters and language  
 2366 constructs. It was necessary to provide extensions to the historical RE syntax and rules to  
 2367 accommodate other languages.

2368 As they are limited to bracket expressions, the rationale for these modifications is in the Base  
 2369 Definitions volume of IEEE Std 1003.1-2001, Section 9.3.5, RE Bracket Expression.

### 2370 **A.9.1 Regular Expression Definitions**

2371 It is possible to determine what strings correspond to subexpressions by recursively applying  
 2372 the leftmost longest rule to each subexpression, but only with the proviso that the overall match  
 2373 is leftmost longest. For example, matching "*\(ac\*\\)c\*d[ac]\*\1*" against *acdacaaa* matches  
 2374 *acdacaaa* (with *\1=a*); simply matching the longest match for "*\(ac\*\)*" would yield *\1=ac*, but  
 2375 the overall match would be smaller (*acdac*). Conceptually, the implementation must examine  
 2376 every possible match and among those that yield the leftmost longest total matches, pick the one  
 2377 that does the longest match for the leftmost subexpression, and so on. Note that this means that  
 2378 matching by subexpressions is context-dependent: a subexpression within a larger RE may  
 2379 match a different string from the one it would match as an independent RE, and two instances of  
 2380 the same subexpression within the same larger RE may match different lengths even in similar  
 2381 sequences of characters. For example, in the ERE "*(a.\*b)(a.\*b)*", the two identical  
 2382 subexpressions would match four and six characters, respectively, of *accbaccccb*.

2383 The definition of single character has been expanded to include also collating elements  
 2384 consisting of two or more characters; this expansion is applicable only when a bracket  
 2385 expression is included in the BRE or ERE. An example of such a collating element may be the  
 2386 Dutch *ij*, which collates as a 'y'. In some encodings, a ligature "i with j" exists as a character  
 2387 and would represent a single-character collating element. In another encoding, no such ligature  
 2388 exists, and the two-character sequence *ij* is defined as a multi-character collating element.  
 2389 Outside brackets, the *ij* is treated as a two-character RE and matches the same characters in a  
 2390 string. Historically, a bracket expression only matched a single character. The ISO POSIX-2: 1993  
 2391 standard required bracket expressions like "*[^[:lower:]]*" to match multi-character collating

elements such as "ij". However, this requirement led to behavior that many users did not expect and that could not feasibly be mimicked in user code, and it was rarely if ever implemented correctly. The current standard leaves it unspecified whether a bracket expression matches a multi-character collating element, allowing both historical and ISO POSIX-2:1993 standard implementations to conform.

Also, in the current standard, it is unspecified whether character class expressions like "[[:lower:]]" can include multi-character collating elements like "ij"; hence "[[:lower:]]" can match "ij", and "[^[:lower:]]" can fail to match "ij". Common practice is for a character class expression to match a collating element if it matches the collating element's first character.

## A.9.2 Regular Expression General Requirements

The definition of which sequence is matched when several are possible is based on the leftmost-longest rule historically used by deterministic recognizers. This rule is easier to define and describe, and arguably more useful, than the first-match rule historically used by non-deterministic recognizers. It is thought that dependencies on the choice of rule are rare; carefully contrived examples are needed to demonstrate the difference.

A formal expression of the leftmost-longest rule is:

The search is performed as if all possible suffixes of the string were tested for a prefix matching the pattern; the longest suffix containing a matching prefix is chosen, and the longest possible matching prefix of the chosen suffix is identified as the matching sequence.

Historically, most RE implementations only match lines, not strings. However, that is more an effect of the usage than of an inherent feature of REs themselves. Consequently, IEEE Std 1003.1-2001 does not regard <newline>s as special; they are ordinary characters, and both a period and a non-matching list can match them. Those utilities (like *grep*) that do not allow <newline>s to match are responsible for eliminating any <newline> from strings before matching against the RE. The *regcomp()* function, however, can provide support for such processing without violating the rules of this section.

Some implementations of *egrep* have had very limited flexibility in handling complex EREs. IEEE Std 1003.1-2001 does not attempt to define the complexity of a BRE or ERE, but does place a lower limit on it—any RE must be handled, as long as it can be expressed in 256 bytes or less. (Of course, this does not place an upper limit on the implementation.) There are historical programs using a non-deterministic-recognizer implementation that should have no difficulty with this limit. It is possible that a good approach would be to attempt to use the faster, but more limited, deterministic recognizer for simple expressions and to fall back on the non-deterministic recognizer for those expressions requiring it. Non-deterministic implementations must be careful to observe the rules on which match is chosen; the longest match, not the first match, starting at a given character is used.

The term “invalid” highlights a difference between this section and some others: IEEE Std 1003.1-2001 frequently avoids mandating of errors for syntax violations because they can be used by implementors to trigger extensions. However, the authors of the internationalization features of REs wanted to mandate errors for certain conditions to identify usage problems or non-portable constructs. These are identified within this rationale as appropriate. The remaining syntax violations have been left implicitly or explicitly undefined. For example, the BRE construct "\{1,2,3\}" does not comply with the grammar. A conforming application cannot rely on it producing an error nor matching the literal characters "\{1,2,3\}".

2438 The term “undefined” was used in favor of “unspecified” because many of the situations are  
 2439 considered errors on some implementations, and the standard developers considered that  
 2440 consistency throughout the section was preferable to mixing undefined and unspecified.

### 2441 **A.9.3 Basic Regular Expressions**

2442 There is no additional rationale provided for this section.

#### 2443 *A.9.3.1 BREs Matching a Single Character or Collating Element*

2444 There is no additional rationale provided for this section.

#### 2445 *A.9.3.2 BRE Ordinary Characters*

2446 There is no additional rationale provided for this section.

#### 2447 *A.9.3.3 BRE Special Characters*

2448 There is no additional rationale provided for this section.

#### 2449 *A.9.3.4 Periods in BREs*

2450 There is no additional rationale provided for this section.

#### 2451 *A.9.3.5 RE Bracket Expression*

2452 Range expressions are, historically, an integral part of REs. However, the requirements of  
 2453 “natural language behavior” and portability do conflict. In the POSIX locale, ranges must be  
 2454 treated according to the collating sequence and include such characters that fall within the range  
 2455 based on that collating sequence, regardless of character values. In other locales, ranges have  
 2456 unspecified behavior.

2457 Some historical implementations allow range expressions where the ending range point of one  
 2458 range is also the starting point of the next (for instance, " [a-m-o] "). This behavior should not  
 2459 be permitted, but to avoid breaking historical implementations, it is now *undefined* whether it is a  
 2460 valid expression and how it should be interpreted.

2461 Current practice in *awk* and *lex* is to accept escape sequences in bracket expressions as per the  
 2462 Base Definitions volume of IEEE Std 1003.1-2001, Table 5-1, Escape Sequences and Associated  
 2463 Actions, while the normal ERE behavior is to regard such a sequence as consisting of two  
 2464 characters. Allowing the *awk/lex* behavior in EREs would change the normal behavior in an  
 2465 unacceptable way; it is expected that *awk* and *lex* will decode escape sequences in EREs before  
 2466 passing them to *regcomp()* or comparable routines. Each utility describes the escape sequences it  
 2467 accepts as an exception to the rules in this section; the list is not the same, for historical reasons.

2468 As noted previously, the new syntax and rules have been added to accommodate other  
 2469 languages than English. The remainder of this section describes the rationale for these  
 2470 modifications.

2471 In the POSIX locale, a regular expression that starts with a range expression matches a set of  
 2472 strings that are contiguously sorted, but this is not necessarily true in other locales. For example,  
 2473 a French locale might have the following behavior:

```
2474 $ ls
2475 alpha Alpha estimé ESTIMÉ été eurêka
2476 $ ls [a-e] *
2477 alpha Alpha estimé eurêka
```

Such disagreements between matching and contiguous sorting are unavoidable because POSIX sorting cannot be implemented in terms of a deterministic finite-state automaton (DFA), but range expressions by design are implementable in terms of DFAs.

Historical implementations used native character order to interpret range expressions. The ISO POSIX-2:1993 standard instead required collating element order (CEO): the order that collating elements were specified between the **order\_start** and **order\_end** keywords in the *LC\_COLLATE* category of the current locale. CEO had some advantages in portability over the native character order, but it also had some disadvantages:

- CEO could not feasibly be mimicked in user code, leading to inconsistencies between POSIX matchers and matchers in popular user programs like Emacs, *ksh*, and Perl.
- CEO caused range expressions to match accented and capitalized letters contrary to many users' expectations. For example, "[a-e]" typically matched both 'E' and 'á' but neither 'A' nor 'é'.
- CEO was not consistent across implementations. In practice, CEO was often less portable than native character order. For example, it was common for the CEOs of two implementation-supplied locales to disagree, even if both locales were named "da\_DK".

Because of these problems, some implementations of regular expressions continued to use native character order. Others used the collation sequence, which is more consistent with sorting than either CEO or native order, but which departs further from the traditional POSIX semantics because it generally requires "[a-e]" to match either 'A' or 'E' but not both. As a result of this kind of implementation variation, programmers who wanted to write portable regular expressions could not rely on the ISO POSIX-2:1993 standard guarantees in practice.

While revising the standard, lengthy consideration was given to proposals to attack this problem by adding an API for querying the CEO to allow user-mode matchers, but none of these proposals had implementation experience and none achieved consensus. Leaving the standard alone was also considered, but rejected due to the problems described above.

The current standard leaves unspecified the behavior of a range expression outside the POSIX locale. This makes it clearer that conforming applications should avoid range expressions outside the POSIX locale, and it allows implementations and compatible user-mode matchers to interpret range expressions using native order, CEO, collation sequence, or other, more advanced techniques. The concerns which led to this change were raised in IEEE PASC interpretation 1003.2 #43 and others, and related to ambiguities in the specification of how multi-character collating elements should be handled in range expressions. These ambiguities had led to multiple interpretations of the specification, in conflicting ways, which led to varying implementations. As noted above, efforts were made to resolve the differences, but no solution has been found that would be specific enough to allow for portable software while not invalidating existing implementations.

The standard developers recognize that collating elements are important, such elements being common in several European languages; for example, 'ch' or 'll' in traditional Spanish; 'aa' in several Scandinavian languages. Existing internationalized implementations have processed, and continue to process, these elements in range expressions. Efforts are expected to continue in the future to find a way to define the behavior of these elements precisely and portably.

The ISO POSIX-2:1993 standard required "[b-a]" to be an invalid expression in the POSIX locale, but this requirement has been relaxed in this version of the standard so that "[b-a]" can instead be treated as a valid expression that does not match any string.

## 2523 A.9.3.6 BREs Matching Multiple Characters

2524 The limit of nine back-references to subexpressions in the RE is based on the use of a single-digit  
 2525 identifier; increasing this to multiple digits would break historical applications. This does not  
 2526 imply that only nine subexpressions are allowed in REs. The following is a valid BRE with ten  
 2527 subexpressions:

2528 `\(\(\(ab\) *c\) *d\) \ (ef\) * \ (gh\) \{2\} \ (ij\) * \ (kl\) * \ (mn\) * \ (op\) * \ (qr\) *`

2529 The standard developers regarded the common historical behavior, which supported "`\n*`", but  
 2530 not "`\n\{min,max\}`", "`\(...\)*`", or "`\(...\)\{min,max\}`", as a non-intentional  
 2531 result of a specific implementation, and they supported both duplication and interval  
 2532 expressions following subexpressions and back-references.

2533 The changes to the processing of the back-reference expression remove an unspecified or  
 2534 ambiguous behavior in the Shell and Utilities volume of IEEE Std 1003.1-2001, aligning it with  
 2535 the requirements specified for the *regcomp()* expression, and is the result of PASC Interpretation  
 2536 1003.2-92 #43 submitted for the ISO POSIX-2: 1993 standard.

## 2537 A.9.3.7 BRE Precedence

2538 There is no additional rationale provided for this section.

## 2539 A.9.3.8 BRE Expression Anchoring

2540 Often, the dollar sign is viewed as matching the ending <newline> in text files. This is not  
 2541 strictly true; the <newline> is typically eliminated from the strings to be matched, and the dollar  
 2542 sign matches the terminating null character.

2543 The ability of '`^`', '`$`', and '`*`' to be non-special in certain circumstances may be confusing to  
 2544 some programmers, but this situation was changed only in a minor way from historical practice  
 2545 to avoid breaking many historical scripts. Some consideration was given to making the use of  
 2546 the anchoring characters undefined if not escaped and not at the beginning or end of strings.  
 2547 This would cause a number of historical BREs, such as "`2^10`", "`$HOME`", and "`$1.35`", that  
 2548 relied on the characters being treated literally, to become invalid.

2549 However, one relatively uncommon case was changed to allow an extension used on some  
 2550 implementations. Historically, the BREs "`^foo`" and "`\(^foo\)`" did not match the same  
 2551 string, despite the general rule that subexpressions and entire BREs match the same strings. To  
 2552 increase consensus, IEEE Std 1003.1-2001 has allowed an extension on some implementations to  
 2553 treat these two cases in the same way by declaring that anchoring *may* occur at the beginning or  
 2554 end of a subexpression. Therefore, portable BREs that require a literal circumflex at the  
 2555 beginning or a dollar sign at the end of a subexpression must escape them. Note that a BRE such  
 2556 as "`a\(^bc\)`" will either match "`a^bc`" or nothing on different systems under the rules.

2557 ERE anchoring has been different from BRE anchoring in all historical systems. An unescaped  
 2558 anchor character has never matched its literal counterpart outside a bracket expression. Some  
 2559 implementations treated "`foo$bar`" as a valid expression that never matched anything; others  
 2560 treated it as invalid. IEEE Std 1003.1-2001 mandates the former, valid unmatched behavior.

2561 Some implementations have extended the BRE syntax to add alternation. For example, the  
 2562 subexpression "`\(foo$|bar\)`" would match either "`foo`" at the end of the string or "`bar`"  
 2563 anywhere. The extension is triggered by the use of the undefined "`|`" sequence. Because the  
 2564 BRE is undefined for portable scripts, the extending system is free to make other assumptions,  
 2565 such that the '`$`' represents the end-of-line anchor in the middle of a subexpression. If it were  
 2566 not for the extension, the '`$`' would match a literal dollar sign under the rules.

#### 2567 **A.9.4 Extended Regular Expressions**

2568 As with BREs, the standard developers decided to make the interpretation of escaped ordinary  
2569 characters undefined.

2570 The right parenthesis is not listed as an ERE special character because it is only special in the  
2571 context of a preceding left parenthesis. If found without a preceding left parenthesis, the right  
2572 parenthesis has no special meaning.

2573 The interval expression, " $\{m, n\}$ ", has been added to EREs. Historically, the interval expression  
2574 has only been supported in some ERE implementations. The standard developers estimated that  
2575 the addition of interval expressions to EREs would not decrease consensus and would also make  
2576 BREs more of a subset of EREs than in many historical implementations.

2577 It was suggested that, in addition to interval expressions, back-references ( $\backslash n$ ) should also be  
2578 added to EREs. This was rejected by the standard developers as likely to decrease consensus.

2579 In historical implementations, multiple duplication symbols are usually interpreted from left to  
2580 right and treated as additive. As an example, " $a^+b$ " matches zero or more instances of ' $a$ '  
2581 followed by a ' $b$ '. In IEEE Std 1003.1-2001, multiple duplication symbols are undefined; that is,  
2582 they cannot be relied upon for conforming applications. One reason for this is to provide some  
2583 scope for future enhancements.

2584 The precedence of operations differs between EREs and those in *lex*; in *lex*, for historical reasons,  
2585 interval expressions have a lower precedence than concatenation.

##### 2586 *A.9.4.1 EREs Matching a Single Character or Collating Element*

2587 There is no additional rationale provided for this section.

##### 2588 *A.9.4.2 ERE Ordinary Characters*

2589 There is no additional rationale provided for this section.

##### 2590 *A.9.4.3 ERE Special Characters*

2591 There is no additional rationale provided for this section.

##### 2592 *A.9.4.4 Periods in EREs*

2593 There is no additional rationale provided for this section.

##### 2594 *A.9.4.5 ERE Bracket Expression*

2595 There is no additional rationale provided for this section.

##### 2596 *A.9.4.6 EREs Matching Multiple Characters*

2597 There is no additional rationale provided for this section.

##### 2598 *A.9.4.7 ERE Alternation*

2599 There is no additional rationale provided for this section.

2600 A.9.4.8 *ERE Precedence*

2601 There is no additional rationale provided for this section.

2602 A.9.4.9 *ERE Expression Anchoring*

2603 There is no additional rationale provided for this section.

2604 **A.9.5 Regular Expression Grammar**

2605 The grammars are intended to represent the range of acceptable syntaxes available to  
 2606 conforming applications. There are instances in the text where undefined constructs are  
 2607 described; as explained previously, these allow implementation extensions. There is no intended  
 2608 requirement that an implementation extension must somehow fit into the grammars shown  
 2609 here.

2610 The BRE grammar does not permit `L_ANCHOR` or `R_ANCHOR` inside `"\"` and `"\"` (which  
 2611 implies that `'^'` and `'$'` are ordinary characters). This reflects the semantic limits on the  
 2612 application, as noted in the Base Definitions volume of IEEE Std 1003.1-2001, Section 9.3.8, BRE  
 2613 Expression Anchoring. Implementations are permitted to extend the language to interpret `'^'`  
 2614 and `'$'` as anchors in these locations, and as such, conforming applications cannot use  
 2615 unescaped `'^'` and `'$'` in positions inside `"\"` and `"\"` that might be interpreted as anchors.

2616 The ERE grammar does not permit several constructs that the Base Definitions volume of  
 2617 IEEE Std 1003.1-2001, Section 9.4.2, ERE Ordinary Characters and the Base Definitions volume of  
 2618 IEEE Std 1003.1-2001, Section 9.4.3, ERE Special Characters specify as having undefined results:

- 2619 • `ORD_CHAR` preceded by `'\"`
- 2620 • *ERE\_dupl\_symbol*(s) appearing first in an ERE, or immediately following `'|'`, `'^'`, or `'('`
- 2621 • `'{'` not part of a valid *ERE\_dupl\_symbol*
- 2622 • `'|'` appearing first or last in an ERE, or immediately following `'|'` or `'('`, or immediately  
 2623 preceding `')'`

2624 Implementations are permitted to extend the language to allow these. Conforming applications  
 2625 cannot use such constructs.

2626 A.9.5.1 *BRE/ERE Grammar Lexical Conventions*

2627 There is no additional rationale provided for this section.

2628 A.9.5.2 *RE and Bracket Expression Grammar*

2629 The removal of the *Back\_open\_paren Back\_close\_paren* option from the *nondupl\_RE* specification is  
 2630 the result of PASC Interpretation 1003.2-92 #43 submitted for the ISO POSIX-2: 1993 standard.  
 2631 Although the grammar required support for null subexpressions, this section does not describe  
 2632 the meaning of, and historical practice did not support, this construct.

2633 A.9.5.3 *ERE Grammar*

2634 There is no additional rationale provided for this section.

## 2635 **A.10 Directory Structure and Devices**

### 2636 **A.10.1 Directory Structure and Files**

2637 A description of the historical **/usr/tmp** was omitted, removing any concept of differences in  
 2638 emphasis between the **/** and **/usr** directories. The descriptions of **/bin**, **/usr/bin**, **/lib**, and **/usr/lib**  
 2639 were omitted because they are not useful for applications. In an early draft, a distinction was  
 2640 made between system and application directory usage, but this was not found to be useful.

2641 The directories **/** and **/dev** are included because the notion of a hierarchical directory structure is  
 2642 key to other information presented elsewhere in IEEE Std 1003.1-2001. In early drafts, it was  
 2643 argued that special devices and temporary files could conceivably be handled without a  
 2644 directory structure on some implementations. For example, the system could treat the characters  
 2645 **"/tmp"** as a special token that would store files using some non-POSIX file system structure.  
 2646 This notion was rejected by the standard developers, who required that all the files in this  
 2647 section be implemented via POSIX file systems.

2648 The **/tmp** directory is retained in IEEE Std 1003.1-2001 to accommodate historical applications  
 2649 that assume its availability. Implementations are encouraged to provide suitable directory  
 2650 names in the environment variable **TMPDIR** and applications are encouraged to use the contents  
 2651 of **TMPDIR** for creating temporary files.

2652 The standard files **/dev/null** and **/dev/tty** are required to be both readable and writable to allow  
 2653 applications to have the intended historical access to these files.

2654 The standard file **/dev/console** has been added for alignment with the Single UNIX Specification.

### 2655 **A.10.2 Output Devices and Terminal Types**

2656 There is no additional rationale provided for this section.

## 2657 **A.11 General Terminal Interface**

2658 If the implementation does not support this interface on any device types, it should behave as if  
 2659 it were being used on a device that is not a terminal device (in most cases *errno* will be set to  
 2660 [ENOTTY] on return from functions defined by this interface). This is based on the fact that  
 2661 many applications are written to run both interactively and in some non-interactive mode, and  
 2662 they adapt themselves at runtime. Requiring that they all be modified to test an environment  
 2663 variable to determine whether they should try to adapt is unnecessary. On a system that  
 2664 provides no general terminal interface, providing all the entry points as stubs that return  
 2665 [ENOTTY] (or an equivalent, as appropriate) has the same effect and requires no changes to the  
 2666 application.

2667 Although the needs of both interface implementors and application developers were addressed  
 2668 throughout IEEE Std 1003.1-2001, this section pays more attention to the needs of the latter. This  
 2669 is because, while many aspects of the programming interface can be hidden from the user by the  
 2670 application developer, the terminal interface is usually a large part of the user interface.  
 2671 Although to some extent the application developer can build missing features or work around  
 2672 inappropriate ones, the difficulties of doing that are greater in the terminal interface than  
 2673 elsewhere. For example, efficiency prohibits the average program from interpreting every  
 2674 character passing through it in order to simulate character erase, line kill, and so on. These  
 2675 functions should usually be done by the operating system, possibly at the interrupt level.

2676 The *tc\*()* functions were introduced as a way of avoiding the problems inherent in the  
 2677 traditional *ioctl()* function and in variants of it that were proposed. For example, *tcsetattr()* is

specified in place of the use of the TCSETA *ioctl()* command function. This allows specification of all the arguments in a manner consistent with the ISO C standard unlike the varying third argument of *ioctl()*, which is sometimes a pointer (to any of many different types) and sometimes an **int**.

The advantages of this new method include:

- It allows strict type checking.
- The direction of transfer of control data is explicit.
- Portable capabilities are clearly identified.
- The need for a general interface routine is avoided.
- Size of the argument is well-defined (there is only one type).

The disadvantages include:

- No historical implementation used the new method.
- There are many small routines instead of one general-purpose one.
- The historical parallel with *fcntl()* is broken.

The issue of modem control was excluded from IEEE Std 1003.1-2001 on the grounds that:

- It was concerned with setting and control of hardware timers.
- The appropriate timers and settings vary widely internationally.
- Feedback from European computer manufacturers indicated that this facility was not consistent with European needs and that specification of such a facility was not a requirement for portability.

## **A.11.1 Interface Characteristics**

### *A.11.1.1 Opening a Terminal Device File*

There is no additional rationale provided for this section.

### *A.11.1.2 Process Groups*

There is a potential race when the members of the foreground process group on a terminal leave that process group, either by exit or by changing process groups. After the last process exits the process group, but before the foreground process group ID of the terminal is changed (usually by a job control shell), it would be possible for a new process to be created with its process ID equal to the terminal's foreground process group ID. That process might then become the process group leader and accidentally be placed into the foreground on a terminal that was not necessarily its controlling terminal. As a result of this problem, the controlling terminal is defined to not have a foreground process group during this time.

The cases where a controlling terminal has no foreground process group occur when all processes in the foreground process group either terminate and are waited for or join other process groups via *setpgid()* or *setsid()*. If the process group leader terminates, this is the first case described; if it leaves the process group via *setpgid()*, this is the second case described (a process group leader cannot successfully call *setsid()*). When one of those cases causes a controlling terminal to have no foreground process group, it has two visible effects on applications. The first is the value returned by *tcgetpgrp()*. The second (which occurs only in the case where the process group leader terminates) is the sending of signals in response to special input characters. The intent of IEEE Std 1003.1-2001 is that no process group be wrongly

identified as the foreground process group by *tcgetpgrp()* or unintentionally receive signals because of placement into the foreground.

In 4.3 BSD, the old process group ID continues to be used to identify the foreground process group and is returned by the function equivalent to *tcgetpgrp()*. In that implementation it is possible for a newly created process to be assigned the same value as a process ID and then form a new process group with the same value as a process group ID. The result is that the new process group would receive signals from this terminal for no apparent reason, and IEEE Std 1003.1-2001 precludes this by forbidding a process group from entering the foreground in this way. It would be more direct to place part of the requirement made by the last sentence under *fork()*, but there is no convenient way for that section to refer to the value that *tcgetpgrp()* returns, since in this case there is no process group and thus no process group ID.

One possibility for a conforming implementation is to behave similarly to 4.3 BSD, but to prevent this reuse of the ID, probably in the implementation of *fork()*, as long as it is in use by the terminal.

Another possibility is to recognize when the last process stops using the terminal's foreground process group ID, which is when the process group lifetime ends, and to change the terminal's foreground process group ID to a reserved value that is never used as a process ID or process group ID. (See the definition of *process group lifetime* in the definitions section.) The process ID can then be reserved until the terminal has another foreground process group.

The 4.3 BSD implementation permits the leader (and only member) of the foreground process group to leave the process group by calling the equivalent of *setpgid()* and to later return, expecting to return to the foreground. There are no known application needs for this behavior, and IEEE Std 1003.1-2001 neither requires nor forbids it (except that it is forbidden for session leaders) by leaving it unspecified.

#### 2743 A.11.1.3 The Controlling Terminal

IEEE Std 1003.1-2001 does not specify a mechanism by which to allocate a controlling terminal. This is normally done by a system utility (such as *getty*) and is considered an administrative feature outside the scope of IEEE Std 1003.1-2001.

Historical implementations allocate controlling terminals on certain *open()* calls. Since *open()* is part of POSIX.1, its behavior had to be dealt with. The traditional behavior is not required because it is not very straightforward or flexible for either implementations or applications. However, because of its prevalence, it was not practical to disallow this behavior either. Thus, a mechanism was standardized to ensure portable, predictable behavior in *open()*.

Some historical implementations deallocate a controlling terminal on the last system-wide close. This behavior is neither required nor prohibited. Even on implementations that do provide this behavior, applications generally cannot depend on it due to its system-wide nature.

#### 2755 A.11.1.4 Terminal Access Control

The access controls described in this section apply only to a process that is accessing its controlling terminal. A process accessing a terminal that is not its controlling terminal is effectively treated the same as a member of the foreground process group. While this may seem unintuitive, note that these controls are for the purpose of job control, not security, and job control relates only to a process' controlling terminal. Normal file access permissions handle security.

If the process calling *read()* or *write()* is in a background process group that is orphaned, it is not desirable to stop the process group, as it is no longer under the control of a job control shell that could put it into the foreground again. Accordingly, calls to *read()* or *write()* functions by such

processes receive an immediate error return. This is different from 4.2 BSD, which kills orphaned processes that receive terminal stop signals.

The foreground/background/orphaned process group check performed by the terminal driver must be repeatedly performed until the calling process moves into the foreground or until the process group of the calling process becomes orphaned. That is, when the terminal driver determines that the calling process is in the background and should receive a job control signal, it sends the appropriate signal (SIGTTIN or SIGTTOU) to every process in the process group of the calling process and then it allows the calling process to immediately receive the signal. The latter is typically performed by blocking the process so that the signal is immediately noticed. Note, however, that after the process finishes receiving the signal and control is returned to the driver, the terminal driver must re-execute the foreground/background/orphaned process group check. The process may still be in the background, either because it was continued in the background by a job control shell, or because it caught the signal and did nothing.

The terminal driver repeatedly performs the foreground/background/orphaned process group checks whenever a process is about to access the terminal. In the case of *write()* or the control *tc\*()* functions, the check is performed at the entry of the function. In the case of *read()*, the check is performed not only at the entry of the function, but also after blocking the process to wait for input characters (if necessary). That is, once the driver has determined that the process calling the *read()* function is in the foreground, it attempts to retrieve characters from the input queue. If the queue is empty, it blocks the process waiting for characters. When characters are available and control is returned to the driver, the terminal driver must return to the repeated foreground/background/orphaned process group check again. The process may have moved from the foreground to the background while it was blocked waiting for input characters.

#### 2788 A.11.1.5 Input Processing and Reading Data

2789 There is no additional rationale provided for this section.

#### 2790 A.11.1.6 Canonical Mode Input Processing

2791 The term “character” is intended here. ERASE should erase the last character, not the last byte.  
2792 In the case of multi-byte characters, these two may be different.

2793 4.3 BSD has a WERASE character that erases the last “word” typed (but not any preceding  
2794 <blank>s or <tab>s). A word is defined as a sequence of non-<blank>s, with <tab>s counted as  
2795 <blank>s. Like ERASE, WERASE does not erase beyond the beginning of the line. This  
2796 WERASE feature has not been specified in POSIX.1 because it is difficult to define in the  
2797 international environment. It is only useful for languages where words are delimited by  
2798 <blank>s. In some ideographic languages, such as Japanese and Chinese, words are not  
2799 delimited at all. The WERASE character should presumably go back to the beginning of a  
2800 sentence in those cases; practically, this means it would not be used much for those languages.

2801 It should be noted that there is a possible inherent deadlock if the application and  
2802 implementation conflict on the value of {MAX\_CANON}. With ICANON set (if IXOFF is  
2803 enabled) and more than {MAX\_CANON} characters transmitted without a <linefeed>,  
2804 transmission will be stopped, the <linefeed> (or <carriage-return> when ICRLF is set) will never  
2805 arrive, and the *read()* will never be satisfied.

2806 An application should not set IXOFF if it is using canonical mode unless it knows that (even in  
2807 the face of a transmission error) the conditions described previously cannot be met or unless it is  
2808 prepared to deal with the possible deadlock in some other way, such as timeouts.

2809 It should also be noted that this can be made to happen in non-canonical mode if the trigger  
2810 value for sending IXOFF is less than VMIN and VTIME is zero.

## 2811 A.11.1.7 Non-Canonical Mode Input Processing

2812 Some points to note about MIN and TIME:

2813 1. The interactions of MIN and TIME are not symmetric. For example, when MIN>0 and  
 2814 TIME=0, TIME has no effect. However, in the opposite case where MIN=0 and TIME>0,  
 2815 both MIN and TIME play a role in that MIN is satisfied with the receipt of a single  
 2816 character.

2817 2. Also note that in case A (MIN>0, TIME>0), TIME represents an inter-character timer, while  
 2818 in case C (MIN=0, TIME>0), TIME represents a read timer.

2819 These two points highlight the dual purpose of the MIN /TIME feature. Cases A and B, where  
 2820 MIN>0, exist to handle burst-mode activity (for example, file transfer programs) where a  
 2821 program would like to process at least MIN characters at a time. In case A, the inter-character  
 2822 timer is activated by a user as a safety measure; in case B, it is turned off.

2823 Cases C and D exist to handle single-character timed transfers. These cases are readily adaptable  
 2824 to screen-based applications that need to know if a character is present in the input queue before  
 2825 refreshing the screen. In case C, the read is timed; in case D, it is not.

2826 Another important note is that MIN is always just a minimum. It does not denote a record  
 2827 length. That is, if a program does a read of 20 bytes, MIN is 10, and 25 characters are present, 20  
 2828 characters are returned to the user. In the special case of MIN=0, this still applies: if more than  
 2829 one character is available, they all will be returned immediately.

## 2830 A.11.1.8 Writing Data and Output Processing

2831 There is no additional rationale provided for this section.

## 2832 A.11.1.9 Special Characters

2833 There is no additional rationale provided for this section.

## 2834 A.11.1.10 Modem Disconnect

2835 There is no additional rationale provided for this section.

## 2836 A.11.1.11 Closing a Terminal Device File

2837 IEEE Std 1003.1-2001 does not specify that a *close()* on a terminal device file include the  
 2838 equivalent of a call to *tcflow(fd,TCOON)*.

2839 An implementation that discards output at the time *close()* is called after reporting the return  
 2840 value to the *write()* call that data was written does not conform with IEEE Std 1003.1-2001. An  
 2841 application has functions such as *tcdrain()*, *tcflush()*, and *tcflow()* available to obtain the detailed  
 2842 behavior it requires with respect to flushing of output.

2843 At the time of the last close on a terminal device, an application relinquishes any ability to exert  
 2844 flow control via *tcflow()*.

## 2845 **A.11.2 Parameters that Can be Set**

### 2846 *A.11.2.1 The termios Structure*

2847 This structure is part of an interface that, in general, retains the historic grouping of flags.  
 2848 Although a more optimal structure for implementations may be possible, the degree of change  
 2849 to applications would be significantly larger.

### 2850 *A.11.2.2 Input Modes*

2851 Some historical implementations treated a long break as multiple events, as many as one per  
 2852 character time. The wording in POSIX.1 explicitly prohibits this.

2853 Although the ISTRIP flag is normally superfluous with today's terminal hardware and software,  
 2854 it is historically supported. Therefore, applications may be using ISTRIP, and there is no  
 2855 technical problem with supporting this flag. Also, applications may wish to receive only 7-bit  
 2856 input bytes and may not be connected directly to the hardware terminal device (for example,  
 2857 when a connection traverses a network).

2858 Also, there is no requirement in general that the terminal device ensures that high-order bits  
 2859 beyond the specified character size are cleared. ISTRIP provides this function for 7-bit  
 2860 characters, which are common.

2861 In dealing with multi-byte characters, the consequences of a parity error in such a character, or in  
 2862 an escape sequence affecting the current character set, are beyond the scope of POSIX.1 and are  
 2863 best dealt with by the application processing the multi-byte characters.

### 2864 *A.11.2.3 Output Modes*

2865 POSIX.1 does not describe postprocessing of output to a terminal or detailed control of that from  
 2866 a conforming application. (That is, translation of <newline> to <carriage-return> followed by  
 2867 <linefeed> or <tab> processing.) There is nothing that a conforming application should do to its  
 2868 output for a terminal because that would require knowledge of the operation of the terminal. It  
 2869 is the responsibility of the operating system to provide postprocessing appropriate to the output  
 2870 device, whether it is a terminal or some other type of device.

2871 Extensions to POSIX.1 to control the type of postprocessing already exist and are expected to  
 2872 continue into the future. The control of these features is primarily to adjust the interface between  
 2873 the system and the terminal device so the output appears on the display correctly. This should  
 2874 be set up before use by any application.

2875 In general, both the input and output modes should not be set absolutely, but rather modified  
 2876 from the inherited state.

### 2877 *A.11.2.4 Control Modes*

2878 This section could be misread that the symbol "CSIZE" is a title in the **termios** *c\_cflag* field.  
 2879 Although it does serve that function, it is also a required symbol, as a literal reading of POSIX.1  
 2880 (and the caveats about typography) would indicate.

### 2881 *A.11.2.5 Local Modes*

2882 Non-canonical mode is provided to allow fast bursts of input to be read efficiently while still  
 2883 allowing single-character input.

2884 The ECHONL function historically has been in many implementations. Since there seems to be  
 2885 no technical problem with supporting ECHONL, it is included in POSIX.1 to increase consensus.

2886 The alternate behavior possible when ECHOK or ECHOE are specified with ICANON is  
 2887 permitted as a compromise depending on what the actual terminal hardware can do. Erasing  
 2888 characters and lines is preferred, but is not always possible.

#### 2889 A.11.2.6 Special Control Characters

2890 Permitting VMIN and VTIME to overlap with VEOF and VEOL was a compromise for historical  
 2891 implementations. Only when backwards-compatibility of object code is a serious concern to an  
 2892 implementor should an implementation continue this practice. Correct applications that work  
 2893 with the overlap (at the source level) should also work if it is not present, but not the reverse.

## 2894 A.12 Utility Conventions

### 2895 A.12.1 Utility Argument Syntax

2896 The standard developers considered that recent trends toward diluting the SYNOPSIS sections  
 2897 of historical reference pages to the equivalent of:

2898 `command [options] [operands]`

2899 were a disservice to the reader. Therefore, considerable effort was placed into rigorous  
 2900 definitions of all the command line arguments and their interrelationships. The relationships  
 2901 depicted in the synopses are normative parts of IEEE Std 1003.1-2001; this information is  
 2902 sometimes repeated in textual form, but that is only for clarity within context.

2903 The use of “undefined” for conflicting argument usage and for repeated usage of the same  
 2904 option is meant to prevent conforming applications from using conflicting arguments or  
 2905 repeated options unless specifically allowed (as is the case with *ls*, which allows simultaneous,  
 2906 repeated use of the *-C*, *-l*, and *-1* options). Many historical implementations will tolerate this  
 2907 usage, choosing either the first or the last applicable argument. This tolerance can continue, but  
 2908 conforming applications cannot rely upon it. (Other implementations may choose to print usage  
 2909 messages instead.)

2910 The use of “undefined” for conflicting argument usage also allows an implementation to make  
 2911 reasonable extensions to utilities where the implementor considers mutually-exclusive options  
 2912 according to IEEE Std 1003.1-2001 to have a sensible meaning and result.

2913 IEEE Std 1003.1-2001 does not define the result of a command when an option-argument or  
 2914 operand is not followed by ellipses and the application specifies more than one of that option-  
 2915 argument or operand. This allows an implementation to define valid (although non-standard)  
 2916 behavior for the utility when more than one such option or operand is specified.

2917 The following table summarizes the requirements for option-arguments:

|                                      | SYNOPSIS Shows:                |                                |                            |
|--------------------------------------|--------------------------------|--------------------------------|----------------------------|
|                                      | <i>-a arg</i>                  | <i>-barg</i>                   | <i>-c [arg]</i>            |
| Conforming application uses:         | <i>-a arg</i>                  | <i>-barg</i>                   | <i>-carg</i> or <i>-c</i>  |
| System supports:                     | <i>-a arg</i> and <i>-aarg</i> | <i>-b arg</i> and <i>-barg</i> | <i>-carg</i> and <i>-c</i> |
| Non-conforming applications may use: | <i>-aarg</i>                   | <i>-b arg</i>                  | N/A                        |

2925 Allowing <blank>s after an option (that is, placing an option and its option-argument into  
 2926 separate argument strings) when IEEE Std 1003.1-2001 does not require it encourages portability  
 2927 of users, while still preserving backwards-compatibility of scripts. Inserting <blank>s between

the option and the option-argument is preferred; however, historical usage has not been consistent in this area; therefore, <blank>s are required to be handled by all implementations, but implementations are also allowed to handle the historical syntax. Another justification for selecting the multiple-argument method was that the single-argument case is inherently ambiguous when the option-argument can legitimately be a null string.

IEEE Std 1003.1-2001 explicitly states that digits are permitted as operands and option-arguments. The lower and upper bounds for the values of the numbers used for operands and option-arguments were derived from the ISO C standard values for {LONG\_MIN} and {LONG\_MAX}. The requirement on the standard utilities is that numbers in the specified range do not cause a syntax error, although the specification of a number need not be semantically correct for a particular operand or option-argument of a utility. For example, the specification of:

```
dd obs=3000000000
```

would yield undefined behavior for the application and could be a syntax error because the number 3 000 000 000 is outside of the range −2 147 483 647 to +2 147 483 647. On the other hand:

```
dd obs=2000000000
```

may cause some error, such as “blocksize too large”, rather than a syntax error.

## A.12.2 Utility Syntax Guidelines

This section is based on the rules listed in the SVID. It was included for two reasons:

1. The individual utility descriptions in the Shell and Utilities volume of IEEE Std 1003.1-2001, Chapter 4, Utilities needed a set of common (although not universal) actions on which they could anchor their descriptions of option and operand syntax. Most of the standard utilities actually do use these guidelines, and many of their historical implementations use the *getopt()* function for their parsing. Therefore, it was simpler to cite the rules and merely identify exceptions.
2. Writers of conforming applications need suggested guidelines if the POSIX community is to avoid the chaos of historical UNIX system command syntax.

It is recommended that all *future* utilities and applications use these guidelines to enhance “user portability”. The fact that some historical utilities could not be changed (to avoid breaking historical applications) should not deter this future goal.

The voluntary nature of the guidelines is highlighted by repeated uses of the word *should* throughout. This usage should not be misinterpreted to imply that utilities that claim conformance in their OPTIONS sections do not always conform.

Guidelines 1 and 2 are offered as guidance for locales using Latin alphabets. No recommendations are made by IEEE Std 1003.1-2001 concerning utility naming in other locales.

In the Shell and Utilities volume of IEEE Std 1003.1-2001, Section 2.9.1, Simple Commands, it is further stated that a command used in the Shell Command Language cannot be named with a trailing colon.

Guideline 3 was changed to allow alphanumeric characters (letters and digits) from the character set to allow compatibility with historical usage. Historical practice allows the use of digits wherever practical, and there are no portability issues that would prohibit the use of digits. In fact, from an internationalization viewpoint, digits (being non-language-dependent) are preferable over letters (a −2 is intuitively self-explanatory to any user, while in the −f *filename* the letter ‘f’ is a mnemonic aid only to speakers of Latin-based languages where “filename” happens to translate to a word that begins with ‘f’). Since guideline 3 still retains the word “single”, multi-digit options are not allowed. Instances of historical utilities that used them have

been marked obsolescent, with the numbers being changed from option names to option-arguments.

It was difficult to achieve a satisfactory solution to the problem of name space in option characters. When the standard developers desired to extend the historical *cc* utility to accept ISO C standard programs, they found that all of the portable alphabet was already in use by various vendors. Thus, they had to devise a new name, *c89* (now superseded by *c99*), rather than something like *cc -X*. There were suggestions that implementors be restricted to providing extensions through various means (such as using a plus sign as the option delimiter or using option characters outside the alphanumeric set) that would reserve all of the remaining alphanumeric characters for future POSIX standards. These approaches were resisted because they lacked the historical style of UNIX systems. Furthermore, if a vendor-provided option should become commonly used in the industry, it would be a candidate for standardization. It would be desirable to standardize such a feature using historical practice for the syntax (the semantics can be standardized with any syntax). This would not be possible if the syntax was one reserved for the vendor. However, since the standardization process may lead to minor changes in the semantics, it may prove to be better for a vendor to use a syntax that will not be affected by standardization.

Guideline 8 includes the concept of comma-separated lists in a single argument. It is up to the utility to parse such a list itself because *getopt()* just returns the single string. This situation was retained so that certain historical utilities would not violate the guidelines. Applications preparing for international use should be aware of an occasional problem with comma-separated lists: in some locales, the comma is used as the radix character. Thus, if an application is preparing operands for a utility that expects a comma-separated list, it should avoid generating non-integer values through one of the means that is influenced by setting the *LC\_NUMERIC* variable (such as *awk*, *bc*, *printf*, or *printf()*).

Applications calling any utility with a first operand starting with *'--'* should usually specify *--*, as indicated by Guideline 10, to mark the end of the options. This is true even if the SYNOPSIS in the Shell and Utilities volume of IEEE Std 1003.1-2001 does not specify any options; implementations may provide options as extensions to the Shell and Utilities volume of IEEE Std 1003.1-2001. The standard utilities that do not support Guideline 10 indicate that fact in the OPTIONS section of the utility description.

Guideline 11 was modified to clarify that the order of different options should not matter relative to one another. However, the order of repeated options that also have option-arguments may be significant; therefore, such options are required to be interpreted in the order that they are specified. The *make* utility is an instance of a historical utility that uses repeated options in which the order is significant. Multiple files are specified by giving multiple instances of the *-f* option; for example:

```
make -f common_header -f specific_rules target
```

Guideline 13 does not imply that all of the standard utilities automatically accept the operand *'--'* to mean standard input or output, nor does it specify the actions of the utility upon encountering multiple *'--'* operands. It simply says that, by default, *'--'* operands are not used for other purposes in the file reading or writing (but not when using *stat()*, *unlink()*, *touch*, and so on) utilities. All information concerning actual treatment of the *'--'* operand is found in the individual utility sections.

An area of concern was that as implementations mature, implementation-defined utilities and implementation-defined utility options will result. The idea was expressed that there needed to be a standard way, say an environment variable or some such mechanism, to identify implementation-defined utilities separately from standard utilities that may have the same name. It was decided that there already exist several ways of dealing with this situation and that

3022 it is outside of the scope to attempt to standardize in the area of non-standard items. A method  
3023 that exists on some historical implementations is the use of the so-called **/local/bin** or  
3024 **/usr/local/bin** directory to separate local or additional copies or versions of utilities. Another  
3025 method that is also used is to isolate utilities into completely separate domains. Still another  
3026 method to ensure that the desired utility is being used is to request the utility by its full  
3027 pathname. There are many approaches to this situation; the examples given above serve to  
3028 illustrate that there is more than one.

## 3029 **A.13 Headers**

### 3030 **A.13.1 Format of Entries**

3031 Each header reference page has a common layout of sections describing the interface. This layout  
3032 is similar to the manual page or “man” page format shipped with most UNIX systems, and each  
3033 header has sections describing the SYNOPSIS and DESCRIPTION. These are the two sections  
3034 that relate to conformance.

3035 Additional sections are informative, and add considerable information for the application  
3036 developer. APPLICATION USAGE sections provide additional caveats, issues, and  
3037 recommendations to the developer. RATIONALE sections give additional information on the  
3038 decisions made in defining the interface.

3039 FUTURE DIRECTIONS sections act as pointers to related work that may impact the interface in  
3040 the future, and often cautions the developer to architect the code to account for a change in this  
3041 area. Note that a future directions statement should not be taken as a commitment to adopt a  
3042 feature or interface in the future.

3043 The CHANGE HISTORY section describes when the interface was introduced, and how it has  
3044 changed.

3045 Option labels and margin markings in the page can be useful in guiding the application  
3046 developer.

# Rationale for System Interfaces

3052

## 3053 **B.1 Introduction**

### 3054 **B.1.1 Scope**

3055 Refer to Section A.1.1 (on page 3).

### 3056 **B.1.2 Conformance**

3057 Refer to Section A.2 (on page 9).

### 3058 **B.1.3 Normative References**

3059 There is no additional rationale provided for this section.

### 3060 **B.1.4 Change History**

3061 The change history is provided as an informative section, to track changes from previous issues  
3062 of IEEE Std 1003.1-2001.

3063 The following sections describe changes made to the System Interfaces volume of  
3064 IEEE Std 1003.1-2001 since Issue 5 of the base document. The CHANGE HISTORY section for  
3065 each entry details the technical changes that have been made to that entry from Issue 5. Changes  
3066 between earlier issues of the base document and Issue 5 are not included.

3067 The change history between Issue 5 and Issue 6 also lists the changes since the  
3068 ISO POSIX-1: 1996 standard.

#### 3069 **Changes from Issue 5 to Issue 6 (IEEE Std 1003.1-2001)**

3070 The following list summarizes the major changes that were made in the System Interfaces  
3071 volume of IEEE Std 1003.1-2001 from Issue 5 to Issue 6:

- 3072 • This volume of IEEE Std 1003.1-2001 is extensively revised so that it can be both an IEEE  
3073 POSIX Standard and an Open Group Technical Standard.
- 3074 • The POSIX System Interfaces requirements incorporate support of FIPS 151-2.
- 3075 • The POSIX System Interfaces requirements are updated to align with some features of the  
3076 Single UNIX Specification.
- 3077 • A RATIONALE section is added to each reference page.
- 3078 • Networking interfaces from the XNS, Issue 5.2 specification are incorporated.
- 3079 • IEEE Std 1003.1d-1999 is incorporated.
- 3080 • IEEE Std 1003.1j-2000 is incorporated.
- 3081 • IEEE Std 1003.1q-2000 is incorporated.
- 3082 • IEEE P1003.1a draft standard is incorporated.

- Existing functionality is aligned with the ISO / IEC 9899: 1999 standard.
- New functionality from the ISO / IEC 9899: 1999 standard is incorporated.
- IEEE PASC Interpretations are applied.
- The Open Group corrigenda and resolutions are applied.

### New Features in Issue 6

The functions first introduced in Issue 6 (over the Issue 5 Base document) are listed in the table below:

| New Functions in Issue 6 |                              |                        |
|--------------------------|------------------------------|------------------------|
| <i>acosf()</i>           | <i>catanhl()</i>             | <i>cprojf()</i>        |
| <i>acoshf()</i>          | <i>catanl()</i>              | <i>cprojl()</i>        |
| <i>acoshl()</i>          | <i>cbrtf()</i>               | <i>creal()</i>         |
| <i>acosl()</i>           | <i>cbrtl()</i>               | <i>crealf()</i>        |
| <i>asinf()</i>           | <i>ccos()</i>                | <i>creall()</i>        |
| <i>asinhf()</i>          | <i>ccosf()</i>               | <i>csin()</i>          |
| <i>asinhl()</i>          | <i>ccosh()</i>               | <i>csinf()</i>         |
| <i>asinl()</i>           | <i>ccoshf()</i>              | <i>csinh()</i>         |
| <i>atan2f()</i>          | <i>ccoshl()</i>              | <i>csinhf()</i>        |
| <i>atan2l()</i>          | <i>ccosl()</i>               | <i>csinhl()</i>        |
| <i>atanf()</i>           | <i>ceilf()</i>               | <i>csinl()</i>         |
| <i>atanhf()</i>          | <i>ceil()</i>                | <i>csqrt()</i>         |
| <i>atanhl()</i>          | <i>cexp()</i>                | <i>csqrtf()</i>        |
| <i>atanl()</i>           | <i>cexpf()</i>               | <i>csqrtl()</i>        |
| <i>atoll()</i>           | <i>cexpl()</i>               | <i>ctan()</i>          |
| <i>cabs()</i>            | <i>cimag()</i>               | <i>ctanf()</i>         |
| <i>cabsf()</i>           | <i>cimagf()</i>              | <i>ctanh()</i>         |
| <i>cabsl()</i>           | <i>cimagl()</i>              | <i>ctanhf()</i>        |
| <i>cacos()</i>           | <i>clock_getcpuclockid()</i> | <i>ctanhl()</i>        |
| <i>cacosf()</i>          | <i>clock_nanosleep()</i>     | <i>ctanl()</i>         |
| <i>cacosh()</i>          | <i>clog()</i>                | <i>erfcf()</i>         |
| <i>cacoshf()</i>         | <i>clogf()</i>               | <i>erfcl()</i>         |
| <i>cacoshl()</i>         | <i>clogl()</i>               | <i>erff()</i>          |
| <i>cacosl()</i>          | <i>conj()</i>                | <i>erfl()</i>          |
| <i>carg()</i>            | <i>conjf()</i>               | <i>exp2()</i>          |
| <i>cargf()</i>           | <i>conjl()</i>               | <i>exp2f()</i>         |
| <i>cargl()</i>           | <i>copysign()</i>            | <i>exp2l()</i>         |
| <i>casin()</i>           | <i>copysignf()</i>           | <i>expf()</i>          |
| <i>casinf()</i>          | <i>copysignl()</i>           | <i>expl()</i>          |
| <i>casinh()</i>          | <i>cosf()</i>                | <i>expm1f()</i>        |
| <i>casinhf()</i>         | <i>coshf()</i>               | <i>expm1l()</i>        |
| <i>casinhl()</i>         | <i>coshl()</i>               | <i>fabsf()</i>         |
| <i>casinl()</i>          | <i>cosl()</i>                | <i>fabsl()</i>         |
| <i>catan()</i>           | <i>cpow()</i>                | <i>fdim()</i>          |
| <i>catanf()</i>          | <i>cpowf()</i>               | <i>fdimf()</i>         |
| <i>catanh()</i>          | <i>cpowl()</i>               | <i>fdiml()</i>         |
| <i>catanhf()</i>         | <i>cproj()</i>               | <i>feclearexcept()</i> |

### **B.1.5 Terminology**

Refer to Section A.1.4 (on page 5).

### **B.1.6 Definitions**

Refer to Section A.3 (on page 13).

### **B.1.7 Relationship to Other Formal Standards**

There is no additional rationale provided for this section.

### **B.1.8 Portability**

Refer to Section A.1.5 (on page 8).

#### **B.1.8.1 Codes**

Refer to Section A.1.5.1 (on page 8).

### **B.1.9 Format of Entries**

Each system interface reference page has a common layout of sections describing the interface. This layout is similar to the manual page or “man” page format shipped with most UNIX systems, and each header has sections describing the SYNOPSIS, DESCRIPTION, RETURN VALUE, and ERRORS. These are the four sections that relate to conformance.

Additional sections are informative, and add considerable information for the application developer. EXAMPLES sections provide example usage. APPLICATION USAGE sections provide additional caveats, issues, and recommendations to the developer. RATIONALE sections give additional information on the decisions made in defining the interface.

FUTURE DIRECTIONS sections act as pointers to related work that may impact the interface in the future, and often cautions the developer to architect the code to account for a change in this area. Note that a future directions statement should not be taken as a commitment to adopt a feature or interface in the future.

The CHANGE HISTORY section describes when the interface was introduced, and how it has changed.

Option labels and margin markings in the page can be useful in guiding the application developer.

## B.2 General Information

### B.2.1 Use and Implementation of Functions

The information concerning the use of functions was adapted from a description in the ISO C standard. Here is an example of how an application program can protect itself from functions that may or may not be macros, rather than true functions:

The `atoi()` function may be used in any of several ways:

- By use of its associated header (possibly generating a macro expansion):

```
#include <stdlib.h>
/* ... */
i = atoi(str);
```

- By use of its associated header (assuredly generating a true function call):

```
#include <stdlib.h>
#undef atoi
/* ... */
i = atoi(str);
```

or:

```
#include <stdlib.h>
/* ... */
i = (atoi) (str);
```

- By explicit declaration:

```
extern int atoi (const char *);
/* ... */
i = atoi(str);
```

- By implicit declaration:

```
/* ... */
i = atoi(str);
```

(Assuming no function prototype is in scope. This is not allowed by the ISO C standard for functions with variable arguments; furthermore, parameter type conversion “widening” is subject to different rules in this case.)

Note that the ISO C standard reserves names starting with ‘\_’ for the compiler. Therefore, the compiler could, for example, implement an intrinsic, built-in function `_asm_builtin_atoi()`, which it recognized and expanded into inline assembly code. Then, in `<stdlib.h>`, there could be the following:

```
#define atoi(X) _asm_builtin_atoi(X)
```

The user’s “normal” call to `atoi()` would then be expanded inline, but the implementor would also be required to provide a callable function named `atoi()` for use when the application requires it; for example, if its address is to be stored in a function pointer variable.

## 3349 **B.2.2 The Compilation Environment**

### 3350 *B.2.2.1 POSIX.1 Symbols*

3351 This and the following section address the issue of “name space pollution”. The ISO C standard  
 3352 requires that the name space beyond what it reserves not be altered except by explicit action of  
 3353 the application writer. This section defines the actions to add the POSIX.1 symbols for those  
 3354 headers where both the ISO C standard and POSIX.1 need to define symbols, and also where the  
 3355 XSI extension extends the base standard.

3356 When headers are used to provide symbols, there is a potential for introducing symbols that the  
 3357 application writer cannot predict. Ideally, each header should only contain one set of symbols,  
 3358 but this is not practical for historical reasons. Thus, the concept of feature test macros is  
 3359 included. Two feature test macros are explicitly defined by IEEE Std 1003.1-2001; it is expected  
 3360 that future revisions may add to this.

3361 **Note:** Feature test macros allow an application to announce to the implementation its desire to have  
 3362 certain symbols and prototypes exposed. They should not be confused with the version test  
 3363 macros and constants for options in `<unistd.h>` which are the implementation’s way of  
 3364 announcing functionality to the application.

3365 It is further intended that these feature test macros apply only to the headers specified by  
 3366 IEEE Std 1003.1-2001. Implementations are expressly permitted to make visible symbols not  
 3367 specified by IEEE Std 1003.1-2001, within both POSIX.1 and other headers, under the control of  
 3368 feature test macros that are not defined by IEEE Std 1003.1-2001.

### 3369 **The `_POSIX_C_SOURCE` Feature Test Macro**

3370 Since `_POSIX_SOURCE` specified by the POSIX.1-1990 standard did not have a value associated  
 3371 with it, the `_POSIX_C_SOURCE` macro replaces it, allowing an application to inform the system  
 3372 of the revision of the standard to which it conforms. This symbol will allow implementations to  
 3373 support various revisions of IEEE Std 1003.1-2001 simultaneously. For instance, when either  
 3374 `_POSIX_SOURCE` is defined or `_POSIX_C_SOURCE` is defined as 1, the system should make  
 3375 visible the same name space as permitted and required by the POSIX.1-1990 standard. When  
 3376 `_POSIX_C_SOURCE` is defined, the state of `_POSIX_SOURCE` is completely irrelevant.

3377 It is expected that C bindings to future POSIX standards will define new values for  
 3378 `_POSIX_C_SOURCE`, with each new value reserving the name space for that new standard, plus  
 3379 all earlier POSIX standards.

### 3380 **The `_XOPEN_SOURCE` Feature Test Macro**

3381 The feature test macro `_XOPEN_SOURCE` is provided as the announcement mechanism for the  
 3382 application that it requires functionality from the Single UNIX Specification. `_XOPEN_SOURCE`  
 3383 must be defined to the value 600 before the inclusion of any header to enable the functionality in  
 3384 the Single UNIX Specification. Its definition subsumes the use of `_POSIX_SOURCE` and  
 3385 `_POSIX_C_SOURCE`.

3386 An extract of code from a conforming application, that appears before any **#include** statements,  
 3387 is given below:

```
3388 #define _XOPEN_SOURCE 600 /* Single UNIX Specification, Version 3 */
3389 #include ...
```

3390 Note that the definition of `_XOPEN_SOURCE` with the value 600 makes the definition of  
 3391 `_POSIX_C_SOURCE` redundant and it can safely be omitted.

## 3392 B.2.2.2 The Name Space

3393 The reservation of identifiers is paraphrased from the ISO C standard. The text is included  
 3394 because it needs to be part of IEEE Std 1003.1-2001, regardless of possible changes in future  
 3395 versions of the ISO C standard.

3396 These identifiers may be used by implementations, particularly for feature test macros.  
 3397 Implementations should not use feature test macro names that might be reasonably used by a  
 3398 standard.

3399 Including headers more than once is a reasonably common practice, and it should be carried  
 3400 forward from the ISO C standard. More significantly, having definitions in more than one  
 3401 header is explicitly permitted. Where the potential declaration is “benign” (the same definition  
 3402 twice) the declaration can be repeated, if that is permitted by the compiler. (This is usually true  
 3403 of macros, for example.) In those situations where a repetition is not benign (for example,  
 3404 **typedefs**), conditional compilation must be used. The situation actually occurs both within the  
 3405 ISO C standard and within POSIX.1: **time\_t** should be in **<sys/types.h>**, and the ISO C standard  
 3406 mandates that it be in **<time.h>**.

3407 The area of name space pollution *versus* additions to structures is difficult because of the macro  
 3408 structure of C. The following discussion summarizes all the various problems with and  
 3409 objections to the issue.

3410 Note the phrase “user-defined macro”. Users are not permitted to define macro names (or any  
 3411 other name) beginning with “\_**[A-Z\_]**”. Thus, the conflict cannot occur for symbols reserved  
 3412 to the vendor’s name space, and the permission to add fields automatically applies, without  
 3413 qualification, to those symbols.

3414 1. Data structures (and unions) need to be defined in headers by implementations to meet  
 3415 certain requirements of POSIX.1 and the ISO C standard.

3416 2. The structures defined by POSIX.1 are typically minimal, and any practical  
 3417 implementation would wish to add fields to these structures either to hold additional  
 3418 related information or for backwards-compatibility (or both). Future standards (and *de*  
 3419 *facto* standards) would also wish to add to these structures. Issues of field alignment make  
 3420 it impractical (at least in the general case) to simply omit fields when they are not defined  
 3421 by the particular standard involved.

3422 The **dirent** structure is an example of such a minimal structure (although one could argue  
 3423 about whether the other fields need visible names). The **st\_rdev** field of most  
 3424 implementations’ **stat** structure is a common example where extension is needed and  
 3425 where a conflict could occur.

3426 3. Fields in structures are in an independent name space, so the addition of such fields  
 3427 presents no problem to the C language itself in that such names cannot interact with  
 3428 identically named user symbols because access is qualified by the specific structure name.

3429 4. There is an exception to this: macro processing is done at a lexical level. Thus, symbols  
 3430 added to a structure might be recognized as user-provided macro names at the location  
 3431 where the structure is declared. This only can occur if the user-provided name is declared  
 3432 as a macro before the header declaring the structure is included. The user’s use of the name  
 3433 after the declaration cannot interfere with the structure because the symbol is hidden and  
 3434 only accessible through access to the structure. Presumably, the user would not declare  
 3435 such a macro if there was an intention to use that field name.

3436 5. Macros from the same or a related header might use the additional fields in the structure,  
 3437 and those field names might also collide with user macros. Although this is a less frequent  
 3438 occurrence, since macros are expanded at the point of use, no constraint on the order of use

of names can apply.

6. An “obvious” solution of using names in the reserved name space and then redefining them as macros when they should be visible does not work because this has the effect of exporting the symbol into the general name space. For example, given a (hypothetical) system-provided header **<h.h>**, and two parts of a C program in **a.c** and **b.c**, in header **<h.h>**:

```
struct foo {
 int __i;
}

#ifdef _FEATURE_TEST
#define i __i;
#endif
```

In file **a.c**:

```
#include h.h
extern int i;
...
```

In file **b.c**:

```
extern int i;
...
```

The symbol that the user thinks of as *i* in both files has an external name of `__i` in **a.c**; the same symbol *i* in **b.c** has an external name *i* (ignoring any hidden manipulations the compiler might perform on the names). This would cause a mysterious name resolution problem when **a.o** and **b.o** are linked.

Simply avoiding definition then causes alignment problems in the structure.

A structure of the form:

```
struct foo {
 union {
 int __i;
#ifdef _FEATURE_TEST
 int i;
#endif
 } __ii;
}
```

does not work because the name of the logical field *i* is `__ii.i`, and introduction of a macro to restore the logical name immediately reintroduces the problem discussed previously (although its manifestation might be more immediate because a syntax error would result if a recursive macro did not cause it to fail first).

7. A more workable solution would be to declare the structure:

```
struct foo {
#ifdef _FEATURE_TEST
 int i;
#else
 int __i;
#endif
}
```

However, if a macro (particularly one required by a standard) is to be defined that uses this field, two must be defined: one that uses *i*, the other that uses *\_\_i*. If more than one additional field is used in a macro and they are conditional on distinct combinations of features, the complexity goes up as  $2^n$ .

All this leaves a difficult situation: vendors must provide very complex headers to deal with what is conceptually simple and safe—adding a field to a structure. It is the possibility of user-provided macros with the same name that makes this difficult.

Several alternatives were proposed that involved constraining the user's access to part of the name space available to the user (as specified by the ISO C standard). In some cases, this was only until all the headers had been included. There were two proposals discussed that failed to achieve consensus:

1. Limiting it for the whole program.
2. Restricting the use of identifiers containing only uppercase letters until after all system headers had been included. It was also pointed out that because macros might wish to access fields of a structure (and macro expansion occurs totally at point of use) restricting names in this way would not protect the macro expansion, and thus the solution was inadequate.

It was finally decided that reservation of symbols would occur, but as constrained.

The current wording also allows the addition of fields to a structure, but requires that user macros of the same name not interfere. This allows vendors to do one of the following:

- Not create the situation (do not extend the structures with user-accessible names or use the solution in (7) above)
- Extend their compilers to allow some way of adding names to structures and macros safely

There are at least two ways that the compiler might be extended: add new preprocessor directives that turn off and on macro expansion for certain symbols (without changing the value of the macro) and a function or lexical operation that suppresses expansion of a word. The latter seems more flexible, particularly because it addresses the problem in macros as well as in declarations.

The following seems to be a possible implementation extension to the C language that will do this: any token that during macro expansion is found to be preceded by three '#' symbols shall not be further expanded in exactly the same way as described for macros that expand to their own name as in Section 3.8.3.4 of the ISO C standard. A vendor may also wish to implement this as an operation that is lexically a function, which might be implemented as:

```
#define __safe_name(x) ###x
```

Using a function notation would insulate vendors from changes in standards until such a functionality is standardized (if ever). Standardization of such a function would be valuable because it would then permit third parties to take advantage of it portably in software they may

3521 supply.

3522 The symbols that are “explicitly permitted, but not required by IEEE Std 1003.1-2001” include  
 3523 those classified below. (That is, the symbols classified below might, but are not required to, be  
 3524 present when `_POSIX_C_SOURCE` is defined to have the value 200112L.)

- 3525 • Symbols in `<limits.h>` and `<unistd.h>` that are defined to indicate support for options or  
 3526 limits that are constant at compile-time
- 3527 • Symbols in the name space reserved for the implementation by the ISO C standard
- 3528 • Symbols in a name space reserved for a particular type of extension (for example, type names  
 3529 ending with `_t` in `<sys/types.h>`)
- 3530 • Additional members of structures or unions whose names do not reduce the name space  
 3531 reserved for applications

3532 Since both implementations and future revisions of IEEE Std 1003.1 and other POSIX standards  
 3533 may use symbols in the reserved spaces described in these tables, there is a potential for name  
 3534 space clashes. To avoid future name space clashes when adding symbols, implementations  
 3535 should not use the `posix_`, `POSIX_`, or `_POSIX_` prefixes.

3536 IEEE Std 1003.1-2001 / Cor 1-2002, item XSH/TC1/D6/2 is applied, deleting the entries `POSIX_`,  
 3537 `_POSIX_`, and `posix_` from the column of allowed name space prefixes for use by an  
 3538 implementation in the first table. The presence of these prefixes was contradicting later text  
 3539 which states that: “The prefixes `posix_`, `POSIX_`, and `_POSIX_` are reserved for use by Shell and  
 3540 Utilities volume of IEEE Std 1003.1-2001, Chapter 2, Shell Command Language and other POSIX  
 3541 standards. Implementations may add symbols to the headers shown in the following table,  
 3542 provided the identifiers ... do not use the reserved prefixes `posix_`, `POSIX_`, or `_POSIX_`.”

3543 IEEE Std 1003.1-2001 / Cor 1-2002, item XSH/TC1/D6/3 is applied, correcting the reserved  
 3544 macro prefix from: “`PRI[a-z]`, `SCN[a-z]`” to: “`PRI[Xa-z]`, `SCN[Xa-z]`” in the second table. The  
 3545 change was needed since the ISO C standard allows implementations to define macros of the  
 3546 form `PRI` or `SCN` followed by any lowercase letter or ‘`X`’ in `<inttypes.h>`. (The  
 3547 ISO / IEC 9899:1999 standard, Subclause 7.26.4.)

3548 IEEE Std 1003.1-2001 / Cor 1-2002, item XSH/TC1/D6/4 is applied, adding a new section listing  
 3549 reserved names for the `<stdint.h>` header. This change is for alignment with the ISO C standard.

### 3550 B.2.3 Error Numbers

3551 It was the consensus of the standard developers that to allow the conformance document to  
 3552 state that an error occurs and under what conditions, but to disallow a statement that it never  
 3553 occurs, does not make sense. It could be implied by the current wording that this is allowed, but  
 3554 to reduce the possibility of future interpretation requests, it is better to make an explicit  
 3555 statement.

3556 The ISO C standard requires that `errno` be an assignable lvalue. Originally, the definition in  
 3557 POSIX.1 was stricter than that in the ISO C standard, **extern int `errno`**, in order to support  
 3558 historical usage. In a multi-threaded environment, implementing `errno` as a global variable  
 3559 results in non-deterministic results when accessed. It is required, however, that `errno` work as a  
 3560 per-thread error reporting mechanism. In order to do this, a separate `errno` value has to be  
 3561 maintained for each thread. The following section discusses the various alternative solutions  
 3562 that were considered.

3563 In order to avoid this problem altogether for new functions, these functions avoid using `errno`  
 3564 and, instead, return the error number directly as the function return value; a return value of zero  
 3565 indicates that no error was detected.

3566 For any function that can return errors, the function return value is not used for any purpose  
 3567 other than for reporting errors. Even when the output of the function is scalar, it is passed  
 3568 through a function argument. While it might have been possible to allow some scalar outputs to  
 3569 be coded as negative function return values and mixed in with positive error status returns, this  
 3570 was rejected—using the return value for a mixed purpose was judged to be of limited use and  
 3571 error prone.

3572 Checking the value of *errno* alone is not sufficient to determine the existence or type of an error,  
 3573 since it is not required that a successful function call clear *errno*. The variable *errno* should only  
 3574 be examined when the return value of a function indicates that the value of *errno* is meaningful.  
 3575 In that case, the function is required to set the variable to something other than zero.

3576 The variable *errno* is never set to zero by any function call; to do so would contradict the ISO C  
 3577 standard.

3578 POSIX.1 requires (in the ERRORS sections of function descriptions) certain error values to be set  
 3579 in certain conditions because many existing applications depend on them. Some error numbers,  
 3580 such as [EFAULT], are entirely implementation-defined and are noted as such in their  
 3581 description in the ERRORS section. This section otherwise allows wide latitude to the  
 3582 implementation in handling error reporting.

3583 Some of the ERRORS sections in IEEE Std 1003.1-2001 have two subsections. The first:

3584 “The function shall fail if:”

3585 could be called the “mandatory” section.

3586 The second:

3587 “The function may fail if:”

3588 could be informally known as the “optional” section.

3589 Attempting to infer the quality of an implementation based on whether it detects optional error  
 3590 conditions is not useful.

3591 Following each one-word symbolic name for an error, there is a description of the error. The  
 3592 rationale for some of the symbolic names follows:

3593 [ECANCELED] This spelling was chosen as being more common.

3594 [EFAULT] Most historical implementations do not catch an error and set *errno* when an  
 3595 invalid address is given to the functions *wait()*, *time()*, or *times()*. Some  
 3596 implementations cannot reliably detect an invalid address. And most systems  
 3597 that detect invalid addresses will do so only for a system call, not for a library  
 3598 routine.

3599 [EFTYPE] This error code was proposed in earlier proposals as “Inappropriate operation  
 3600 for file type”, meaning that the operation requested is not appropriate for the  
 3601 file specified in the function call. This code was proposed, although the same  
 3602 idea was covered by [ENOTTY], because the connotations of the name would  
 3603 be misleading. It was pointed out that the *fcntl()* function uses the error code  
 3604 [EINVAL] for this notion, and hence all instances of [EFTYPE] were changed  
 3605 to this code.

3606 [EINTR] POSIX.1 prohibits conforming implementations from restarting interrupted  
 3607 system calls of conforming applications unless the SA\_RESTART flag is in  
 3608 effect for the signal. However, it does not require that [EINTR] be returned  
 3609 when another legitimate value may be substituted; for example, a partial  
 3610 transfer count when *read()* or *write()* are interrupted. This is only given when

|      |                |                                                                                                                                                                                                                |
|------|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3611 |                | the signal-catching function returns normally as opposed to returns by                                                                                                                                         |
| 3612 |                | mechanisms like <i>longjmp()</i> or <i>siglongjmp()</i> .                                                                                                                                                      |
| 3613 | [ELOOP]        | In specifying conditions under which implementations would generate this                                                                                                                                       |
| 3614 |                | error, the following goals were considered:                                                                                                                                                                    |
| 3615 |                | <ul style="list-style-type: none"> <li>• To ensure that actual loops are detected, including loops that result from symbolic links across distributed file systems.</li> </ul>                                 |
| 3616 |                |                                                                                                                                                                                                                |
| 3617 |                | <ul style="list-style-type: none"> <li>• To ensure that during pathname resolution an application can rely on the ability to follow at least {SYMLOOP_MAX} symbolic links in the absence of a loop.</li> </ul> |
| 3618 |                |                                                                                                                                                                                                                |

| 3625 |                | When a symbolic link is encountered during pathname resolution, the                                                                                                                                            |
| 3626 |                | contents of that symbolic link are used to create a new pathname. The                                                                                                                                          |
| 3627 |                | standard developers intended to allow, but not require, that implementations                                                                                                                                   |
| 3628 |                | enforce the restriction of {PATH_MAX} on the result of this pathname                                                                                                                                           |
| 3629 |                | substitution.                                                                                                                                                                                                  |
| 3630 | [ENOMEM]       | The term “main memory” is not used in POSIX.1 because it is                                                                                                                                                    |
| 3631 |                | implementation-defined.                                                                                                                                                                                        |
| 3632 | [ENOTSUP]      | This error code is to be used when an implementation chooses to implement                                                                                                                                      |
| 3633 |                | the required functionality of IEEE Std 1003.1-2001 but does not support                                                                                                                                        |
| 3634 |                | optional facilities defined by IEEE Std 1003.1-2001. The return of [ENOSYS] is                                                                                                                                 |
| 3635 |                | to be taken to indicate that the function of the interface is not supported at all;                                                                                                                            |
| 3636 |                | the function will always fail with this error code.                                                                                                                                                            |
| 3637 | [ENOTTY]       | The symbolic name for this error is derived from a time when device control                                                                                                                                    |
| 3638 |                | was done by <i>ioctl()</i> and that operation was only permitted on a terminal                                                                                                                                 |
| 3639 |                | interface. The term “TTY” is derived from “teletypewriter”, the devices to                                                                                                                                     |
| 3640 |                | which this error originally applied.                                                                                                                                                                           |
| 3641 | [EOVERFLOW]    | Most of the uses of this error code are related to large file support. Typically,                                                                                                                              |
| 3642 |                | these cases occur on systems which support multiple programming                                                                                                                                                |
| 3643 |                | environments with different sizes for <b>off_t</b> , but they may also occur in                                                                                                                                |
| 3644 |                | connection with remote file systems.                                                                                                                                                                           |
| 3645 |                | In addition, when different programming environments have different widths                                                                                                                                     |
| 3646 |                | for types such as <b>int</b> and <b>uid_t</b> , several functions may encounter a condition                                                                                                                    |
| 3647 |                | where a value in a particular environment is too wide to be represented. In                                                                                                                                    |
| 3648 |                | that case, this error should be raised. For example, suppose the currently                                                                                                                                     |
| 3649 |                | running process has 64-bit <b>int</b> , and file descriptor 9 223 372 036 854 775 807 is                                                                                                                       |
| 3650 |                | open and does not have the close-on-exec flag set. If the process then uses                                                                                                                                    |
| 3651 |                | <i>execl()</i> to <i>exec</i> a file compiled in a programming environment with 32-bit <b>int</b> ,                                                                                                            |
| 3652 |                | the call to <i>execl()</i> can fail with <i>errno</i> set to [EOVERFLOW]. A similar failure                                                                                                                    |
| 3653 |                | can occur with <i>execl()</i> if any of the user IDs or any of the group IDs to be                                                                                                                             |
| 3654 |                | assigned to the new process image are out of range for the executed file's                                                                                                                                     |
| 3655 |                | programming environment.                                                                                                                                                                                       |

3656 Note, however, that this condition cannot occur for functions that are  
3657 explicitly described as always being successful, such as *getpid()*.

3658 [EPIPE] This condition normally generates the signal SIGPIPE; the error is returned if  
3659 the signal does not terminate the process.

3660 [EROFS] In historical implementations, attempting to *unlink()* or *rmdir()* a mount point  
3661 would generate an [EBUSY] error. An implementation could be envisioned  
3662 where such an operation could be performed without error. In this case, if  
3663 *either* the directory entry or the actual data structures reside on a read-only file  
3664 system, [EROFS] is the appropriate error to generate. (For example, changing  
3665 the link count of a file on a read-only file system could not be done, as is  
3666 required by *unlink()*, and thus an error should be reported.)

3667 Three error numbers, [EDOM], [EILSEQ], and [ERANGE], were added to this section primarily  
3668 for consistency with the ISO C standard.

### 3669 **Alternative Solutions for Per-Thread *errno***

3670 The usual implementation of *errno* as a single global variable does not work in a multi-threaded  
3671 environment. In such an environment, a thread may make a POSIX.1 call and get a *-1* error  
3672 return, but before that thread can check the value of *errno*, another thread might have made a  
3673 second POSIX.1 call that also set *errno*. This behavior is unacceptable in robust programs. There  
3674 were a number of alternatives that were considered for handling the *errno* problem:

- 3675 • Implement *errno* as a per-thread integer variable.
- 3676 • Implement *errno* as a service that can access the per-thread error number.
- 3677 • Change all POSIX.1 calls to accept an extra status argument and avoid setting *errno*.
- 3678 • Change all POSIX.1 calls to raise a language exception.

3679 The first option offers the highest level of compatibility with existing practice but requires  
3680 special support in the linker, compiler, and/or virtual memory system to support the new  
3681 concept of thread private variables. When compared with current practice, the third and fourth  
3682 options are much cleaner, more efficient, and encourage a more robust programming style, but  
3683 they require new versions of all of the POSIX.1 functions that might detect an error. The second  
3684 option offers compatibility with existing code that uses the **<errno.h>** header to define the  
3685 symbol *errno*. In this option, *errno* may be a macro defined:

```
3686 #define errno (*__errno())
3687 extern int *__errno();
```

3688 This option may be implemented as a per-thread variable whereby an *errno* field is allocated in  
3689 the user space object representing a thread, and whereby the function *\_\_errno()* makes a system  
3690 call to determine the location of its user space object and returns the address of the *errno* field of  
3691 that object. Another implementation, one that avoids calling the kernel, involves allocating  
3692 stacks in chunks. The stack allocator keeps a side table indexed by chunk number containing a  
3693 pointer to the thread object that uses that chunk. The *\_\_errno()* function then looks at the stack  
3694 pointer, determines the chunk number, and uses that as an index into the chunk table to find its  
3695 thread object and thus its private value of *errno*. On most architectures, this can be done in four  
3696 to five instructions. Some compilers may wish to implement *\_\_errno()* inline to improve  
3697 performance.

### Disallowing Return of the [EINTR] Error Code

Many blocking interfaces defined by IEEE Std 1003.1-2001 may return [EINTR] if interrupted during their execution by a signal handler. Blocking interfaces introduced under the Threads option do not have this property. Instead, they require that the interface appear to be atomic with respect to interruption. In particular, clients of blocking interfaces need not handle any possible [EINTR] return as a special case since it will never occur. If it is necessary to restart operations or complete incomplete operations following the execution of a signal handler, this is handled by the implementation, rather than by the application.

Requiring applications to handle [EINTR] errors on blocking interfaces has been shown to be a frequent source of often unreproducible bugs, and it adds no compelling value to the available functionality. Thus, blocking interfaces introduced for use by multi-threaded programs do not use this paradigm. In particular, in none of the functions *flockfile()*, *pthread\_cond\_timedwait()*, *pthread\_cond\_wait()*, *pthread\_join()*, *pthread\_mutex\_lock()*, and *sigwait()* did providing [EINTR] returns add value, or even particularly make sense. Thus, these functions do not provide for an [EINTR] return, even when interrupted by a signal handler. The same arguments can be applied to *sem\_wait()*, *sem\_trywait()*, *sigwaitinfo()*, and *sigtimedwait()*, but implementations are permitted to return [EINTR] error codes for these functions for compatibility with earlier versions of IEEE Std 1003.1. Applications cannot rely on calls to these functions returning [EINTR] error codes when signals are delivered to the calling thread, but they should allow for the possibility.

#### B.2.3.1 Additional Error Numbers

The ISO C standard defines the name space for implementations to add additional error numbers.

### B.2.4 Signal Concepts

Historical implementations of signals, using the *signal()* function, have shortcomings that make them unreliable for many application uses. Because of this, a new signal mechanism, based very closely on the one of 4.2 BSD and 4.3 BSD, was added to POSIX.1.

#### Signal Names

The restriction on the actual type used for **sigset\_t** is intended to guarantee that these objects can always be assigned, have their address taken, and be passed as parameters by value. It is not intended that this type be a structure including pointers to other data structures, as that could impact the portability of applications performing such operations. A reasonable implementation could be a structure containing an array of some integer type.

The signals described in IEEE Std 1003.1-2001 must have unique values so that they may be named as parameters of **case** statements in the body of a C-language **switch** clause. However, implementation-defined signals may have values that overlap with each other or with signals specified in IEEE Std 1003.1-2001. An example of this is SIGABRT, which traditionally overlaps some other signal, such as SIGIOT.

SIGKILL, SIGTERM, SIGUSR1, and SIGUSR2 are ordinarily generated only through the explicit use of the *kill()* function, although some implementations generate SIGKILL under extraordinary circumstances. SIGTERM is traditionally the default signal sent by the *kill* command.

The signals SIGBUS, SIGEMT, SIGIOT, SIGTRAP, and SIGSYS were omitted from POSIX.1 because their behavior is implementation-defined and could not be adequately categorized. Conforming implementations may deliver these signals, but must document the circumstances

under which they are delivered and note any restrictions concerning their delivery. The signals SIGFPE, SIGILL, and SIGSEGV are similar in that they also generally result only from programming errors. They were included in POSIX.1 because they do indicate three relatively well-categorized conditions. They are all defined by the ISO C standard and thus would have to be defined by any system with an ISO C standard binding, even if not explicitly included in POSIX.1.

There is very little that a Conforming POSIX.1 Application can do by catching, ignoring, or masking any of the signals SIGILL, SIGTRAP, SIGIOT, SIGEMT, SIGBUS, SIGSEGV, SIGSYS, or SIGFPE. They will generally be generated by the system only in cases of programming errors. While it may be desirable for some robust code (for example, a library routine) to be able to detect and recover from programming errors in other code, these signals are not nearly sufficient for that purpose. One portable use that does exist for these signals is that a command interpreter can recognize them as the cause of a process' termination (with *wait()*) and print an appropriate message. The mnemonic tags for these signals are derived from their PDP-11 origin.

The signals SIGSTOP, SIGTSTP, SIGTTIN, SIGTTOU, and SIGCONT are provided for job control and are unchanged from 4.2 BSD. The signal SIGCHLD is also typically used by job control shells to detect children that have terminated or, as in 4.2 BSD, stopped.

Some implementations, including System V, have a signal named SIGCLD, which is similar to SIGCHLD in 4.2 BSD. POSIX.1 permits implementations to have a single signal with both names. POSIX.1 carefully specifies ways in which conforming applications can avoid the semantic differences between the two different implementations. The name SIGCHLD was chosen for POSIX.1 because most current application usages of it can remain unchanged in conforming applications. SIGCLD in System V has more cases of semantics that POSIX.1 does not specify, and thus applications using it are more likely to require changes in addition to the name change.

The signals SIGUSR1 and SIGUSR2 are commonly used by applications for notification of exceptional behavior and are described as “reserved as application-defined” so that such use is not prohibited. Implementations should not generate SIGUSR1 or SIGUSR2, except when explicitly requested by *kill()*. It is recommended that libraries not use these two signals, as such use in libraries could interfere with their use by applications calling the libraries. If such use is unavoidable, it should be documented. It is prudent for non-portable libraries to use non-standard signals to avoid conflicts with use of standard signals by portable libraries.

There is no portable way for an application to catch or ignore non-standard signals. Some implementations define the range of signal numbers, so applications can install signal-catching functions for all of them. Unfortunately, implementation-defined signals often cause problems when caught or ignored by applications that do not understand the reason for the signal. While the desire exists for an application to be more robust by handling all possible signals (even those only generated by *kill()*), no existing mechanism was found to be sufficiently portable to include in POSIX.1. The value of such a mechanism, if included, would be diminished given that SIGKILL would still not be catchable.

A number of new signal numbers are reserved for applications because the two user signals defined by POSIX.1 are insufficient for many realtime applications. A range of signal numbers is specified, rather than an enumeration of additional reserved signal names, because different applications and application profiles will require a different number of application signals. It is not desirable to burden all application domains and therefore all implementations with the maximum number of signals required by all possible applications. Note that in this context, signal numbers are essentially different signal priorities.

The relatively small number of required additional signals, {\_POSIX\_RTSIG\_MAX}, was chosen so as not to require an unreasonably large signal mask/set. While this number of signals defined

in POSIX.1 will fit in a single 32-bit word signal mask, it is recognized that most existing implementations define many more signals than are specified in POSIX.1 and, in fact, many implementations have already exceeded 32 signals (including the “null signal”). Support of `{_POSIX_RTSIG_MAX}` additional signals may push some implementation over the single 32-bit word line, but is unlikely to push any implementations that are already over that line beyond the 64-signal line.

#### B.2.4.1 Signal Generation and Delivery

The terms defined in this section are not used consistently in documentation of historical systems. Each signal can be considered to have a lifetime beginning with generation and ending with delivery or acceptance. The POSIX.1 definition of “delivery” does not exclude ignored signals; this is considered a more consistent definition. This revised text in several parts of IEEE Std 1003.1-2001 clarifies the distinct semantics of asynchronous signal delivery and synchronous signal acceptance. The previous wording attempted to categorize both under the term “delivery”, which led to conflicts over whether the effects of asynchronous signal delivery applied to synchronous signal acceptance.

Signals generated for a process are delivered to only one thread. Thus, if more than one thread is eligible to receive a signal, one has to be chosen. The choice of threads is left entirely up to the implementation both to allow the widest possible range of conforming implementations and to give implementations the freedom to deliver the signal to the “easiest possible” thread should there be differences in ease of delivery between different threads.

Note that should multiple delivery among cooperating threads be required by an application, this can be trivially constructed out of the provided single-delivery semantics. The construction of a `sigwait_multiple()` function that accomplishes this goal is presented with the rationale for `sigwaitinfo()`.

Implementations should deliver unblocked signals as soon after they are generated as possible. However, it is difficult for POSIX.1 to make specific requirements about this, beyond those in `kill()` and `sigprocmask()`. Even on systems with prompt delivery, scheduling of higher priority processes is always likely to cause delays.

In general, the interval between the generation and delivery of unblocked signals cannot be detected by an application. Thus, references to pending signals generally apply to blocked, pending signals. An implementation registers a signal as pending on the process when no thread has the signal unblocked and there are no threads blocked in a `sigwait()` function for that signal. Thereafter, the implementation delivers the signal to the first thread that unblocks the signal or calls a `sigwait()` function on a signal set containing this signal rather than choosing the recipient thread at the time the signal is sent.

In the 4.3 BSD system, signals that are blocked and set to `SIG_IGN` are discarded immediately upon generation. For a signal that is ignored as its default action, if the action is `SIG_DFL` and the signal is blocked, a generated signal remains pending. In the 4.1 BSD system and in System V Release 3 (two other implementations that support a somewhat similar signal mechanism), all ignored blocked signals remain pending if generated. Because it is not normally useful for an application to simultaneously ignore and block the same signal, it was unnecessary for POSIX.1 to specify behavior that would invalidate any of the historical implementations.

There is one case in some historical implementations where an unblocked, pending signal does not remain pending until it is delivered. In the System V implementation of `signal()`, pending signals are discarded when the action is set to `SIG_DFL` or a signal-catching routine (as well as to `SIG_IGN`). Except in the case of setting `SIGCHLD` to `SIG_DFL`, implementations that do this do not conform completely to POSIX.1. Some earlier proposals for POSIX.1 explicitly stated this, but these statements were redundant due to the requirement that functions defined by POSIX.1

not change attributes of processes defined by POSIX.1 except as explicitly stated.

POSIX.1 specifically states that the order in which multiple, simultaneously pending signals are delivered is unspecified. This order has not been explicitly specified in historical implementations, but has remained quite consistent and been known to those familiar with the implementations. Thus, there have been cases where applications (usually system utilities) have been written with explicit or implicit dependencies on this order. Implementors and others porting existing applications may need to be aware of such dependencies.

When there are multiple pending signals that are not blocked, implementations should arrange for the delivery of all signals at once, if possible. Some implementations stack calls to all pending signal-catching routines, making it appear that each signal-catcher was interrupted by the next signal. In this case, the implementation should ensure that this stacking of signals does not violate the semantics of the signal masks established by *sigaction()*. Other implementations process at most one signal when the operating system is entered, with remaining signals saved for later delivery. Although this practice is widespread, this behavior is neither standardized nor endorsed. In either case, implementations should attempt to deliver signals associated with the current state of the process (for example, SIGFPE) before other signals, if possible.

In 4.2 BSD and 4.3 BSD, it is not permissible to ignore or explicitly block SIGCONT, because if blocking or ignoring this signal prevented it from continuing a stopped process, such a process could never be continued (only killed by SIGKILL). However, 4.2 BSD and 4.3 BSD do block SIGCONT during execution of its signal-catching function when it is caught, creating exactly this problem. A proposal was considered to disallow catching SIGCONT in addition to ignoring and blocking it, but this limitation led to objections. The consensus was to require that SIGCONT always continue a stopped process when generated. This removed the need to disallow ignoring or explicit blocking of the signal; note that SIG\_IGN and SIG\_DFL are equivalent for SIGCONT.

#### B.2.4.2 Realtime Signal Generation and Delivery

The Realtime Signals Extension option to POSIX.1 signal generation and delivery behavior is required for the following reasons:

- The **sigevent** structure is used by other POSIX.1 functions that result in asynchronous event notifications to specify the notification mechanism to use and other information needed by the notification mechanism. IEEE Std 1003.1-2001 defines only three symbolic values for the notification mechanism:

- SIGEV\_NONE is used to indicate that no notification is required when the event occurs. This is useful for applications that use asynchronous I/O with polling for completion.

- SIGEV\_SIGNAL indicates that a signal is generated when the event occurs.

- SIGEV\_THREAD provides for “callback functions” for asynchronous notifications done by a function call within the context of a new thread. This provides a multi-threaded process with a more natural means of notification than signals.

The primary difficulty with previous notification approaches has been to specify the environment of the notification routine.

- One approach is to limit the notification routine to call only functions permitted in a signal handler. While the list of permissible functions is clearly stated, this is overly restrictive.

- A second approach is to define a new list of functions or classes of functions that are explicitly permitted or not permitted. This would give a programmer more lists to deal with, which would be awkward.

— The third approach is to define completely the environment for execution of the notification function. A clear definition of an execution environment for notification is provided by executing the notification function in the environment of a newly created thread.

Implementations may support additional notification mechanisms by defining new values for *sigev\_notify*.

For a notification type of `SIGEV_SIGNAL`, the other members of the **sigevent** structure defined by IEEE Std 1003.1-2001 specify the realtime signal—that is, the signal number and application-defined value that differentiates between occurrences of signals with the same number—that will be generated when the event occurs. The structure is defined in `<signal.h>`, even though the structure is not directly used by any of the signal functions, because it is part of the signals interface used by the POSIX.1b “client functions”. When the client functions include `<signal.h>` to define the signal names, the **sigevent** structure will also be defined.

An application-defined value passed to the signal handler is used to differentiate between different “events” instead of requiring that the application use different signal numbers for several reasons:

— Realtime applications potentially handle a very large number of different events. Requiring that implementations support a correspondingly large number of distinct signal numbers will adversely impact the performance of signal delivery because the signal masks to be manipulated on entry and exit to the handlers will become large.

— Event notifications are prioritized by signal number (the rationale for this is explained in the following paragraphs) and the use of different signal numbers to differentiate between the different event notifications overloads the signal number more than has already been done. It also requires that the application writer make arbitrary assignments of priority to events that are logically of equal priority.

A union is defined for the application-defined value so that either an integer constant or a pointer can be portably passed to the signal-catching function. On some architectures a pointer cannot be cast to an **int** and *vice versa*.

Use of a structure here with an explicit notification type discriminant rather than explicit parameters to realtime functions, or embedded in other realtime structures, provides for future extensions to IEEE Std 1003.1-2001. Additional, perhaps more efficient, notification mechanisms can be supported for existing realtime function interfaces, such as timers and asynchronous I/O, by extending the **sigevent** structure appropriately. The existing realtime function interfaces will not have to be modified to use any such new notification mechanism. The revised text concerning the `SIGEV_SIGNAL` value makes consistent the semantics of the members of the **sigevent** structure, particularly in the definitions of *lio\_listio()* and *aio\_fsync()*. For uniformity, other revisions cause this specification to be referred to rather than inaccurately duplicated in the descriptions of functions and structures using the **sigevent** structure. The revised wording does not relax the requirement that the signal number be in the range `SIGRTMIN` to `SIGRTMAX` to guarantee queuing and passing of the application value, since that requirement is still implied by the signal names.

- IEEE Std 1003.1-2001 is intentionally vague on whether “non-realtime” signal-generating mechanisms can result in a **siginfo\_t** being supplied to the handler on delivery. In one existing implementation, a **siginfo\_t** is posted on signal generation, even though the implementation does not support queuing of multiple occurrences of a signal. It is not the intent of IEEE Std 1003.1-2001 to preclude this, independent of the mandate to define signals that do support queuing. Any interpretation that appears to preclude this is a mistake in the

reading or writing of the standard.

- Signals handled by realtime signal handlers might be generated by functions or conditions that do not allow the specification of an application-defined value and do not queue. IEEE Std 1003.1-2001 specifies the *si\_code* member of the **siginfo\_t** structure used in existing practice and defines additional codes so that applications can detect whether an application-defined value is present or not. The code `SI_USER` for `kill()`-generated signals is adopted from existing practice.

- The `sigaction()` *sa\_flags* value `SA_SIGINFO` tells the implementation that the signal-catching function expects two additional arguments. When the flag is not set, a single argument, the signal number, is passed as specified by IEEE Std 1003.1-2001. Although IEEE Std 1003.1-2001 does not explicitly allow the *info* argument to the handler function to be `NULL`, this is existing practice. This provides for compatibility with programs whose signal-catching functions are not prepared to accept the additional arguments. IEEE Std 1003.1-2001 is explicitly unspecified as to whether signals actually queue when `SA_SIGINFO` is not set for a signal, as there appear to be no benefits to applications in specifying one behavior or another. One existing implementation queues a **siginfo\_t** on each signal generation, unless the signal is already pending, in which case the implementation discards the new **siginfo\_t**; that is, the queue length is never greater than one. This implementation only examines `SA_SIGINFO` on signal delivery, discarding the queued **siginfo\_t** if its delivery was not requested.

IEEE Std 1003.1-2001 specifies several new values for the *si\_code* member of the **siginfo\_t** structure. In existing practice, a *si\_code* value of less than or equal to zero indicates that the signal was generated by a process via the `kill()` function. In existing practice, values of *si\_code* that provide additional information for implementation-generated signals, such as `SIGFPE` or `SIGSEGV`, are all positive. Thus, if implementations define the new constants specified in IEEE Std 1003.1-2001 to be negative numbers, programs written to use existing practice will not break. IEEE Std 1003.1-2001 chose not to attempt to specify existing practice values of *si\_code* other than `SI_USER` both because it was deemed beyond the scope of IEEE Std 1003.1-2001 and because many of the values in existing practice appear to be platform and implementation-defined. But, IEEE Std 1003.1-2001 does specify that if an implementation—for example, one that does not have existing practice in this area—chooses to define additional values for *si\_code*, these values have to be different from the values of the symbols specified by IEEE Std 1003.1-2001. This will allow conforming applications to differentiate between signals generated by one of the POSIX.1b asynchronous events and those generated by other implementation events in a manner compatible with existing practice.

The unique values of *si\_code* for the POSIX.1b asynchronous events have implications for implementations of, for example, asynchronous I/O or message passing in user space library code. Such an implementation will be required to provide a hidden interface to the signal generation mechanism that allows the library to specify the standard values of *si\_code*.

Existing practice also defines additional members of **siginfo\_t**, such as the process ID and user ID of the sending process for `kill()`-generated signals. These members were deemed not necessary to meet the requirements of realtime applications and are not specified by IEEE Std 1003.1-2001. Neither are they precluded.

The third argument to the signal-catching function, *context*, is left undefined by IEEE Std 1003.1-2001, but is specified in the interface because it matches existing practice for the `SA_SIGINFO` flag. It was considered undesirable to require a separate implementation for `SA_SIGINFO` for POSIX conformance on implementations that already support the two additional parameters.

- The requirement to deliver lower numbered signals in the range SIGRTMIN to SIGRTMAX first, when multiple unblocked signals are pending, results from several considerations:

- A method is required to prioritize event notifications. The signal number was chosen instead of, for instance, associating a separate priority with each request, because an implementation has to check pending signals at various points and select one for delivery when more than one is pending. Specifying a selection order is the minimal additional semantic that will achieve prioritized delivery. If a separate priority were to be associated with queued signals, it would be necessary for an implementation to search all non-empty, non-blocked signal queues and select from among them the pending signal with the highest priority. This would significantly increase the cost of and decrease the determinism of signal delivery.

- Given the specified selection of the lowest numeric unblocked pending signal, preemptive priority signal delivery can be achieved using signal numbers and signal masks by ensuring that the *sa\_mask* for each signal number blocks all signals with a higher numeric value.

For realtime applications that want to use only the newly defined realtime signal numbers without interference from the standard signals, this can be achieved by blocking all of the standard signals in the thread signal mask and in the *sa\_mask* installed by the signal action for the realtime signal handlers.

IEEE Std 1003.1-2001 explicitly leaves unspecified the ordering of signals outside of the range of realtime signals and the ordering of signals within this range with respect to those outside the range. It was believed that this would unduly constrain implementations or standards in the future definition of new signals.

### B.2.4.3 Signal Actions

Early proposals mentioned SIGCONT as a second exception to the rule that signals are not delivered to stopped processes until continued. Because IEEE Std 1003.1-2001 now specifies that SIGCONT causes the stopped process to continue when it is generated, delivery of SIGCONT is not prevented because a process is stopped, even without an explicit exception to this rule.

Ignoring a signal by setting the action to SIG\_IGN (or SIG\_DFL for signals whose default action is to ignore) is not the same as installing a signal-catching function that simply returns. Invoking such a function will interrupt certain system functions that block processes (for example, *wait()*, *sigsuspend()*, *pause()*, *read()*, *write()*) while ignoring a signal has no such effect on the process.

Historical implementations discard pending signals when the action is set to SIG\_IGN. However, they do not always do the same when the action is set to SIG\_DFL and the default action is to ignore the signal. IEEE Std 1003.1-2001 requires this for the sake of consistency and also for completeness, since the only signal this applies to is SIGCHLD, and IEEE Std 1003.1-2001 disallows setting its action to SIG\_IGN.

Some implementations (System V, for example) assign different semantics for SIGCLD depending on whether the action is set to SIG\_IGN or SIG\_DFL. Since POSIX.1 requires that the default action for SIGCHLD be to ignore the signal, applications should always set the action to SIG\_DFL in order to avoid SIGCHLD.

Whether or not an implementation allows SIG\_IGN as a SIGCHLD disposition to be inherited across a call to one of the *exec* family of functions or *posix\_spawn()* is explicitly left as unspecified. This change was made as a result of IEEE PASC Interpretation 1003.1 #132, and permits the implementation to decide between the following alternatives:

- Unconditionally leave SIGCHLD set to SIG\_IGN, in which case the implementation would not allow applications that assume inheritance of SIG\_DFL to conform to IEEE Std 1003.1-2001 without change. The implementation would, however, retain an ability to control applications that create child processes but never call on the *wait* family of functions, potentially filling up the process table.
- Unconditionally reset SIGCHLD to SIG\_DFL, in which case the implementation would allow applications that assume inheritance of SIG\_DFL to conform. The implementation would, however, lose an ability to control applications that spawn child processes but never reap them.
- Provide some mechanism, not specified in IEEE Std 1003.1-2001, to control inherited SIGCHLD dispositions.

Some implementations (System V, for example) will deliver a SIGCHLD signal immediately when a process establishes a signal-catching function for SIGCHLD when that process has a child that has already terminated. Other implementations, such as 4.3 BSD, do not generate a new SIGCHLD signal in this way. In general, a process should not attempt to alter the signal action for the SIGCHLD signal while it has any outstanding children. However, it is not always possible for a process to avoid this; for example, shells sometimes start up processes in pipelines with other processes from the pipeline as children. Processes that cannot ensure that they have no children when altering the signal action for SIGCHLD thus need to be prepared for, but not depend on, generation of an immediate SIGCHLD signal.

The default action of the stop signals (SIGSTOP, SIGTSTP, SIGTTIN, SIGTTOU) is to stop a process that is executing. If a stop signal is delivered to a process that is already stopped, it has no effect. In fact, if a stop signal is generated for a stopped process whose signal mask blocks the signal, the signal will never be delivered to the process since the process must receive a SIGCONT, which discards all pending stop signals, in order to continue executing.

The SIGCONT signal continues a stopped process even if SIGCONT is blocked (or ignored). However, if a signal-catching routine has been established for SIGCONT, it will not be entered until SIGCONT is unblocked.

If a process in an orphaned process group stops, it is no longer under the control of a job control shell and hence would not normally ever be continued. Because of this, orphaned processes that receive terminal-related stop signals (SIGTSTP, SIGTTIN, SIGTTOU, but not SIGSTOP) must not be allowed to stop. The goal is to prevent stopped processes from languishing forever. (As SIGSTOP is sent only via *kill()*, it is assumed that the process or user sending a SIGSTOP can send a SIGCONT when desired.) Instead, the system must discard the stop signal. As an extension, it may also deliver another signal in its place. 4.3 BSD sends a SIGKILL, which is overly effective because SIGKILL is not catchable. Another possible choice is SIGHUP. 4.3 BSD also does this for orphaned processes (processes whose parent has terminated) rather than for members of orphaned process groups; this is less desirable because job control shells manage process groups. POSIX.1 also prevents SIGTTIN and SIGTTOU signals from being generated for processes in orphaned process groups as a direct result of activity on a terminal, preventing infinite loops when *read()* and *write()* calls generate signals that are discarded; see Section A.11.1.4 (on page 67). A similar restriction on the generation of SIGTSTP was considered, but that would be unnecessary and more difficult to implement due to its asynchronous nature.

Although POSIX.1 requires that signal-catching functions be called with only one argument, there is nothing to prevent conforming implementations from extending POSIX.1 to pass additional arguments, as long as Strictly Conforming POSIX.1 Applications continue to compile and execute correctly. Most historical implementations do, in fact, pass additional, signal-specific arguments to certain signal-catching routines.

There was a proposal to change the declared type of the signal handler to:

```
void func (int sig, ...);
```

The usage of ellipses ("...") is ISO C standard syntax to indicate a variable number of arguments. Its use was intended to allow the implementation to pass additional information to the signal handler in a standard manner.

Unfortunately, this construct would require all signal handlers to be defined with this syntax because the ISO C standard allows implementations to use a different parameter passing mechanism for variable parameter lists than for non-variable parameter lists. Thus, all existing signal handlers in all existing applications would have to be changed to use the variable syntax in order to be standard and portable. This is in conflict with the goal of Minimal Changes to Existing Application Code.

When terminating a process from a signal-catching function, processes should be aware of any interpretation that their parent may make of the status returned by *wait()* or *waitpid()*. In particular, a signal-catching function should not call *exit(0)* or *\_exit(0)* unless it wants to indicate successful termination. A non-zero argument to *exit()* or *\_exit()* can be used to indicate unsuccessful termination. Alternatively, the process can use *kill()* to send itself a fatal signal (first ensuring that the signal is set to the default action and not blocked). See also the RATIONALE section of the *\_exit()* function.

The behavior of *unsafe* functions, as defined by this section, is undefined when they are invoked from signal-catching functions in certain circumstances. The behavior of reentrant functions, as defined by this section, is as specified by POSIX.1, regardless of invocation from a signal-catching function. This is the only intended meaning of the statement that reentrant functions may be used in signal-catching functions without restriction. Applications must still consider all effects of such functions on such things as data structures, files, and process state. In particular, application writers need to consider the restrictions on interactions when interrupting *sleep()* (see *sleep()*) and interactions among multiple handles for a file description. The fact that any specific function is listed as reentrant does not necessarily mean that invocation of that function from a signal-catching function is recommended.

In order to prevent errors arising from interrupting non-reentrant function calls, applications should protect calls to these functions either by blocking the appropriate signals or through the use of some programmatic semaphore. POSIX.1 does not address the more general problem of synchronizing access to shared data structures. Note in particular that even the "safe" functions may modify the global variable *errno*; the signal-catching function may want to save and restore its value. The same principles apply to the reentrancy of application routines and asynchronous data access.

Note that *longjmp()* and *siglongjmp()* are not in the list of reentrant functions. This is because the code executing after *longjmp()* or *siglongjmp()* can call any unsafe functions with the same danger as calling those unsafe functions directly from the signal handler. Applications that use *longjmp()* or *siglongjmp()* out of signal handlers require rigorous protection in order to be portable. Many of the other functions that are excluded from the list are traditionally implemented using either the C language *malloc()* or *free()* functions or the ISO C standard I/O library, both of which traditionally use data structures in a non-reentrant manner. Because any combination of different functions using a common data structure can cause reentrancy problems, POSIX.1 does not define the behavior when any unsafe function is called in a signal handler that interrupts any unsafe function.

The only realtime extension to signal actions is the addition of the additional parameters to the signal-catching function. This extension has been explained and motivated in the previous section. In making this extension, though, developers of POSIX.1b ran into issues relating to

function prototypes. In response to input from the POSIX.1 standard developers, members were added to the **sigaction** structure to specify function prototypes for the newer signal-catching function specified by POSIX.1b. These members follow changes that are being made to POSIX.1. Note that IEEE Std 1003.1-2001 explicitly states that these fields may overlap so that a union can be defined. This enabled existing implementations of POSIX.1 to maintain binary-compatibility when these extensions were added.

The **siginfo\_t** structure was adopted for passing the application-defined value to match existing practice, but the existing practice has no provision for an application-defined value, so this was added. Note that POSIX normally reserves the “\_t” type designation for opaque types. The **siginfo\_t** structure breaks with this convention to follow existing practice and thus promote portability. Standardization of the existing practice for the other members of this structure may be addressed in the future.

Although it is not explicitly visible to applications, there are additional semantics for signal actions implied by queued signals and their interaction with other POSIX.1b realtime functions. Specifically:

- It is not necessary to queue signals whose action is SIG\_IGN.
- For implementations that support POSIX.1b timers, some interaction with the timer functions at signal delivery is implied to manage the timer overrun count.

IEEE Std 1003.1-2001 / Cor 1-2002, item XSH/TC1/D6/5 is applied, reordering the RTS shaded text under the third and fourth paragraphs of the SIG\_DFL description. This corrects an earlier editorial error in this section.

IEEE Std 1003.1-2001 / Cor 1-2002, item XSH/TC1/D6/6 is applied, adding the *abort()* function to the list of async-cancel-safe functions.

#### B.2.4.4 Signal Effects on Other Functions

The most common behavior of an interrupted function after a signal-catching function returns is for the interrupted function to give an [EINTR] error unless the SA\_RESTART flag is in effect for the signal. However, there are a number of specific exceptions, including *sleep()* and certain situations with *read()* and *write()*.

The historical implementations of many functions defined by IEEE Std 1003.1-2001 are not interruptible, but delay delivery of signals generated during their execution until after they complete. This is never a problem for functions that are guaranteed to complete in a short (imperceptible to a human) period of time. It is normally those functions that can suspend a process indefinitely or for long periods of time (for example, *wait()*, *pause()*, *sigsuspend()*, *sleep()*, or *read()/write()* on a slow device like a terminal) that are interruptible. This permits applications to respond to interactive signals or to set timeouts on calls to most such functions with *alarm()*. Therefore, implementations should generally make such functions (including ones defined as extensions) interruptible.

Functions not mentioned explicitly as interruptible may be so on some implementations, possibly as an extension where the function gives an [EINTR] error. There are several functions (for example, *getpid()*, *getuid()*) that are specified as never returning an error, which can thus never be extended in this way.

If a signal-catching function returns while the SA\_RESTART flag is in effect, an interrupted function is restarted at the point it was interrupted. Conforming applications cannot make assumptions about the internal behavior of interrupted functions, even if the functions are async-signal-safe. For example, suppose the *read()* function is interrupted with SA\_RESTART in effect, the signal-catching function closes the file descriptor being read from and returns, and the

4169 *read()* function is then restarted; in this case the application cannot assume that the *read()*  
4170 function will give an [EBADF] error, since *read()* might have checked the file descriptor for  
4171 validity before being interrupted.

## 4172 **B.2.5 Standard I/O Streams**

### 4173 *B.2.5.1 Interaction of File Descriptors and Standard I/O Streams*

4174 There is no additional rationale provided for this section.

### 4175 *B.2.5.2 Stream Orientation and Encoding Rules*

4176 There is no additional rationale provided for this section.

## 4177 **B.2.6 STREAMS**

4178 STREAMS are introduced into IEEE Std 1003.1-2001 as part of the alignment with the Single  
4179 UNIX Specification, but marked as an option in recognition that not all systems may wish to  
4180 implement the facility. The option within IEEE Std 1003.1-2001 is denoted by the XSR margin  
4181 marker. The standard developers made this option independent of the XSI option.

4182 STREAMS are a method of implementing network services and other character-based  
4183 input/output mechanisms, with the STREAM being a full-duplex connection between a process  
4184 and a device. STREAMS provides direct access to protocol modules, and optional protocol  
4185 modules can be interposed between the process-end of the STREAM and the device-driver at the  
4186 device-end of the STREAM. Pipes can be implemented using the STREAMS mechanism, so they  
4187 can provide process-to-process as well as process-to-device communications.

4188 This section introduces STREAMS I/O, the message types used to control them, an overview of  
4189 the priority mechanism, and the interfaces used to access them.

### 4190 *B.2.6.1 Accessing STREAMS*

4191 There is no additional rationale provided for this section.

## 4192 **B.2.7 XSI Interprocess Communication**

4193 There are two forms of IPC supported as options in IEEE Std 1003.1-2001. The traditional  
4194 System V IPC routines derived from the SVID—that is, the *msg\*()*, *sem\*()*, and *shm\*()*  
4195 interfaces—are mandatory on XSI-conformant systems. Thus, all XSI-conformant systems  
4196 provide the same mechanisms for manipulating messages, shared memory, and semaphores.

4197 In addition, the POSIX Realtime Extension provides an alternate set of routines for those systems  
4198 supporting the appropriate options.

4199 The application writer is presented with a choice: the System V interfaces or the POSIX  
4200 interfaces (loosely derived from the Berkeley interfaces). The XSI profile prefers the System V  
4201 interfaces, but the POSIX interfaces may be more suitable for realtime or other performance-  
4202 sensitive applications.

4203 **B.2.7.1** *IPC General Information*

4204 General information that is shared by all three mechanisms is described in this section. The  
 4205 common permissions mechanism is briefly introduced, describing the mode bits, and how they  
 4206 are used to determine whether or not a process has access to read or write/alter the appropriate  
 4207 instance of one of the IPC mechanisms. All other relevant information is contained in the  
 4208 reference pages themselves.

4209 The semaphore type of IPC allows processes to communicate through the exchange of  
 4210 semaphore values. A semaphore is a positive integer. Since many applications require the use of  
 4211 more than one semaphore, XSI-conformant systems have the ability to create sets or arrays of  
 4212 semaphores.

4213 Calls to support semaphores include:

4214 `semctl()`, `semget()`, `semop()`

4215 Semaphore sets are created by using the `semget()` function.

4216 The message type of IPC allows processes to communicate through the exchange of data stored  
 4217 in buffers. This data is transmitted between processes in discrete portions known as messages.

4218 Calls to support message queues include:

4219 `msgctl()`, `msgget()`, `msgrcv()`, `msgsnd()`

4220 The shared memory type of IPC allows two or more processes to share memory and  
 4221 consequently the data contained therein. This is done by allowing processes to set up access to a  
 4222 common memory address space. This sharing of memory provides a fast means of exchange of  
 4223 data between processes.

4224 Calls to support shared memory include:

4225 `shmctl()`, `shmdt()`, `shmget()`

4226 The `ftok()` interface is also provided.

4227 **B.2.8** **Realtime**4228 **Advisory Information**

4229 POSIX.1b contains an Informative Annex with proposed interfaces for “realtime files”. These  
 4230 interfaces could determine groups of the exact parameters required to do “direct I/O” or  
 4231 “extents”. These interfaces were objected to by a significant portion of the balloting group as too  
 4232 complex. A conforming application had little chance of correctly navigating the large parameter  
 4233 space to match its desires to the system. In addition, they only applied to a new type of file  
 4234 (realtime files) and they told the implementation exactly what to do as opposed to advising the  
 4235 implementation on application behavior and letting it optimize for the system the (portable)  
 4236 application was running on. For example, it was not clear how a system that had a disk array  
 4237 should set its parameters.

4238 There seemed to be several overall goals:

- 4239 • Optimizing sequential access
- 4240 • Optimizing caching behavior
- 4241 • Optimizing I/O data transfer
- 4242 • Preallocation

The advisory interfaces, *posix\_fadvise()* and *posix\_madvise()*, satisfy the first two goals. The `POSIX_FADV_SEQUENTIAL` and `POSIX_MADV_SEQUENTIAL` advice tells the implementation to expect serial access. Typically the system will prefetch the next several serial accesses in order to overlap I/O. It may also free previously accessed serial data if memory is tight. If the application is not doing serial access it can use `POSIX_FADV_WILLNEED` and `POSIX_MADV_WILLNEED` to accomplish I/O overlap, as required. When the application advises `POSIX_FADV_RANDOM` or `POSIX_MADV_RANDOM` behavior, the implementation usually tries to fetch a minimum amount of data with each request and it does not expect much locality. `POSIX_FADV_DONTNEED` and `POSIX_MADV_DONTNEED` allow the system to free up caching resources as the data will not be required in the near future.

`POSIX_FADV_NOREUSE` tells the system that caching the specified data is not optimal. For file I/O, the transfer should go directly to the user buffer instead of being cached internally by the implementation. To portably perform direct disk I/O on all systems, the application must perform its I/O transfers according to the following rules:

1. The user buffer should be aligned according to the `{POSIX_REC_XFER_ALIGN}` *pathconf()* variable.
2. The number of bytes transferred in an I/O operation should be a multiple of the `{POSIX_ALLOC_SIZE_MIN}` *pathconf()* variable.
3. The offset into the file at the start of an I/O operation should be a multiple of the `{POSIX_ALLOC_SIZE_MIN}` *pathconf()* variable.
4. The application should ensure that all threads which open a given file specify `POSIX_FADV_NOREUSE` to be sure that there is no unexpected interaction between threads using buffered I/O and threads using direct I/O to the same file.

In some cases, a user buffer must be properly aligned in order to be transferred directly to/from the device. The `{POSIX_REC_XFER_ALIGN}` *pathconf()* variable tells the application the proper alignment.

The preallocation goal is met by the space control function, *posix\_fallocate()*. The application can use *posix\_fallocate()* to guarantee no `[ENOSPC]` errors and to improve performance by prepaying any overhead required for block allocation.

Implementations may use information conveyed by a previous *posix\_fadvise()* call to influence the manner in which allocation is performed. For example, if an application did the following calls:

```
fd = open("file");
posix_fadvise(fd, offset, len, POSIX_FADV_SEQUENTIAL);
posix_fallocate(fd, len, size);
```

an implementation might allocate the file contiguously on disk.

Finally, the *pathconf()* variables `{POSIX_REC_MIN_XFER_SIZE}`, `{POSIX_REC_MAX_XFER_SIZE}`, and `{POSIX_REC_INCR_XFER_SIZE}` tell the application a range of transfer sizes that are recommended for best I/O performance.

Where bounded response time is required, the vendor can supply the appropriate settings of the advisories to achieve a guaranteed performance level.

The interfaces meet the goals while allowing applications using regular files to take advantage of performance optimizations. The interfaces tell the implementation expected application behavior which the implementation can use to optimize performance on a particular system with a particular dynamic load.

The *posix\_memalign()* function was added to allow for the allocation of specifically aligned buffers; for example, for {POSIX\_REC\_XFER\_ALIGN}.

The working group also considered the alternative of adding a function which would return an aligned pointer to memory within a user-supplied buffer. This was not considered to be the best method, because it potentially wastes large amounts of memory when buffers need to be aligned on large alignment boundaries.

## Message Passing

This section provides the rationale for the definition of the message passing interface in IEEE Std 1003.1-2001. This is presented in terms of the objectives, models, and requirements imposed upon this interface.

- Objectives

Many applications, including both realtime and database applications, require a means of passing arbitrary amounts of data between cooperating processes comprising the overall application on one or more processors. Many conventional interfaces for interprocess communication are insufficient for realtime applications in that efficient and deterministic data passing methods cannot be implemented. This has prompted the definition of message passing interfaces providing these facilities:

- Open a message queue.
- Send a message to a message queue.
- Receive a message from a queue, either synchronously or asynchronously.
- Alter message queue attributes for flow and resource control.

It is assumed that an application may consist of multiple cooperating processes and that these processes may wish to communicate and coordinate their activities. The message passing facility described in IEEE Std 1003.1-2001 allows processes to communicate through system-wide queues. These message queues are accessed through names that may be pathnames. A message queue can be opened for use by multiple sending and/or multiple receiving processes.

- Background on Embedded Applications

Interprocess communication utilizing message passing is a key facility for the construction of deterministic, high-performance realtime applications. The facility is present in all realtime systems and is the framework upon which the application is constructed. The performance of the facility is usually a direct indication of the performance of the resulting application.

Realtime applications, especially for embedded systems, are typically designed around the performance constraints imposed by the message passing mechanisms. Applications for embedded systems are typically very tightly constrained. Application writers expect to design and control the entire system. In order to minimize system costs, the writer will attempt to use all resources to their utmost and minimize the requirement to add additional memory or processors.

The embedded applications usually share address spaces and only a simple message passing mechanism is required. The application can readily access common data incurring only mutual-exclusion overheads. The models desired are the simplest possible with the application building higher-level facilities only when needed.

- Requirements

The following requirements determined the features of the message passing facilities defined in IEEE Std 1003.1-2001:

- Naming of Message Queues

The mechanism for gaining access to a message queue is a pathname evaluated in a context that is allowed to be a file system name space, or it can be independent of any file system. This is a specific attempt to allow implementations based on either method in order to address both embedded systems and to also allow implementation in larger systems.

The interface of *mq\_open()* is defined to allow but not require the access control and name conflicts resulting from utilizing a file system for name resolution. All required behavior is specified for the access control case. Yet a conforming implementation, such as an embedded system kernel, may define that there are no distinctions between users and may define that all processes have all access privileges.

- Embedded System Naming

Embedded systems need to be able to utilize independent name spaces for accessing the various system objects. They typically do not have a file system, precluding its utilization as a common name resolution mechanism. The modularity of an embedded system limits the connections between separate mechanisms that can be allowed.

Embedded systems typically do not have any access protection. Since the system does not support the mixing of applications from different areas, and usually does not even have the concept of an authorization entity, access control is not useful.

- Large System Naming

On systems with more functionality, the name resolution must support the ability to use the file system as the name resolution mechanism/object storage medium and to have control over access to the objects. Utilizing the pathname space can result in further errors when the names conflict with other objects.

- Fixed Size of Messages

The interfaces impose a fixed upper bound on the size of messages that can be sent to a specific message queue. The size is set on an individual queue basis and cannot be changed dynamically.

The purpose of the fixed size is to increase the ability of the system to optimize the implementation of *mq\_send()* and *mq\_receive()*. With fixed sizes of messages and fixed numbers of messages, specific message blocks can be pre-allocated. This eliminates a significant amount of checking for errors and boundary conditions. Additionally, an implementation can optimize data copying to maximize performance. Finally, with a restricted range of message sizes, an implementation is better able to provide deterministic operations.

- Prioritization of Messages

Message prioritization allows the application to determine the order in which messages are received. Prioritization of messages is a key facility that is provided by most realtime kernels and is heavily utilized by the applications. The major purpose of having priorities in message queues is to avoid priority inversions in the message system, where a high-priority message is delayed behind one or more lower-priority messages. This allows the applications to be designed so that they do not need to be interrupted in order to change

the flow of control when exceptional conditions occur. The prioritization does add additional overhead to the message operations in those cases it is actually used but a clever implementation can optimize for the FIFO case to make that more efficient.

#### — Asynchronous Notification

The interface supports the ability to have a task asynchronously notified of the availability of a message on the queue. The purpose of this facility is to allow the task to perform other functions and yet still be notified that a message has become available on the queue.

To understand the requirement for this function, it is useful to understand two models of application design: a single task performing multiple functions and multiple tasks performing a single function. Each of these models has advantages.

Asynchronous notification is required to build the model of a single task performing multiple operations. This model typically results from either the expectation that interruption is less expensive than utilizing a separate task or from the growth of the application to include additional functions.

### Semaphores

Semaphores are a high-performance process synchronization mechanism. Semaphores are named by null-terminated strings of characters.

A semaphore is created using the *sem\_init()* function or the *sem\_open()* function with the *O\_CREAT* flag set in *oflag*.

To use a semaphore, a process has to first initialize the semaphore or inherit an open descriptor for the semaphore via *fork()*.

A semaphore preserves its state when the last reference is closed. For example, if a semaphore has a value of 13 when the last reference is closed, it will have a value of 13 when it is next opened.

When a semaphore is created, an initial state for the semaphore has to be provided. This value is a non-negative integer. Negative values are not possible since they indicate the presence of blocked processes. The persistence of any of these objects across a system crash or a system reboot is undefined. Conforming applications must not depend on any sort of persistence across a system reboot or a system crash.

#### • Models and Requirements

A realtime system requires synchronization and communication between the processes comprising the overall application. An efficient and reliable synchronization mechanism has to be provided in a realtime system that will allow more than one schedulable process mutually-exclusive access to the same resource. This synchronization mechanism has to allow for the optimal implementation of synchronization or systems implementors will define other, more cost-effective methods.

At issue are the methods whereby multiple processes (tasks) can be designed and implemented to work together in order to perform a single function. This requires interprocess communication and synchronization. A semaphore mechanism is the lowest level of synchronization that can be provided by an operating system.

A semaphore is defined as an object that has an integral value and a set of blocked processes associated with it. If the value is positive or zero, then the set of blocked processes is empty; otherwise, the size of the set is equal to the absolute value of the semaphore value. The value of the semaphore can be incremented or decremented by any process with access to the

semaphore and must be done as an indivisible operation. When a semaphore value is less than or equal to zero, any process that attempts to lock it again will block or be informed that it is not possible to perform the operation.

A semaphore may be used to guard access to any resource accessible by more than one schedulable task in the system. It is a global entity and not associated with any particular process. As such, a method of obtaining access to the semaphore has to be provided by the operating system. A process that wants access to a critical resource (section) has to wait on the semaphore that guards that resource. When the semaphore is locked on behalf of a process, it knows that it can utilize the resource without interference by any other cooperating process in the system. When the process finishes its operation on the resource, leaving it in a well-defined state, it posts the semaphore, indicating that some other process may now obtain the resource associated with that semaphore.

In this section, mutexes and condition variables are specified as the synchronization mechanisms between threads.

These primitives are typically used for synchronizing threads that share memory in a single process. However, this section provides an option allowing the use of these synchronization interfaces and objects between processes that share memory, regardless of the method for sharing memory.

Much experience with semaphores shows that there are two distinct uses of synchronization: locking, which is typically of short duration; and waiting, which is typically of long or unbounded duration. These distinct usages map directly onto mutexes and condition variables, respectively.

Semaphores are provided in IEEE Std 1003.1-2001 primarily to provide a means of synchronization for processes; these processes may or may not share memory. Mutexes and condition variables are specified as synchronization mechanisms between threads; these threads always share (some) memory. Both are synchronization paradigms that have been in widespread use for a number of years. Each set of primitives is particularly well matched to certain problems.

With respect to binary semaphores, experience has shown that condition variables and mutexes are easier to use for many synchronization problems than binary semaphores. The primary reason for this is the explicit appearance of a Boolean predicate that specifies when the condition wait is satisfied. This Boolean predicate terminates a loop, including the call to *pthread\_cond\_wait()*. As a result, extra wakeups are benign since the predicate governs whether the thread will actually proceed past the condition wait. With stateful primitives, such as binary semaphores, the wakeup in itself typically means that the wait is satisfied. The burden of ensuring correctness for such waits is thus placed on *all* signalers of the semaphore rather than on an *explicitly coded* Boolean predicate located at the condition wait. Experience has shown that the latter creates a major improvement in safety and ease-of-use.

Counting semaphores are well matched to dealing with producer/consumer problems, including those that might exist between threads of different processes, or between a signal handler and a thread. In the former case, there may be little or no memory shared by the processes; in the latter case, one is not communicating between co-equal threads, but between a thread and an interrupt-like entity. It is for these reasons that IEEE Std 1003.1-2001 allows semaphores to be used by threads.

Mutexes and condition variables have been effectively used with and without priority inheritance, priority ceiling, and other attributes to synchronize threads that share memory. The efficiency of their implementation is comparable to or better than that of other synchronization primitives that are sometimes harder to use (for example, binary

semaphores). Furthermore, there is at least one known implementation of Ada tasking that uses these primitives. Mutexes and condition variables together constitute an appropriate, sufficient, and complete set of inter-thread synchronization primitives.

Efficient multi-threaded applications require high-performance synchronization primitives. Considerations of efficiency and generality require a small set of primitives upon which more sophisticated synchronization functions can be built.

- Standardization Issues

It is possible to implement very high-performance semaphores using test-and-set instructions on shared memory locations. The library routines that implement such a high-performance interface have to properly ensure that a *sem\_wait()* or *sem\_trywait()* operation that cannot be performed will issue a blocking semaphore system call or properly report the condition to the application. The same interface to the application program would be provided by a high-performance implementation.

#### B.2.8.1 Realtime Signals

##### Realtime Signals Extension

This portion of the rationale presents models, requirements, and standardization issues relevant to the Realtime Signals Extension. This extension provides the capability required to support reliable, deterministic, asynchronous notification of events. While a new mechanism, unencumbered by the historical usage and semantics of POSIX.1 signals, might allow for a more efficient implementation, the application requirements for event notification can be met with a small number of extensions to signals. Therefore, a minimal set of extensions to signals to support the application requirements is specified.

The realtime signal extensions specified in this section are used by other realtime functions requiring asynchronous notification:

- Models

The model supported is one of multiple cooperating processes, each of which handles multiple asynchronous external events. Events represent occurrences that are generated as the result of some activity in the system. Examples of occurrences that can constitute an event include:

- Completion of an asynchronous I/O request
- Expiration of a POSIX.1b timer
- Arrival of an interprocess message
- Generation of a user-defined event

Processing of these events may occur synchronously via polling for event notifications or asynchronously via a software interrupt mechanism. Existing practice for this model is well established for traditional proprietary realtime operating systems, realtime executives, and realtime extended POSIX-like systems.

A contrasting model is that of “cooperating sequential processes” where each process handles a single priority of events via polling. Each process blocks while waiting for events, and each process depends on the preemptive, priority-based process scheduling mechanism to arbitrate between events of different priority that need to be processed concurrently. Existing practice for this model is also well established for small realtime executives that typically execute in an unprotected physical address space, but it is just emerging in the

context of a fuller function operating system with multiple virtual address spaces.

It could be argued that the cooperating sequential process model, and the facilities supported by the POSIX Threads Extension obviate a software interrupt model. But, even with the cooperating sequential process model, the need has been recognized for a software interrupt model to handle exceptional conditions and process aborting, so the mechanism must be supported in any case. Furthermore, it is not the purview of IEEE Std 1003.1-2001 to attempt to convince realtime practitioners that their current application models based on software interrupts are “broken” and should be replaced by the cooperating sequential process model. Rather, it is the charter of IEEE Std 1003.1-2001 to provide standard extensions to mechanisms that support existing realtime practice.

- Requirements

This section discusses the following realtime application requirements for asynchronous event notification:

- Reliable delivery of asynchronous event notification

The events notification mechanism guarantees delivery of an event notification. Asynchronous operations (such as asynchronous I/O and timers) that complete significantly after they are invoked have to guarantee that delivery of the event notification can occur at the time of completion.

- Prioritized handling of asynchronous event notifications

The events notification mechanism supports the assigning of a user function as an event notification handler. Furthermore, the mechanism supports the preemption of an event handler function by a higher priority event notification and supports the selection of the highest priority pending event notification when multiple notifications (of different priority) are pending simultaneously.

The model here is based on hardware interrupts. Asynchronous event handling allows the application to ensure that time-critical events are immediately processed when delivered, without the indeterminism of being at a random location within a polling loop. Use of handler priority allows the specification of how handlers are interrupted by other higher priority handlers.

- Differentiation between multiple occurrences of event notifications of the same type

The events notification mechanism passes an application-defined value to the event handler function. This value can be used for a variety of purposes, such as enabling the application to identify which of several possible events of the same type (for example, timer expirations) has occurred.

- Polled reception of asynchronous event notifications

The events notification mechanism supports blocking and non-blocking polls for asynchronous event notification.

The polled mode of operation is often preferred over the interrupt mode by those practitioners accustomed to this model. Providing support for this model facilitates the porting of applications based on this model to POSIX.1b conforming systems.

- Deterministic response to asynchronous event notifications

The events notification mechanism does not preclude implementations that provide deterministic event dispatch latency and minimizes the number of system calls needed to use the event facilities during realtime processing.

- Rationale for Extension

POSIX.1 signals have many of the characteristics necessary to support the asynchronous handling of event notifications, and the Realtime Signals Extension addresses the following deficiencies in the POSIX.1 signal mechanism:

- Signals do not support reliable delivery of event notification. Subsequent occurrences of a pending signal are not guaranteed to be delivered.
- Signals do not support prioritized delivery of event notifications. The order of signal delivery when multiple unblocked signals are pending is undefined.
- Signals do not support the differentiation between multiple signals of the same type.

### B.2.8.2 Asynchronous I/O

Many applications need to interact with the I/O subsystem in an asynchronous manner. The asynchronous I/O mechanism provides the ability to overlap application processing and I/O operations initiated by the application. The asynchronous I/O mechanism allows a single process to perform I/O simultaneously to a single file multiple times or to multiple files multiple times.

#### Overview

Asynchronous I/O operations proceed in logical parallel with the processing done by the application after the asynchronous I/O has been initiated. Other than this difference, asynchronous I/O behaves similarly to normal I/O using *read()*, *write()*, *lseek()*, and *fsync()*. The effect of issuing an asynchronous I/O request is as if a separate thread of execution were to perform atomically the implied *lseek()* operation, if any, and then the requested I/O operation (either *read()*, *write()*, or *fsync()*). There is no seek implied with a call to *aio\_fsync()*. Concurrent asynchronous operations and synchronous operations applied to the same file update the file as if the I/O operations had proceeded serially.

When asynchronous I/O completes, a signal can be delivered to the application to indicate the completion of the I/O. This signal can be used to indicate that buffers and control blocks used for asynchronous I/O can be reused. Signal delivery is not required for an asynchronous operation and may be turned off on a per-operation basis by the application. Signals may also be synchronously polled using *aio\_suspend()*, *sigtimedwait()*, or *sigwaitinfo()*.

Normal I/O has a return value and an error status associated with it. Asynchronous I/O returns a value and an error status when the operation is first submitted, but that only relates to whether the operation was successfully queued up for servicing. The I/O operation itself also has a return status and an error value. To allow the application to retrieve the return status and the error value, functions are provided that, given the address of an asynchronous I/O control block, yield the return and error status associated with the operation. Until an asynchronous I/O operation is done, its error status is [EINPROGRESS]. Thus, an application can poll for completion of an asynchronous I/O operation by waiting for the error status to become equal to a value other than [EINPROGRESS]. The return status of an asynchronous I/O operation is undefined so long as the error status is equal to [EINPROGRESS].

Storage for asynchronous operation return and error status may be limited. Submission of asynchronous I/O operations may fail if this storage is exceeded. When an application retrieves the return status of a given asynchronous operation, therefore, any system-maintained storage used for this status and the error status may be reclaimed for use by other asynchronous operations.

Asynchronous I/O can be performed on file descriptors that have been enabled for POSIX.1b synchronized I/O. In this case, the I/O operation still occurs asynchronously, as defined herein; however, the asynchronous operation I/O in this case is not completed until the I/O has reached either the state of synchronized I/O data integrity completion or synchronized I/O file integrity completion, depending on the sort of synchronized I/O that is enabled on the file descriptor.

## Models

Three models illustrate the use of asynchronous I/O: a journalization model, a data acquisition model, and a model of the use of asynchronous I/O in supercomputing applications.

- Journalization Model

Many realtime applications perform low-priority journalizing functions. Journalizing requires that logging records be queued for output without blocking the initiating process.

- Data Acquisition Model

A data acquisition process may also serve as a model. The process has two or more channels delivering intermittent data that must be read within a certain time. The process issues one asynchronous read on each channel. When one of the channels needs data collection, the process reads the data and posts it through an asynchronous write to secondary memory for future processing.

- Supercomputing Model

The supercomputing community has used asynchronous I/O much like that specified in POSIX.1 for many years. This community requires the ability to perform multiple I/O operations to multiple devices with a minimal number of entries to “the system”; each entry to “the system” provokes a major delay in operations when compared to the normal progress made by the application. This existing practice motivated the use of combined *lseek()* and *read()* or *write()* calls, as well as the *lio\_listio()* call. Another common practice is to disable signal notification for I/O completion, and simply poll for I/O completion at some interval by which the I/O should be completed. Likewise, interfaces like *aio\_cancel()* have been in successful commercial use for many years. Note also that an underlying implementation of asynchronous I/O will require the ability, at least internally, to cancel outstanding asynchronous I/O, at least when the process exits. (Consider an asynchronous read from a terminal, when the process intends to exit immediately.)

## Requirements

Asynchronous input and output for realtime implementations have these requirements:

- The ability to queue multiple asynchronous read and write operations to a single open instance. Both sequential and random access should be supported.
- The ability to queue asynchronous read and write operations to multiple open instances.
- The ability to obtain completion status information by polling and/or asynchronous event notification.
- Asynchronous event notification on asynchronous I/O completion is optional.
- It has to be possible for the application to associate the event with the *aiocbp* for the operation that generated the event.
- The ability to cancel queued requests.
- The ability to wait upon asynchronous I/O completion in conjunction with other types of events.

- The ability to accept an *aio\_read()* and an *aio\_cancel()* for a device that accepts a *read()*, and the ability to accept an *aio\_write()* and an *aio\_cancel()* for a device that accepts a *write()*. This does not imply that the operation is asynchronous.

### Standardization Issues

The following issues are addressed by the standardization of asynchronous I/O:

- Rationale for New Interface

Non-blocking I/O does not satisfy the needs of either realtime or high-performance computing models; these models require that a process overlap program execution and I/O processing. Realtime applications will often make use of direct I/O to or from the address space of the process, or require synchronized (unbuffered) I/O; they also require the ability to overlap this I/O with other computation. In addition, asynchronous I/O allows an application to keep a device busy at all times, possibly achieving greater throughput. Supercomputing and database architectures will often have specialized hardware that can provide true asynchrony underlying the logical asynchrony provided by this interface. In addition, asynchronous I/O should be supported by all types of files and devices in the same manner.

- Effect of Buffering

If asynchronous I/O is performed on a file that is buffered prior to being actually written to the device, it is possible that asynchronous I/O will offer no performance advantage over normal I/O; the cycles *stolen* to perform the asynchronous I/O will be taken away from the running process and the I/O will occur at interrupt time. This potential lack of gain in performance in no way obviates the need for asynchronous I/O by realtime applications, which very often will use specialized hardware support, multiple processors, and/or unbuffered, synchronized I/O.

### B.2.8.3 Memory Management

All memory management and shared memory definitions are located in the `<sys/mman.h>` header. This is for alignment with historical practice.

IEEE Std 1003.1-2001/Cor 1-2002, item XSH/TC1/D6/7 is applied, correcting the shading and margin markers in the introduction to Section 2.8.3.1.

### Memory Locking Functions

This portion of the rationale presents models, requirements, and standardization issues relevant to process memory locking.

- Models

Realtime systems that conform to IEEE Std 1003.1-2001 are expected (and desired) to be supported on systems with demand-paged virtual memory management, non-paged swapping memory management, and physical memory systems with no memory management hardware. The general case, however, is the demand-paged, virtual memory system with each POSIX process running in a virtual address space. Note that this includes architectures where each process resides in its own virtual address space and architectures where the address space of each process is only a portion of a larger global virtual address space.

The concept of memory locking is introduced to eliminate the indeterminacy introduced by paging and swapping, and to support an upper bound on the time required to access the memory mapped into the address space of a process. Ideally, this upper bound will be the

same as the time required for the processor to access “main memory”, including any address translation and cache miss overheads. But some implementations—primarily on mainframes—will not actually force locked pages to be loaded and held resident in main memory. Rather, they will handle locked pages so that accesses to these pages will meet the performance metrics for locked process memory in the implementation. Also, although it is not, for example, the intention that this interface, as specified, be used to lock process memory into “cache”, it is conceivable that an implementation could support a large static RAM memory and define this as “main memory” and use a large[r] dynamic RAM as “backing store”. These interfaces could then be interpreted as supporting the locking of process memory into the static RAM. Support for multiple levels of backing store would require extensions to these interfaces.

Implementations may also use memory locking to guarantee a fixed translation between virtual and physical addresses where such is beneficial to improving determinancy for direct-to/from-process input/output. IEEE Std 1003.1-2001 does not guarantee to the application that the virtual-to-physical address translations, if such exist, are fixed, because such behavior would not be implementable on all architectures on which implementations of IEEE Std 1003.1-2001 are expected. But IEEE Std 1003.1-2001 does mandate that an implementation define, for the benefit of potential users, whether or not locking guarantees fixed translations.

Memory locking is defined with respect to the address space of a process. Only the pages mapped into the address space of a process may be locked by the process, and when the pages are no longer mapped into the address space—for whatever reason—the locks established with respect to that address space are removed. Shared memory areas warrant special mention, as they may be mapped into more than one address space or mapped more than once into the address space of a process; locks may be established on pages within these areas with respect to several of these mappings. In such a case, the lock state of the underlying physical pages is the logical OR of the lock state with respect to each of the mappings. Only when all such locks have been removed are the shared pages considered unlocked.

In recognition of the page granularity of Memory Management Units (MMU), and in order to support locking of ranges of address space, memory locking is defined in terms of “page” granularity. That is, for the interfaces that support an address and size specification for the region to be locked, the address must be on a page boundary, and all pages mapped by the specified range are locked, if valid. This means that the length is implicitly rounded up to a multiple of the page size. The page size is implementation-defined and is available to applications as a compile-time symbolic constant or at runtime via *sysconf()*.

A “real memory” POSIX.1b implementation that has no MMU could elect not to support these interfaces, returning [ENOSYS]. But an application could easily interpret this as meaning that the implementation would unconditionally page or swap the application when such is not the case. It is the intention of IEEE Std 1003.1-2001 that such a system could define these interfaces as “NO-OPs”, returning success without actually performing any function except for mandated argument checking.

- Requirements

For realtime applications, memory locking is generally considered to be required as part of application initialization. This locking is performed after an application has been loaded (that is, *exec'd*) and the program remains locked for its entire lifetime. But to support applications that undergo major mode changes where, in one mode, locking is required, but in another it is not, the specified interfaces allow repeated locking and unlocking of memory within the lifetime of a process.

When a realtime application locks its address space, it should not be necessary for the application to then “touch” all of the pages in the address space to guarantee that they are resident or else suffer potential paging delays the first time the page is referenced. Thus, IEEE Std 1003.1-2001 requires that the pages locked by the specified interfaces be resident when the locking functions return successfully.

Many architectures support system-managed stacks that grow automatically when the current extent of the stack is exceeded. A realtime application has a requirement to be able to “preallocate” sufficient stack space and lock it down so that it will not suffer page faults to grow the stack during critical realtime operation. There was no consensus on a portable way to specify how much stack space is needed, so IEEE Std 1003.1-2001 supports no specific interface for preallocating stack space. But an application can portably lock down a specific amount of stack space by specifying `MCL_FUTURE` in a call to `mlockall()` and then calling a dummy function that declares an automatic array of the desired size.

Memory locking for realtime applications is also generally considered to be an “all or nothing” proposition. That is, the entire process, or none, is locked down. But, for applications that have well-defined sections that need to be locked and others that do not, IEEE Std 1003.1-2001 supports an optional set of interfaces to lock or unlock a range of process addresses. Reasons for locking down a specific range include:

- An asynchronous event handler function that must respond to external events in a deterministic manner such that page faults cannot be tolerated
- An input/output “buffer” area that is the target for direct-to-process I/O, and the overhead of implicit locking and unlocking for each I/O call cannot be tolerated

Finally, locking is generally viewed as an “application-wide” function. That is, the application is globally aware of which regions are locked and which are not over time. This is in contrast to a function that is used temporarily within a “third party” library routine whose function is unknown to the application, and therefore must have no “side effects”. The specified interfaces, therefore, do not support “lock stacking” or “lock nesting” within a process. But, for pages that are shared between processes or mapped more than once into a process address space, “lock stacking” is essentially mandated by the requirement that unlocking of pages that are mapped by more than one process or more than once by the same process does not affect locks established on the other mappings.

There was some support for “lock stacking” so that locking could be transparently used in functions or opaque modules. But the consensus was not to burden all implementations with lock stacking (and reference counting), and an implementation option was proposed. There were strong objections to the option because applications would have to support both options in order to remain portable. The consensus was to eliminate lock stacking altogether, primarily through overwhelming support for the System V “`m[un]lock[all]`” interface on which IEEE Std 1003.1-2001 is now based.

Locks are not inherited across `fork()`s because some implementations implement `fork()` by creating new address spaces for the child. In such an implementation, requiring locks to be inherited would lead to new situations in which a fork would fail due to the inability of the system to lock sufficient memory to lock both the parent and the child. The consensus was that there was no benefit to such inheritance. Note that this does not mean that locks are removed when, for instance, a thread is created in the same address space.

Similarly, locks are not inherited across `exec` because some implementations implement `exec` by unmapping all of the pages in the address space (which, by definition, removes the locks on these pages), and maps in pages of the `exec`’d image. In such an implementation, requiring locks to be inherited would lead to new situations in which `exec` would fail. Reporting this

failure would be very cumbersome to detect in time to report to the calling process, and no appropriate mechanism exists for informing the *exec'd* process of its status.

It was determined that, if the newly loaded application required locking, it was the responsibility of that application to establish the locks. This is also in keeping with the general view that it is the responsibility of the application to be aware of all locks that are established.

There was one request to allow (not mandate) locks to be inherited across *fork()*, and a request for a flag, *MCL\_INHERIT*, that would specify inheritance of memory locks across *execs*. Given the difficulties raised by this and the general lack of support for the feature in IEEE Std 1003.1-2001, it was not added. IEEE Std 1003.1-2001 does not preclude an implementation from providing this feature for administrative purposes, such as a “run” command that will lock down and execute a specified application. Additionally, the rationale for the objection equated *fork()* with creating a thread in the address space. IEEE Std 1003.1-2001 does not mandate releasing locks when creating additional threads in an existing process.

- Standardization Issues

One goal of IEEE Std 1003.1-2001 is to define a set of primitives that provide the necessary functionality for realtime applications, with consideration for the needs of other application domains where such were identified, which is based to the extent possible on existing industry practice.

The Memory Locking option is required by many realtime applications to tune performance. Such a facility is accomplished by placing constraints on the virtual memory system to limit paging of time of the process or of critical sections of the process. This facility should not be used by most non-realtime applications.

Optional features provided in IEEE Std 1003.1-2001 allow applications to lock selected address ranges with the caveat that the process is responsible for being aware of the page granularity of locking and the unnested nature of the locks.

## **Mapped Files Functions**

The Memory Mapped Files option provides a mechanism that allows a process to access files by directly incorporating file data into its address space. Once a file is “mapped” into a process address space, the data can be manipulated by instructions as memory. The use of mapped files can significantly reduce I/O data movement since file data does not have to be copied into process data buffers as in *read()* and *write()*. If more than one process maps a file, its contents are shared among them. This provides a low overhead mechanism by which processes can synchronize and communicate.

- Historical Perspective

Realtime applications have historically been implemented using a collection of cooperating processes or tasks. In early systems, these processes ran on bare hardware (that is, without an operating system) with no memory relocation or protection. The application paradigms that arose from this environment involve the sharing of data between the processes.

When realtime systems were implemented on top of vendor-supplied operating systems, the paradigm or performance benefits of direct access to data by multiple processes was still deemed necessary. As a result, operating systems that claim to support realtime applications must support the shared memory paradigm.

Additionally, a number of realtime systems provide the ability to map specific sections of the physical address space into the address space of a process. This ability is required if an

application is to obtain direct access to memory locations that have specific properties (for example, refresh buffers or display devices, dual ported memory locations, DMA target locations). The use of this ability is common enough to warrant some degree of standardization of its interface. This ability overlaps the general paradigm of shared memory in that, in both instances, common global objects are made addressable by individual processes or tasks.

Finally, a number of systems also provide the ability to map process addresses to files. This provides both a general means of sharing persistent objects, and using files in a manner that optimizes memory and swapping space usage.

Simple shared memory is clearly a special case of the more general file mapping capability. In addition, there is relatively widespread agreement and implementation of the file mapping interface. In these systems, many different types of objects can be mapped (for example, files, memory, devices, and so on) using the same mapping interfaces. This approach both minimizes interface proliferation and maximizes the generality of programs using the mapping interfaces.

- Memory Mapped Files Usage

A memory object can be concurrently mapped into the address space of one or more processes. The *mmap()* and *munmap()* functions allow a process to manipulate their address space by mapping portions of memory objects into it and removing them from it. When multiple processes map the same memory object, they can share access to the underlying data. Implementations may restrict the size and alignment of mappings to be on *page*-size boundaries. The page size, in bytes, is the value of the system-configurable variable {PAGESIZE}, typically accessed by calling *sysconf()* with a *name* argument of *\_SC\_PAGESIZE*. If an implementation has no restrictions on size or alignment, it may specify a 1-byte page size.

To map memory, a process first opens a memory object. The *ftruncate()* function can be used to contract or extend the size of the memory object even when the object is currently mapped. If the memory object is extended, the contents of the extended areas are zeros.

After opening a memory object, the application maps the object into its address space using the *mmap()* function call. Once a mapping has been established, it remains mapped until unmapped with *munmap()*, even if the memory object is closed. The *mprotect()* function can be used to change the memory protections initially established by *mmap()*.

A *close()* of the file descriptor, while invalidating the file descriptor itself, does not unmap any mappings established for the memory object. The address space, including all mapped regions, is inherited on *fork()*. The entire address space is unmapped on process termination or by successful calls to any of the *exec* family of functions.

The *msync()* function is used to force mapped file data to permanent storage.

- Effects on Other Functions

When the Memory Mapped Files option is supported, the operation of the *open()*, *creat()*, and *unlink()* functions are a natural result of using the file system name space to map the global names for memory objects.

The *ftruncate()* function can be used to set the length of a sharable memory object.

The meaning of *stat()* fields other than the size and protection information is undefined on implementations where memory objects are not implemented using regular files. When regular files are used, the times reflect when the implementation updated the file image of the data, not when a process updated the data in memory.

The operations of *fdopen()*, *write()*, *read()*, and *lseek()* were made unspecified for objects opened with *shm\_open()*, so that implementations that did not implement memory objects as regular files would not have to support the operation of these functions on shared memory objects.

The behavior of memory objects with respect to *close()*, *dup()*, *dup2()*, *open()*, *close()*, *fork()*, *\_exit()*, and the *exec* family of functions is the same as the behavior of the existing practice of the *mmap()* function.

A memory object can still be referenced after a close. That is, any mappings made to the file are still in effect, and reads and writes that are made to those mappings are still valid and are shared with other processes that have the same mapping. Likewise, the memory object can still be used if any references remain after its name(s) have been deleted. Any references that remain after a close must not appear to the application as file descriptors.

This is existing practice for *mmap()* and *close()*. In addition, there are already mappings present (text, data, stack) that do not have open file descriptors. The text mapping in particular is considered a reference to the file containing the text. The desire was to treat all mappings by the process uniformly. Also, many modern implementations use *mmap()* to implement shared libraries, and it would not be desirable to keep file descriptors for each of the many libraries an application can use. It was felt there were many other existing programs that used this behavior to free a file descriptor, and thus IEEE Std 1003.1-2001 could not forbid it and still claim to be using existing practice.

For implementations that implement memory objects using memory only, memory objects will retain the memory allocated to the file after the last close and will use that same memory on the next open. Note that closing the memory object is not the same as deleting the name, since the memory object is still defined in the memory object name space.

The locks of *fcntl()* do not block any read or write operation, including read or write access to shared memory or mapped files. In addition, implementations that only support shared memory objects should not be required to implement record locks. The reference to *fcntl()* is added to make this point explicitly. The other *fcntl()* commands are useful with shared memory objects.

The size of pages that mapping hardware may be able to support may be a configurable value, or it may change based on hardware implementations. The addition of the *\_SC\_PAGESIZE* parameter to the *sysconf()* function is provided for determining the mapping page size at runtime.

## Shared Memory Functions

Implementations may support the Shared Memory Objects option without supporting a general Memory Mapped Files option. Shared memory objects are named regions of storage that may be independent of the file system and can be mapped into the address space of one or more processes to allow them to share the associated memory.

- Requirements

Shared memory is used to share data among several processes, each potentially running at different priority levels, responding to different inputs, or performing separate tasks. Shared memory is not just simply providing common access to data, it is providing the fastest possible communication between the processes. With one memory write operation, a process can pass information to as many processes as have the memory region mapped.

As a result, shared memory provides a mechanism that can be used for all other interprocess communication facilities. It may also be used by an application for implementing more

sophisticated mechanisms than semaphores and message queues.

The need for a shared memory interface is obvious for virtual memory systems, where the operating system is directly preventing processes from accessing each other's data. However, in unprotected systems, such as those found in some embedded controllers, a shared memory interface is needed to provide a portable mechanism to allocate a region of memory to be shared and then to communicate the address of that region to other processes.

This, then, provides the minimum functionality that a shared memory interface must have in order to support realtime applications: to allocate and name an object to be mapped into memory for potential sharing (*open()* or *shm\_open()*), and to make the memory object available within the address space of a process (*mmap()*). To complete the interface, a mechanism to release the claim of a process on a shared memory object (*munmap()*) is also needed, as well as a mechanism for deleting the name of a sharable object that was previously created (*unlink()* or *shm\_unlink()*).

After a mapping has been established, an implementation should not have to provide services to maintain that mapping. All memory writes into that area will appear immediately in the memory mapping of that region by any other processes.

Thus, requirements include:

- Support creation of sharable memory objects and the mapping of these objects into the address space of a process.
- Sharable memory objects should be accessed by global names accessible from all processes.
- Support the mapping of specific sections of physical address space (such as a memory mapped device) into the address space of a process. This should not be done by the process specifying the actual address, but again by an implementation-defined global name (such as a special device name) dedicated to this purpose.
- Support the mapping of discrete portions of these memory objects.
- Support for minimum hardware configurations that contain no physical media on which to store shared memory contents permanently.
- The ability to preallocate the entire shared memory region so that minimum hardware configurations without virtual memory support can guarantee contiguous space.
- The maximizing of performance by not requiring functionality that would require implementation interaction above creating the shared memory area and returning the mapping.

Note that the above requirements do not preclude:

- The sharable memory object from being implemented using actual files on an actual file system.
- The global name that is accessible from all processes being restricted to a file system area that is dedicated to handling shared memory.
- An implementation not providing implementation-defined global names for the purpose of physical address mapping.

#### • Shared Memory Objects Usage

If the Shared Memory Objects option is supported, a shared memory object may be created, or opened if it already exists, with the *shm\_open()* function. If the shared memory object is created, it has a length of zero. The *ftruncate()* function can be used to set the size of the

shared memory object after creation. The *shm\_unlink()* function removes the name for a shared memory object created by *shm\_open()*.

- Shared Memory Overview

The shared memory facility defined by IEEE Std 1003.1-2001 usually results in memory locations being added to the address space of the process. The implementation returns the address of the new space to the application by means of a pointer. This works well in languages like C. However, in languages without pointer types it will not work. In the bindings for such a language, either a special COMMON section will need to be defined (which is unlikely), or the binding will have to allow existing structures to be mapped. The implementation will likely have to place restrictions on the size and alignment of such structures or will have to map a suitable region of the address space of the process into the memory object, and thus into other processes. These are issues for that particular language binding. For IEEE Std 1003.1-2001, however, the practice will not be forbidden, merely undefined.

Two potentially different name spaces are used for naming objects that may be mapped into process address spaces. When the Memory Mapped Files option is supported, files may be accessed via *open()*. When the Shared Memory Objects option is supported, sharable memory objects that might not be files may be accessed via the *shm\_open()* function. These options are not mutually-exclusive.

Some implementations supporting the Shared Memory Objects option may choose to implement the shared memory object name space as part of the file system name space. There are several reasons for this:

- It allows applications to prevent name conflicts by use of the directory structure.
- It uses an existing mechanism for accessing global objects and prevents the creation of a new mechanism for naming global objects.

In such implementations, memory objects can be implemented using regular files, if that is what the implementation chooses. The *shm\_open()* function can be implemented as an *open()* call in a fixed directory followed by a call to *fcntl()* to set FD\_CLOEXEC. The *shm\_unlink()* function can be implemented as an *unlink()* call.

On the other hand, it is also expected that small embedded systems that support the Shared Memory Objects option may wish to implement shared memory without having any file systems present. In this case, the implementations may choose to use a simple string valued name space for shared memory regions. The *shm\_open()* function permits either type of implementation.

Some implementations have hardware that supports protection of mapped data from certain classes of access and some do not. Systems that supply this functionality can support the Memory Protection option.

Some implementations restrict size, alignment, and protections to be on *page*-size boundaries. If an implementation has no restrictions on size or alignment, it may specify a 1-byte page size. Applications on implementations that do support larger pages must be cognizant of the page size since this is the alignment and protection boundary.

Simple embedded implementations may have a 1-byte page size and only support the Shared Memory Objects option. This provides simple shared memory between processes without requiring mapping hardware.

IEEE Std 1003.1-2001 specifically allows a memory object to remain referenced after a close because that is existing practice for the *mmap()* function.

## Typed Memory Functions

Implementations may support the Typed Memory Objects option without supporting either the Shared Memory option or the Memory Mapped Files option. Typed memory objects are pools of specialized storage, different from the main memory resource normally used by a processor to hold code and data, that can be mapped into the address space of one or more processes.

### • Model

Realtime systems conforming to one of the POSIX.13 realtime profiles are expected (and desired) to be supported on systems with more than one type or pool of memory (for example, SRAM, DRAM, ROM, EPROM, EEPROM), where each type or pool of memory may be accessible by one or more processors via one or more busses (ports). Memory mapped files, shared memory objects, and the language-specific storage allocation operators (*malloc()* for the ISO C standard, *new* for ISO Ada) fail to provide application program interfaces versatile enough to allow applications to control their utilization of such diverse memory resources. The typed memory interfaces *posix\_typed\_mem\_open()*, *posix\_mem\_offset()*, *posix\_typed\_mem\_get\_info()*, *mmap()*, and *munmap()* defined herein support the model of typed memory described below.

For purposes of this model, a system comprises several processors (for example,  $P_1$  and  $P_2$ ), several physical memory pools (for example,  $M_1$ ,  $M_2$ ,  $M_{2a}$ ,  $M_{2b}$ ,  $M_3$ ,  $M_4$ , and  $M_5$ ), and several busses or “ports” (for example,  $B_1$ ,  $B_2$ ,  $B_3$ , and  $B_4$ ) interconnecting the various processors and memory pools in some system-specific way. Notice that some memory pools may be contained in others (for example,  $M_{2a}$  and  $M_{2b}$  are contained in  $M_2$ ).

Figure B-1 shows an example of such a model. In a system like this, an application should be able to perform the following operations:

\* All addresses in pool  $M_2$  (comprising pools  $M_{2a}$  and  $M_{2b}$ ) accessible via port  $B_1$ .  
 Addresses in pool  $M_{2b}$  are also accessible via port  $B_2$ .  
 Addresses in pool  $M_{2a}$  are *not* accessible via port  $B_2$ .

**Figure B-1** Example of a System with Typed Memory

### — Typed Memory Allocation

An application should be able to allocate memory dynamically from the desired pool using the desired bus, and map it into a process' address space. For example, processor  $P_1$  can allocate some portion of memory pool  $M_1$  through port  $B_1$ , treating all unmapped subareas of  $M_1$  as a heap-storage resource from which memory may be allocated. This portion of memory is mapped into the process' address space, and subsequently deallocated when unmapped from all processes.

— Using the Same Storage Region from Different Busses

An application process with a mapped region of storage that is accessed from one bus should be able to map that same storage area at another address (subject to page size restrictions detailed in *mmap()*), to allow it to be accessed from another bus. For example, processor  $P_1$  may wish to access the same region of memory pool  $M_{2b}$  both through ports  $B_1$  and  $B_2$ .

— Sharing Typed Memory Regions

Several application processes running on the same or different processors may wish to share a particular region of a typed memory pool. Each process or processor may wish to access this region through different busses. For example, processor  $P_1$  may want to share a region of memory pool  $M_4$  with processor  $P_2$ , and they may be required to use busses  $B_2$  and  $B_3$ , respectively, to minimize bus contention. A problem arises here when a process allocates and maps a portion of fragmented memory and then wants to share this region of memory with another process, either in the same processor or different processors. The solution adopted is to allow the first process to find out the memory map (offsets and lengths) of all the different fragments of memory that were mapped into its address space, by repeatedly calling *posix\_mem\_offset()*. Then, this process can pass the offsets and lengths obtained to the second process, which can then map the same memory fragments into its address space.

— Contiguous Allocation

The problem of finding the memory map of the different fragments of the memory pool that were mapped into logically contiguous addresses of a given process can be solved by requesting contiguous allocation. For example, a process in  $P_1$  can allocate 10 Kbytes of physically contiguous memory from  $M_3-B_1$ , and obtain the offset (within pool  $M_3$ ) of this block of memory. Then, it can pass this offset (and the length) to a process in  $P_2$  using some interprocess communication mechanism. The second process can map the same block of memory by using the offset transferred and specifying  $M_3-B_2$ .

— Unallocated Mapping

Any subarea of a memory pool that is mapped to a process, either as the result of an allocation request or an explicit mapping, is normally unavailable for allocation. Special processes such as debuggers, however, may need to map large areas of a typed memory pool, yet leave those areas available for allocation.

Typed memory allocation and mapping has to coexist with storage allocation operators like *malloc()*, but systems are free to choose how to implement this coexistence. For example, it may be system configuration-dependent if all available system memory is made part of one of the typed memory pools or if some part will be restricted to conventional allocation operators. Equally system configuration-dependent may be the availability of operators like *malloc()* to allocate storage from certain typed memory pools. It is not excluded to configure a system such that a given named pool,  $P_1$ , is in turn split into non-overlapping named subpools. For example,  $M_1-B_1$ ,  $M_2-B_1$ , and  $M_3-B_1$  could also be accessed as one common pool  $M_{123}-B_1$ . A call to *malloc()* on  $P_1$  could work on such a larger pool while full optimization of memory usage by  $P_1$  would require typed memory allocation at the subpool level.

• Existing Practice

OS-9 provides for the naming (numbering) and prioritization of memory types by a system administrator. It then provides APIs to request memory allocation of typed (colored) memory by number, and to generate a bus address from a mapped memory address (translate). When requesting colored memory, the user can specify type 0 to signify allocation

from the first available type in priority order.

HP-RT presents interfaces to map different kinds of storage regions that are visible through a VME bus, although it does not provide allocation operations. It also provides functions to perform address translation between VME addresses and virtual addresses. It represents a VME-bus unique solution to the general problem.

The PSOS approach is similar (that is, based on a pre-established mapping of bus address ranges to specific memories) with a concept of segments and regions (regions dynamically allocated from a heap which is a special segment). Therefore, PSOS does not fully address the general allocation problem either. PSOS does not have a “process”-based model, but more of a “thread”-only-based model of multi-tasking. So mapping to a process address space is not an issue.

QNX uses the System V approach of opening specially named devices (shared memory segments) and using *mmap()* to then gain access from the process. They do not address allocation directly, but once typed shared memory can be mapped, an “allocation manager” process could be written to handle requests for allocation.

The System V approach also included allocation, implemented by opening yet other special “devices” which allocate, rather than appearing as a whole memory object.

The Orkid realtime kernel interface definition has operations to manage memory “regions” and “pools”, which are areas of memory that may reflect the differing physical nature of the memory. Operations to allocate memory from these regions and pools are also provided.

#### • Requirements

Existing practice in SVID-derived UNIX systems relies on functionality similar to *mmap()* and its related interfaces to achieve mapping and allocation of typed memory. However, the issue of sharing typed memory (allocated or mapped) and the complication of multiple ports are not addressed in any consistent way by existing UNIX system practice. Part of this functionality is existing practice in specialized realtime operating systems. In order to solidify the capabilities implied by the model above, the following requirements are imposed on the interface:

##### — Identification of Typed Memory Pools and Ports

All processes (running in all processors) in the system are able to identify a particular (system configured) typed memory pool accessed through a particular (system configured) port by a name. That name is a member of a name space common to all these processes, but need not be the same name space as that containing ordinary filenames. The association between memory pools/ports and corresponding names is typically established when the system is configured. The “open” operation for typed memory objects should be distinct from the *open()* function, for consistency with other similar services, but implementable on top of *open()*. This implies that the handle for a typed memory object will be a file descriptor.

##### — Allocation and Mapping of Typed Memory

Once a typed memory object has been identified by a process, it is possible to both map user-selected subareas of that object into process address space and to map system-selected (that is, dynamically allocated) subareas of that object, with user-specified length, into process address space. It is also possible to determine the maximum length of memory allocation that may be requested from a given typed memory object.

5134 — Sharing Typed Memory

5135 Two or more processes are able to share portions of typed memory, either user-selected or  
5136 dynamically allocated. This requirement applies also to dynamically allocated regions of  
5137 memory that are composed of several non-contiguous pieces.

5138 — Contiguous Allocation

5139 For dynamic allocation, it is the user's option whether the system is required to allocate a  
5140 contiguous subarea within the typed memory object, or whether it is permitted to allocate  
5141 discontinuous fragments which appear contiguous in the process mapping. Contiguous  
5142 allocation simplifies the process of sharing allocated typed memory, while discontinuous  
5143 allocation allows for potentially better recovery of deallocated typed memory.

5144 — Accessing Typed Memory Through Different Ports

5145 Once a subarea of a typed memory object has been mapped, it is possible to determine the  
5146 location and length corresponding to a user-selected portion of that object within the  
5147 memory pool. This location and length can then be used to remap that portion of memory  
5148 for access from another port. If the referenced portion of typed memory was allocated  
5149 discontinuously, the length thus determined may be shorter than anticipated, and the  
5150 user code must adapt to the value returned.

5151 — Deallocation

5152 When a previously mapped subarea of typed memory is no longer mapped by any  
5153 process in the system—as a result of a call or calls to *munmap()*—that subarea becomes  
5154 potentially reusable for dynamic allocation; actual reuse of the subarea is a function of the  
5155 dynamic typed memory allocation policy.

5156 — Unallocated Mapping

5157 It must be possible to map user-selected subareas of a typed memory object without  
5158 marking that subarea as unavailable for allocation. This option is not the default behavior,  
5159 and requires appropriate privilege.

5160 • Scenario

5161 The following scenario will serve to clarify the use of the typed memory interfaces.

5162 Process A running on  $P_1$  (see Figure B-1 (on page 122)) wants to allocate some memory from  
5163 memory pool  $M_2$ , and it wants to share this portion of memory with process B running on  $P_2$ .  
5164 Since  $P_2$  only has access to the lower part of  $M_2$ , both processes will use the memory pool  
5165 named  $M_{2b}$  which is the part of  $M_2$  that is accessible both from  $P_1$  and  $P_2$ . The operations that  
5166 both processes need to perform are shown below:

5167 — Allocating Typed Memory

5168 Process A calls *posix\_typed\_mem\_open()* with the name **/typed.m2b-b1** and a *tflag* of  
5169 `POSIX_TYPED_MEM_ALLOCATE` to get a file descriptor usable for allocating from pool  
5170  $M_{2b}$  accessed through port  $B_1$ . It then calls *mmap()* with this file descriptor requesting a  
5171 length of 4096 bytes. The system allocates two discontinuous blocks of sizes 1024 and  
5172 3072 bytes within  $M_{2b}$ . The *mmap()* function returns a pointer to a 4096-byte array in  
5173 process A's logical address space, mapping the allocated blocks contiguously. Process A  
5174 can then utilize the array, and store data in it.

5175 — Determining the Location of the Allocated Blocks

5176 Process A can determine the lengths and offsets (relative to  $M_{2b}$ ) of the two blocks  
5177 allocated, by using the following procedure: First, process A calls *posix\_mem\_offset()* with

the address of the first element of the array and length 4096. Upon return, the offset and length (1024 bytes) of the first block are returned. A second call to *posix\_mem\_offset()* is then made using the address of the first element of the array plus 1024 (the length of the first block), and a new length of 4096–1024. If there were more fragments allocated, this procedure could have been continued within a loop until the offsets and lengths of all the blocks were obtained. Notice that this relatively complex procedure can be avoided if contiguous allocation is requested (by opening the typed memory object with the *tflag* `POSIX_TYPED_MEM_ALLOCATE_CONTIG`).

— Sharing Data Across Processes

Process A passes the two offset values and lengths obtained from the *posix\_mem\_offset()* calls to process B running on  $P_2$ , via some form of interprocess communication. Process B can gain access to process A's data by calling *posix\_typed\_mem\_open()* with the name **/typed.m2b-b2** and a *tflag* of zero, then using two *mmap()* calls on the resulting file descriptor to map the two subareas of that typed memory object to its own address space.

- Rationale for no *mem\_alloc()* and *mem\_free()*

The standard developers had originally proposed a pair of new flags to *mmap()* which, when applied to a typed memory object descriptor, would cause *mmap()* to allocate dynamically from an unallocated and unmapped area of the typed memory object. Deallocation was similarly accomplished through the use of *munmap()*. This was rejected by the ballot group because it excessively complicated the (already rather complex) *mmap()* interface and introduced semantics useful only for typed memory, to a function which must also map shared memory and files. They felt that a memory allocator should be built on top of *mmap()* instead of being incorporated within the same interface, much as the ISO C standard libraries build *malloc()* on top of the virtual memory mapping functions *brk()* and *sbrk()*. This would eliminate the complicated semantics involved with unmapping only part of an allocated block of typed memory.

To attempt to achieve ballot group consensus, typed memory allocation and deallocation was first migrated from *mmap()* and *munmap()* to a pair of complementary functions modeled on the ISO C standard *malloc()* and *free()*. The *mem\_alloc()* function specified explicitly the typed memory object (typed memory pool/access port) from which allocation takes place, unlike *malloc()* where the memory pool and port are unspecified. The *mem\_free()* function handled deallocation. These new semantics still met all of the requirements detailed above without modifying the behavior of *mmap()* except to allow it to map specified areas of typed memory objects. An implementation would have been free to implement *mem\_alloc()* and *mem\_free()* over *mmap()*, through *mmap()*, or independently but cooperating with *mmap()*.

The ballot group was queried to see if this was an acceptable alternative, and while there was some agreement that it achieved the goal of removing the complicated semantics of allocation from the *mmap()* interface, several balloters realized that it just created two additional functions that behaved, in great part, like *mmap()*. These balloters proposed an alternative which has been implemented here in place of a separate *mem\_alloc()* and *mem\_free()*. This alternative is based on four specific suggestions:

1. The *posix\_typed\_mem\_open()* function should provide a flag which specifies “allocate on *mmap()*” (otherwise, *mmap()* just maps the underlying object). This allows things roughly similar to **/dev/zero** versus **/dev/swap**. Two such flags have been implemented, one of which forces contiguous allocation.
2. The *posix\_mem\_offset()* function is acceptable because it can be applied usefully to mapped objects in general. It should return the file descriptor of the underlying object.

3. The `mem_get_info()` function in an earlier draft should be renamed `posix_typed_mem_get_info()` because it is not generally applicable to memory objects. It should probably return the file descriptor's allocation attribute. The renaming of the function has been implemented, but having it return a piece of information which is readily known by an application without this function has been rejected. Its whole purpose is to query the typed memory object for attributes that are not user-specified, but determined by the implementation.

4. There should be no separate `mem_alloc()` or `mem_free()` functions. Instead, using `mmap()` on a typed memory object opened with an "allocate on `mmap()`" flag should be used to force allocation. These are precisely the semantics defined in the current draft.

- Rationale for no Typed Memory Access Management

The working group had originally defined an additional interface (and an additional kind of object: typed memory master) to establish and dissolve mappings to typed memory on behalf of devices or processors which were independent of the operating system and had no inherent capability to directly establish mappings on their own. This was to have provided functionality similar to device driver interfaces such as `physio()` and their underlying bus-specific interfaces (for example, `mballoc()`) which serve to set up and break down DMA pathways, and derive mapped addresses for use by hardware devices and processor cards.

The ballot group felt that this was beyond the scope of POSIX.1 and its amendments. Furthermore, the removal of interrupt handling interfaces from a preceding amendment (the IEEE Std 1003.1d-1999) during its balloting process renders these typed memory access management interfaces an incomplete solution to portable device management from a user process; it would be possible to initiate a device transfer to/from typed memory, but impossible to handle the transfer-complete interrupt in a portable way.

To achieve ballot group consensus, all references to typed memory access management capabilities were removed. The concept of portable interfaces from a device driver to both operating system and hardware is being addressed by the Uniform Driver Interface (UDI) industry forum, with formal standardization deferred until proof of concept and industry-wide acceptance and implementation.

#### B.2.8.4 Process Scheduling

IEEE PASC Interpretation 1003.1 #96 has been applied, adding the `pthread_setschedprio()` function. This was added since previously there was no way for a thread to lower its own priority without going to the tail of the threads list for its new priority. This capability is necessary to bound the duration of priority inversion encountered by a thread.

The following portion of the rationale presents models, requirements, and standardization issues relevant to process scheduling; see also Section B.2.9.4 (on page 167).

In an operating system supporting multiple concurrent processes, the system determines the order in which processes execute to meet implementation-defined goals. For time-sharing systems, the goal is to enhance system throughput and promote fairness; the application is provided with little or no control over this sequencing function. While this is acceptable and desirable behavior in a time-sharing system, it is inappropriate in a realtime system; realtime applications must specifically control the execution sequence of their concurrent processes in order to meet externally defined response requirements.

In IEEE Std 1003.1-2001, the control over process sequencing is provided using a concept of scheduling policies. These policies, described in detail in this section, define the behavior of the system whenever processor resources are to be allocated to competing processes. Only the behavior of the policy is defined; conforming implementations are free to use any mechanism

5272 desired to achieve the described behavior.

5273 • Models

5274 In an operating system supporting multiple concurrent processes, the system determines the  
5275 order in which processes execute and might force long-running processes to yield to other  
5276 processes at certain intervals. Typically, the scheduling code is executed whenever an event  
5277 occurs that might alter the process to be executed next.

5278 The simplest scheduling strategy is a “first-in, first-out” (FIFO) dispatcher. Whenever a  
5279 process becomes runnable, it is placed on the end of a ready list. The process at the front of  
5280 the ready list is executed until it exits or becomes blocked, at which point it is removed from  
5281 the list. This scheduling technique is also known as “run-to-completion” or “run-to-block”.

5282 A natural extension to this scheduling technique is the assignment of a “non-migrating  
5283 priority” to each process. This policy differs from strict FIFO scheduling in only one respect:  
5284 whenever a process becomes runnable, it is placed at the end of the list of processes runnable  
5285 at that priority level. When selecting a process to run, the system always selects the first  
5286 process from the highest priority queue with a runnable process. Thus, when a process  
5287 becomes unblocked, it will preempt a running process of lower priority without otherwise  
5288 altering the ready list. Further, if a process elects to alter its priority, it is removed from the  
5289 ready list and reinserted, using its new priority, according to the policy above.

5290 While the above policy might be considered unfriendly in a time-sharing environment in  
5291 which multiple users require more balanced resource allocation, it could be ideal in a  
5292 realtime environment for several reasons. The most important of these is that it is  
5293 deterministic: the highest-priority process is always run and, among processes of equal  
5294 priority, the process that has been runnable for the longest time is executed first. Because of  
5295 this determinism, cooperating processes can implement more complex scheduling simply by  
5296 altering their priority. For instance, if processes at a single priority were to reschedule  
5297 themselves at fixed time intervals, a time-slice policy would result.

5298 In a dedicated operating system in which all processes are well-behaved realtime  
5299 applications, non-migrating priority scheduling is sufficient. However, many existing  
5300 implementations provide for more complex scheduling policies.

5301 IEEE Std 1003.1-2001 specifies a linear scheduling model. In this model, every process in the  
5302 system has a priority. The system scheduler always dispatches a process that has the highest  
5303 (generally the most time-critical) priority among all runnable processes in the system. As  
5304 long as there is only one such process, the dispatching policy is trivial. When multiple  
5305 processes of equal priority are eligible to run, they are ordered according to a strict run-to-  
5306 completion (FIFO) policy.

5307 The priority is represented as a positive integer and is inherited from the parent process. For  
5308 processes running under a fixed priority scheduling policy, the priority is never altered  
5309 except by an explicit function call.

5310 It was determined arbitrarily that larger integers correspond to “higher priorities”.

5311 Certain implementations might impose restrictions on the priority ranges to which processes  
5312 can be assigned. There also can be restrictions on the set of policies to which processes can be  
5313 set.

5314 • Requirements

5315 Realtime processes require that scheduling be fast and deterministic, and that it guarantees  
5316 to preempt lower priority processes.

Thus, given the linear scheduling model, realtime processes require that they be run at a priority that is higher than other processes. Within this framework, realtime processes are free to yield execution resources to each other in a completely portable and implementation-defined manner.

As there is a generally perceived requirement for processes at the same priority level to share processor resources more equitably, provisions are made by providing a scheduling policy (that is, SCHED\_RR) intended to provide a timeslice-like facility.

**Note:** The following topics assume that low numeric priority implies low scheduling criticality and *vice versa*.

- Rationale for New Interface

Realtime applications need to be able to determine when processes will run in relation to each other. It must be possible to guarantee that a critical process will run whenever it is runnable; that is, whenever it wants to for as long as it needs. SCHED\_FIFO satisfies this requirement. Additionally, SCHED\_RR was defined to meet a realtime requirement for a well-defined time-sharing policy for processes at the same priority.

It would be possible to use the BSD *setpriority()* and *getpriority()* functions by redefining the meaning of the “nice” parameter according to the scheduling policy currently in use by the process. The System V *nice()* interface was felt to be undesirable for realtime because it specifies an adjustment to the “nice” value, rather than setting it to an explicit value. Realtime applications will usually want to set priority to an explicit value. Also, System V *nice()* does not allow for changing the priority of another process.

With the POSIX.1b interfaces, the traditional “nice” value does not affect the SCHED\_FIFO or SCHED\_RR scheduling policies. If a “nice” value is supported, it is implementation-defined whether it affects the SCHED\_OTHER policy.

An important aspect of IEEE Std 1003.1-2001 is the explicit description of the queuing and preemption rules. It is critical, to achieve deterministic scheduling, that such rules be stated clearly in IEEE Std 1003.1-2001.

IEEE Std 1003.1-2001 does not address the interaction between priority and swapping. The issues involved with swapping and virtual memory paging are extremely implementation-defined and would be nearly impossible to standardize at this point. The proposed scheduling paradigm, however, fully describes the scheduling behavior of runnable processes, of which one criterion is that the working set be resident in memory. Assuming the existence of a portable interface for locking portions of a process in memory, paging behavior need not affect the scheduling of realtime processes.

IEEE Std 1003.1-2001 also does not address the priorities of “system” processes. In general, these processes should always execute in low-priority ranges to avoid conflict with other realtime processes. Implementations should document the priority ranges in which system processes run.

The default scheduling policy is not defined. The effect of I/O interrupts and other system processing activities is not defined. The temporary lending of priority from one process to another (such as for the purposes of affecting freeing resources) by the system is not addressed. Preemption of resources is not addressed. Restrictions on the ability of a process to affect other processes beyond a certain level (influence levels) is not addressed.

The rationale used to justify the simple time-quantum scheduler is that it is common practice to depend upon this type of scheduling to ensure “fair” distribution of processor resources among portions of the application that must interoperate in a serial fashion. Note that IEEE Std 1003.1-2001 is silent with respect to the setting of this time quantum, or whether it is

a system-wide value or a per-process value, although it appears that the prevailing realtime practice is for it to be a system-wide value.

In a system with  $N$  processes at a given priority, all processor-bound, in which the time quantum is equal for all processes at a specific priority level, the following assumptions are made of such a scheduling policy:

1. A time quantum  $Q$  exists and the current process will own control of the processor for at least a duration of  $Q$  and will have the processor for a duration of  $Q$ .
2. The  $N$ th process at that priority will control a processor within a duration of  $(N-1) \times Q$ .

These assumptions are necessary to provide equal access to the processor and bounded response from the application.

The assumptions hold for the described scheduling policy only if no system overhead, such as interrupt servicing, is present. If the interrupt servicing load is non-zero, then one of the two assumptions becomes fallacious, based upon how  $Q$  is measured by the system.

If  $Q$  is measured by clock time, then the assumption that the process obtains a duration  $Q$  processor time is false if interrupt overhead exists. Indeed, a scenario can be constructed with  $N$  processes in which a single process undergoes complete processor starvation if a peripheral device, such as an analog-to-digital converter, generates significant interrupt activity periodically with a period of  $N \times Q$ .

If  $Q$  is measured as actual processor time, then the assumption that the  $N$ th process runs in within the duration  $(N-1) \times Q$  is false.

It should be noted that SCHED\_FIFO suffers from interrupt-based delay as well. However, for SCHED\_FIFO, the implied response of the system is “as soon as possible”, so that the interrupt load for this case is a vendor selection and not a compliance issue.

With this in mind, it is necessary either to complete the definition by including bounds on the interrupt load, or to modify the assumptions that can be made about the scheduling policy.

Since the motivation of inclusion of the policy is common usage, and since current applications do not enjoy the luxury of bounded interrupt load, item (2) above is sufficient to express existing application needs and is less restrictive in the standard definition. No difference in interface is necessary.

In an implementation in which the time quantum is equal for all processes at a specific priority, our assumptions can then be restated as:

- A time quantum  $Q$  exists, and a processor-bound process will be rescheduled after a duration of, at most,  $Q$ . Time quantum  $Q$  may be defined in either wall clock time or execution time.
- In general, the  $N$ th process of a priority level should wait no longer than  $(N-1) \times Q$  time to execute, assuming no processes exist at higher priority levels.
- No process should wait indefinitely.

For implementations supporting per-process time quanta, these assumptions can be readily extended.

## Sporadic Server Scheduling Policy

The sporadic server is a mechanism defined for scheduling aperiodic activities in time-critical realtime systems. This mechanism reserves a certain bounded amount of execution capacity for processing aperiodic events at a high priority level. Any aperiodic events that cannot be processed within the bounded amount of execution capacity are executed in the background at a low priority level. Thus, a certain amount of execution capacity can be guaranteed to be available for processing periodic tasks, even under burst conditions in the arrival of aperiodic processing requests (that is, a large number of requests in a short time interval). The sporadic server also simplifies the schedulability analysis of the realtime system, because it allows aperiodic processes or threads to be treated as if they were periodic. The sporadic server was first described by Sprunt, et al.

The key concept of the sporadic server is to provide and limit a certain amount of computation capacity for processing aperiodic events at their assigned normal priority, during a time interval called the “replenishment period”. Once the entity controlled by the sporadic server mechanism is initialized with its period and execution-time budget attributes, it preserves its execution capacity until an aperiodic request arrives. The request will be serviced (if there are no higher priority activities pending) as long as there is execution capacity left. If the request is completed, the actual execution time used to service it is subtracted from the capacity, and a replenishment of this amount of execution time is scheduled to happen one replenishment period after the arrival of the aperiodic request. If the request is not completed, because there is no execution capacity left, then the aperiodic process or thread is assigned a lower background priority. For each portion of consumed execution capacity the execution time used is replenished after one replenishment period. At the time of replenishment, if the sporadic server was executing at a background priority level, its priority is elevated to the normal level. Other similar replenishment policies have been defined, but the one presented here represents a compromise between efficiency and implementation complexity.

The interface that appears in this section defines a new scheduling policy for threads and processes that behaves according to the rules of the sporadic server mechanism. Scheduling attributes are defined and functions are provided to allow the user to set and get the parameters that control the scheduling behavior of this mechanism, namely the normal and low priority, the replenishment period, the maximum number of pending replenishment operations, and the initial execution-time budget.

- Scheduling Aperiodic Activities

Virtually all realtime applications are required to process aperiodic activities. In many cases, there are tight timing constraints that the response to the aperiodic events must meet. Usual timing requirements imposed on the response to these events are:

- The effects of an aperiodic activity on the response time of lower priority activities must be controllable and predictable.
- The system must provide the fastest possible response time to aperiodic events.
- It must be possible to take advantage of all the available processing bandwidth not needed by time-critical activities to enhance average-case response times to aperiodic events.

Traditional methods for scheduling aperiodic activities are background processing, polling tasks, and direct event execution:

- Background processing consists of assigning a very low priority to the processing of aperiodic events. It utilizes all the available bandwidth in the system that has not been consumed by higher priority threads. However, it is very difficult, or impossible, to meet

5450 requirements on average-case response time, because the aperiodic entity has to wait for  
5451 the execution of all other entities which have higher priority.

5452 — Polling consists of creating a periodic process or thread for servicing aperiodic requests.  
5453 At regular intervals, the polling entity is started and its services accumulated pending  
5454 aperiodic requests. If no aperiodic requests are pending, the polling entity suspends itself  
5455 until its next period. Polling allows the aperiodic requests to be processed at a higher  
5456 priority level. However, worst and average-case response times of polling entities are a  
5457 direct function of the polling period, and there is execution overhead for each polling  
5458 period, even if no event has arrived. If the deadline of the aperiodic activity is short  
5459 compared to the inter-arrival time, the polling frequency must be increased to guarantee  
5460 meeting the deadline. For this case, the increase in frequency can dramatically reduce the  
5461 efficiency of the system and, therefore, its capacity to meet all deadlines. Yet, polling  
5462 represents a good way to handle a large class of practical problems because it preserves  
5463 system predictability, and because the amortized overhead drops as load increases.

5464 — Direct event execution consists of executing the aperiodic events at a high fixed-priority  
5465 level. Typically, the aperiodic event is processed by an interrupt service routine as soon as  
5466 it arrives. This technique provides predictable response times for aperiodic events, but  
5467 makes the response times of all lower priority activities completely unpredictable under  
5468 burst arrival conditions. Therefore, if the density of aperiodic event arrivals is  
5469 unbounded, it may be a dangerous technique for time-critical systems. Yet, for those cases  
5470 in which the physics of the system imposes a bound on the event arrival rate, it is  
5471 probably the most efficient technique.

5472 — The sporadic server scheduling algorithm combines the predictability of the polling  
5473 approach with the short response times of the direct event execution. Thus, it allows  
5474 systems to meet an important class of application requirements that cannot be met by  
5475 using the traditional approaches. Multiple sporadic servers with different attributes can  
5476 be applied to the scheduling of multiple classes of aperiodic events, each with different  
5477 kinds of timing requirements, such as individual deadlines, average response times, and  
5478 so on. It also has many other interesting applications for realtime, such as scheduling  
5479 producer/consumer tasks in time-critical systems, limiting the effects of faults on the  
5480 estimation of task execution-time requirements, and so on.

#### 5481 • Existing Practice

5482 The sporadic server has been used in different kinds of applications, including military  
5483 avionics, robot control systems, industrial automation systems, and so on. There are  
5484 examples of many systems that cannot be successfully scheduled using the classic  
5485 approaches, such as direct event execution, or polling, and are schedulable using a sporadic  
5486 server scheduler. The sporadic server algorithm itself can successfully schedule all systems  
5487 scheduled with direct event execution or polling.

5488 The sporadic server scheduling policy has been implemented as a commercial product in the  
5489 run-time system of the Verdix Ada compiler. There are also many applications that have  
5490 used a much less efficient application-level sporadic server. These realtime applications  
5491 would benefit from a sporadic server scheduler implemented at the scheduler level.

#### 5492 • Library-Level versus Kernel-Level Implementation

5493 The sporadic server interface described in this section requires the sporadic server policy to  
5494 be implemented at the same level as the scheduler. This means that the process sporadic  
5495 server must be implemented at the kernel level and the thread sporadic server policy  
5496 implemented at the same level as the thread scheduler; that is, kernel or library level.

In an earlier interface for the sporadic server, this mechanism was implementable at a different level than the scheduler. This feature allowed the implementor to choose between an efficient scheduler-level implementation, or a simpler user or library-level implementation. However, the working group considered that this interface made the use of sporadic servers more complex, and that library-level implementations would lack some of the important functionality of the sporadic server, namely the limitation of the actual execution time of aperiodic activities. The working group also felt that the interface described in this chapter does not preclude library-level implementations of threads intended to provide efficient low-overhead scheduling for those threads that are not scheduled under the sporadic server policy.

- Range of Scheduling Priorities

Each of the scheduling policies supported in IEEE Std 1003.1-2001 has an associated range of priorities. The priority ranges for each policy might or might not overlap with the priority ranges of other policies. For time-critical realtime applications it is usual for periodic and aperiodic activities to be scheduled together in the same processor. Periodic activities will usually be scheduled using the SCHED\_FIFO scheduling policy, while aperiodic activities may be scheduled using SCHED\_SPORADIC. Since the application developer will require complete control over the relative priorities of these activities in order to meet his timing requirements, it would be desirable for the priority ranges of SCHED\_FIFO and SCHED\_SPORADIC to overlap completely. Therefore, although IEEE Std 1003.1-2001 does not require any particular relationship between the different priority ranges, it is recommended that these two ranges should coincide.

- Dynamically Setting the Sporadic Server Policy

Several members of the working group requested that implementations should not be required to support dynamically setting the sporadic server scheduling policy for a thread. The reason is that this policy may have a high overhead for library-level implementations of threads, and if threads are allowed to dynamically set this policy, this overhead can be experienced even if the thread does not use that policy. By disallowing the dynamic setting of the sporadic server scheduling policy, these implementations can accomplish efficient scheduling for threads using other policies. If a strictly conforming application needs to use the sporadic server policy, and is therefore willing to pay the overhead, it must set this policy at the time of thread creation.

- Limitation of the Number of Pending Replenishments

The number of simultaneously pending replenishment operations must be limited for each sporadic server for two reasons: an unlimited number of replenishment operations would need an unlimited number of system resources to store all the pending replenishment operations; on the other hand, in some implementations each replenishment operation will represent a source of priority inversion (just for the duration of the replenishment operation) and thus, the maximum amount of replenishments must be bounded to guarantee bounded response times. The way in which the number of replenishments is bounded is by lowering the priority of the sporadic server to *sched\_ss\_low\_priority* when the number of pending replenishments has reached its limit. In this way, no new replenishments are scheduled until the number of pending replenishments decreases.

In the sporadic server scheduling policy defined in IEEE Std 1003.1-2001, the application can specify the maximum number of pending replenishment operations for a single sporadic server, by setting the value of the *sched\_ss\_max\_repl* scheduling parameter. This value must be between one and {SS\_REPL\_MAX}, which is a maximum limit imposed by the implementation. The limit {SS\_REPL\_MAX} must be greater than or equal to {\_POSIX\_SS\_REPL\_MAX}, which is defined to be four in IEEE Std 1003.1-2001. The minimum

5546 limit of four was chosen so that an application can at least guarantee that four different  
 5547 aperiodic events can be processed during each interval of length equal to the replenishment  
 5548 period.

#### 5549 B.2.8.5 Clocks and Timers

##### 5550 • Clocks

5551 IEEE Std 1003.1-2001 and the ISO C standard both define functions for obtaining system time.  
 5552 Implicit behind these functions is a mechanism for measuring passage of time. This  
 5553 specification makes this mechanism explicit and calls it a clock. The `CLOCK_REALTIME`  
 5554 clock required by IEEE Std 1003.1-2001 is a higher resolution version of the clock that  
 5555 maintains POSIX.1 system time. This is a “system-wide” clock, in that it is visible to all  
 5556 processes and, were it possible for multiple processes to all read the clock at the same time,  
 5557 they would see the same value.

5558 An extensible interface was defined, with the ability for implementations to define additional  
 5559 clocks. This was done because of the observation that many realtime platforms support  
 5560 multiple clocks, and it was desired to fit this model within the standard interface. But  
 5561 implementation-defined clocks need not represent actual hardware devices, nor are they  
 5562 necessarily system-wide.

##### 5563 • Timers

5564 Two timer types are required for a system to support realtime applications:

##### 5565 1. One-shot

5566 A one-shot timer is a timer that is armed with an initial expiration time, either relative  
 5567 to the current time or at an absolute time (based on some timing base, such as time in  
 5568 seconds and nanoseconds since the Epoch). The timer expires once and then is  
 5569 disarmed. With the specified facilities, this is accomplished by setting the *it\_value*  
 5570 member of the *value* argument to the desired expiration time and the *it\_interval* member  
 5571 to zero.

##### 5572 2. Periodic

5573 A periodic timer is a timer that is armed with an initial expiration time, again either  
 5574 relative or absolute, and a repetition interval. When the initial expiration occurs, the  
 5575 timer is reloaded with the repetition interval and continues counting. With the  
 5576 specified facilities, this is accomplished by setting the *it\_value* member of the *value*  
 5577 argument to the desired initial expiration time and the *it\_interval* member to the desired  
 5578 repetition interval.

5579 For both of these types of timers, the time of the initial timer expiration can be specified in  
 5580 two ways:

##### 5581 1. Relative (to the current time)

##### 5582 2. Absolute

##### 5583 • Examples of Using Realtime Timers

5584 In the diagrams below, *S* indicates a program schedule, *R* shows a schedule method request,  
 5585 and *E* suggests an internal operating system event.

##### 5586 — Periodic Timer: Data Logging

5587 During an experiment, it might be necessary to log realtime data periodically to an  
 5588 internal buffer or to a mass storage device. With a periodic scheduling method, a logging

5589 module can be started automatically at fixed time intervals to log the data.

5590 Program schedule is requested every 10 seconds.

5594 [Time (in Seconds)]

5595 To achieve this type of scheduling using the specified facilities, one would allocate a per-  
5596 process timer based on clock ID `CLOCK_REALTIME`. Then the timer would be armed via  
5597 a call to `timer_settime()` with the `TIMER_ABSTIME` flag reset, and with an initial  
5598 expiration value and a repetition interval of 10 seconds.

5599 — One-shot Timer (Relative Time): Device Initialization

5600 In an emission test environment, large sample bags are used to capture the exhaust from  
5601 a vehicle. The exhaust is purged from these bags before each and every test. With a one-  
5602 shot timer, a module could initiate the purge function and then suspend itself for a  
5603 predetermined period of time while the sample bags are prepared.

5604 Program schedule requested 20 seconds after call is issued.

5608 [Time (in Seconds)]

5609 To achieve this type of scheduling using the specified facilities, one would allocate a per-  
5610 process timer based on clock ID `CLOCK_REALTIME`. Then the timer would be armed via  
5611 a call to `timer_settime()` with the `TIMER_ABSTIME` flag reset, and with an initial  
5612 expiration value of 20 seconds and a repetition interval of zero.

5613 Note that if the program wishes merely to suspend itself for the specified interval, it  
5614 could more easily use `nanosleep()`.

5615 — One-shot Timer (Absolute Time): Data Transmission

5616 The results from an experiment are often moved to a different system within a network  
5617 for postprocessing or archiving. With an absolute one-shot timer, a module that moves  
5618 data from a test-cell computer to a host computer can be automatically scheduled on a  
5619 daily basis.

5620 Program schedule requested for 2:30 a.m.

5624 [Time of Day]

5625 To achieve this type of scheduling using the specified facilities, a per-process timer would  
5626 be allocated based on clock ID `CLOCK_REALTIME`. Then the timer would be armed via  
5627 a call to `timer_settime()` with the `TIMER_ABSTIME` flag set, and an initial expiration value  
5628 equal to 2:30 a.m. of the next day.

5629 — Periodic Timer (Relative Time): Signal Stabilization

5630 Some measurement devices, such as emission analyzers, do not respond instantaneously  
5631 to an introduced sample. With a periodic timer with a relative initial expiration time, a

module that introduces a sample and records the average response could suspend itself for a predetermined period of time while the signal is stabilized and then sample at a fixed rate.

Program schedule requested 15 seconds after call is issued and every 2 seconds thereafter.

[Time (in Seconds)]

To achieve this type of scheduling using the specified facilities, one would allocate a per-process timer based on clock ID `CLOCK_REALTIME`. Then the timer would be armed via a call to `timer_settime()` with `TIMER_ABSTIME` flag reset, and with an initial expiration value of 15 seconds and a repetition interval of 2 seconds.

#### — Periodic Timer (Absolute Time): Work Shift-related Processing

Resource utilization data is useful when time to perform experiments is being scheduled at a facility. With a periodic timer with an absolute initial expiration time, a module can be scheduled at the beginning of a work shift to gather resource utilization data throughout the shift. This data can be used to allocate resources effectively to minimize bottlenecks and delays and maximize facility throughput.

Program schedule requested for 2:00 a.m. and every 15 minutes thereafter.

[Time of Day]

To achieve this type of scheduling using the specified facilities, one would allocate a per-process timer based on clock ID `CLOCK_REALTIME`. Then the timer would be armed via a call to `timer_settime()` with `TIMER_ABSTIME` flag set, and with an initial expiration value equal to 2:00 a.m. and a repetition interval equal to 15 minutes.

#### • Relationship of Timers to Clocks

The relationship between clocks and timers armed with an absolute time is straightforward: a timer expiration signal is requested when the associated clock reaches or exceeds the specified time. The relationship between clocks and timers armed with a relative time (an interval) is less obvious, but not unintuitive. In this case, a timer expiration signal is requested when the specified interval, *as measured by the associated clock*, has passed. For the required `CLOCK_REALTIME` clock, this allows timer expiration signals to be requested at specified “wall clock” times (absolute), or when a specified interval of “realtime” has passed (relative). For an implementation-defined clock—say, a process virtual time clock—timer expirations could be requested when the process has used a specified total amount of virtual time (absolute), or when it has used a specified *additional* amount of virtual time (relative).

The interfaces also allow flexibility in the implementation of the functions. For example, an implementation could convert all absolute times to intervals by subtracting the clock value at the time of the call from the requested expiration time and “counting down” at the supported resolution. Or it could convert all relative times to absolute expiration time by adding in the clock value at the time of the call and comparing the clock value to the expiration time at the supported resolution. Or it might even choose to maintain absolute times as absolute and compare them to the clock value at the supported resolution for absolute timers, and maintain relative times as intervals and count them down at the

5678 resolution supported for relative timers. The choice will be driven by efficiency  
 5679 considerations and the underlying hardware or software clock implementation.

5680 • Data Definitions for Clocks and Timers

5681 IEEE Std 1003.1-2001 uses a time representation capable of supporting nanosecond resolution  
 5682 timers for the following reasons:

5683 — To enable IEEE Std 1003.1-2001 to represent those computer systems already using  
 5684 nanosecond or submicrosecond resolution clocks.

5685 — To accommodate those per-process timers that might need nanoseconds to specify an  
 5686 absolute value of system-wide clocks, even though the resolution of the per-process timer  
 5687 may only be milliseconds, or *vice versa*.

5688 — Because the number of nanoseconds in a second can be represented in 32 bits.

5689 Time values are represented in the **timespec** structure. The *tv\_sec* member is of type **time\_t**  
 5690 so that this member is compatible with time values used by POSIX.1 functions and the ISO C  
 5691 standard. The *tv\_nsec* member is a **signed long** in order to simplify and clarify code that  
 5692 decrements or finds differences of time values. Note that because 1 billion (number of  
 5693 nanoseconds per second) is less than half of the value representable by a signed 32-bit value,  
 5694 it is always possible to add two valid fractional seconds represented as integral nanoseconds  
 5695 without overflowing the signed 32-bit value.

5696 A maximum allowable resolution for the CLOCK\_REALTIME clock of 20 ms (1/50 seconds)  
 5697 was chosen to allow line frequency clocks in European countries to be conforming. 60 Hz  
 5698 clocks in the U.S. will also be conforming, as will finer granularity clocks, although a Strictly  
 5699 Conforming Application cannot assume a granularity of less than 20 ms (1/50 seconds).

5700 The minimum allowable maximum time allowed for the CLOCK\_REALTIME clock and the  
 5701 function *nanosleep()*, and timers created with *clock\_id*=CLOCK\_REALTIME, is determined by  
 5702 the fact that the *tv\_sec* member is of type **time\_t**.

5703 IEEE Std 1003.1-2001 specifies that timer expirations must not be delivered early, and  
 5704 *nanosleep()* must not return early due to quantization error. IEEE Std 1003.1-2001 discusses  
 5705 the various implementations of *alarm()* in the rationale and states that implementations that  
 5706 do not allow alarm signals to occur early are the most appropriate, but refrained from  
 5707 mandating this behavior. Because of the importance of predictability to realtime applications,  
 5708 IEEE Std 1003.1-2001 takes a stronger stance.

5709 The developers of IEEE Std 1003.1-2001 considered using a time representation that differs  
 5710 from POSIX.1b in the second 32 bit of the 64-bit value. Whereas POSIX.1b defines this field  
 5711 as a fractional second in nanoseconds, the other methodology defines this as a binary fraction  
 5712 of one second, with the radix point assumed before the most significant bit.

5713 POSIX.1b is a software, source-level standard and most of the benefits of the alternate  
 5714 representation are enjoyed by hardware implementations of clocks and algorithms. It was  
 5715 felt that mandating this format for POSIX.1b clocks and timers would unnecessarily burden  
 5716 the application writer with writing, possibly non-portable, multiple precision arithmetic  
 5717 packages to perform conversion between binary fractions and integral units such as  
 5718 nanoseconds, milliseconds, and so on.

**Rationale for the Monotonic Clock**

For those applications that use time services to achieve realtime behavior, changing the value of the clock on which these services rely may cause erroneous timing behavior. For these applications, it is necessary to have a monotonic clock which cannot run backwards, and which has a maximum clock jump that is required to be documented by the implementation. Additionally, it is desirable (but not required by IEEE Std 1003.1-2001) that the monotonic clock increases its value uniformly. This clock should not be affected by changes to the system time; for example, to synchronize the clock with an external source or to account for leap seconds. Such changes would cause errors in the measurement of time intervals for those time services that use the absolute value of the clock.

One could argue that by defining the behavior of time services when the value of a clock is changed, deterministic realtime behavior can be achieved. For example, one could specify that relative time services should be unaffected by changes in the value of a clock. However, there are time services that are based upon an absolute time, but that are essentially intended as relative time services. For example, *pthread\_cond\_timedwait()* uses an absolute time to allow it to wake up after the required interval despite spurious wakeups. Although sometimes the *pthread\_cond\_timedwait()* timeouts are absolute in nature, there are many occasions in which they are relative, and their absolute value is determined from the current time plus a relative time interval. In this latter case, if the clock changes while the thread is waiting, the wait interval will not be the expected length. If a *pthread\_cond\_timedwait()* function were created that would take a relative time, it would not solve the problem because to retain the intended “deadline” a thread would need to compensate for latency due to the spurious wakeup, and preemption between wakeup and the next wait.

The solution is to create a new monotonic clock, whose value does not change except for the regular ticking of the clock, and use this clock for implementing the various relative timeouts that appear in the different POSIX interfaces, as well as allow *pthread\_cond\_timedwait()* to choose this new clock for its timeout. A new *clock\_nanosleep()* function is created to allow an application to take advantage of this newly defined clock. Notice that the monotonic clock may be implemented using the same hardware clock as the system clock.

Relative timeouts for *sigtimedwait()* and *aio\_suspend()* have been redefined to use the monotonic clock, if present. The *alarm()* function has not been redefined, because the same effect but with better resolution can be achieved by creating a timer (for which the appropriate clock may be chosen).

The *pthread\_cond\_timedwait()* function has been treated in a different way, compared to other functions with absolute timeouts, because it is used to wait for an event, and thus it may have a deadline, while the other timeouts are generally used as an error recovery mechanism, and for them the use of the monotonic clock is not so important. Since the desired timeout for the *pthread\_cond\_timedwait()* function may either be a relative interval or an absolute time of day deadline, a new initialization attribute has been created for condition variables to specify the clock that is used for measuring the timeout in a call to *pthread\_cond\_timedwait()*. In this way, if a relative timeout is desired, the monotonic clock will be used; if an absolute deadline is required instead, the *CLOCK\_REALTIME* or another appropriate clock may be used. This capability has not been added to other functions with absolute timeouts because for those functions the expected use of the timeout is mostly to prevent errors, and not so often to meet precise deadlines. As a consequence, the complexity of adding this capability is not justified by its perceived application usage.

The *nanosleep()* function has not been modified with the introduction of the monotonic clock. Instead, a new *clock\_nanosleep()* function has been created, in which the desired clock may be specified in the function call.

- History of Resolution Issues

Due to the shift from relative to absolute timeouts in IEEE Std 1003.1d-1999, the amendments to the `sem_timedwait()`, `pthread_mutex_timedlock()`, `mq_timedreceive()`, and `mq_timedsend()` functions of that standard have been removed. Those amendments specified that `CLOCK_MONOTONIC` would be used for the (relative) timeouts if the Monotonic Clock option was supported.

Having these functions continue to be tied solely to `CLOCK_MONOTONIC` would not work. Since the absolute value of a time value obtained from `CLOCK_MONOTONIC` is unspecified, under the absolute timeouts interface, applications would behave differently depending on whether the Monotonic Clock option was supported or not (because the absolute value of the clock would have different meanings in either case).

Two options were considered:

1. Leave the current behavior unchanged, which specifies the `CLOCK_REALTIME` clock for these (absolute) timeouts, to allow portability of applications between implementations supporting or not the Monotonic Clock option.
2. Modify these functions in the way that `pthread_cond_timedwait()` was modified to allow a choice of clock, so that an application could use `CLOCK_REALTIME` when it is trying to achieve an absolute timeout and `CLOCK_MONOTONIC` when it is trying to achieve a relative timeout.

It was decided that the features of `CLOCK_MONOTONIC` are not as critical to these functions as they are to `pthread_cond_timedwait()`. The `pthread_cond_timedwait()` function is given a relative timeout; the timeout may represent a deadline for an event. When these functions are given relative timeouts, the timeouts are typically for error recovery purposes and need not be so precise.

Therefore, it was decided that these functions should be tied to `CLOCK_REALTIME` and not complicated by being given a choice of clock.

## Execution Time Monitoring

- Introduction

The main goals of the execution time monitoring facilities defined in this chapter are to measure the execution time of processes and threads and to allow an application to establish CPU time limits for these entities.

The analysis phase of time-critical realtime systems often relies on the measurement of execution times of individual threads or processes to determine whether the timing requirements will be met. Also, performance analysis techniques for soft deadline realtime systems rely heavily on the determination of these execution times. The execution time monitoring functions provide application developers with the ability to measure these execution times online and open the possibility of dynamic execution-time analysis and system reconfiguration, if required.

The second goal of allowing an application to establish execution time limits for individual processes or threads and detecting when they overrun allows program robustness to be increased by enabling online checking of the execution times.

If errors are detected—possibly because of erroneous program constructs, the existence of errors in the analysis phase, or a burst of event arrivals—online detection and recovery is possible in a portable way. This feature can be extremely important for many time-critical applications. Other applications require trapping CPU-time errors as a normal way to exit an

algorithm; for instance, some realtime artificial intelligence applications trigger a number of independent inference processes of varying accuracy and speed, limit how long they can run, and pick the best answer available when time runs out. In many periodic systems, overrun processes are simply restarted in the next resource period, after necessary end-of-period actions have been taken. This allows algorithms that are inherently data-dependent to be made predictable.

The interface that appears in this chapter defines a new type of clock, the CPU-time clock, which measures execution time. Each process or thread can invoke the clock and timer functions defined in POSIX.1 to use them. Functions are also provided to access the CPU-time clock of other processes or threads to enable remote monitoring of these clocks. Monitoring of threads of other processes is not supported, since these threads are not visible from outside of their own process with the interfaces defined in POSIX.1.

- Execution Time Monitoring Interface

The clock and timer interface defined in POSIX.1 historically only defined one clock, which measures wall-clock time. The requirements for measuring execution time of processes and threads, and setting limits to their execution time by detecting when they overrun, can be accomplished with that interface if a new kind of clock is defined. These new clocks measure execution time, and one is associated with each process and with each thread. The clock functions currently defined in POSIX.1 can be used to read and set these CPU-time clocks, and timers can be created using these clocks as their timing base. These timers can then be used to send a signal when some specified execution time has been exceeded. The CPU-time clocks of each process or thread can be accessed by using the symbols `CLOCK_PROCESS_CPUTIME_ID` or `CLOCK_THREAD_CPUTIME_ID`.

The clock and timer interface defined in POSIX.1 and extended with the new kind of CPU-time clock would only allow processes or threads to access their own CPU-time clocks. However, many realtime systems require the possibility of monitoring the execution time of processes or threads from independent monitoring entities. In order to allow applications to construct independent monitoring entities that do not require cooperation from or modification of the monitored entities, two functions have been added: `clock_getcpuclockid()`, for accessing CPU-time clocks of other processes, and `pthread_getcpuclockid()`, for accessing CPU-time clocks of other threads. These functions return the clock identifier associated with the process or thread specified in the call. These clock IDs can then be used in the rest of the clock function calls.

The clocks accessed through these functions could also be used as a timing base for the creation of timers, thereby allowing independent monitoring entities to limit the CPU time consumed by other entities. However, this possibility would imply additional complexity and overhead because of the need to maintain a timer queue for each process or thread, to store the different expiration times associated with timers created by different processes or threads. The working group decided this additional overhead was not justified by application requirements. Therefore, creation of timers attached to the CPU-time clocks of other processes or threads has been specified as implementation-defined.

- Overhead Considerations

The measurement of execution time may introduce additional overhead in the thread scheduling, because of the need to keep track of the time consumed by each of these entities. In library-level implementations of threads, the efficiency of scheduling could be somehow compromised because of the need to make a kernel call, at each context switch, to read the process CPU-time clock. Consequently, a thread creation attribute called *cpu-clock-requirement* was defined, to allow threads to disconnect their respective CPU-time clocks. However, the Ballot Group considered that this attribute itself introduced some overhead,

and that in current implementations it was not worth the effort. Therefore, the attribute was deleted, and thus thread CPU-time clocks are required for all threads if the Thread CPU-Time Clocks option is supported.

- Accuracy of CPU-Time Clocks

The mechanism used to measure the execution time of processes and threads is specified in IEEE Std 1003.1-2001 as implementation-defined. The reason for this is that both the underlying hardware and the implementation architecture have a very strong influence on the accuracy achievable for measuring CPU time. For some implementations, the specification of strict accuracy requirements would represent very large overheads, or even the impossibility of being implemented.

Since the mechanism for measuring execution time is implementation-defined, realtime applications will be able to take advantage of accurate implementations using a portable interface. Of course, strictly conforming applications cannot rely on any particular degree of accuracy, in the same way as they cannot rely on a very accurate measurement of wall clock time. There will always exist applications whose accuracy or efficiency requirements on the implementation are more rigid than the values defined in IEEE Std 1003.1-2001 or any other standard.

In any case, there is a minimum set of characteristics that realtime applications would expect from most implementations. One such characteristic is that the sum of all the execution times of all the threads in a process equals the process execution time, when no CPU-time clocks are disabled. This need not always be the case because implementations may differ in how they account for time during context switches. Another characteristic is that the sum of the execution times of all processes in a system equals the number of processors, multiplied by the elapsed time, assuming that no processor is idle during that elapsed time. However, in some implementations it might not be possible to relate CPU time to elapsed time. For example, in a heterogeneous multi-processor system in which each processor runs at a different speed, an implementation may choose to define each “second” of CPU time to be a certain number of “cycles” that a CPU has executed.

- Existing Practice

Measuring and limiting the execution time of each concurrent activity are common features of most industrial implementations of realtime systems. Almost all critical realtime systems are currently built upon a cyclic executive. With this approach, a regular timer interrupt kicks off the next sequence of computations. It also checks that the current sequence has completed. If it has not, then some error recovery action can be undertaken (or at least an overrun is avoided). Current software engineering principles and the increasing complexity of software are driving application developers to implement these systems on multi-threaded or multi-process operating systems. Therefore, if a POSIX operating system is to be used for this type of application, then it must offer the same level of protection.

Execution time clocks are also common in most UNIX implementations, although these clocks usually have requirements different from those of realtime applications. The POSIX.1 *times()* function supports the measurement of the execution time of the calling process, and its terminated child processes. This execution time is measured in clock ticks and is supplied as two different values with the user and system execution times, respectively. BSD supports the function *getrusage()*, which allows the calling process to get information about the resources used by itself and/or all of its terminated child processes. The resource usage includes user and system CPU time. Some UNIX systems have options to specify high resolution (up to one microsecond) CPU-time clocks using the *times()* or the *getrusage()* functions.

The *times()* and *getrusage()* interfaces do not meet important realtime requirements, such as the possibility of monitoring execution time from a different process or thread, or the possibility of detecting an execution time overrun. The latter requirement is supported in some UNIX implementations that are able to send a signal when the execution time of a process has exceeded some specified value. For example, BSD defines the functions *getitimer()* and *setitimer()*, which can operate either on a realtime clock (wall-clock), or on virtual-time or profile-time clocks which measure CPU time in two different ways. These functions do not support access to the execution time of other processes.

IBM's MVS operating system supports per-process and per-thread execution time clocks. It also supports limiting the execution time of a given process.

Given all this existing practice, the working group considered that the POSIX.1 clocks and timers interface was appropriate to meet most of the requirements that realtime applications have for execution time clocks. Functions were added to get the CPU time clock IDs, and to allow/disallow the thread CPU-time clocks (in order to preserve the efficiency of some implementations of threads).

- Clock Constants

The definition of the manifest constants `CLOCK_PROCESS_CPUTIME_ID` and `CLOCK_THREAD_CPUTIME_ID` allows processes or threads, respectively, to access their own execution-time clocks. However, given a process or thread, access to its own execution-time clock is also possible if the clock ID of this clock is obtained through a call to *clock\_getcpuclockid()* or *pthread\_getcpuclockid()*. Therefore, these constants are not necessary and could be deleted to make the interface simpler. Their existence saves one system call in the first access to the CPU-time clock of each process or thread. The working group considered this issue and decided to leave the constants in IEEE Std 1003.1-2001 because they are closer to the POSIX.1b use of clock identifiers.

- Library Implementations of Threads

In library implementations of threads, kernel entities and library threads can coexist. In this case, if the CPU-time clocks are supported, most of the clock and timer functions will need to have two implementations: one in the thread library, and one in the system calls library. The main difference between these two implementations is that the thread library implementation will have to deal with clocks and timers that reside in the thread space, while the kernel implementation will operate on timers and clocks that reside in kernel space. In the library implementation, if the clock ID refers to a clock that resides in the kernel, a kernel call will have to be made. The correct version of the function can be chosen by specifying the appropriate order for the libraries during the link process.

- History of Resolution Issues: Deletion of the *enable* Attribute

In early proposals, consideration was given to inclusion of an attribute called *enable* for CPU-time clocks. This would allow implementations to avoid the overhead of measuring execution time for those processes or threads for which this measurement was not required. However, this is unnecessary since processes are already required to measure execution time by the POSIX.1 *times()* function. Consequently, the *enable* attribute is not present.

**Rationale Relating to Timeouts**

- Requirements for Timeouts

Realtime systems which must operate reliably over extended periods without human intervention are characteristic in embedded applications such as avionics, machine control, and space exploration, as well as more mundane applications such as cable TV, security systems, and plant automation. A multi-tasking paradigm, in which many independent and/or cooperating software functions relinquish the processor(s) while waiting for a specific stimulus, resource, condition, or operation completion, is very useful in producing well engineered programs for such systems. For such systems to be robust and fault-tolerant, expected occurrences that are unduly delayed or that never occur must be detected so that appropriate recovery actions may be taken. This is difficult if there is no way for a task to regain control of a processor once it has relinquished control (blocked) awaiting an occurrence which, perhaps because of corrupted code, hardware malfunction, or latent software bugs, will not happen when expected. Therefore, the common practice in realtime operating systems is to provide a capability to time out such blocking services. Although there are several methods to achieve this already defined by POSIX, none are as reliable or efficient as initiating a timeout simultaneously with initiating a blocking service. This is especially critical in hard-realtime embedded systems because the processors typically have little time reserve, and allowed fault recovery times are measured in milliseconds rather than seconds.

The working group largely agreed that such timeouts were necessary and ought to become part of IEEE Std 1003.1-2001, particularly vendors of realtime operating systems whose customers had already expressed a strong need for timeouts. There was some resistance to inclusion of timeouts in IEEE Std 1003.1-2001 because the desired effect, fault tolerance, could, in theory, be achieved using existing facilities and alternative software designs, but there was no compelling evidence that realtime system designers would embrace such designs at the sacrifice of performance and/or simplicity.

- Which Services should be Timed Out?

Originally, the working group considered the prospect of providing timeouts on all blocking services, including those currently existing in POSIX.1, POSIX.1b, and POSIX.1c, and future interfaces to be defined by other working groups, as sort of a general policy. This was rather quickly rejected because of the scope of such a change, and the fact that many of those services would not normally be used in a realtime context. More traditional timesharing solutions to timeout would suffice for most of the POSIX.1 interfaces, while others had asynchronous alternatives which, while more complex to utilize, would be adequate for some realtime and all non-realtime applications.

The list of potential candidates for timeouts was narrowed to the following for further consideration:

- POSIX.1b

- `sem_wait()`

- `mq_receive()`

- `mq_send()`

- `lio_listio()`

- `aio_suspend()`

- `sigwait()` (timeout already implemented by `sigtimedwait()`)

5996 — POSIX.1c  
 5997 — *pthread\_mutex\_lock()*  
 5998 — *pthread\_join()*  
 5999 — *pthread\_cond\_wait()* (timeout already implemented by *pthread\_cond\_timedwait()*)  
 6000 — POSIX.1  
 6001 — *read()*  
 6002 — *write()*

6003 After further review by the working group, the *lio\_listio()*, *read()*, and *write()* functions (all  
 6004 forms of blocking synchronous I/O) were eliminated from the list because of the following:

6005 — Asynchronous alternatives exist  
 6006 — Timeouts can be implemented, albeit non-portably, in device drivers  
 6007 — A strong desire not to introduce modifications to POSIX.1 interfaces

6008 The working group ultimately rejected *pthread\_join()* since both that interface and a timed  
 6009 variant of that interface are non-minimal and may be implemented as a function. See below  
 6010 for a library implementation of *pthread\_join()*.

6011 Thus, there was a consensus among the working group members to add timeouts to 4 of the  
 6012 remaining 5 functions (the timeout for *aio\_suspend()* was ultimately added directly to  
 6013 POSIX.1b, while the others were added by POSIX.1d). However, *pthread\_mutex\_lock()*  
 6014 remained contentious.

6015 Many feel that *pthread\_mutex\_lock()* falls into the same class as the other functions; that is, it  
 6016 is desirable to time out a mutex lock because a mutex may fail to be unlocked due to errant or  
 6017 corrupted code in a critical section (looping or branching outside of the unlock code), and  
 6018 therefore is equally in need of a reliable, simple, and efficient timeout. In fact, since mutexes  
 6019 are intended to guard small critical sections, most *pthread\_mutex\_lock()* calls would be  
 6020 expected to obtain the lock without blocking nor utilizing any kernel service, even in  
 6021 implementations of threads with global contention scope; the timeout alternative need only  
 6022 be considered after it is determined that the thread must block.

6023 Those opposed to timing out mutexes feel that the very simplicity of the mutex is  
 6024 compromised by adding a timeout semantic, and that to do so is senseless. They claim that if  
 6025 a timed mutex is really deemed useful by a particular application, then it can be constructed  
 6026 from the facilities already in POSIX.1b and POSIX.1c. The following two C-language library  
 6027 implementations of mutex locking with timeout represent the solutions offered (in both  
 6028 implementations, the timeout parameter is specified as absolute time, not relative time as in  
 6029 the proposed POSIX.1c interfaces).

- Spinlock Implementation

```

6030
6031 #include <pthread.h>
6032 #include <time.h>
6033 #include <errno.h>
6034
6035 int pthread_mutex_timedlock(pthread_mutex_t *mutex,
6036 const struct timespec *timeout)
6037 {
6038 struct timespec timenow;
6039
6040 while (pthread_mutex_trylock(mutex) == EBUSY)
6041 {
6042 clock_gettime(CLOCK_REALTIME, &timenow);
6043 if (timespec_cmp(&timenow, timeout) >= 0)
6044 {
6045 return ETIMEDOUT;
6046 }
6047 pthread_yield();
6048 }
6049 return 0;
6050 }

```

The Spinlock implementation is generally unsuitable for any application using priority-based thread scheduling policies such as SCHED\_FIFO or SCHED\_RR, since the mutex could currently be held by a thread of lower priority within the same allocation domain, but since the waiting thread never blocks, only threads of equal or higher priority will ever run, and the mutex cannot be unlocked. Setting priority inheritance or priority ceiling protocol on the mutex does not solve this problem, since the priority of a mutex owning thread is only boosted if higher priority threads are blocked waiting for the mutex; clearly not the case for this spinlock.

- Condition Wait Implementation

```

6057
6058 #include <pthread.h>
6059 #include <time.h>
6060 #include <errno.h>
6061
6062 struct timed_mutex
6063 {
6064 int locked;
6065 pthread_mutex_t mutex;
6066 pthread_cond_t cond;
6067 };
6068
6069 typedef struct timed_mutex timed_mutex_t;
6070
6071 int timed_mutex_lock(timed_mutex_t *tm,
6072 const struct timespec *timeout)
6073 {
6074 int timedout=FALSE;
6075 int error_status;
6076
6077 pthread_mutex_lock(&tm->mutex);
6078
6079 while (tm->locked && !timedout)
6080 {
6081 if ((error_status=pthread_cond_timedwait(&tm->cond,

```

```

6077 &tm->mutex,
6078 timeout)) != 0)
6079 {
6080 if (error_status==ETIMEDOUT) timedout = TRUE;
6081 }
6082 }
6083
6084 if(timedout)
6085 {
6086 pthread_mutex_unlock(&tm->mutex);
6087 return ETIMEDOUT;
6088 }
6089 else
6090 {
6091 tm->locked = TRUE;
6092 pthread_mutex_unlock(&tm->mutex);
6093 return 0;
6094 }
6095
6096 void timed_mutex_unlock(timed_mutex_t *tm)
6097 {
6098 pthread_mutex_lock(&tm->mutex); / for case assignment not atomic /
6099 tm->locked = FALSE;
6100 pthread_mutex_unlock(&tm->mutex);
6101 pthread_cond_signal(&tm->cond);
6102 }

```

The Condition Wait implementation effectively substitutes the *pthread\_cond\_timedwait()* function (which is currently timed out) for the desired *pthread\_mutex\_timedlock()*. Since waits on condition variables currently do not include protocols which avoid priority inversion, this method is generally unsuitable for realtime applications because it does not provide the same priority inversion protection as the untimed *pthread\_mutex\_lock()*. Also, for any given implementations of the current mutex and condition variable primitives, this library implementation has a performance cost at least 2.5 times that of the untimed *pthread\_mutex\_lock()* even in the case where the timed mutex is readily locked without blocking (the interfaces required for this case are shown in bold). Even in uniprocessors or where assignment is atomic, at least an additional *pthread\_cond\_signal()* is required. *pthread\_mutex\_timedlock()* could be implemented at effectively no performance penalty in this case because the timeout parameters need only be considered after it is determined that the mutex cannot be locked immediately.

Thus it has not yet been shown that the full semantics of mutex locking with timeout can be efficiently and reliably achieved using existing interfaces. Even if the existence of an acceptable library implementation were proven, it is difficult to justify why the interface itself should not be made portable, especially considering approval for the other four timeouts.

- Rationale for Library Implementation of *pthread\_timedjoin()*

Library implementation of *pthread\_timedjoin()*:

```

6120
6121
6122 /*
6123 * Construct a thread variety entirely from existing functions
6124 * with which a join can be done, allowing the join to time out.
6125 */
6126 #include <pthread.h>
6127 #include <time.h>
6128
6129 struct timed_thread {
6130 pthread_t t;
6131 pthread_mutex_t m;
6132 int exiting;
6133 pthread_cond_t exit_c;
6134 void *(*start_routine)(void *arg);
6135 void *arg;
6136 void *status;
6137 };
6138
6139 typedef struct timed_thread *timed_thread_t;
6140 static pthread_key_t timed_thread_key;
6141 static pthread_once_t timed_thread_once = PTHREAD_ONCE_INIT;
6142
6143 static void timed_thread_init()
6144 {
6145 pthread_key_create(&timed_thread_key, NULL);
6146 }
6147
6148 static void *timed_thread_start_routine(void *args)
6149 /*
6150 * Routine to establish thread-specific data value and run the actual
6151 * thread start routine which was supplied to timed_thread_create().
6152 */
6153 {
6154 timed_thread_t tt = (timed_thread_t) args;
6155
6156 pthread_once(&timed_thread_once, timed_thread_init);
6157 pthread_setspecific(timed_thread_key, (void *)tt);
6158 timed_thread_exit((tt->start_routine)(tt->arg));
6159 }
6160
6161 int timed_thread_create(timed_thread_t ttp, const pthread_attr_t *attr,
6162 void *(*start_routine)(void *), void *arg)
6163 /*
6164 * Allocate a thread which can be used with timed_thread_join().
6165 */
6166 {
6167 timed_thread_t tt;
6168 int result;
6169
6170 tt = (timed_thread_t) malloc(sizeof(struct timed_thread));
6171 pthread_mutex_init(&tt->m, NULL);
6172 tt->exiting = FALSE;
6173 pthread_cond_init(&tt->exit_c, NULL);

```

```

6167 tt->start_routine = start_routine;
6168 tt->arg = arg;
6169 tt->status = NULL;

6170 if ((result = pthread_create(&tt->t, attr,
6171 timed_thread_start_routine, (void *)tt)) != 0) {
6172 free(tt);
6173 return result;
6174 }

6175 pthread_detach(tt->t);
6176 ttp = tt;
6177 return 0;
6178 }

6179 int timed_thread_join(timed_thread_t tt,
6180 struct timespec *timeout,
6181 void **status)
6182 {
6183 int result;

6184 pthread_mutex_lock(&tt->m);
6185 result = 0;
6186 /*
6187 * Wait until the thread announces that it is exiting,
6188 * or until timeout.
6189 */
6190 while (result == 0 && ! tt->exiting) {
6191 result = pthread_cond_timedwait(&tt->exit_c, &tt->m, timeout);
6192 }
6193 pthread_mutex_unlock(&tt->m);
6194 if (result == 0 && tt->exiting) {
6195 *status = tt->status;
6196 free((void *)tt);
6197 return result;
6198 }
6199 return result;
6200 }

6201 void timed_thread_exit(void *status)
6202 {
6203 timed_thread_t tt;
6204 void *specific;

6205 if ((specific=pthread_getspecific(timed_thread_key)) == NULL){
6206 /*
6207 * Handle cases which won't happen with correct usage.
6208 */
6209 pthread_exit(NULL);
6210 }
6211 tt = (timed_thread_t) specific;
6212 pthread_mutex_lock(&tt->m);
6213 /*
6214 * Tell a joiner that we're exiting.
6215 */

```

```

6216 tt->status = status;
6217 tt->exiting = TRUE;
6218 pthread_cond_signal(&tt->exit_c);
6219 pthread_mutex_unlock(&tt->m);
6220 /*
6221 * Call pthread_exit() to call destructors and really
6222 * exit the thread.
6223 */
6224 pthread_exit(NULL);
6225 }

```

6226 The *pthread\_join()* C-language example shown above demonstrates that it is possible, using  
 6227 existing pthread facilities, to construct a variety of thread which allows for joining such a  
 6228 thread, but which allows the join operation to time out. It does this by using a  
 6229 *pthread\_cond\_timedwait()* to wait for the thread to exit. A **timed\_thread\_t** descriptor structure  
 6230 is used to pass parameters from the creating thread to the created thread, and from the  
 6231 exiting thread to the joining thread. This implementation is roughly equivalent to what a  
 6232 normal *pthread\_join()* implementation would do, with the single change being that  
 6233 *pthread\_cond\_timedwait()* is used in place of a simple *pthread\_cond\_wait()*.

6234 Since it is possible to implement such a facility entirely from existing pthread interfaces, and  
 6235 with roughly equal efficiency and complexity to an implementation which would be  
 6236 provided directly by a pthreads implementation, it was the consensus of the working group  
 6237 members that any *pthread\_timedjoin()* facility would be unnecessary, and should not be  
 6238 provided.

#### 6239 • Form of the Timeout Interfaces

6240 The working group considered a number of alternative ways to add timeouts to blocking  
 6241 services. At first, a system interface which would specify a one-shot or persistent timeout to  
 6242 be applied to subsequent blocking services invoked by the calling process or thread was  
 6243 considered because it allowed all blocking services to be timed out in a uniform manner with  
 6244 a single additional interface; this was rather quickly rejected because it could easily result in  
 6245 the wrong services being timed out.

6246 It was suggested that a timeout value might be specified as an attribute of the object  
 6247 (semaphore, mutex, message queue, and so on), but there was no consensus on this, either on  
 6248 a case-by-case basis or for all timeouts.

6249 Looking at the two existing timeouts for blocking services indicates that the working group  
 6250 members favor a separate interface for the timed version of a function. However,  
 6251 *pthread\_cond\_timedwait()* utilizes an absolute timeout value while *sigtimedwait()* uses a  
 6252 relative timeout value. The working group members agreed that relative timeout values are  
 6253 appropriate where the timeout mechanism's primary use was to deal with an unexpected or  
 6254 error situation, but they are inappropriate when the timeout must expire at a particular time,  
 6255 or before a specific deadline. For the timeouts being introduced in IEEE Std 1003.1-2001, the  
 6256 working group considered allowing both relative and absolute timeouts as is done with  
 6257 POSIX.1b timers, but ultimately favored the simpler absolute timeout form.

6258 An absolute time measure can be easily implemented on top of an interface that specifies  
 6259 relative time, by reading the clock, calculating the difference between the current time and  
 6260 the desired wake-up time, and issuing a relative timeout call. But there is a race condition  
 6261 with this approach because the thread could be preempted after reading the clock, but before  
 6262 making the timed-out call; in this case, the thread would be awakened later than it should  
 6263 and, thus, if the wake-up time represented a deadline, it would miss it.

There is also a race condition when trying to build a relative timeout on top of an interface that specifies absolute timeouts. In this case, the clock would have to be read to calculate the absolute wake-up time as the sum of the current time plus the relative timeout interval. In this case, if the thread is preempted after reading the clock but before making the timed-out call, the thread would be awakened earlier than desired.

But the race condition with the absolute timeouts interface is not as bad as the one that happens with the relative timeout interface, because there are simple workarounds. For the absolute timeouts interface, if the timing requirement is a deadline, the deadline can still be met because the thread woke up earlier than the deadline. If the timeout is just used as an error recovery mechanism, the precision of timing is not really important. If the timing requirement is that between actions A and B a minimum interval of time must elapse, the absolute timeout interface can be safely used by reading the clock after action A has been started. It could be argued that, since the call with the absolute timeout is atomic from the application point of view, it is not possible to read the clock after action A, if this action is part of the timed-out call. But looking at the nature of the calls for which timeouts are specified (locking a mutex, waiting for a semaphore, waiting for a message, or waiting until there is space in a message queue), the timeouts that an application would build on these actions would not be triggered by these actions themselves, but by some other external action. For example, if waiting for a message to arrive to a message queue, and waiting for at least 20 milliseconds, this time interval would start to be counted from some event that would trigger both the action that produces the message, as well as the action that waits for the message to arrive, and not by the wait-for-message operation itself. In this case, the workaround proposed above could be used.

For these reasons, the absolute timeout is preferred over the relative timeout interface.

## **B.2.9 Threads**

Threads will normally be more expensive than subroutines (or functions, routines, and so on) if specialized hardware support is not provided. Nevertheless, threads should be sufficiently efficient to encourage their use as a medium to fine-grained structuring mechanism for parallelism in an application. Structuring an application using threads then allows it to take immediate advantage of any underlying parallelism available in the host environment. This means implementors are encouraged to optimize for fast execution at the possible expense of efficient utilization of storage. For example, a common thread creation technique is to cache appropriate thread data structures. That is, rather than releasing system resources, the implementation retains these resources and reuses them when the program next asks to create a new thread. If this reuse of thread resources is to be possible, there has to be very little unique state associated with each thread, because any such state has to be reset when the thread is reused.

### **Thread Creation Attributes**

Attributes objects are provided for threads, mutexes, and condition variables as a mechanism to support probable future standardization in these areas without requiring that the interface itself be changed.

Attributes objects provide clean isolation of the configurable aspects of threads. For example, “stack size” is an important attribute of a thread, but it cannot be expressed portably. When porting a threaded program, stack sizes often need to be adjusted. The use of attributes objects can help by allowing the changes to be isolated in a single place, rather than being spread across every instance of thread creation.

Attributes objects can be used to set up *classes* of threads with similar attributes; for example, “threads with large stacks and high priority” or “threads with minimal stacks”. These classes can be defined in a single place and then referenced wherever threads need to be created. Changes to “class” decisions become straightforward, and detailed analysis of each *pthread\_create()* call is not required.

The attributes objects are defined as opaque types as an aid to extensibility. If these objects had been specified as structures, adding new attributes would force recompilation of all multi-threaded programs when the attributes objects are extended; this might not be possible if different program components were supplied by different vendors.

Additionally, opaque attributes objects present opportunities for improving performance. Argument validity can be checked once when attributes are set, rather than each time a thread is created. Implementations will often need to cache kernel objects that are expensive to create. Opaque attributes objects provide an efficient mechanism to detect when cached objects become invalid due to attribute changes.

Because assignment is not necessarily defined on a given opaque type, implementation-defined default values cannot be defined in a portable way. The solution to this problem is to allow attribute objects to be initialized dynamically by attributes object initialization functions, so that default values can be supplied automatically by the implementation.

The following proposal was provided as a suggested alternative to the supplied attributes:

1. Maintain the style of passing a parameter formed by the bitwise-inclusive OR of flags to the initialization routines (*pthread\_create()*, *pthread\_mutex\_init()*, *pthread\_cond\_init()*). The parameter containing the flags should be an opaque type for extensibility. If no flags are set in the parameter, then the objects are created with default characteristics. An implementation may specify implementation-defined flag values and associated behavior.
2. If further specialization of mutexes and condition variables is necessary, implementations may specify additional procedures that operate on the **pthread\_mutex\_t** and **pthread\_cond\_t** objects (instead of on attributes objects).

The difficulties with this solution are:

1. A bitmask is not opaque if bits have to be set into bit-vector attributes objects using explicitly-coded bitwise-inclusive OR operations. If the set of options exceeds an **int**, application programmers need to know the location of each bit. If bits are set or read by encapsulation (that is, *get\*()* or *set\*()* functions), then the bitmask is merely an implementation of attributes objects as currently defined and should not be exposed to the programmer.
2. Many attributes are not Boolean or very small integral values. For example, scheduling policy may be placed in 3 bits or 4 bits, but priority requires 5 bits or more, thereby taking up at least 8 bits out of a possible 16 bits on machines with 16-bit integers. Because of this, the bitmask can only reasonably control whether particular attributes are set or not, and it cannot serve as the repository of the value itself. The value needs to be specified as a function parameter (which is non-extensible), or by setting a structure field (which is non-opaque), or by *get\*()* and *set\*()* functions (making the bitmask a redundant addition to the attributes objects).

Stack size is defined as an optional attribute because the very notion of a stack is inherently machine-dependent. Some implementations may not be able to change the size of the stack, for example, and others may not need to because stack pages may be discontinuous and can be allocated and released on demand.

The attribute mechanism has been designed in large measure for extensibility. Future extensions to the attribute mechanism or to any attributes object defined in IEEE Std 1003.1-2001 have to be done with care so as not to affect binary-compatibility.

Attribute objects, even if allocated by means of dynamic allocation functions such as *malloc()*, may have their size fixed at compile time. This means, for example, a *pthread\_create()* in an implementation with extensions to the **pthread\_attr\_t** cannot look beyond the area that the binary application assumes is valid. This suggests that implementations should maintain a size field in the attributes object, as well as possibly version information, if extensions in different directions (possibly by different vendors) are to be accommodated.

### Thread Implementation Models

There are various thread implementation models. At one end of the spectrum is the “library-thread model”. In such a model, the threads of a process are not visible to the operating system kernel, and the threads are not kernel-scheduled entities. The process is the only kernel-scheduled entity. The process is scheduled onto the processor by the kernel according to the scheduling attributes of the process. The threads are scheduled onto the single kernel-scheduled entity (the process) by the runtime library according to the scheduling attributes of the threads. A problem with this model is that it constrains concurrency. Since there is only one kernel-scheduled entity (namely, the process), only one thread per process can execute at a time. If the thread that is executing blocks on I/O, then the whole process blocks.

At the other end of the spectrum is the “kernel-thread model”. In this model, all threads are visible to the operating system kernel. Thus, all threads are kernel-scheduled entities, and all threads can concurrently execute. The threads are scheduled onto processors by the kernel according to the scheduling attributes of the threads. The drawback to this model is that the creation and management of the threads entails operating system calls, as opposed to subroutine calls, which makes kernel threads heavier weight than library threads.

Hybrids of these two models are common. A hybrid model offers the speed of library threads and the concurrency of kernel threads. In hybrid models, a process has some (relatively small) number of kernel scheduled entities associated with it. It also has a potentially much larger number of library threads associated with it. Some library threads may be bound to kernel-scheduled entities, while the other library threads are multiplexed onto the remaining kernel-scheduled entities. There are two levels of thread scheduling:

1. The runtime library manages the scheduling of (unbound) library threads onto kernel-scheduled entities.
2. The kernel manages the scheduling of kernel-scheduled entities onto processors.

For this reason, a hybrid model is referred to as a two-level threads scheduling model. In this model, the process can have multiple concurrently executing threads; specifically, it can have as many concurrently executing threads as it has kernel-scheduled entities.

### Thread-Specific Data

Many applications require that a certain amount of context be maintained on a per-thread basis across procedure calls. A common example is a multi-threaded library routine that allocates resources from a common pool and maintains an active resource list for each thread. The thread-specific data interface provided to meet these needs may be viewed as a two-dimensional array of values with keys serving as the row index and thread IDs as the column index (although the implementation need not work this way).

- Models

Three possible thread-specific data models were considered:

1. No Explicit Support

A standard thread-specific data interface is not strictly necessary to support applications that require per-thread context. One could, for example, provide a hash function that converted a **pthread\_t** into an integer value that could then be used to index into a global array of per-thread data pointers. This hash function, in conjunction with *pthread\_self()*, would be all the interface required to support a mechanism of this sort. Unfortunately, this technique is cumbersome. It can lead to duplicated code as each set of cooperating modules implements their own per-thread data management schemes.

2. Single (**void \***) Pointer

Another technique would be to provide a single word of per-thread storage and a pair of functions to fetch and store the value of this word. The word could then hold a pointer to a block of per-thread memory. The allocation, partitioning, and general use of this memory would be entirely up to the application. Although this method is not as problematic as technique 1, it suffers from interoperability problems. For example, all modules using the per-thread pointer would have to agree on a common usage protocol.

3. Key/Value Mechanism

This method associates an opaque key (for example, stored in a variable of type **pthread\_key\_t**) with each per-thread datum. These keys play the role of identifiers for per-thread data. This technique is the most generic and avoids the problems noted above, albeit at the cost of some complexity.

The primary advantage of the third model is its information hiding properties. Modules using this model are free to create and use their own key(s) independent of all other such usage, whereas the other models require that all modules that use thread-specific context explicitly cooperate with all other such modules. The data-independence provided by the third model is worth the additional interface.

- Requirements

It is important that it be possible to implement the thread-specific data interface without the use of thread private memory. To do otherwise would increase the weight of each thread, thereby limiting the range of applications for which the threads interfaces provided by IEEE Std 1003.1-2001 is appropriate.

The values that one binds to the key via *pthread\_setspecific()* may, in fact, be pointers to shared storage locations available to all threads. It is only the key/value bindings that are maintained on a per-thread basis, and these can be kept in any portion of the address space that is reserved for use by the calling thread (for example, on the stack). Thus, no per-thread MMU state is required to implement the interface. On the other hand, there is nothing in the interface specification to preclude the use of a per-thread MMU state if it is available (for example, the key values returned by *pthread\_key\_create()* could be thread private memory addresses).

- Standardization Issues

Thread-specific data is a requirement for a usable thread interface. The binding described in this section provides a portable thread-specific data mechanism for languages that do not directly support a thread-specific storage class. A binding to IEEE Std 1003.1-2001 for a

language that does include such a storage class need not provide this specific interface.

If a language were to include the notion of thread-specific storage, it would be desirable (but *not* required) to provide an implementation of the pthreads thread-specific data interface based on the language feature. For example, assume that a compiler for a C-like language supports a *private* storage class that provides thread-specific storage. Something similar to the following macros might be used to effect a compatible implementation:

```
#define pthread_key_t private void *
#define pthread_key_create(key) /* no-op */
#define pthread_setspecific(key,value) (key)=(value)
#define pthread_getspecific(key) (key)
```

**Note:** For the sake of clarity, this example ignores destructor functions. A correct implementation would have to support them.

## Barriers

- Background

Barriers are typically used in parallel DO/FOR loops to ensure that all threads have reached a particular stage in a parallel computation before allowing any to proceed to the next stage. Highly efficient implementation is possible on machines which support a “Fetch and Add” operation as described in the referenced Almasi and Gottlieb (1989).

The use of return value PTHREAD\_BARRIER\_SERIAL\_THREAD is shown in the following example:

```
if ((status=pthread_barrier_wait(&barrier)) ==
 PTHREAD_BARRIER_SERIAL_THREAD) {
 ...serial section
}
else if (status != 0) {
 ...error processing
}
status=pthread_barrier_wait(&barrier);
...
```

This behavior allows a serial section of code to be executed by one thread as soon as all threads reach the first barrier. The second barrier prevents the other threads from proceeding until the serial section being executed by the one thread has completed.

Although barriers can be implemented with mutexes and condition variables, the referenced Almasi and Gottlieb (1989) provides ample illustration that such implementations are significantly less efficient than is possible. While the relative efficiency of barriers may well vary by implementation, it is important that they be recognized in the IEEE Std 1003.1-2001 to facilitate applications portability while providing the necessary freedom to implementors.

- Lack of Timeout Feature

Alternate versions of most blocking routines have been provided to support watchdog timeouts. No alternate interface of this sort has been provided for barrier waits for the following reasons:

- Multiple threads may use different timeout values, some of which may be indefinite. It is not clear which threads should break through the barrier with a timeout error if and when these timeouts expire.

6490                   • The barrier may become unusable once a thread breaks out of a *pthread\_barrier\_wait()*  
 6491                    with a timeout error. There is, in general, no way to guarantee the consistency of a  
 6492                    barrier's internal data structures once a thread has timed out of a *pthread\_barrier\_wait()*.  
 6493                    Even the inclusion of a special barrier reinitialization function would not help much since  
 6494                    it is not clear how this function would affect the behavior of threads that reach the barrier  
 6495                    between the original timeout and the call to the reinitialization function.

## 6496                   **Spin Locks**

### 6497                   • Background

6498                   Spin locks represent an extremely low-level synchronization mechanism suitable primarily  
 6499                   for use on shared memory multi-processors. It is typically an atomically modified Boolean  
 6500                   value that is set to one when the lock is held and to zero when the lock is freed.

6501                   When a caller requests a spin lock that is already held, it typically spins in a loop testing  
 6502                   whether the lock has become available. Such spinning wastes processor cycles so the lock  
 6503                   should only be held for short durations and not across sleep / block operations. Callers should  
 6504                   unlock spin locks before calling sleep operations.

6505                   Spin locks are available on a variety of systems. The functions included in  
 6506                   IEEE Std 1003.1-2001 are an attempt to standardize that existing practice.

### 6507                   • Lack of Timeout Feature

6508                   Alternate versions of most blocking routines have been provided to support watchdog  
 6509                   timeouts. No alternate interface of this sort has been provided for spin locks for the following  
 6510                   reasons:

6511                   • It is impossible to determine appropriate timeout intervals for spin locks in a portable  
 6512                   manner. The amount of time one can expect to spend spin-waiting is inversely  
 6513                   proportional to the degree of parallelism provided by the system.

6514                   It can vary from a few cycles when each competing thread is running on its own  
 6515                   processor, to an indefinite amount of time when all threads are multiplexed on a single  
 6516                   processor (which is why spin locking is not advisable on uniprocessors).

6517                   • When used properly, the amount of time the calling thread spends waiting on a spin lock  
 6518                   should be considerably less than the time required to set up a corresponding watchdog  
 6519                   timer. Since the primary purpose of spin locks is to provide a low-overhead  
 6520                   synchronization mechanism for multi-processors, the overhead of a timeout mechanism  
 6521                   was deemed unacceptable.

6522                   It was also suggested that an additional *count* argument be provided (on the  
 6523                   *pthread\_spin\_lock()* call) in lieu of a true timeout so that a spin lock call could fail gracefully if  
 6524                   it was unable to apply the lock after *count* attempts. This idea was rejected because it is not  
 6525                   existing practice. Furthermore, the same effect can be obtained with *pthread\_spin\_trylock()*,  
 6526                   as illustrated below:

```

6527 int n = MAX_SPIN;
6528 while (--n >= 0)
6529 {
6530 if (!pthread_spin_try_lock(...))
6531 break;
6532 }
6533 if (n >= 0)
6534 {
6535 /* Successfully acquired the lock */
6536 }
6537 else
6538 {
6539 /* Unable to acquire the lock */
6540 }

```

#### 6541 • *process-shared* Attribute

6542 The initialization functions associated with most POSIX synchronization objects (for  
6543 example, mutexes, barriers, and read-write locks) take an attributes object with a *process-*  
6544 *shared* attribute that specifies whether or not the object is to be shared across processes. In the  
6545 draft corresponding to the first balloting round, two separate initialization functions are  
6546 provided for spin locks, however: one for spin locks that were to be shared across processes  
6547 (*spin\_init()*), and one for locks that were only used by multiple threads within a single  
6548 process (*pthread\_spin\_init()*). This was done so as to keep the overhead associated with spin  
6549 waiting to an absolute minimum. However, the balloting group requested that, since the  
6550 overhead associated to a bit check was small, spin locks should be consistent with the rest of  
6551 the synchronization primitives, and thus the *process-shared* attribute was introduced for spin  
6552 locks.

#### 6553 • Spin Locks versus Mutexes

6554 It has been suggested that mutexes are an adequate synchronization mechanism and spin  
6555 locks are not necessary. Locking mechanisms typically must trade off the processor resources  
6556 consumed while setting up to block the thread and the processor resources consumed by the  
6557 thread while it is blocked. Spin locks require very little resources to set up the blocking of a  
6558 thread. Existing practice is to simply loop, repeating the atomic locking operation until the  
6559 lock is available. While the resources consumed to set up blocking of the thread are low, the  
6560 thread continues to consume processor resources while it is waiting.

6561 On the other hand, mutexes may be implemented such that the processor resources  
6562 consumed to block the thread are large relative to a spin lock. After detecting that the mutex  
6563 lock is not available, the thread must alter its scheduling state, add itself to a set of waiting  
6564 threads, and, when the lock becomes available again, undo all of this before taking over  
6565 ownership of the mutex. However, while a thread is blocked by a mutex, no processor  
6566 resources are consumed.

6567 Therefore, spin locks and mutexes may be implemented to have different characteristics.  
6568 Spin locks may have lower overall overhead for very short-term blocking, and mutexes may  
6569 have lower overall overhead when a thread will be blocked for longer periods of time. The  
6570 presence of both interfaces allows implementations with these two different characteristics,  
6571 both of which may be useful to a particular application.

6572 It has also been suggested that applications can build their own spin locks from the  
6573 *pthread\_mutex\_trylock()* function:

```
6574 while (pthread_mutex_trylock(&mutex));
```

6575 The apparent simplicity of this construct is somewhat deceiving, however. While the actual  
6576 wait is quite efficient, various guarantees on the integrity of mutex objects (for example,  
6577 priority inheritance rules) may add overhead to the successful path of the trylock operation  
6578 that is not required of spin locks. One could, of course, add an attribute to the mutex to  
6579 bypass such overhead, but the very act of finding and testing this attribute represents more  
6580 overhead than is found in the typical spin lock.

6581 The need to hold spin lock overhead to an absolute minimum also makes it impossible to  
6582 provide guarantees against starvation similar to those provided for mutexes or read-write  
6583 locks. The overhead required to implement such guarantees (for example, disabling  
6584 preemption before spinning) may well exceed the overhead of the spin wait itself by many  
6585 orders of magnitude. If a “safe” spin wait seems desirable, it can always be provided (albeit  
6586 at some performance cost) via appropriate mutex attributes.

## 6587 XSI Supported Functions

6588 On XSI-conformant systems, the following symbolic constants are always defined:

```
6589 _POSIX_READER_WRITER_LOCKS
6590 _POSIX_THREAD_ATTR_STACKADDR
6591 _POSIX_THREAD_ATTR_STACKSIZE
6592 _POSIX_THREAD_PROCESS_SHARED
6593 _POSIX_THREADS
```

6594 Therefore, the following threads functions are always supported:

|                                           |                                        |
|-------------------------------------------|----------------------------------------|
| 6595 <i>pthread_atfork()</i>              | <i>pthread_key_create()</i>            |
| 6596 <i>pthread_attr_destroy()</i>        | <i>pthread_key_delete()</i>            |
| 6597 <i>pthread_attr_getdetachstate()</i> | <i>pthread_kill()</i>                  |
| 6598 <i>pthread_attr_getguardsize()</i>   | <i>pthread_mutex_destroy()</i>         |
| 6599 <i>pthread_attr_getschedparam()</i>  | <i>pthread_mutex_init()</i>            |
| 6600 <i>pthread_attr_getstack()</i>       | <i>pthread_mutex_lock()</i>            |
| 6601 <i>pthread_attr_getstackaddr()</i>   | <i>pthread_mutex_trylock()</i>         |
| 6602 <i>pthread_attr_getstacksize()</i>   | <i>pthread_mutex_unlock()</i>          |
| 6603 <i>pthread_attr_init()</i>           | <i>pthread_mutexattr_destroy()</i>     |
| 6604 <i>pthread_attr_setdetachstate()</i> | <i>pthread_mutexattr_getpshared()</i>  |
| 6605 <i>pthread_attr_setguardsize()</i>   | <i>pthread_mutexattr_gettype()</i>     |
| 6606 <i>pthread_attr_setschedparam()</i>  | <i>pthread_mutexattr_init()</i>        |
| 6607 <i>pthread_attr_setstack()</i>       | <i>pthread_mutexattr_setpshared()</i>  |
| 6608 <i>pthread_attr_setstackaddr()</i>   | <i>pthread_mutexattr_settype()</i>     |
| 6609 <i>pthread_attr_setstacksize()</i>   | <i>pthread_once()</i>                  |
| 6610 <i>pthread_cancel()</i>              | <i>pthread_rwlock_destroy()</i>        |
| 6611 <i>pthread_cleanup_pop()</i>         | <i>pthread_rwlock_init()</i>           |
| 6612 <i>pthread_cleanup_push()</i>        | <i>pthread_rwlock_rdlock()</i>         |
| 6613 <i>pthread_cond_broadcast()</i>      | <i>pthread_rwlock_tryrdlock()</i>      |
| 6614 <i>pthread_cond_destroy()</i>        | <i>pthread_rwlock_trywrlock()</i>      |
| 6615 <i>pthread_cond_init()</i>           | <i>pthread_rwlock_unlock()</i>         |
| 6616 <i>pthread_cond_signal()</i>         | <i>pthread_rwlock_wrlock()</i>         |
| 6617 <i>pthread_cond_timedwait()</i>      | <i>pthread_rwlockattr_destroy()</i>    |
| 6618 <i>pthread_cond_wait()</i>           | <i>pthread_rwlockattr_getpshared()</i> |
| 6619 <i>pthread_condattr_destroy()</i>    | <i>pthread_rwlockattr_init()</i>       |

|      |                                      |                                        |
|------|--------------------------------------|----------------------------------------|
| 6620 | <i>pthread_condattr_getpshared()</i> | <i>pthread_rwlockattr_setpshared()</i> |
| 6621 | <i>pthread_condattr_init()</i>       | <i>pthread_self()</i>                  |
| 6622 | <i>pthread_condattr_setpshared()</i> | <i>pthread_setcancelstate()</i>        |
| 6623 | <i>pthread_create()</i>              | <i>pthread_setcanceltype()</i>         |
| 6624 | <i>pthread_detach()</i>              | <i>pthread_setconcurrency()</i>        |
| 6625 | <i>pthread_equal()</i>               | <i>pthread_setspecific()</i>           |
| 6626 | <i>pthread_exit()</i>                | <i>pthread_sigmask()</i>               |
| 6627 | <i>pthread_getconcurrency()</i>      | <i>pthread_testcancel()</i>            |
| 6628 | <i>pthread_getspecific()</i>         | <i>sigwait()</i>                       |
| 6629 | <i>pthread_join()</i>                |                                        |

6630 On XSI-conformant systems, the symbolic constant `_POSIX_THREAD_SAFE_FUNCTIONS` is  
 6631 always defined. Therefore, the following functions are always supported:

|      |                           |                           |
|------|---------------------------|---------------------------|
| 6632 | <i>asctime_r()</i>        | <i>getpwuid_r()</i>       |
| 6633 | <i>ctime_r()</i>          | <i>gmtime_r()</i>         |
| 6634 | <i>flockfile()</i>        | <i>localtime_r()</i>      |
| 6635 | <i>ftrylockfile()</i>     | <i>putc_unlocked()</i>    |
| 6636 | <i>funlockfile()</i>      | <i>putchar_unlocked()</i> |
| 6637 | <i>getc_unlocked()</i>    | <i>rand_r()</i>           |
| 6638 | <i>getchar_unlocked()</i> | <i>readdir_r()</i>        |
| 6639 | <i>getgrgid_r()</i>       | <i>strerror_r()</i>       |
| 6640 | <i>getgrnam_r()</i>       | <i>strtok_r()</i>         |
| 6641 | <i>getpwnam_r()</i>       |                           |

6642 The following threads functions are only supported on XSI-conformant systems if the Realtime  
 6643 Threads Option Group is supported :

|      |                                       |                                           |
|------|---------------------------------------|-------------------------------------------|
| 6644 | <i>pthread_attr_getinheritsched()</i> | <i>pthread_mutex_getprioceiling()</i>     |
| 6645 | <i>pthread_attr_getschedpolicy()</i>  | <i>pthread_mutex_setprioceiling()</i>     |
| 6646 | <i>pthread_attr_getscope()</i>        | <i>pthread_mutexattr_getprioceiling()</i> |
| 6647 | <i>pthread_attr_setinheritsched()</i> | <i>pthread_mutexattr_getprotocol()</i>    |
| 6648 | <i>pthread_attr_setschedpolicy()</i>  | <i>pthread_mutexattr_setprioceiling()</i> |
| 6649 | <i>pthread_attr_setscope()</i>        | <i>pthread_mutexattr_setprotocol()</i>    |
| 6650 | <i>pthread_getschedparam()</i>        | <i>pthread_setschedparam()</i>            |

## 6651 XSI Threads Extensions

6652 The following XSI extensions to POSIX.1c are now supported in IEEE Std 1003.1-2001 as part of  
 6653 the alignment with the Single UNIX Specification:

- 6654 • Extended mutex attribute types
- 6655 • Read-write locks and attributes (also introduced by the IEEE Std 1003.1j-2000 amendment)
- 6656 • Thread concurrency level
- 6657 • Thread stack guard size
- 6658 • Parallel I/O

6659 A total of 19 new functions were added.

6660 These extensions carefully follow the threads programming model specified in POSIX.1c. As  
 6661 with POSIX.1c, all the new functions return zero if successful; otherwise, an error number is

returned to indicate the error.

The concept of attribute objects was introduced in POSIX.1c to allow implementations to extend IEEE Std 1003.1-2001 without changing the existing interfaces. Attribute objects were defined for threads, mutexes, and condition variables. Attributes objects are defined as implementation-defined opaque types to aid extensibility, and functions are defined to allow attributes to be set or retrieved. This model has been followed when adding the new type attribute of **pthread\_mutexattr\_t** or the new read-write lock attributes object **pthread\_rwlockattr\_t**.

- Extended Mutex Attributes

POSIX.1c defines a mutex attributes object as an implementation-defined opaque object of type **pthread\_mutexattr\_t**, and specifies a number of attributes which this object must have and a number of functions which manipulate these attributes. These attributes include *detachstate*, *inheritsched*, *schedparm*, *schedpolicy*, *contentionscope*, *stackaddr*, and *stacksize*.

The System Interfaces volume of IEEE Std 1003.1-2001 specifies another mutex attribute called *type*. The *type* attribute allows applications to specify the behavior of mutex locking operations in situations where POSIX.1c behavior is undefined. The OSF DCE threads implementation, based on Draft 4 of POSIX.1c, specified a similar attribute. Note that the names of the attributes have changed somewhat from the OSF DCE threads implementation.

The System Interfaces volume of IEEE Std 1003.1-2001 also extends the specification of the following POSIX.1c functions which manipulate mutexes:

```
pthread_mutex_lock()
pthread_mutex_trylock()
pthread_mutex_unlock()
```

to take account of the new mutex attribute type and to specify behavior which was declared as undefined in POSIX.1c. How a calling thread acquires or releases a mutex now depends upon the mutex *type* attribute.

The *type* attribute can have the following values:

#### PTHREAD\_MUTEX\_NORMAL

Basic mutex with no specific error checking built in. Does not report a deadlock error.

#### PTHREAD\_MUTEX\_RECURSIVE

Allows any thread to recursively lock a mutex. The mutex must be unlocked an equal number of times to release the mutex.

#### PTHREAD\_MUTEX\_ERRORCHECK

Detects and reports simple usage errors; that is, an attempt to unlock a mutex that is not locked by the calling thread or that is not locked at all, or an attempt to relock a mutex the thread already owns.

#### PTHREAD\_MUTEX\_DEFAULT

The default mutex type. May be mapped to any of the above mutex types or may be an implementation-defined type.

*Normal* mutexes do not detect deadlock conditions; for example, a thread will hang if it tries to relock a normal mutex that it already owns. Attempting to unlock a mutex locked by another thread, or unlocking an unlocked mutex, results in undefined behavior. Normal mutexes will usually be the fastest type of mutex available on a platform but provide the least error checking.

*Recursive* mutexes are useful for converting old code where it is difficult to establish clear boundaries of synchronization. A thread can relock a recursive mutex without first unlocking

it. The relocking deadlock which can occur with normal mutexes cannot occur with this type of mutex. However, multiple locks of a recursive mutex require the same number of unlocks to release the mutex before another thread can acquire the mutex. Furthermore, this type of mutex maintains the concept of an owner. Thus, a thread attempting to unlock a recursive mutex which another thread has locked returns with an error. A thread attempting to unlock a recursive mutex that is not locked returns with an error. Never use a recursive mutex with condition variables because the implicit unlock performed by *pthread\_cond\_wait()* or *pthread\_cond\_timedwait()* will not actually release the mutex if it had been locked multiple times.

*Errorcheck* mutexes provide error checking and are useful primarily as a debugging aid. A thread attempting to relock an errorcheck mutex without first unlocking it returns with an error. Again, this type of mutex maintains the concept of an owner. Thus, a thread attempting to unlock an errorcheck mutex which another thread has locked returns with an error. A thread attempting to unlock an errorcheck mutex that is not locked also returns with an error. It should be noted that errorcheck mutexes will almost always be much slower than normal mutexes due to the extra state checks performed.

The default mutex type provides implementation-defined error checking. The default mutex may be mapped to one of the other defined types or may be something entirely different. This enables each vendor to provide the mutex semantics which the vendor feels will be most useful to their target users. Most vendors will probably choose to make normal mutexes the default so as to give applications the benefit of the fastest type of mutexes available on their platform. Check your implementation's documentation.

An application developer can use any of the mutex types almost interchangeably as long as the application does not depend upon the implementation detecting (or failing to detect) any particular errors. Note that a recursive mutex can be used with condition variable waits as long as the application never recursively locks the mutex.

Two functions are provided for manipulating the *type* attribute of a mutex attributes object. This attribute is set or returned in the *type* parameter of these functions. The *pthread\_mutexattr\_settype()* function is used to set a specific type value while *pthread\_mutexattr\_gettype()* is used to return the type of the mutex. Setting the *type* attribute of a mutex attributes object affects only mutexes initialized using that mutex attributes object. Changing the *type* attribute does not affect mutexes previously initialized using that mutex attributes object.

- Read-Write Locks and Attributes

The read-write locks introduced have been harmonized with those in IEEE Std 1003.1j-2000; see also Section B.2.9.6 (on page 175).

Read-write locks (also known as reader-writer locks) allow a thread to exclusively lock some shared data while updating that data, or allow any number of threads to have simultaneous read-only access to the data.

Unlike a mutex, a read-write lock distinguishes between reading data and writing data. A mutex excludes all other threads. A read-write lock allows other threads access to the data, providing no thread is modifying the data. Thus, a read-write lock is less primitive than either a mutex-condition variable pair or a semaphore.

Application developers should consider using a read-write lock rather than a mutex to protect data that is frequently referenced but seldom modified. Most threads (readers) will be able to read the data without waiting and will only have to block when some other thread (a writer) is in the process of modifying the data. Conversely a thread that wants to change the data is forced to wait until there are no readers. This type of lock is often used to facilitate

parallel access to data on multi-processor platforms or to avoid context switches on single processor platforms where multiple threads access the same data.

If a read-write lock becomes unlocked and there are multiple threads waiting to acquire the write lock, the implementation's scheduling policy determines which thread acquires the read-write lock for writing. If there are multiple threads blocked on a read-write lock for both read locks and write locks, it is unspecified whether the readers or a writer acquire the lock first. However, for performance reasons, implementations often favor writers over readers to avoid potential writer starvation.

A read-write lock object is an implementation-defined opaque object of type **pthread\_rwlock\_t** as defined in **<pthread.h>**. There are two different sorts of locks associated with a read-write lock: a read lock and a write lock.

The *pthread\_rwlockattr\_init()* function initializes a read-write lock attributes object with the default value for all the attributes defined in the implementation. After a read-write lock attributes object has been used to initialize one or more read-write locks, changes to the read-write lock attributes object, including destruction, do not affect previously initialized read-write locks.

Implementations must provide at least the read-write lock attribute *process-shared*. This attribute can have the following values:

**PTHREAD\_PROCESS\_SHARED**  
Any thread of any process that has access to the memory where the read-write lock resides can manipulate the read-write lock.

**PTHREAD\_PROCESS\_PRIVATE**  
Only threads created within the same process as the thread that initialized the read-write lock can manipulate the read-write lock. This is the default value.

The *pthread\_rwlockattr\_setpshared()* function is used to set the *process-shared* attribute of an initialized read-write lock attributes object while the function *pthread\_rwlockattr\_getpshared()* obtains the current value of the *process-shared* attribute.

A read-write lock attributes object is destroyed using the *pthread\_rwlockattr\_destroy()* function. The effect of subsequent use of the read-write lock attributes object is undefined.

A thread creates a read-write lock using the *pthread\_rwlock\_init()* function. The attributes of the read-write lock can be specified by the application developer; otherwise, the default implementation-defined read-write lock attributes are used if the pointer to the read-write lock attributes object is NULL. In cases where the default attributes are appropriate, the **PTHREAD\_RWLOCK\_INITIALIZER** macro can be used to initialize statically allocated read-write locks.

A thread which wants to apply a read lock to the read-write lock can use either *pthread\_rwlock\_rdlock()* or *pthread\_rwlock\_tryrdlock()*. If *pthread\_rwlock\_rdlock()* is used, the thread acquires a read lock if a writer does not hold the write lock and there are no writers blocked on the write lock. If a read lock is not acquired, the calling thread blocks until it can acquire a lock. However, if *pthread\_rwlock\_tryrdlock()* is used, the function returns immediately with the error [EBUSY] if any thread holds a write lock or there are blocked writers waiting for the write lock.

A thread which wants to apply a write lock to the read-write lock can use either of two functions: *pthread\_rwlock\_wrlock()* or *pthread\_rwlock\_trywrlock()*. If *pthread\_rwlock\_wrlock()* is used, the thread acquires the write lock if no other reader or writer threads hold the read-write lock. If the write lock is not acquired, the thread blocks until it can acquire the write lock. However, if *pthread\_rwlock\_trywrlock()* is used, the function returns immediately with

the error [EBUSY] if any thread is holding either a read or a write lock.

The `pthread_rwlock_unlock()` function is used to unlock a read-write lock object held by the calling thread. Results are undefined if the read-write lock is not held by the calling thread. If there are other read locks currently held on the read-write lock object, the read-write lock object remains in the read locked state but without the current thread as one of its owners. If this function releases the last read lock for this read-write lock object, the read-write lock object is put in the unlocked read state. If this function is called to release a write lock for this read-write lock object, the read-write lock object is put in the unlocked state.

- Thread Concurrency Level

On threads implementations that multiplex user threads onto a smaller set of kernel execution entities, the system attempts to create a reasonable number of kernel execution entities for the application upon application startup.

On some implementations, these kernel entities are retained by user threads that block in the kernel. Other implementations do not *timeslice* user threads so that multiple compute-bound user threads can share a kernel thread. On such implementations, some applications may use up all the available kernel execution entities before their user-space threads are used up. The process may be left with user threads capable of doing work for the application but with no way to schedule them.

The `pthread_setconcurrency()` function enables an application to request more kernel entities; that is, specify a desired concurrency level. However, this function merely provides a hint to the implementation. The implementation is free to ignore this request or to provide some other number of kernel entities. If an implementation does not multiplex user threads onto a smaller number of kernel execution entities, the `pthread_setconcurrency()` function has no effect.

The `pthread_setconcurrency()` function may also have an effect on implementations where the kernel mode and user mode schedulers cooperate to ensure that ready user threads are not prevented from running by other threads blocked in the kernel.

The `pthread_getconcurrency()` function always returns the value set by a previous call to `pthread_setconcurrency()`. However, if `pthread_setconcurrency()` was not previously called, this function returns zero to indicate that the threads implementation is maintaining the concurrency level.

- Thread Stack Guard Size

DCE threads introduced the concept of a “thread stack guard size”. Most thread implementations add a region of protected memory to a thread’s stack, commonly known as a “guard region”, as a safety measure to prevent stack pointer overflow in one thread from corrupting the contents of another thread’s stack. The default size of the guard regions attribute is {PAGESIZE} bytes and is implementation-defined.

Some application developers may wish to change the stack guard size. When an application creates a large number of threads, the extra page allocated for each stack may strain system resources. In addition to the extra page of memory, the kernel’s memory manager has to keep track of the different protections on adjoining pages. When this is a problem, the application developer may request a guard size of 0 bytes to conserve system resources by eliminating stack overflow protection.

Conversely an application that allocates large data structures such as arrays on the stack may wish to increase the default guard size in order to detect stack overflow. If a thread allocates two pages for a data array, a single guard page provides little protection against thread stack overflows since the thread can corrupt adjoining memory beyond the guard page.

6849 The System Interfaces volume of IEEE Std 1003.1-2001 defines a new attribute of a thread  
 6850 attributes object; that is, the *guardsize* attribute which allows applications to specify the size  
 6851 of the guard region of a thread's stack.

6852 Two functions are provided for manipulating a thread's stack guard size. The  
 6853 *pthread\_attr\_setguardsize()* function sets the thread *guardsize* attribute, and the  
 6854 *pthread\_attr\_getguardsize()* function retrieves the current value.

6855 An implementation may round up the requested guard size to a multiple of the configurable  
 6856 system variable {PAGESIZE}. In this case, *pthread\_attr\_getguardsize()* returns the guard size  
 6857 specified by the previous *pthread\_attr\_setguardsize()* function call and not the rounded up  
 6858 value.

6859 If an application is managing its own thread stacks using the *stackaddr* attribute, the *guardsize*  
 6860 attribute is ignored and no stack overflow protection is provided. In this case, it is the  
 6861 responsibility of the application to manage stack overflow along with stack allocation.

#### 6862 • Parallel I/O

6863 Suppose two or more threads independently issue read requests on the same file. To read  
 6864 specific data from a file, a thread must first call *lseek()* to seek to the proper offset in the file,  
 6865 and then call *read()* to retrieve the required data. If more than one thread does this at the  
 6866 same time, the first thread may complete its seek call, but before it gets a chance to issue its  
 6867 read call a second thread may complete its seek call, resulting in the first thread accessing  
 6868 incorrect data when it issues its read call. One workaround is to lock the file descriptor while  
 6869 seeking and reading or writing, but this reduces parallelism and adds overhead.

6870 Instead, the System Interfaces volume of IEEE Std 1003.1-2001 provides two functions to  
 6871 make seek/read and seek/write operations atomic. The file descriptor's current offset is  
 6872 unchanged, thus allowing multiple read and write operations to proceed in parallel. This  
 6873 improves the I/O performance of threaded applications. The *pread()* function is used to do  
 6874 an atomic read of data from a file into a buffer. Conversely, the *pwrite()* function does an  
 6875 atomic write of data from a buffer to a file.

#### 6876 B.2.9.1 Thread-Safety

6877 All functions required by IEEE Std 1003.1-2001 need to be thread-safe. Implementations have to  
 6878 provide internal synchronization when necessary in order to achieve this goal. In certain  
 6879 cases—for example, most floating-point implementations—context switch code may have to  
 6880 manage the writable shared state.

6881 While a read from a pipe of {PIPE\_MAX}\*2 bytes may not generate a single atomic and thread-  
 6882 safe stream of bytes, it should generate “several” (individually atomic) thread-safe streams of  
 6883 bytes. Similarly, while reading from a terminal device may not generate a single atomic and  
 6884 thread-safe stream of bytes, it should generate some finite number of (individually atomic) and  
 6885 thread-safe streams of bytes. That is, concurrent calls to read for a pipe, FIFO, or terminal device  
 6886 are not allowed to result in corrupting the stream of bytes or other internal data. However,  
 6887 *read()*, in these cases, is not required to return a single contiguous and atomic stream of bytes.

6888 It is not required that all functions provided by IEEE Std 1003.1-2001 be either async-cancel-safe  
 6889 or async-signal-safe.

6890 As it turns out, some functions are inherently not thread-safe; that is, their interface  
 6891 specifications preclude reentrancy. For example, some functions (such as *asctime()*) return a  
 6892 pointer to a result stored in memory space allocated by the function on a per-process basis. Such  
 6893 a function is not thread-safe, because its result can be overwritten by successive invocations.  
 6894 Other functions, while not inherently non-thread-safe, may be implemented in ways that lead to

them not being thread-safe. For example, some functions (such as *rand()*) store state information (such as a seed value, which survives multiple function invocations) in memory space allocated by the function on a per-process basis. The implementation of such a function is not thread-safe if the implementation fails to synchronize invocations of the function and thus fails to protect the state information. The problem is that when the state information is not protected, concurrent invocations can interfere with one another (for example, applications using *rand()* may see the same seed value).

#### *Thread-Safety and Locking of Existing Functions*

Originally, POSIX.1 was not designed to work in a multi-threaded environment, and some implementations of some existing functions will not work properly when executed concurrently. To provide routines that will work correctly in an environment with threads (“thread-safe”), two problems need to be solved:

1. Routines that maintain or return pointers to static areas internal to the routine (which may now be shared) need to be modified. The routines *ttyname()* and *localtime()* are examples.
2. Routines that access data space shared by more than one thread need to be modified. The *malloc()* function and the *stdio* family routines are examples.

There are a variety of constraints on these changes. The first is compatibility with the existing versions of these functions—non-thread-safe functions will continue to be in use for some time, as the original interfaces are used by existing code. Another is that the new thread-safe versions of these functions represent as small a change as possible over the familiar interfaces provided by the existing non-thread-safe versions. The new interfaces should be independent of any particular threads implementation. In particular, they should be thread-safe without depending on explicit thread-specific memory. Finally, there should be minimal performance penalty due to the changes made to the functions.

It is intended that the list of functions from POSIX.1 that cannot be made thread-safe and for which corrected versions are provided be complete.

#### *Thread-Safety and Locking Solutions*

Many of the POSIX.1 functions were thread-safe and did not change at all. However, some functions (for example, the math functions typically found in **libm**) are not thread-safe because of writable shared global state. For instance, in IEEE Std 754-1985 floating-point implementations, the computation modes and flags are global and shared.

Some functions are not thread-safe because a particular implementation is not reentrant, typically because of a non-essential use of static storage. These require only a new implementation.

Thread-safe libraries are useful in a wide range of parallel (and asynchronous) programming environments, not just within pthreads. In order to be used outside the context of pthreads, however, such libraries still have to use some synchronization method. These could either be independent of the pthread synchronization operations, or they could be a subset of the pthread interfaces. Either method results in thread-safe library implementations that can be used without the rest of pthreads.

Some functions, such as the *stdio* family interface and dynamic memory allocation functions such as *malloc()*, are inter-dependent routines that share resources (for example, buffers) across related calls. These require synchronization to work correctly, but they do not require any change to their external (user-visible) interfaces.

In some cases, such as *getc()* and *putc()*, adding synchronization is likely to create an unacceptable performance impact. In this case, slower thread-safe synchronized functions are to

be provided, but the original, faster (but unsafe) functions (which may be implemented as macros) are retained under new names. Some additional special-purpose synchronization facilities are necessary for these macros to be usable in multi-threaded programs. This also requires changes in `<stdio.h>`.

The other common reason that functions are unsafe is that they return a pointer to static storage, making the functions non-thread-safe. This has to be changed, and there are three natural choices:

1. Return a pointer to thread-specific storage

This could incur a severe performance penalty on those architectures with a costly implementation of the thread-specific data interface.

A variation on this technique is to use `malloc()` to allocate storage for the function output and return a pointer to this storage. This technique may also have an undesirable performance impact, however, and a simplistic implementation requires that the user program explicitly free the storage object when it is no longer needed. This technique is used by some existing POSIX.1 functions. With careful implementation for infrequently used functions, there may be little or no performance or storage penalty, and the maintenance of already-standardized interfaces is a significant benefit.

2. Return the actual value computed by the function

This technique can only be used with functions that return pointers to structures—routines that return character strings would have to wrap their output in an enclosing structure in order to return the output on the stack. There is also a negative performance impact inherent in this solution in that the output value has to be copied twice before it can be used by the calling function: once from the called routine's local buffers to the top of the stack, then from the top of the stack to the assignment target. Finally, many older compilers cannot support this technique due to a historical tendency to use internal static buffers to deliver the results of structure-valued functions.

3. Have the caller pass the address of a buffer to contain the computed value

The only disadvantage of this approach is that extra arguments have to be provided by the calling program. It represents the most efficient solution to the problem, however, and, unlike the `malloc()` technique, it is semantically clear.

There are some routines (often groups of related routines) whose interfaces are inherently non-thread-safe because they communicate across multiple function invocations by means of static memory locations. The solution is to redesign the calls so that they are thread-safe, typically by passing the needed data as extra parameters. Unfortunately, this may require major changes to the interface as well.

A floating-point implementation using IEEE Std 754-1985 is a case in point. A less problematic example is the `rand48` family of pseudo-random number generators. The functions `getgrgid()`, `getgrnam()`, `getpwnam()`, and `getpwuid()` are another such case.

The problems with `errno` are discussed in **Alternative Solutions for Per-Thread `errno`** (on page 92).

Some functions can be thread-safe or not, depending on their arguments. These include the `tmpnam()` and `ctermid()` functions. These functions have pointers to character strings as arguments. If the pointers are not NULL, the functions store their results in the character string; however, if the pointers are NULL, the functions store their results in an area that may be static and thus subject to overwriting by successive calls. These should only be called by multi-thread applications when their arguments are non-NULL.

*Asynchronous Safety and Thread-Safety*

A floating-point implementation has many modes that effect rounding and other aspects of computation. Functions in some math library implementations may change the computation modes for the duration of a function call. If such a function call is interrupted by a signal or cancellation, the floating-point state is not required to be protected.

There is a significant cost to make floating-point operations async-cancel-safe or async-signal-safe; accordingly, neither form of async safety is required.

*Functions Returning Pointers to Static Storage*

For those functions that are not thread-safe because they return values in fixed size statically allocated structures, alternate “\_r” forms are provided that pass a pointer to an explicit result structure. Those that return pointers into library-allocated buffers have forms provided with explicit buffer and length parameters.

For functions that return pointers to library-allocated buffers, it makes sense to provide “\_r” versions that allow the application control over allocation of the storage in which results are returned. This allows the state used by these functions to be managed on an application-specific basis, supporting per-thread, per-process, or other application-specific sharing relationships.

Early proposals had provided “\_r” versions for functions that returned pointers to variable-size buffers without providing a means for determining the required buffer size. This would have made using such functions exceedingly clumsy, potentially requiring iteratively calling them with increasingly larger guesses for the amount of storage required. Hence, *sysconf()* variables have been provided for such functions that return the maximum required buffer size.

Thus, the rule that has been followed by IEEE Std 1003.1-2001 when adapting single-threaded non-thread-safe functions is as follows: all functions returning pointers to library-allocated storage should have “\_r” versions provided, allowing the application control over the storage allocation. Those with variable-sized return values accept both a buffer address and a length parameter. The *sysconf()* variables are provided to supply the appropriate buffer sizes when required. Implementors are encouraged to apply the same rule when adapting their own existing functions to a pthreads environment.

*B.2.9.2 Thread IDs*

Separate applications should communicate through well-defined interfaces and should not depend on each other's implementation. For example, if a programmer decides to rewrite the *sort* utility using multiple threads, it should be easy to do this so that the interface to the *sort* utility does not change. Consider that if the user causes SIGINT to be generated while the *sort* utility is running, keeping the same interface means that the entire *sort* utility is killed, not just one of its threads. As another example, consider a realtime application that manages a reactor. Such an application may wish to allow other applications to control the priority at which it watches the control rods. One technique to accomplish this is to write the ID of the thread watching the control rods into a file and allow other programs to change the priority of that thread as they see fit. A simpler technique is to have the reactor process accept IPCs (Interprocess Communication messages) from other processes, telling it at a semantic level what priority the program should assign to watching the control rods. This allows the programmer greater flexibility in the implementation. For example, the programmer can change the implementation from having one thread per rod to having one thread watching all of the rods without changing the interface. Having threads live inside the process means that the implementation of a process is invisible to outside processes (excepting debuggers and system management tools).

Threads do not provide a protection boundary. Every thread model allows threads to share memory with other threads and encourages this sharing to be widespread. This means that one

7034 thread can wipe out memory that is needed for the correct functioning of other threads that are  
7035 sharing its memory. Consequently, providing each thread with its own user and/or group IDs  
7036 would not provide a protection boundary between threads sharing memory.

### 7037 B.2.9.3 Thread Mutexes

7038 There is no additional rationale provided for this section.

### 7039 B.2.9.4 Thread Scheduling

#### 7040 • Scheduling Implementation Models

7041 The following scheduling implementation models are presented in terms of threads and  
7042 “kernel entities”. This is to simplify exposition of the models, and it does not imply that an  
7043 implementation actually has an identifiable “kernel entity”.

7044 A kernel entity is not defined beyond the fact that it has scheduling attributes that are used to  
7045 resolve contention with other kernel entities for execution resources. A kernel entity may be  
7046 thought of as an envelope that holds a thread or a separate kernel thread. It is not a  
7047 conventional process, although it shares with the process the attribute that it has a single  
7048 thread of control; it does not necessarily imply an address space, open files, and so on. It is  
7049 better thought of as a primitive facility upon which conventional processes and threads may  
7050 be constructed.

#### 7051 — System Thread Scheduling Model

7052 This model consists of one thread per kernel entity. The kernel entity is solely responsible  
7053 for scheduling thread execution on one or more processors. This model schedules all  
7054 threads against all other threads in the system using the scheduling attributes of the  
7055 thread.

#### 7056 — Process Scheduling Model

7057 A generalized process scheduling model consists of two levels of scheduling. A threads  
7058 library creates a pool of kernel entities, as required, and schedules threads to run on them  
7059 using the scheduling attributes of the threads. Typically, the size of the pool is a function  
7060 of the simultaneously runnable threads, not the total number of threads. The kernel then  
7061 schedules the kernel entities onto processors according to their scheduling attributes,  
7062 which are managed by the threads library. This set model potentially allows a wide range  
7063 of mappings between threads and kernel entities.

#### 7064 • System and Process Scheduling Model Performance

7065 There are a number of important implications on the performance of applications using these  
7066 scheduling models. The process scheduling model potentially provides lower overhead for  
7067 making scheduling decisions, since there is no need to access kernel-level information or  
7068 functions and the set of schedulable entities is smaller (only the threads within the process).

7069 On the other hand, since the kernel is also making scheduling decisions regarding the system  
7070 resources under its control (for example, CPU(s), I/O devices, memory), decisions that do  
7071 not take thread scheduling parameters into account can result in unspecified delays for  
7072 realtime application threads, causing them to miss maximum response time limits.

#### 7073 • Rate Monotonic Scheduling

7074 Rate monotonic scheduling was considered, but rejected for standardization in the context of  
7075 pthreads. A sporadic server policy is included.

- Scheduling Options

In IEEE Std 1003.1-2001, the basic thread scheduling functions are defined under the Threads option, so that they are required of all threads implementations. However, there are no specific scheduling policies required by this option to allow for conforming thread implementations that are not targeted to realtime applications.

Specific standard scheduling policies are defined to be under the Thread Execution Scheduling option, and they are specifically designed to support realtime applications by providing predictable resource-sharing sequences. The name of this option was chosen to emphasize that this functionality is defined as appropriate for realtime applications that require simple priority-based scheduling.

It is recognized that these policies are not necessarily satisfactory for some multi-processor implementations, and work is ongoing to address a wider range of scheduling behaviors. The interfaces have been chosen to create abundant opportunity for future scheduling policies to be implemented and standardized based on this interface. In order to standardize a new scheduling policy, all that is required (from the standpoint of thread scheduling attributes) is to define a new policy name, new members of the thread attributes object, and functions to set these members when the scheduling policy is equal to the new value.

### **Scheduling Contention Scope**

In order to accommodate the requirement for realtime response, each thread has a scheduling contention scope attribute. Threads with a system scheduling contention scope have to be scheduled with respect to all other threads in the system. These threads are usually bound to a single kernel entity that reflects their scheduling attributes and are directly scheduled by the kernel.

Threads with a process scheduling contention scope need be scheduled only with respect to the other threads in the process. These threads may be scheduled within the process onto a pool of kernel entities. The implementation is also free to bind these threads directly to kernel entities and let them be scheduled by the kernel. Process scheduling contention scope allows the implementation the most flexibility and is the default if both contention scopes are supported and none is specified.

Thus, the choice by implementors to provide one or the other (or both) of these scheduling models is driven by the need of their supported application domains for worst-case (that is, realtime) response, or average-case (non-realtime) response.

### **Scheduling Allocation Domain**

The SCHED\_FIFO and SCHED\_RR scheduling policies take on different characteristics on a multi-processor. Other scheduling policies are also subject to changed behavior when executed on a multi-processor. The concept of scheduling allocation domain determines the set of processors on which the threads of an application may run. By considering the application's processor scheduling allocation domain for its threads, scheduling policies can be defined in terms of their behavior for varying processor scheduling allocation domain values. It is conceivable that not all scheduling allocation domain sizes make sense for all scheduling policies on all implementations. The concept of scheduling allocation domain, however, is a useful tool for the description of multi-processor scheduling policies.

The “process control” approach to scheduling obtains significant performance advantages from dynamic scheduling allocation domain sizes when it is applicable.

Non-Uniform Memory Access (NUMA) multi-processors may use a system scheduling structure that involves reassignment of threads among scheduling allocation domains. In NUMA

machines, a natural model of scheduling is to match scheduling allocation domains to clusters of processors. Load balancing in such an environment requires changing the scheduling allocation domain to which a thread is assigned.

### **Scheduling Documentation**

Implementation-provided scheduling policies need to be completely documented in order to be useful. This documentation includes a description of the attributes required for the policy, the scheduling interaction of threads running under this policy and all other supported policies, and the effects of all possible values for processor scheduling allocation domain. Note that for the implementor wishing to be minimally-compliant, it is (minimally) acceptable to define the behavior as undefined.

### **Scheduling Contention Scope Attribute**

The scheduling contention scope defines how threads compete for resources. Within IEEE Std 1003.1-2001, scheduling contention scope is used to describe only how threads are scheduled in relation to one another in the system. That is, either they are scheduled against all other threads in the system (“system scope”) or only against those threads in the process (“process scope”). In fact, scheduling contention scope may apply to additional resources, including virtual timers and profiling, which are not currently considered by IEEE Std 1003.1-2001.

### **Mixed Scopes**

If only one scheduling contention scope is supported, the scheduling decision is straightforward. To perform the processor scheduling decision in a mixed scope environment, it is necessary to map the scheduling attributes of the thread with process-wide contention scope to the same attribute space as the thread with system-wide contention scope.

Since a conforming implementation has to support one and may support both scopes, it is useful to discuss the effects of such choices with respect to example applications. If an implementation supports both scopes, mixing scopes provides a means of better managing system-level (that is, kernel-level) and library-level resources. In general, threads with system scope will require the resources of a separate kernel entity in order to guarantee the scheduling semantics. On the other hand, threads with process scope can share the resources of a kernel entity while maintaining the scheduling semantics.

The application is free to create threads with dedicated kernel resources, and other threads that multiplex kernel resources. Consider the example of a window server. The server allocates two threads per widget: one thread manages the widget user interface (including drawing), while the other thread takes any required application action. This allows the widget to be “active” while the application is computing. A screen image may be built from thousands of widgets. If each of these threads had been created with system scope, then most of the kernel-level resources might be wasted, since only a few widgets are active at any one time. In addition, mixed scope is particularly useful in a window server where one thread with high priority and system scope handles the mouse so that it tracks well. As another example, consider a database server. For each of the hundreds or thousands of clients supported by a large server, an equivalent number of threads will have to be created. If each of these threads were system scope, the consequences would be the same as for the window server example above. However, the server could be constructed so that actual retrieval of data is done by several dedicated threads. Dedicated threads that do work for all clients frequently justify the added expense of system scope. If it were not permissible to mix system and process threads in the same process, this type of solution would not be possible.

**Dynamic Thread Scheduling Parameters Access**

In many time-constrained applications, there is no need to change the scheduling attributes dynamically during thread or process execution, since the general use of these attributes is to reflect directly the time constraints of the application. Since these time constraints are generally imposed to meet higher-level system requirements, such as accuracy or availability, they frequently should remain unchanged during application execution.

However, there are important situations in which the scheduling attributes should be changed. Generally, this will occur when external environmental conditions exist in which the time constraints change. Consider, for example, a space vehicle major mode change, such as the change from ascent to descent mode, or the change from the space environment to the atmospheric environment. In such cases, the frequency with which many of the sensors or actuators need to be read or written will change, which will necessitate a priority change. In other cases, even the existence of a time constraint might be temporary, necessitating not just a priority change, but also a policy change for ongoing threads or processes. For this reason, it is critical that the interface should provide functions to change the scheduling parameters dynamically, but, as with many of the other realtime functions, it is important that applications use them properly to avoid the possibility of unnecessarily degrading performance.

In providing functions for dynamically changing the scheduling behavior of threads, there were two options: provide functions to get and set the individual scheduling parameters of threads, or provide a single interface to get and set all the scheduling parameters for a given thread simultaneously. Both approaches have merit. Access functions for individual parameters allow simpler control of thread scheduling for simple thread scheduling parameters. However, a single function for setting all the parameters for a given scheduling policy is required when first setting that scheduling policy. Since the single all-encompassing functions are required, it was decided to leave the interface as minimal as possible. Note that simpler functions (such as *pthread\_setprio()* for threads running under the priority-based schedulers) can be easily defined in terms of the all-encompassing functions.

If the *pthread\_setschedparam()* function executes successfully, it will have set all of the scheduling parameter values indicated in *param*; otherwise, none of the scheduling parameters will have been modified. This is necessary to ensure that the scheduling of this and all other threads continues to be consistent in the presence of an erroneous scheduling parameter.

The [EPERM] error value is included in the list of possible *pthread\_setschedparam()* error returns as a reflection of the fact that the ability to change scheduling parameters increases risks to the implementation and application performance if the scheduling parameters are changed improperly. For this reason, and based on some existing practice, it was felt that some implementations would probably choose to define specific permissions for changing either a thread's own or another thread's scheduling parameters. IEEE Std 1003.1-2001 does not include portable methods for setting or retrieving permissions, so any such use of permissions is completely unspecified.

**Mutex Initialization Scheduling Attributes**

In a priority-driven environment, a direct use of traditional primitives like mutexes and condition variables can lead to unbounded priority inversion, where a higher priority thread can be blocked by a lower priority thread, or set of threads, for an unbounded duration of time. As a result, it becomes impossible to guarantee thread deadlines. Priority inversion can be bounded and minimized by the use of priority inheritance protocols. This allows thread deadlines to be guaranteed even in the presence of synchronization requirements.

Two useful but simple members of the family of priority inheritance protocols are the basic priority inheritance protocol and the priority ceiling protocol emulation. Under the Basic Priority

7216 Inheritance protocol (governed by the Thread Priority Inheritance option), a thread that is  
 7217 blocking higher priority threads executes at the priority of the highest priority thread that it  
 7218 blocks. This simple mechanism allows priority inversion to be bounded by the duration of  
 7219 critical sections and makes timing analysis possible.

7220 Under the Priority Ceiling Protocol Emulation protocol (governed by the Thread Priority  
 7221 Protection option), each mutex has a priority ceiling, usually defined as the priority of the  
 7222 highest priority thread that can lock the mutex. When a thread is executing inside critical  
 7223 sections, its priority is unconditionally increased to the highest of the priority ceilings of all the  
 7224 mutexes owned by the thread. This protocol has two very desirable properties in uni-processor  
 7225 systems. First, a thread can be blocked by a lower priority thread for at most the duration of one  
 7226 single critical section. Furthermore, when the protocol is correctly used in a single processor, and  
 7227 if threads do not become blocked while owning mutexes, mutual deadlocks are prevented.

7228 The priority ceiling emulation can be extended to multiple processor environments, in which  
 7229 case the values of the priority ceilings will be assigned depending on the kind of mutex that is  
 7230 being used: local to only one processor, or global, shared by several processors. Local priority  
 7231 ceilings will be assigned the usual way, equal to the priority of the highest priority thread that  
 7232 may lock that mutex. Global priority ceilings will usually be assigned a priority level higher than  
 7233 all the priorities assigned to any of the threads that reside in the involved processors to avoid the  
 7234 effect called remote blocking.

#### 7235 **Change the Priority Ceiling of a Mutex**

7236 In order for the priority protect protocol to exhibit its desired properties of bounding priority  
 7237 inversion and avoidance of deadlock, it is critical that the ceiling priority of a mutex be the same  
 7238 as the priority of the highest thread that can ever hold it, or higher. Thus, if the priorities of the  
 7239 threads using such mutexes never change dynamically, there is no need ever to change the  
 7240 priority ceiling of a mutex.

7241 However, if a major system mode change results in an altered response time requirement for one  
 7242 or more application threads, their priority has to change to reflect it. It will occasionally be the  
 7243 case that the priority ceilings of mutexes held also need to change. While changing priority  
 7244 ceilings should generally be avoided, it is important that IEEE Std 1003.1-2001 provide these  
 7245 interfaces for those cases in which it is necessary.

#### 7246 **B.2.9.5 Thread Cancellation**

7247 Many existing threads packages have facilities for canceling an operation or canceling a thread.  
 7248 These facilities are used for implementing user requests (such as the CANCEL button in a  
 7249 window-based application), for implementing OR parallelism (for example, telling the other  
 7250 threads to stop working once one thread has found a forced mate in a parallel chess program), or  
 7251 for implementing the ABORT mechanism in Ada.

7252 POSIX programs traditionally have used the signal mechanism combined with either *longjmp()*  
 7253 or polling to cancel operations. Many POSIX programmers have trouble using these facilities to  
 7254 solve their problems efficiently in a single-threaded process. With the introduction of threads,  
 7255 these solutions become even more difficult to use.

7256 The main issues with implementing a cancellation facility are specifying the operation to be  
 7257 canceled, cleanly releasing any resources allocated to that operation, controlling when the target  
 7258 notices that it has been canceled, and defining the interaction between asynchronous signals and  
 7259 cancellation.

## Specifying the Operation to Cancel

Consider a thread that calls through five distinct levels of program abstraction and then, inside the lowest-level abstraction, calls a function that suspends the thread. (An abstraction boundary is a layer at which the client of the abstraction sees only the service being provided and can remain ignorant of the implementation. Abstractions are often layered, each level of abstraction being a client of the lower-level abstraction and implementing a higher-level abstraction.) Depending on the semantics of each abstraction, one could imagine wanting to cancel only the call that causes suspension, only the bottom two levels, or the operation being done by the entire thread. Canceling operations at a finer grain than the entire thread is difficult because threads are active and they may be run in parallel on a multi-processor. By the time one thread can make a request to cancel an operation, the thread performing the operation may have completed that operation and gone on to start another operation whose cancellation is not desired. Thread IDs are not reused until the thread has exited, and either it was created with the *Attr detachstate* attribute set to *PTHREAD\_CREATE\_DETACHED* or the *pthread\_join()* or *pthread\_detach()* function has been called for that thread. Consequently, a thread cancellation will never be misdirected when the thread terminates. For these reasons, the canceling of operations is done at the granularity of the thread. Threads are designed to be inexpensive enough so that a separate thread may be created to perform each separately cancelable operation; for example, each possibly long running user request.

For cancellation to be used in existing code, cancellation scopes and handlers will have to be established for code that needs to release resources upon cancellation, so that it follows the programming discipline described in the text.

## A Special Signal Versus a Special Interface

Two different mechanisms were considered for providing the cancellation interfaces. The first was to provide an interface to direct signals at a thread and then to define a special signal that had the required semantics. The other alternative was to use a special interface that delivered the correct semantics to the target thread.

The solution using signals produced a number of problems. It required the implementation to provide cancellation in terms of signals whereas a perfectly valid (and possibly more efficient) implementation could have both layered on a low-level set of primitives. There were so many exceptions to the special signal (it cannot be used with *kill()*, no POSIX.1 interfaces can be used with it) that it was clearly not a valid signal. Its semantics on delivery were also completely different from any existing POSIX.1 signal. As such, a special interface that did not mandate the implementation and did not confuse the semantics of signals and cancellation was felt to be the better solution.

## Races Between Cancellation and Resuming Execution

Due to the nature of cancellation, there is generally no synchronization between the thread requesting the cancellation of a blocked thread and events that may cause that thread to resume execution. For this reason, and because excess serialization hurts performance, when both an event that a thread is waiting for has occurred and a cancellation request has been made and cancellation is enabled, IEEE Std 1003.1-2001 explicitly allows the implementation to choose between returning from the blocking call or acting on the cancellation request.

## Interaction of Cancellation with Asynchronous Signals

A typical use of cancellation is to acquire a lock on some resource and to establish a cancellation cleanup handler for releasing the resource when and if the thread is canceled.

A correct and complete implementation of cancellation in the presence of asynchronous signals requires considerable care. An implementation has to push a cancellation cleanup handler on the cancellation cleanup stack while maintaining the integrity of the stack data structure. If an asynchronously-generated signal is posted to the thread during a stack operation, the signal handler cannot manipulate the cancellation cleanup stack. As a consequence, asynchronous signal handlers may not cancel threads or otherwise manipulate the cancellation state of a thread. Threads may, of course, be canceled by another thread that used a *sigwait()* function to wait synchronously for an asynchronous signal.

In order for cancellation to function correctly, it is required that asynchronous signal handlers not change the cancellation state. This requires that some elements of existing practice, such as using *longjmp()* to exit from an asynchronous signal handler implicitly, be prohibited in cases where the integrity of the cancellation state of the interrupt thread cannot be ensured.

## Thread Cancellation Overview

### • Cancelability States

The three possible cancelability states (disabled, deferred, and asynchronous) are encoded into two separate bits ((disable, enable) and (deferred, asynchronous)) to allow them to be changed and restored independently. For instance, short code sequences that will not block sometimes disable cancelability on entry and restore the previous state upon exit. Likewise, long or unbounded code sequences containing no convenient explicit cancellation points will sometimes set the cancelability type to asynchronous on entry and restore the previous value upon exit.

### • Cancellation Points

Cancellation points are points inside of certain functions where a thread has to act on any pending cancellation request when cancelability is enabled, if the function would block. As with checking for signals, operations need only check for pending cancellation requests when the operation is about to block indefinitely.

The idea was considered of allowing implementations to define whether blocking calls such as *read()* should be cancellation points. It was decided that it would adversely affect the design of conforming applications if blocking calls were not cancellation points because threads could be left blocked in an uncancelable state.

There are several important blocking routines that are specifically not made cancellation points:

— *pthread\_mutex\_lock()*

If *pthread\_mutex\_lock()* were a cancellation point, every routine that called it would also become a cancellation point (that is, any routine that touched shared state would automatically become a cancellation point). For example, *malloc()*, *free()*, and *rand()* would become cancellation points under this scheme. Having too many cancellation points makes programming very difficult, leading to either much disabling and restoring of cancelability or much difficulty in trying to arrange for reliable cleanup at every possible place.

Since *pthread\_mutex\_lock()* is not a cancellation point, threads could result in being blocked uninterruptibly for long periods of time if mutexes were used as a general

synchronization mechanism. As this is normally not acceptable, mutexes should only be used to protect resources that are held for small fixed lengths of time where not being able to be canceled will not be a problem. Resources that need to be held exclusively for long periods of time should be protected with condition variables.

— `pthread_barrier_wait()`

Canceled a barrier wait will render a barrier unusable. Similar to a barrier timeout (which the standard developers rejected), there is no way to guarantee the consistency of a barrier's internal data structures if a barrier wait is canceled.

— `pthread_spin_lock()`

As with mutexes, spin locks should only be used to protect resources that are held for small fixed lengths of time where not being cancelable will not be a problem.

Every library routine should specify whether or not it includes any cancellation points. Typically, only those routines that may block or compute indefinitely need to include cancellation points.

Correctly coded routines only reach cancellation points after having set up a cancellation cleanup handler to restore invariants if the thread is canceled at that point. Being cancelable only at specified cancellation points allows programmers to keep track of actions needed in a cancellation cleanup handler more easily. A thread should only be made asynchronously cancelable when it is not in the process of acquiring or releasing resources or otherwise in a state from which it would be difficult or impossible to recover.

#### • Thread Cancellation Cleanup Handlers

The cancellation cleanup handlers provide a portable mechanism, easy to implement, for releasing resources and restoring invariants. They are easier to use than signal handlers because they provide a stack of cancellation cleanup handlers rather than a single handler, and because they have an argument that can be used to pass context information to the handler.

The alternative to providing these simple cancellation cleanup handlers (whose only use is for cleaning up when a thread is canceled) is to define a general exception package that could be used for handling and cleaning up after hardware traps and software-detected errors. This was too far removed from the charter of providing threads to handle asynchrony. However, it is an explicit goal of IEEE Std 1003.1-2001 to be compatible with existing exception facilities and languages having exceptions.

The interaction of this facility and other procedure-based or language-level exception facilities is unspecified in this version of IEEE Std 1003.1-2001. However, it is intended that it be possible for an implementation to define the relationship between these cancellation cleanup handlers and Ada, C++, or other language-level exception handling facilities.

It was suggested that the cancellation cleanup handlers should also be called when the process exits or calls the `exec` function. This was rejected partly due to the performance problem caused by having to call the cancellation cleanup handlers of every thread before the operation could continue. The other reason was that the only state expected to be cleaned up by the cancellation cleanup handlers would be the intraprocess state. Any handlers that are to clean up the interprocess state would be registered with `atexit()`. There is the orthogonal problem that the `exec` functions do not honor the `atexit()` handlers, but resolving this is beyond the scope of IEEE Std 1003.1-2001.

- Async-Cancel Safety

A function is said to be async-cancel-safe if it is written in such a way that entering the function with asynchronous cancelability enabled will not cause any invariants to be violated, even if a cancellation request is delivered at any arbitrary instruction. Functions that are async-cancel-safe are often written in such a way that they need to acquire no resources for their operation and the visible variables that they may write are strictly limited.

Any routine that gets a resource as a side effect cannot be made async-cancel-safe (for example, `malloc()`). If such a routine were called with asynchronous cancelability enabled, it might acquire the resource successfully, but as it was returning to the client, it could act on a cancellation request. In such a case, the application would have no way of knowing whether the resource was acquired or not.

Indeed, because many interesting routines cannot be made async-cancel-safe, most library routines in general are not async-cancel-safe. Every library routine should specify whether or not it is async-cancel safe so that programmers know which routines can be called from code that is asynchronously cancelable.

IEEE Std 1003.1-2001/Cor 1-2002, item XSH/TC1/D6/8 is applied, adding the `pselect()` function to the list of functions with cancellation points.

#### B.2.9.6 Thread Read-Write Locks

##### Background

Read-write locks are often used to allow parallel access to data on multi-processors, to avoid context switches on uni-processors when multiple threads access the same data, and to protect data structures that are frequently accessed (that is, read) but rarely updated (that is, written). The in-core representation of a file system directory is a good example of such a data structure. One would like to achieve as much concurrency as possible when searching directories, but limit concurrent access when adding or deleting files.

Although read-write locks can be implemented with mutexes and condition variables, such implementations are significantly less efficient than is possible. Therefore, this synchronization primitive is included in IEEE Std 1003.1-2001 for the purpose of allowing more efficient implementations in multi-processor systems.

##### Queuing of Waiting Threads

The `pthread_rwlock_unlock()` function description states that one writer or one or more readers must acquire the lock if it is no longer held by any thread as a result of the call. However, the function does not specify which thread(s) acquire the lock, unless the Thread Execution Scheduling option is supported.

The standard developers considered the issue of scheduling with respect to the queuing of threads blocked on a read-write lock. The question turned out to be whether IEEE Std 1003.1-2001 should require priority scheduling of read-write locks for threads whose execution scheduling policy is priority-based (for example, `SCHED_FIFO` or `SCHED_RR`). There are tradeoffs between priority scheduling, the amount of concurrency achievable among readers, and the prevention of writer and/or reader starvation.

For example, suppose one or more readers hold a read-write lock and the following threads request the lock in the listed order:

7433 pthread\_rwlock\_wrlock() - Low priority thread writer\_a  
 7434 pthread\_rwlock\_rdlock() - High priority thread reader\_a  
 7435 pthread\_rwlock\_rdlock() - High priority thread reader\_b  
 7436 pthread\_rwlock\_rdlock() - High priority thread reader\_c

7437 When the lock becomes available, should *writer\_a* block the high priority readers? Or, suppose a  
 7438 read-write lock becomes available and the following are queued:

7439 pthread\_rwlock\_rdlock() - Low priority thread reader\_a  
 7440 pthread\_rwlock\_rdlock() - Low priority thread reader\_b  
 7441 pthread\_rwlock\_rdlock() - Low priority thread reader\_c  
 7442 pthread\_rwlock\_wrlock() - Medium priority thread writer\_a  
 7443 pthread\_rwlock\_rdlock() - High priority thread reader\_d

7444 If priority scheduling is applied then *reader\_d* would acquire the lock and *writer\_a* would block  
 7445 the remaining readers. But should the remaining readers also acquire the lock to increase  
 7446 concurrency? The solution adopted takes into account that when the Thread Execution  
 7447 Scheduling option is supported, high priority threads may in fact starve low priority threads (the  
 7448 application developer is responsible in this case for designing the system in such a way that this  
 7449 starvation is avoided). Therefore, IEEE Std 1003.1-2001 specifies that high priority readers take  
 7450 precedence over lower priority writers. However, to prevent writer starvation from threads of  
 7451 the same or lower priority, writers take precedence over readers of the same or lower priority.

7452 Priority inheritance mechanisms are non-trivial in the context of read-write locks. When a high  
 7453 priority writer is forced to wait for multiple readers, for example, it is not clear which subset of  
 7454 the readers should inherit the writer's priority. Furthermore, the internal data structures that  
 7455 record the inheritance must be accessible to all readers, and this implies some sort of  
 7456 serialization that could negate any gain in parallelism achieved through the use of multiple  
 7457 readers in the first place. Finally, existing practice does not support the use of priority  
 7458 inheritance for read-write locks. Therefore, no specification of priority inheritance or priority  
 7459 ceiling is attempted. If reliable priority-scheduled synchronization is absolutely required, it can  
 7460 always be obtained through the use of mutexes.

## 7461 **Comparison to *fcntl()* Locks**

7462 The read-write locks and the *fcntl()* locks in IEEE Std 1003.1-2001 share a common goal:  
 7463 increasing concurrency among readers, thus increasing throughput and decreasing delay.

7464 However, the read-write locks have two features not present in the *fcntl()* locks. First, under  
 7465 priority scheduling, read-write locks are granted in priority order. Second, also under priority  
 7466 scheduling, writer starvation is prevented by giving writers preference over readers of equal or  
 7467 lower priority.

7468 Also, read-write locks can be used in systems lacking a file system, such as those conforming to  
 7469 the minimal realtime system profile of IEEE Std 1003.13-1998.

## 7470 **History of Resolution Issues**

7471 Based upon some balloting objections, early drafts specified the behavior of threads waiting on a  
 7472 read-write lock during the execution of a signal handler, as if the thread had not called the lock  
 7473 operation. However, this specified behavior would require implementations to establish  
 7474 internal signal handlers even though this situation would be rare, or never happen for many  
 7475 programs. This would introduce an unacceptable performance hit in comparison to the little  
 7476 additional functionality gained. Therefore, the behavior of read-write locks and signals was  
 7477 reverted back to its previous mutex-like specification.

7478 *B.2.9.7 Thread Interactions with Regular File Operations*

7479 There is no additional rationale provided for this section.

7480 **B.2.10 Sockets**

7481 The base document for the sockets interfaces in IEEE Std 1003.1-2001 is the XNS, Issue 5.2  
7482 specification. This was primarily chosen as it aligns with IPv6. Additional material has been  
7483 added from IEEE Std 1003.1g-2000, notably socket concepts, raw sockets, the *pselect()* function,  
7484 the *socketmark()* function, and the `<sys/select.h>` header.

7485 *B.2.10.1 Address Families*

7486 There is no additional rationale provided for this section.

7487 *B.2.10.2 Addressing*

7488 There is no additional rationale provided for this section.

7489 *B.2.10.3 Protocols*

7490 There is no additional rationale provided for this section.

7491 *B.2.10.4 Routing*

7492 There is no additional rationale provided for this section.

7493 *B.2.10.5 Interfaces*

7494 There is no additional rationale provided for this section.

7495 *B.2.10.6 Socket Types*

7496 The type **socklen\_t** was invented to cover the range of implementations seen in the field. The  
7497 intent of **socklen\_t** is to be the type for all lengths that are naturally bounded in size; that is, that  
7498 they are the length of a buffer which cannot sensibly become of massive size: network addresses,  
7499 host names, string representations of these, ancillary data, control messages, and socket options  
7500 are examples. Truly boundless sizes are represented by **size\_t** as in *read()*, *write()*, and so on.

7501 All **socklen\_t** types were originally (in BSD UNIX) of type **int**. During the development of  
7502 IEEE Std 1003.1-2001, it was decided to change all buffer lengths to **size\_t**, which appears at face  
7503 value to make sense. When dual mode 32/64-bit systems came along, this choice unnecessarily  
7504 complicated system interfaces because **size\_t** (with **long**) was a different size under ILP32 and  
7505 LP64 models. Reverting to **int** would have happened except that some implementations had  
7506 already shipped 64-bit-only interfaces. The compromise was a type which could be defined to be  
7507 any size by the implementation: **socklen\_t**.

7508 *B.2.10.7 Socket I/O Mode*

7509 There is no additional rationale provided for this section.

7510 *B.2.10.8 Socket Owner*

7511 There is no additional rationale provided for this section.

7512 *B.2.10.9 Socket Queue Limits*

7513 There is no additional rationale provided for this section.

7514 *B.2.10.10 Pending Error*

7515 There is no additional rationale provided for this section.

7516 *B.2.10.11 Socket Receive Queue*

7517 There is no additional rationale provided for this section.

7518 *B.2.10.12 Socket Out-of-Band Data State*

7519 There is no additional rationale provided for this section.

7520 *B.2.10.13 Connection Indication Queue*

7521 There is no additional rationale provided for this section.

7522 *B.2.10.14 Signals*

7523 There is no additional rationale provided for this section.

7524 *B.2.10.15 Asynchronous Errors*

7525 There is no additional rationale provided for this section.

7526 *B.2.10.16 Use of Options*

7527 There is no additional rationale provided for this section.

7528 *B.2.10.17 Use of Sockets for Local UNIX Connections*

7529 There is no additional rationale provided for this section.

7530 *B.2.10.18 Use of Sockets over Internet Protocols*

7531 A raw socket allows privileged users direct access to a protocol; for example, raw access to the  
7532 IP and ICMP protocols is possible through raw sockets. Raw sockets are intended for  
7533 knowledgeable applications that wish to take advantage of some protocol feature not directly  
7534 accessible through the other sockets interfaces.

7535 *B.2.10.19 Use of Sockets over Internet Protocols Based on IPv4*

7536 There is no additional rationale provided for this section.

7537 *B.2.10.20 Use of Sockets over Internet Protocols Based on IPv6*

7538 The Open Group Base Resolution bwg2001-012 is applied, clarifying that IPv6 implementations  
7539 are required to support use of AF\_INET6 sockets over IPv6.

## 7540 **B.2.11 Tracing**

7541 The organization of the tracing rationale differs from the traditional rationale in that this tracing  
7542 rationale text is written against the trace interface as a whole, rather than against the individual  
7543 components of the trace interface or the normative section in which those components are  
7544 defined. Therefore the sections below do not parallel the sections of normative text in  
7545 IEEE Std 1003.1-2001.

### 7546 *B.2.11.1 Objectives*

7547 The intended uses of tracing are application-system debugging during system development, as a  
7548 “flight recorder” for maintenance of fielded systems, and as a performance measurement tool. In  
7549 all of these intended uses, the vendor-supplied computer system and its software are, for this  
7550 discussion, assumed error-free; the intent being to debug the user-written and/or third-party  
7551 application code, and their interactions. Clearly, problems with the vendor-supplied system and  
7552 its software will be uncovered from time to time, but this is a byproduct of the primary activity,  
7553 debugging user code.

7554 Another need for defining a trace interface in POSIX stems from the objective to provide an  
7555 efficient portable way to perform benchmarks. Existing practice shows that such interfaces are  
7556 commonly used in a variety of systems but with little commonality. As part of the benchmarking  
7557 needs, two aspects within the trace interface must be considered.

7558 The first, and perhaps more important one, is the qualitative aspect.

7559 The second is the quantitative aspect.

#### 7560 • Qualitative Aspect

7561 To better understand this aspect, let us consider an example. Suppose that you want to  
7562 organize a number of actions to be performed during the day. Some of these actions are  
7563 known at the beginning of the day. Some others, which may be more or less important, will  
7564 be triggered by reading your mail. During the day you will make some phone calls and  
7565 synchronously receive some more information. Finally you will receive asynchronous phone  
7566 calls that also will trigger actions. If you, or somebody else, examines your day at work, you,  
7567 or he, can discover that you have not efficiently organized your work. For instance, relative  
7568 to the phone calls you made, would it be preferable to make some of these early in the  
7569 morning? Or to delay some others until the end of the day? Relative to the phone calls you  
7570 have received, you might find that somebody you called in the morning has called you 10  
7571 times while you were performing some important work. To examine, afterwards, your day at  
7572 work, you record in sequence all the trace events relative to your work. This should give you  
7573 a chance of organizing your next day at work.

7574 This is the qualitative aspect of the trace interface. The user of a system needs to keep a trace  
7575 of particular points the application passes through, so that he can eventually make some  
7576 changes in the application and/or system configuration, to give the application a chance of  
7577 running more efficiently.

#### 7578 • Quantitative Aspect

7579 This aspect concerns primarily realtime applications, where missed deadlines can be  
7580 undesirable. Although there are, in IEEE Std 1003.1-2001, some interfaces useful for such  
7581 applications (timeouts, execution time monitoring, and so on), there are no APIs to aid in the  
7582 tuning of a realtime application's behavior (**timespec** in timeouts, length of message queues,  
7583 duration of driver interrupt service routine, and so on). The tuning of an application needs a  
7584 means of recording timestamped important trace events during execution in order to analyze  
7585 offline, and eventually, to tune some realtime features (redesign the system with less

7586 functionalities, readjust timeouts, redesign driver interrupts, and so on).

## 7587 **Detailed Objectives**

7588 Objectives were defined to build the trace interface and are kept for historical interest. Although  
7589 some objectives are not fully respected in this trace interface, the concept of the POSIX trace  
7590 interface assumes the following points:

- 7591 1. It must be possible to trace both system and user trace events concurrently.
- 7592 2. It must be possible to trace per-process trace events and also to trace system trace events  
7593 which are unrelated to any particular process. A per-process trace event is either user-  
7594 initiated or system-initiated.
- 7595 3. It must be possible to control tracing on a per-process basis from either inside or outside  
7596 the process.
- 7597 4. It must be possible to control tracing on a per-thread basis from inside the enclosing  
7598 process.
- 7599 5. Trace points must be controllable by trace event type ID from inside and outside of the  
7600 process. Multiple trace points can have the same trace event type ID, and will be controlled  
7601 jointly.
- 7602 6. Recording of trace events is dependent on both trace event type ID and the  
7603 process/thread. Both must be enabled in order to record trace events. System trace events  
7604 may or may not be handled differently.
- 7605 7. The API must not mandate the ability to control tracing for more than one process at the  
7606 same time.
- 7607 8. There is no objective for trace control on anything bigger than a process; for example,  
7608 group or session.
- 7609 9. Trace propagation and control:
  - 7610 a. Trace propagation across *fork()* is optional; the default is to not trace a child process.
  - 7611 b. Trace control must span *pthread\_create()* operations; that is, if a process is being  
7612 traced, any thread will be traced as well if this thread allows tracing. The default is to  
7613 allow tracing.
- 7614 10. Trace control must not span *exec* or *posix\_spawn()* operations.
- 7615 11. A triggering API is not required. The triggering API is the ability to command or stop  
7616 tracing based on the occurrence of a specific trace event other than a  
7617 POSIX\_TRACE\_START trace event or a POSIX\_TRACE\_STOP trace event.
- 7618 12. Trace log entries must have timestamps of implementation-defined resolution.  
7619 Implementations are exhorted to support at least microsecond resolution. When a trace log  
7620 entry is retrieved, it must have timestamp, PC address, PID, and TID of the entity that  
7621 generated the trace event.
- 7622 13. Independently developed code should be able to use trace facilities without coordination  
7623 and without conflict.
- 7624 14. Even if the trace points in the trace calls are not unique, the trace log entries (after any  
7625 processing) must be uniquely identified as to trace point.
- 7626 15. There must be a standard API to read the trace stream.

- 7627 16. The format of the trace stream and the trace log is opaque and unspecified.
- 7628 17. It must be possible to read a completed trace, if recorded on some suitable non-volatile  
7629 storage, even subsequent to a power cycle or subsequent cold boot of the system.
- 7630 18. Support of analysis of a trace log while it is being formed is implementation-defined.
- 7631 19. The API must allow the application to write trace stream identification information into  
7632 the trace stream and to be able to retrieve it, without it being overwritten by trace entries,  
7633 even if the trace stream is full.
- 7634 20. It must be possible to specify the destination of trace data produced by trace events.
- 7635 21. It must be possible to have different trace streams, and for the tracing enabled by one trace  
7636 stream to be completely independent of the tracing of another trace stream.
- 7637 22. It must be possible to trace events from threads in different CPUs.
- 7638 23. The API must support one or more trace streams per-system, and one or more trace  
7639 streams per-process, up to an implementation-defined set of per-system and per-process  
7640 maximums.
- 7641 24. It must be possible to determine the order in which the trace events happened, without  
7642 necessarily depending on the clock, up to an implementation-defined time resolution.
- 7643 25. For performance reasons, the trace event point call(s) must be implementable as a macro  
7644 (see the ISO POSIX-1: 1996 standard, 1.3.4, Statement 2).
- 7645 26. IEEE Std 1003.1-2001 must not define the trace points which a conforming system must  
7646 implement, except for trace points used in the control of tracing.
- 7647 27. The APIs must be thread-safe, and trace points should be lock-free (that is, not require a  
7648 lock to gain exclusive access to some resource).
- 7649 28. The user-provided information associated with a trace event is variable-sized, up to some  
7650 maximum size.
- 7651 29. Bounds on record and trace stream sizes:
- 7652 a. The API must permit the application to declare the upper bounds on the length of an  
7653 application data record. The system must return the limit it used. The limit used may  
7654 be smaller than requested.
- 7655 b. The API must permit the application to declare the upper bounds on the size of trace  
7656 streams. The system must return the limit it used. The limit used may be different,  
7657 either larger or smaller, than requested.
- 7658 30. The API must be able to pass any fundamental data type, and a structured data type  
7659 composed only of fundamental types. The API must be able to pass data by reference,  
7660 given only as an address and a length. Fundamental types are the POSIX.1 types (see the  
7661 **<sys/types.h>** header) plus those defined in the ISO C standard.
- 7662 31. The API must apply the POSIX notions of ownership and permission to recorded trace  
7663 data, corresponding to the sources of that data.

**Comments on Objectives**

**Note:** In the following comments, numbers in square brackets refer to the above objectives.

It is necessary to be able to obtain a trace stream for a complete activity. Thus there is a requirement to be able to trace both application and system trace events. A per-process trace event is either user-initiated, like the *write()* function, or system-initiated, like a timer expiration. There is also a need to be able to trace an entire process' activity even when it has threads in multiple CPUs. To avoid excess trace activity, it is necessary to be able to control tracing on a trace event type basis.

[Objectives 1,2,5,22]

There is a need to be able to control tracing on a per-process basis, both from inside and outside the process; that is, a process can start a trace activity on itself or any other process. There is also the perceived need to allow the definition of a maximum number of trace streams per system.

[Objectives 3,23]

From within a process, it is necessary to be able to control tracing on a per-thread basis. This provides an additional filtering capability to keep the amount of traced data to a minimum. It also allows for less ambiguity as to the origin of trace events. It is recognized that thread-level control is only valid from within the process itself. It is also desirable to know the maximum number of trace streams per process that can be started. The API should not require thread synchronization or mandate priority inversions that would cause the thread to block. However, the API must be thread-safe.

[Objectives 4,23,24,27]

There was no perceived objective to control tracing on anything larger than a process; for example, a group or session. Also, the ability to start or stop a trace activity on multiple processes atomically may be very difficult or cumbersome in some implementations.

[Objectives 6,8]

It is also necessary to be able to control tracing by trace event type identifier, sometimes called a trace hook ID. However, there is no mandated set of system trace events, since such trace points are implementation-defined. The API must not require from the operating system facilities that are not standard.

[Objectives 6,26]

Trace control must span *fork()* and *pthread\_create()*. If not, there will be no way to ensure that an application's activity is entirely traced. The newly forked child would not be able to turn on its tracing until after it obtained control after the fork, and trace control externally would be even more problematic.

[Objective 9]

Since *exec* and *posix\_spawn()* represent a complete change in the execution of a task (a new program), trace control need not persist over an *exec* or *posix\_spawn()*.

[Objective 10]

Where trace activities are started on multiple processes, these trace activities should not interfere with each other.

[Objective 21]

There is no need for a triggering objective, primarily for performance reasons; see also Section B.2.11.8 (on page 202), rationale on triggering.

[Objective 11]

It must be possible to determine the origin of each traced event. The process and thread identifiers for each trace event are needed. Also there was a perceived need for a user-specifiable origin, but it was felt that this would create too much overhead.

|      |                                                                                                      |
|------|------------------------------------------------------------------------------------------------------|
| 7711 | [Objectives 12,14]                                                                                   |
| 7712 | An allowance must be made for trace points to come embedded in software components from              |
| 7713 | several different sources and vendors without requiring coordination.                                |
| 7714 | [Objective 13]                                                                                       |
| 7715 | There is a requirement to be able to uniquely identify trace points that may have the same trace     |
| 7716 | stream identifier. This is only necessary when a trace report is produced.                           |
| 7717 | [Objectives 12,14]                                                                                   |
| 7718 | Tracing is a very performance-sensitive activity, and will therefore likely be implemented at a      |
| 7719 | low level within the system. Hence the interface must not mandate any particular buffering or        |
| 7720 | storage method. Therefore, a standard API is needed to read a trace stream. Also the interface       |
| 7721 | must not mandate the format of the trace data, and the interface must not assume a trace storage     |
| 7722 | method. Due to the possibility of a monolithic kernel and the possible presence of multiple          |
| 7723 | processes capable of running trace activities, the two kinds of trace events may be stored in two    |
| 7724 | separate streams for performance reasons. A mandatory dump mechanism, common in some                 |
| 7725 | existing practice, has been avoided to allow the implementation of this set of functions on small    |
| 7726 | realtime profiles for which the concept of a file system is not defined. The trace API calls should  |
| 7727 | be implemented as macros.                                                                            |
| 7728 | [Objectives 15,16,25,30]                                                                             |
| 7729 | Since a trace facility is a valuable service tool, the output (or log) of a completed trace stream   |
| 7730 | that is written to permanent storage must be readable on other systems of the type that              |
| 7731 | produced the trace log. Note that there is no objective to be able to interpret a trace log that was |
| 7732 | not successfully completed.                                                                          |
| 7733 | [Objectives 17,18,19]                                                                                |
| 7734 | For trace streams written to permanent storage, a way to specify the destination of the trace        |
| 7735 | stream is needed.                                                                                    |
| 7736 | [Objective 20]                                                                                       |
| 7737 | There is a requirement to be able to depend on the ordering of trace events up to some               |
| 7738 | implementation-defined time interval. For example, there is a need to know the time period           |
| 7739 | during which, if trace events are closer together, their ordering is unspecified. Events that occur  |
| 7740 | within an interval smaller than this resolution may or may not be read back in the correct order.    |
| 7741 | [Objective 24]                                                                                       |
| 7742 | The application should be able to know how much data can be traced. When trace event types           |
| 7743 | can be filtered, the application should be able to specify the approximate maximum amount of         |
| 7744 | data that will be traced in a trace event so resources can be more efficiently allocated.            |
| 7745 | [Objectives 28,29]                                                                                   |
| 7746 | Users should not be able to trace data to which they would not normally have access. System          |
| 7747 | trace events corresponding to a process/thread should be associated with the ownership of that       |
| 7748 | process/thread.                                                                                      |
| 7749 | [Objective 31]                                                                                       |

## 7750 B.2.11.2 Trace Model

7751 **Introduction**

7752 The model is based on two base entities: the “Trace Stream” and the “Trace Log”, and a recorded  
 7753 unit called the “Trace Event”. The possibility of using Trace Streams and Trace Logs separately  
 7754 gives two use dimensions and solves both the performance issue and the full-information  
 7755 system issue. In the case of a trace stream without log, specific information, although reduced in  
 7756 quantity, is required to be registered, in a possibly small realtime system, with as little overhead  
 7757 as possible. The Trace Log option has been added for small realtime systems. In the case of a  
 7758 trace stream with log, considerable complex application-specific information needs to be  
 7759 collected.

7760 **Trace Model Description**

7761 The trace model can be examined for three different subfunctions: Application Instrumentation,  
 7762 Trace Operation Control, and Trace Analysis.

7763

7764

**Figure B-2** Trace System Overview: for Offline Analysis

7765 Each of these subfunctions requires specific characteristics of the trace mechanism API.

## 7766 • Application Instrumentation

7767 When instrumenting an application, the programmer is not concerned about the future use of  
 7768 the trace events in the trace stream or the trace log, the full policy of the trace stream, or the  
 7769 eventual pre-filtering of trace events. But he is concerned about the correct determination of  
 7770 the specific trace event type identifier, regardless of how many independent libraries are  
 7771 used in the same user application; see Figure B-2 and Figure B-3 (on page 185).

7772 This trace API provides the necessary operations to accomplish this subfunction. This is done  
 7773 by providing functions to associate a programmer-defined name with an implementation-  
 7774 defined trace event type identifier (see the `posix_trace_eventid_open()` function), and to send  
 7775 this trace event into a potential trace stream (see the `posix_trace_event()` function).

• Trace Operation Control

When controlling the recording of trace events in a trace stream, the programmer is concerned with the correct initialization of the trace mechanism (that is, the sizing of the trace stream), the correct retention of trace events in a permanent storage, the correct dynamic recording of trace events, and so on.

This trace API provides the necessary material to permit this efficiently. This is done by providing functions to initialize a new trace stream, and optionally a trace log:

- Trace Stream Attributes Object Initialization (see *posix\_trace\_attr\_init()*)
- Functions to Retrieve or Set Information About a Trace Stream (see *posix\_trace\_attr\_getgenversion()*)
- Functions to Retrieve or Set the Behavior of a Trace Stream (see *posix\_trace\_attr\_getinherited()*)
- Functions to Retrieve or Set Trace Stream Size Attributes (see *posix\_trace\_attr\_getmaxusereventsize()*)
- Trace Stream Initialization, Flush, and Shutdown from a Process (see *posix\_trace\_create()*)
- Clear Trace Stream and Trace Log (see *posix\_trace\_clear()*)

To select the trace event types that are to be traced:

- Manipulate Trace Event Type Identifier (see *posix\_trace\_trid\_eventid\_open()*)
- Iterate over a Mapping of Trace Event Type (see *posix\_trace\_eventtypelist\_getnext\_id()*)
- Manipulate Trace Event Type Sets (see *posix\_trace\_eventset\_empty()*)
- Set Filter of an Initialized Trace Stream (see *posix\_trace\_set\_filter()*)

To control the execution of an active trace stream:

- Trace Start and Stop (see *posix\_trace\_start()*)
- Functions to Retrieve the Trace Attributes or Trace Statuses (see *posix\_trace\_get\_attr()*)

**Figure B-3** Trace System Overview: for Online Analysis

• Trace Analysis

Once correctly recorded, on permanent storage or not, an ultimate activity consists of the analysis of the recorded information. If the recorded data is on permanent storage, a specific open operation is required to associate a trace stream to a trace log.

The first intent of the group was to request the presence of a system identification structure in the trace stream attribute. This was, for the application, to allow some portable way to process the recorded information. However, there is no requirement that the **utsname** structure, on which this system identification was based, be portable from one machine to another, so the contents of the attribute cannot be interpreted correctly by an application conforming to IEEE Std 1003.1-2001.

This modification has been incorporated and requests that some unspecified information be recorded in the trace log in order to fail opening it if the analysis process and the controller process were running in different types of machine, but does not request that this information be accessible to the application. This modification has implied a modification in the *posix\_trace\_open()* function error code returns.

This trace API provides functions to:

- Extract trace stream identification attributes (see *posix\_trace\_attr\_getgenversion()*)
- Extract trace stream behavior attributes (see *posix\_trace\_attr\_getinherited()*)
- Extract trace event, stream, and log size attributes (see *posix\_trace\_attr\_getmaxusereventsize()*)
- Look up trace event type names (see *posix\_trace\_eventid\_get\_name()*)
- Iterate over trace event type identifiers (see *posix\_trace\_eventtypelist\_getnext\_id()*)
- Open, rewind, and close a trace log (see *posix\_trace\_open()*)
- Read trace stream attributes and status (see *posix\_trace\_get\_attr()*)
- Read trace events (see *posix\_trace\_getnext\_event()*)

Due to the following two reasons:

1. The requirement that the trace system must not add unacceptable overhead to the traced process and so that the trace event point execution must be fast
2. The traced application does not care about tracing errors

the trace system cannot return any internal error to the application. Internal error conditions can range from unrecoverable errors that will force the active trace stream to abort, to small errors that can affect the quality of tracing without aborting the trace stream. The group decided to define a system trace event to report to the analysis process such internal errors. It is not the intention of IEEE Std 1003.1-2001 to require an implementation to report an internal error that corrupts or terminates tracing operation. The implementor is free to decide which internal documented errors, if any, the trace system is able to report.

### States of a Trace Stream

**Figure B-4** Trace System Overview: States of a Trace Stream

Figure B-4 shows the different states an active trace stream passes through. After the `posix_trace_create()` function call, a trace stream becomes `CREATED` and a trace stream is associated for the future collection of trace events. The status of the trace stream is `POSIX_TRACE_SUSPENDED`. The state becomes `STARTED` after a call to the `posix_trace_start()` function, and the status becomes `POSIX_TRACE_RUNNING`. In this state, all trace events that are not filtered out will be stored into the trace stream. After a call to `posix_trace_stop()`, the trace stream becomes `STOPPED` (and the status `POSIX_TRACE_SUSPENDED`). In this state, no new trace events will be recorded in the trace stream, but previously recorded trace events may continue to be read.

After a call to `posix_trace_shutdown()`, the trace stream is in the state `COMPLETED`. The trace stream no longer exists but, if the Trace Log option is supported, all the information contained in it has been logged. If a log object has not been associated with the trace stream at the creation, it is the responsibility of the trace controller process to not shut the trace stream down while trace events remain to be read in the stream.

### Tracing All Processes

Some implementations have a tracing subsystem with the ability to trace all processes. This is useful to debug some types of device drivers such as those for ATM or X25 adapters. These types of adapters are used by several independent processes, that are not issued from the same process.

The POSIX trace interface does not define any constant or option to create a trace stream tracing all processes. POSIX.1 does not prevent this type of implementation and an implementor is free to add this capability. Nevertheless, the trace interface allows tracing of all the system trace events and all the processes issued from the same process.

If such a tracing system capability has to be implemented, when a trace stream is created, it is recommended that a constant named `POSIX_TRACE_ALLPROC` be used instead of the process identifier in the argument of the `posix_trace_create()` or `posix_trace_create_withlog()` function. A possible value for `POSIX_TRACE_ALLPROC` may be `-1` instead of a real process identifier.

The implementor has to be aware that there is some impact on the tracing behavior as defined in the POSIX trace interface. For example:

- If the default value for the inheritance attribute is set to `POSIX_TRACE_CLOSE_FOR_CHILD`, the implementation has to stop tracing for the child process.
- The trace controller which is creating this type of trace stream must have the appropriate privilege to trace all the processes.

### Trace Storage

The model is based on two types of trace events: system trace events and user-defined trace events. The internal representation of trace events is implementation-defined, and so the implementor is free to choose the more suitable, practical, and efficient way to design the internal management of trace events. For the timestamping operation, the model does not impose the `CLOCK_REALTIME` or any other clock. The buffering allocation and operation follow the same principle. The implementor is free to use one or more buffers to record trace events; the interface assumes only a logical trace stream of sequentially recorded trace events. Regarding flushing of trace events, the interface allows the definition of a trace log object which typically can be a file. But the group was also aware of defining functions to permit the use of this interface in small realtime systems, which may not have general file system capabilities. For instance, the three functions `posix_trace_getnext_event()` (blocking), `posix_trace_timedgetnext_event()` (blocking with timeout), and `posix_trace_trygetnext_event()` (non-blocking) are proposed to read the recorded trace events.

The policy to be used when the trace stream becomes full also relies on common practice:

- For an active trace stream, the `POSIX_TRACE_LOOP` trace stream policy permits automatic overrun (overwrite of oldest trace events) while waiting for some user-defined condition to cause tracing to stop. By contrast, the `POSIX_TRACE_UNTIL_FULL` trace stream policy requires the system to stop tracing when the trace stream is full. However, if the trace stream that is full is at least partially emptied by a call to the `posix_trace_flush()` function or by calls to the `posix_trace_getnext_event()` function, the trace system will automatically resume tracing.

If the Trace Log option is supported, the operation of the `POSIX_TRACE_FLUSH` policy is an extension of the `POSIX_TRACE_UNTIL_FULL` policy. The automatic free operation (by flushing to the associated trace log) is added.

- If a log is associated with the trace stream and this log is a regular file, these policies also apply for the log. One more policy, `POSIX_TRACE_APPEND`, is defined to allow indefinite extension of the log. Since the log destination can be any device or pseudo-device, the implementation may not be able to manipulate the destination as required by IEEE Std 1003.1-2001. For this reason, the behavior of the log full policy may be unspecified depending on the trace log type.

The current trace interface does not define a service to preallocate space for a trace log file, because this space can be preallocated by means of a call to the `posix_fallocate()` function. This function could be called after the file has been opened, but before the trace stream is created. The `posix_fallocate()` function ensures that any required storage for regular file data is allocated on the file system storage media. If `posix_fallocate()` returns successfully,

7911 subsequent writes to the specified file data will not fail due to the lack of free space on the file  
 7912 system storage media. Besides trace events, a trace stream also includes trace attributes and  
 7913 the mapping from trace event names to trace event type identifiers. The implementor is free  
 7914 to choose how to store the trace attributes and the trace event type map, but must ensure that  
 7915 this information is not lost when a trace stream overrun occurs.

### 7916 *B.2.11.3 Trace Programming Examples*

7917 Several programming examples are presented to show the code of the different possible  
 7918 subfunctions using a trace subsystem. All these programs need to include the **<trace.h>** header.  
 7919 In the examples shown, error checking is omitted for more simplicity.

### 7920 **Trace Operation Control**

7921 These examples show the creation of a trace stream for another process; one which is already  
 7922 trace instrumented. All the default trace stream attributes are used to simplify programming in  
 7923 the first example. The second example shows more possibilities.

### 7924 **First Example**

```

7925 /* Caution. Error checks omitted */
7926 {
7927 trace_attr_t attr;
7928 pid_t pid = traced_process_pid;
7929 int fd;
7930 trace_id_t trid;
7931
7932 - - - - -
7933 /* Initialize trace stream attributes */
7934 posix_trace_attr_init(&attr);
7935 /* Open a trace log */
7936 fd=open("/tmp/mytracelog",...);
7937 /*
7938 * Create a new trace associated with a log
7939 * and with default attributes
7940 */
7941 posix_trace_create_withlog(pid, &attr, fd, &trid);
7942
7943 /* Trace attribute structure can now be destroyed */
7944 posix_trace_attr_destroy(&attr);
7945 /* Start of trace event recording */
7946 posix_trace_start(trid);
7947 - - - - -
7948 /* Duration of tracing */
7949 - - - - -
7950 /* Stop and shutdown of trace activity */
7951 posix_trace_shutdown(trid);
7952 - - - - -
7953 }
```

**Second Example**

Between the initialization of the trace stream attributes and the creation of the trace stream, these trace stream attributes may be modified; see **Trace Stream Attribute Manipulation** (on page 194) for a specific programming example. Between the creation and the start of the trace stream, the event filter may be set; after the trace stream is started, the event filter may be changed. The setting of an event set and the change of a filter is shown in **Create a Trace Event Type Set and Change the Trace Event Type Filter** (on page 194).

```

/* Caution. Error checks omitted */
{
 trace_attr_t attr;
 pid_t pid = traced_process_pid;
 int fd;
 trace_id_t trid;
 - - - - -
 /* Initialize trace stream attributes */
 posix_trace_attr_init(&attr);
 /* Attr default may be changed at this place; see example */
 - - - - -
 /* Create and open a trace log with R/W user access */
 fd=open("/tmp/mytracelog",O_WRONLY|O_CREAT,S_IRUSR|S_IWUSR);
 /* Create a new trace associated with a log */
 posix_trace_create_withlog(pid, &attr, fd, &trid);
 /*
 * If the Trace Filter option is supported
 * trace event type filter default may be changed at this place;
 * see example about changing the trace event type filter
 */
 posix_trace_start(trid);
 - - - - -

 /*
 * If you have an uninteresting part of the application
 * you can stop temporarily.
 *
 * posix_trace_stop(trid);
 * - - - - -
 * - - - - -
 * posix_trace_start(trid);
 */
 - - - - -

 /*
 * If the Trace Filter option is supported
 * the current trace event type filter can be changed
 * at any time (see example about how to set
 * a trace event type filter)
 */
 - - - - -

 /* Stop the recording of trace events */
 posix_trace_stop(trid);
 /* Shutdown the trace stream */
 posix_trace_shutdown(trid);

```

```

8004 /*
8005 * Destroy trace stream attributes; attr structure may have
8006 * been used during tracing to fetch the attributes
8007 */
8008 posix_trace_attr_destroy(&attr);
8009 - - - - -
8010 }

```

### 8011 **Application Instrumentation**

8012 This example shows an instrumented application. The code is included in a block of instructions,  
 8013 perhaps a function from a library. Possibly in an initialization part of the instrumented  
 8014 application, two user trace events names are mapped to two trace event type identifiers  
 8015 (function *posix\_trace\_eventid\_open()*). Then two trace points are programmed.

```

8016 /* Caution. Error checks omitted */
8017 {
8018 trace_event_id_t eventid1, eventid2;
8019 - - - - -
8020 /* Initialization of two trace event type ids */
8021 posix_trace_eventid_open("my_first_event",&eventid1);
8022 posix_trace_eventid_open("my_second_event",&eventid2);
8023 - - - - -
8024 - - - - -
8025 - - - - -
8026 /* Trace point */
8027 posix_trace_event(eventid1,NULL,0);
8028 - - - - -
8029 /* Trace point */
8030 posix_trace_event(eventid2,NULL,0);
8031 - - - - -
8032 }

```

### 8033 **Trace Analyzer**

8034 This example shows the manipulation of a trace log resulting from the dumping of a completed  
 8035 trace stream. All the default attributes are used to simplify programming, and data associated  
 8036 with a trace event is not shown in the first example. The second example shows more  
 8037 possibilities.

### 8038 **First Example**

```

8039 /* Caution. Error checks omitted */
8040 {
8041 int fd;
8042 trace_id_t trid;
8043 posix_trace_event_info trace_event;
8044 char trace_event_name[TRACE_EVENT_NAME_MAX];
8045 int return_value;
8046 size_t returndatasize;
8047 int lost_event_number;
8048 - - - - -

```

```

8049 /* Open an existing trace log */
8050 fd=open("/tmp/tracelog", O_RDONLY);
8051 /* Open a trace stream on the open log */
8052 posix_trace_open(fd, &trid);
8053 /* Read a trace event */
8054 posix_trace_getnext_event(trid, &trace_event,
8055 NULL, 0, &returndatasize,&return_value);

8056 /* Read and print all trace event names out in a loop */
8057 while (return_value == NULL)
8058 {
8059 /*
8060 * Get the name of the trace event associated
8061 * with trid trace ID
8062 */
8063 posix_trace_eventid_get_name(trid, trace_event.event_id,
8064 trace_event_name);
8065 /* Print the trace event name out */
8066 printf("%s\n",trace_event_name);
8067 /* Read a trace event */
8068 posix_trace_getnext_event(trid, &trace_event,
8069 NULL, 0, &returndatasize,&return_value);
8070 }

8071 /* Close the trace stream */
8072 posix_trace_close(trid);
8073 /* Close the trace log */
8074 close(fd);
8075 }

```

## 8076 Second Example

8077 The complete example includes the two other examples in **Retrieve Information from a Trace**  
8078 **Log** (on page 195) and in **Retrieve the List of Trace Event Types Used in a Trace Log** (on page  
8079 196). For example, the *maxdatasize* variable is set in **Retrieve the List of Trace Event Types Used**  
8080 **in a Trace Log** (on page 196).

```

8081 /* Caution. Error checks omitted */
8082 {
8083 int fd;
8084 trace_id_t trid;
8085 posix_trace_event_info trace_event;
8086 char trace_event_name[TRACE_EVENT_NAME_MAX];
8087 char * data;
8088 size_t maxdatasize=1024, returndatasize;
8089 int return_value;
8090 - - - - -

8091 /* Open an existing trace log */
8092 fd=open("/tmp/tracelog", O_RDONLY);
8093 /* Open a trace stream on the open log */
8094 posix_trace_open(fd, &trid);
8095 /*
8096 * Retrieve information about the trace stream which

```

```

8097 * was dumped in this trace log (see example)
8098 */
8099 - - - - -
8100 /* Allocate a buffer for trace event data */
8101 data=(char *)malloc(maxdatasize);
8102 /*
8103 * Retrieve the list of trace events used in this
8104 * trace log (see example)
8105 */
8106 - - - - -
8107 /* Read and print all trace event names and data out in a loop */
8108 while (1)
8109 {
8110 posix_trace_getnext_event(trid, &trace_event,
8111 data, maxdatasize, &returndatasize,&return_value);
8112 if (return_value != NULL) break;
8113 /*
8114 * Get the name of the trace event type associated
8115 * with trid trace ID
8116 */
8117 posix_trace_eventid_get_name(trid, trace_event.event_id,
8118 trace_event_name);
8119 {
8120 int i;
8121 /* Print the trace event name out */
8122 printf("%s: ", trace_event_name);
8123 /* Print the trace event data out */
8124 for (i=0; i<returndatasize, i++) printf("%02.2X",
8125 (unsigned char)data[i]);
8126 printf("\n");
8127 }
8128 }
8129 /* Close the trace stream */
8130 posix_trace_close(trid);
8131 /* The buffer data is deallocated */
8132 free(data);
8133 /* Now the file can be closed */
8134 close(fd);
8135 }

```

### Several Programming Manipulations

The following examples show some typical sets of operations needed in some contexts.

**Trace Stream Attribute Manipulation**

This example shows the manipulation of a trace stream attribute object in order to change the default value provided by a previous *posix\_trace\_attr\_init()* call.

```

/* Caution. Error checks omitted */
{
 trace_attr_t attr;
 size_t logsize=100000;
 - - - - -
 /* Initialize trace stream attributes */
 posix_trace_attr_init(&attr);
 /* Set the trace name in the attributes structure */
 posix_trace_attr_setname(&attr, "my_trace");
 /* Set the trace full policy */
 posix_trace_attr_setstreamfullpolicy(&attr, POSIX_TRACE_LOOP);
 /* Set the trace log size */
 posix_trace_attr_setlogsize(&attr, logsize);
 - - - - -
}

```

**Create a Trace Event Type Set and Change the Trace Event Type Filter**

This example is valid only if the Trace Event Filter option is supported. This example shows the manipulation of a trace event type set in order to change the trace event type filter for an existing active trace stream, which may be just-created, running, or suspended. Some sets of trace event types are well-known, such as the set of trace event types not associated with a process, some trace event types are just-built trace event types for this trace stream; one trace event type is the predefined trace event error type which is deleted from the trace event type set.

```

/* Caution. Error checks omitted */
{
 trace_id_t trid = existing_trace;
 trace_event_set_t set;
 trace_event_id_t trace_event1, trace_event2;
 - - - - -
 /* Initialize to an empty set of trace event types */
 /* (not strictly required because posix_trace_event_set_fill() */
 /* will ignore the prior contents of the event set.) */
 posix_trace_eventset_emptyset(&set);
 /*
 * Fill the set with all system trace events
 * not associated with a process
 */
 posix_trace_eventset_fill(&set, POSIX_TRACE_WOPID_EVENTS);

 /*
 * Get the trace event type identifier of the known trace event name
 * my_first_event for the trid trace stream
 */
 posix_trace_trid_eventid_open(trid, "my_first_event", &trace_event1);
 /* Add the set with this trace event type identifier */
 posix_trace_eventset_add_event(trace_event1, &set);
 /*

```

```

8186 * Get the trace event type identifier of the known trace event name
8187 * my_second_event for the trid trace stream
8188 */
8189 posix_trace_trid_eventid_open(trid, "my_second_event", &trace_event2);
8190 /* Add the set with this trace event type identifier */
8191 posix_trace_eventset_add_event(trace_event2, &set);
8192 - - - - -
8193 /* Delete the system trace event POSIX_TRACE_ERROR from the set */
8194 posix_trace_eventset_del_event(POSIX_TRACE_ERROR, &set);
8195 - - - - -
8196
8197 /* Modify the trace stream filter making it equal to the new set */
8198 posix_trace_set_filter(trid, &set, POSIX_TRACE_SET_EVENTSET);
8199 - - - - -
8200 /*
8201 * Now trace_event1, trace_event2, and all system trace event types
8202 * not associated with a process, except for the POSIX_TRACE_ERROR
8203 * system trace event type, are filtered out of (not recorded in) the
8204 * existing trace stream.
8205 */
8206 }

```

## Retrieve Information from a Trace Log

This example shows how to extract information from a trace log, the dump of a trace stream. This code:

- Asks if the trace stream has lost trace events
- Extracts the information about the version of the trace subsystem which generated this trace log
- Retrieves the maximum size of trace event data; this may be used to dynamically allocate an array for extracting trace event data from the trace log without overflow

```

8209 /* Caution. Error checks omitted */
8210 {
8211 struct posix_trace_status_info statusinfo;
8212 trace_attr_t attr;
8213 trace_id_t trid = existing_trace;
8214 size_t maxdatasize;
8215 char genversion[TRACE_NAME_MAX];
8216 - - - - -
8217 /* Get the trace stream status */
8218 posix_trace_get_status(trid, &statusinfo);
8219 /* Detect an overrun condition */
8220 if (statusinfo.posix_stream_overrun_status == POSIX_TRACE_OVERRUN)
8221 printf("trace events have been lost\n");
8222
8223 /* Get attributes from the trid trace stream */
8224 posix_trace_get_attr(trid, &attr);
8225 /* Get the trace generation version from the attributes */
8226 posix_trace_attr_getgenversion(&attr, genversion);
8227 /* Print the trace generation version out */
8228 printf("Information about Trace Generator:%s\n", genversion);
8229 }

```

```

8233 /* Get the trace event max data size from the attributes */
8234 posix_trace_attr_getmaxdatasize(&attr, &maxdatasize);
8235 /* Print the trace event max data size out */
8236 printf("Maximum size of associated data:%d\n",maxdatasize);
8237 /* Destroy the trace stream attributes */
8238 posix_trace_attr_destroy(&attr);
8239 }

```

#### 8240 **Retrieve the List of Trace Event Types Used in a Trace Log**

8241 This example shows the retrieval of a trace stream's trace event type list. This operation may be  
 8242 very useful if you are interested only in tracking the type of trace events in a trace log.

```

8243 /* Caution. Error checks omitted */
8244 {
8245 trace_id_t trid = existing_trace;
8246 trace_event_id_t event_id;
8247 char event_name[TRACE_EVENT_NAME_MAX];
8248 int return_value;
8249 - - - - -
8250
8251 /*
8252 * In a loop print all existing trace event names out
8253 * for the trid trace stream
8254 */
8255 while (1)
8256 {
8257 posix_trace_eventtypelist_getnext_id(trid, &event_id
8258 &return_value);
8259 if (return_value != NULL) break;
8260 /*
8261 * Get the name of the trace event associated
8262 * with trid trace ID
8263 */
8264 posix_trace_eventid_get_name(trid, event_id, event_name);
8265 /* Print the name out */
8266 printf("%s\n", event_name);
8267 }
8268 }

```

## 8268 B.2.11.4 Rationale on Trace for Debugging

8269

8270

**Figure B-5** Trace Another Process

8271

8272

8273

8274

8275

8276

8277

Among the different possibilities offered by the trace interface defined in IEEE Std 1003.1-2001, the debugging of an application is the most interesting one. Typical operations in the controlling debugger process are to filter trace event types, to get trace events from the trace stream, to stop the trace stream when the debugged process is executing uninteresting code, to start the trace stream when some interesting point is reached, and so on. The interface defined in IEEE Std 1003.1-2001 should define all the necessary base functions to allow this dynamic debug handling.

8278

8279

8280

8281

Figure B-5 shows an example in which the trace stream is created after the call to the `fork()` function. If the user does not want to lose trace events, some synchronization mechanism (represented in the figure) may be needed before calling the `exec` function, to give the parent a chance to create the trace stream before the child begins the execution of its trace points.

## 8282 B.2.11.5 Rationale on Trace Event Type Name Space

8283

8284

8285

8286

8287

8288

8289

8290

At first, the working group was in favor of the representation of a trace event type by an integer (`event_name`). It seems that existing practice shows the weakness of such a representation. The collision of trace event types is the main problem that cannot be simply resolved using this sort of representation. Suppose, for example, that a third party designs an instrumented library. The user does not have the source of this library and wants to trace his application which uses in some part the third-party library. There is no means for him to know what are the trace event types used in the instrumented library so he has some chance of duplicating some of them and thus to obtain a contaminated tracing of his application.

8291

8292

**Figure B-6** Trace Name Space Overview: With Third-Party Library

8293

8294

8295

8296

8297

8298

8299

8300

8301

8302

8303

There are requirements to allow program images containing pieces from various vendors to be traced without also requiring those of any other vendors to coordinate their uses of the trace facility, and especially the naming of their various trace event types and trace point IDs. The chosen solution is to provide a very large name space, large enough so that the individual vendors can give their trace types and tracepoint IDs sufficiently long and descriptive names making the occurrence of collisions quite unlikely. The probability of collision is thus made sufficiently low so that the problem may, as a practical matter, be ignored. By requirement, the consequence of collisions will be a slight ambiguity in the trace streams; tracing will continue in spite of collisions and ambiguities. “The show must go on”. The *posix\_prog\_address* member of the **posix\_trace\_event\_info** structure is used to allow trace streams to be unambiguously interpreted, despite the fact that trace event types and trace event names need not be unique.

8304

8305

8306

8307

8308

8309

8310

8311

8312

8313

The *posix\_trace\_eventid\_open()* function is required to allow the instrumented third-party library to get a valid trace event type identifier for its trace event names. This operation is, somehow, an allocation, and the group was aware of proposing some deallocation mechanism which the instrumented application could use to recover the resources used by a trace event type identifier. This would have given the instrumented application the benefit of being capable of reusing a possible minimum set of trace event type identifiers, but also the inconvenience to have, possibly in the same trace stream, one trace event type identifier identifying two different trace event types. After some discussions the group decided to not define such a function which would make this API thicker for little benefit, the user having always the possibility of adding identification information in the *data* member of the trace event structure.

8314

8315

8316

8317

8318

8319

8320

The set of the trace event type identifiers the controlling process wants to filter out is initialized in the trace mechanism using the function *posix\_trace\_set\_filter()*, setting the arguments according to the definitions explained in *posix\_trace\_set\_filter()*. This operation can be done statically (when the trace is in the STOPPED state) or dynamically (when the trace is in the STARTED state). The preparation of the filter is normally done using the function defined in *posix\_trace\_eventtypelist\_getnext\_id()* and eventually the function *posix\_trace\_eventtypelist\_rewind()* in order to know (before the recording) the list of the potential

set of trace event types that can be recorded. In the case of an active trace stream, this list may not be exhaustive. Actually, the target process may not have yet called the function `posix_trace_eventid_open()`. But it is a common practice, for a controlling process, to prepare the filtering of a future trace stream before its start. Therefore the user must have a way to get the trace event type identifier corresponding to a well-known trace event name before its future association by the pre-cited function. This is done by calling the `posix_trace_trid_eventid_open()` function, given the trace stream identifier and the trace name, and described hereafter. Because this trace event type identifier is associated with a trace stream identifier, where a unique process has initialized two or more traces, the implementation is expected to return the same trace event type identifier for successive calls to `posix_trace_trid_eventid_open()` with different trace stream identifiers. The `posix_trace_eventid_get_name()` function is used by the controller process to identify, by the name, the trace event type returned by a call to the `posix_trace_eventtypelist_getnext_id()` function.

Afterwards, the set of trace event types is constructed using the functions defined in `posix_trace_eventset_empty()`, `posix_trace_eventset_fill()`, `posix_trace_eventset_add()`, and `posix_trace_eventset_del()`.

A set of functions is provided devoted to the manipulation of the trace event type identifier and names for an active trace stream. All these functions require the trace stream identifier argument as the first parameter. The opacity of the trace event type identifier implies that the user cannot associate directly its well-known trace event name with the system-associated trace event type identifier.

The `posix_trace_trid_eventid_open()` function allows the application to get the system trace event type identifier back from the system, given its well-known trace event name. This function is useful only when a controlling process needs to specify specific events to be filtered.

The `posix_trace_eventid_get_name()` function allows the application to obtain a trace event name given its trace event type identifier. One possible use of this function is to identify the type of a trace event retrieved from the trace stream, and print it. The easiest way to implement this requirement, is to use a single trace event type map for all the processes whose maps are required to be identical. A more difficult way is to attempt to keep multiple maps identical at every call to `posix_trace_eventid_open()` and `posix_trace_trid_eventid_open()`.

#### B.2.11.6 Rationale on Trace Events Type Filtering

The most basic rationale for runtime and pre-registration filtering (selection/rejection) of trace event types is to prevent choking of the trace collection facility, and/or overloading of the computer system. Any worthwhile trace facility can bring even the largest computer to its knees. Otherwise, everything would be recorded and filtered after the fact; it would be much simpler, but impractical.

To achieve debugging, measurement, or whatever the purpose of tracing, the filtering of trace event types is an important part of trace analysis. Due to the fact that the trace events are put into a trace stream and probably logged afterwards into a file, different levels of filtering—that is, rejection of trace event types—are possible.

**Filtering of Trace Event Types Before Tracing**

This function, represented by the `posix_trace_set_filter()` function in IEEE Std 1003.1-2001 (see `posix_trace_set_filter()`), selects, before or during tracing, the set of trace event types to be filtered out. It should be possible also (as OSF suggested in their ETAP trace specifications) to select the kernel trace event types to be traced in a system-wide fashion. These two functionalities are called the pre-filtering of trace event types.

The restriction on the actual type used for the `trace_event_set_t` type is intended to guarantee that these objects can always be assigned, have their address taken, and be passed by value as parameters. It is not intended that this type be a structure including pointers to other data structures, as that could impact the portability of applications performing such operations. A reasonable implementation could be a structure containing an array of integer types.

**Filtering of Trace Event Types at Runtime**

It is possible to build this functionality using the `posix_trace_set_filter()` function. A privileged process or a privileged thread can get trace events from the trace stream of another process or thread, and thus specify the type of trace events to record into a file, using implementation-defined methods and interfaces. This functionality, called inline filtering of trace event types, is used for runtime analysis of trace streams.

**Post-Mortem Filtering of Trace Event Types**

The word “post-mortem” is used here to indicate that some unanticipated situation occurs during execution that does not permit a pre or inline filtering of trace events and that it is necessary to record all trace event types to have a chance to discover the problem afterwards. When the program stops, all the trace events recorded previously can be analyzed in order to find the solution. This functionality could be named the post-filtering of trace event types.

**Discussions about Trace Event Type-Filtering**

After long discussions with the parties involved in the process of defining the trace interface, it seems that the sensitivity to the filtering problem is different, but everybody agrees that the level of the overhead introduced during the tracing operation depends on the filtering method elected. If the time that it takes the trace event to be recorded can be neglected, the overhead introduced by the filtering process can be classified as follows:

|                  |                                          |
|------------------|------------------------------------------|
| Pre-filtering    | System and process/thread-level overhead |
| Inline-filtering | Process/thread-level overhead            |
| Post-filtering   | No overhead; done offline                |

The pre-filtering could be named “critical realtime” filtering in the sense that the filtering of trace event type is manageable at the user level so the user can lower to a minimum the filtering overhead at some user selected level of priority for the inline filtering, or delay the filtering to after execution for the post-filtering. The counterpart of this solution is that the size of the trace stream must be sufficient to record all the trace events. The advantage of the pre-filtering is that the utilization of the trace stream is optimized.

Only pre-filtering is defined by IEEE Std 1003.1-2001. However, great care must be taken in specifying pre-filtering, so that it does not impose unacceptable overhead. Moreover, it is necessary to isolate all the functionality relative to the pre-filtering.

The result of this rationale is to define a new option, the Trace Event Filter option, not necessarily implemented in small realtime systems, where system overhead is minimized to the extent possible.

8405 B.2.11.7 Tracing, *pthread* API

8406 The objective to be able to control tracing for individual threads may be in conflict with the  
 8407 efficiency expected in threads with a *contentionscope* attribute of `PTHREAD_SCOPE_PROCESS`.  
 8408 For these threads, context switches from one thread that has tracing enabled to another thread  
 8409 that has tracing disabled may require a kernel call to inform the kernel whether it has to trace  
 8410 system events executed by that thread or not. For this reason, it was proposed that the ability to  
 8411 enable or disable tracing for `PTHREAD_SCOPE_PROCESS` threads be made optional, through  
 8412 the introduction of a Trace Scope Process option. A trace implementation which did not  
 8413 implement the Trace Scope Process option would not honor the tracing-state attribute of a  
 8414 thread with `PTHREAD_SCOPE_PROCESS`; it would, however, honor the tracing-state attribute  
 8415 of a thread with `PTHREAD_SCOPE_SYSTEM`. This proposal was rejected as:

- 8416 1. Removing desired functionality (per-thread trace control)
- 8417 2. Introducing counter-intuitive behavior for the tracing-state attribute
- 8418 3. Mixing logically orthogonal ideas (thread scheduling and thread tracing)
- 8419 [Objective 4]

8420 Finally, to solve this complex issue, this API does not provide *pthread\_gettracingstate()*,  
 8421 *pthread\_settracingstate()*, *pthread\_attr\_gettracingstate()*, and *pthread\_attr\_settracingstate()*  
 8422 interfaces. These interfaces force the thread implementation to add to the weight of the thread  
 8423 and cause a revision of the threads libraries, just to support tracing. Worse yet,  
 8424 *posix\_trace\_event()* must always test this per-thread variable even in the common case where it is  
 8425 not used at all. Per-thread tracing is easy to implement using existing interfaces where necessary;  
 8426 see the following example.

8427 **Example**

```
8428 /* Caution. Error checks omitted */
8429 static pthread_key_t my_key;
8430 static trace_event_id_t my_event_id;
8431 static pthread_once_t my_once = PTHREAD_ONCE_INIT;

8432 void my_init(void)
8433 {
8434 (void) pthread_key_create(&my_key, NULL);
8435 (void) posix_trace_eventid_open("my", &my_event_id);
8436 }

8437 int get_trace_flag(void)
8438 {
8439 pthread_once(&my_once, my_init);
8440 return (pthread_getspecific(my_key) != NULL);
8441 }

8442 void set_trace_flag(int f)
8443 {
8444 pthread_once(&my_once, my_init);
8445 pthread_setspecific(my_key, f? &my_event_id: NULL);
8446 }

8447 fn()
8448 {
8449 if (get_trace_flag())
8450 posix_trace_event(my_event_id, ...)
```

8451 }

8452 The above example does not implement third-party state setting.

8453 Lastly, per-thread tracing works poorly for threads with `PTHREAD_SCOPE_PROCESS`  
8454 contention scope. These “library” threads have minimal interaction with the kernel and would  
8455 have to explicitly set the attributes whenever they are context switched to a new kernel thread in  
8456 order to trace system events. Such state was explicitly avoided in POSIX threads to keep  
8457 `PTHREAD_SCOPE_PROCESS` threads lightweight.

8458 The reason that keeping `PTHREAD_SCOPE_PROCESS` threads lightweight is important is that  
8459 such threads can be used not just for simple multi-processors but also for co-routine style  
8460 programming (such as discrete event simulation) without inventing a new threads paradigm.  
8461 Adding extra runtime cost to thread context switches will make using POSIX threads less  
8462 attractive in these situations.

#### 8463 B.2.11.8 Rationale on Triggering

8464 The ability to start or stop tracing based on the occurrence of specific trace event types has been  
8465 proposed as a parallel to similar functionality appearing in logic analyzers. Such triggering, in  
8466 order to be very useful, should be based not only on the trace event type, but on trace event-  
8467 specific data, including tests of user-specified fields for matching or threshold values.

8468 Such a facility is unnecessary where the buffering of the stream is not a constraint, since such  
8469 checks can be performed offline during post-mortem analysis.

8470 For example, a large system could incorporate a daemon utility to collect the trace records from  
8471 memory buffers and spool them to secondary storage for later analysis. In the instances where  
8472 resources are truly limited, such as embedded applications, the application incorporation of  
8473 application code to test the circumstances of a trace event and call the trace point only if needed  
8474 is usually straightforward.

8475 For performance reasons, the `posix_trace_event()` function should be implemented using a macro,  
8476 so if the trace is inactive, the trace event point calls are latent code and must cost no more than a  
8477 scalar test.

8478 The API proposed in IEEE Std 1003.1-2001 does not include any triggering functionality.

#### 8479 B.2.11.9 Rationale on Timestamp Clock

8480 It has been suggested that the tracing mechanism should include the possibility of specifying the  
8481 clock to be used in timestamping the trace events. When application trace events must be  
8482 correlated to remote trace events, such a facility could provide a global time reference not  
8483 available from a local clock. Further, the application may be driven by timers based on a clock  
8484 different from that used for the timestamp, and the correlation of the trace to those untraced  
8485 timer activities could be an important part of the analysis of the application.

8486 However, the tracing mechanism needs to be fast and just the provision of such an option can  
8487 materially affect its performance. Leaving aside the performance costs of reading some clocks,  
8488 this notion is also ill-defined when kernel trace events are to be traced by two applications  
8489 making use of different tracing clocks. This can even happen within a single application where  
8490 different parts of the application are served by different clocks. Another complication can occur  
8491 when a clock is maintained strictly at the user level and is unavailable at the kernel level.

8492 It is felt that the benefits of a selectable trace clock do not match its costs. Applications that wish  
8493 to correlate clocks other than the default tracing clock can include trace events with sample  
8494 values of those other clocks, allowing correlation of timestamps from the various independent  
8495 clocks. In any case, such a technique would be required when applications are sensitive to

8496 multiple clocks.

#### 8497 *B.2.11.10 Rationale on Different Overrun Conditions*

8498 The analysis of the dynamic behavior of the trace mechanism shows that different overrun  
8499 conditions may occur. The API must provide a means to manage such conditions in a portable  
8500 way.

#### 8501 **Overrun in Trace Streams Initialized with POSIX\_TRACE\_LOOP Policy**

8502 In this case, the user of the trace mechanism is interested in using the trace stream with  
8503 POSIX\_TRACE\_LOOP policy to record trace events continuously, but ideally without losing any  
8504 trace events. The online analyzer process must get the trace events at a mean speed equivalent to  
8505 the recording speed. Should the trace stream become full, a trace stream overrun occurs. This  
8506 condition is detected by getting the status of the active trace stream (function  
8507 *posix\_trace\_get\_status()*) and looking at the member *posix\_stream\_overrun\_status* of the read  
8508 **posix\_stream\_status** structure. In addition, two predefined trace event types are defined:

- 8509 1. The beginning of a trace overflow, to locate the beginning of an overflow when reading a  
8510 trace stream
- 8511 2. The end of a trace overflow, to locate the end of an overflow, when reading a trace stream

8512 As a timestamp is associated with these predefined trace events, it is possible to know the  
8513 duration of the overflow.

#### 8514 **Overrun in Dumping Trace Streams into Trace Logs**

8515 The user lets the trace mechanism dump the trace stream initialized with  
8516 POSIX\_TRACE\_FLUSH policy automatically into a trace log. If the dump operation is slower  
8517 than the recording of trace events, the trace stream can overrun. This condition is detected by  
8518 getting the status of the active trace stream (function *posix\_trace\_get\_status()*) and looking at the  
8519 member *posix\_log\_overrun\_status* of the read **posix\_stream\_status** structure. This overrun  
8520 indicates that the trace mechanism is not able to operate in this mode at this speed. It is the  
8521 responsibility of the user to modify one of the trace parameters (the stream size or the trace  
8522 event type filter, for instance) to avoid such overrun conditions, if overruns are to be prevented.  
8523 The same already predefined trace event types (see **Overrun in Trace Streams Initialized with**  
8524 **POSIX\_TRACE\_LOOP Policy**) are used to detect and to know the duration of an overflow.

#### 8525 **Reading an Active Trace Stream**

8526 Although this trace API allows one to read an active trace stream with log while it is tracing, this  
8527 feature can lead to false overflow origin interpretation: the trace log or the reader of the trace  
8528 stream. Reading from an active trace stream with log is thus non-portable, and has been left  
8529 unspecified.

#### 8530 **B.2.12 Data Types**

8531 The requirement that additional types defined in this section end in “\_t” was prompted by the  
8532 problem of name space pollution. It is difficult to define a type (where that type is not one  
8533 defined by IEEE Std 1003.1-2001) in one header file and use it in another without adding symbols  
8534 to the name space of the program. To allow implementors to provide their own types, all  
8535 conforming applications are required to avoid symbols ending in “\_t”, which permits the  
8536 implementor to provide additional types. Because a major use of types is in the definition of  
8537 structure members, which can (and in many cases must) be added to the structures defined in  
8538 IEEE Std 1003.1-2001, the need for additional types is compelling.

8539 The types, such as **ushort** and **ulong**, which are in common usage, are not defined in  
 8540 IEEE Std 1003.1-2001 (although **ushort\_t** would be permitted as an extension). They can be  
 8541 added to **<sys/types.h>** using a feature test macro (see Section B.2.2.1 (on page 85)). A suggested  
 8542 symbol for these is **\_SYSIII**. Similarly, the types like **u\_short** would probably be best controlled  
 8543 by **\_BSD**.

8544 Some of these symbols may appear in other headers; see Section B.2.2.2 (on page 86).

8545 **dev\_t** This type may be made large enough to accommodate host-locality considerations  
 8546 of networked systems.

8547 This type must be arithmetic. Earlier proposals allowed this to be non-arithmetic  
 8548 (such as a structure) and provided a *samefile()* function for comparison.

8549 **gid\_t** Some implementations had separated **gid\_t** from **uid\_t** before POSIX.1 was  
 8550 completed. It would be difficult for them to coalesce them when it was  
 8551 unnecessary. Additionally, it is quite possible that user IDs might be different from  
 8552 group IDs because the user ID might wish to span a heterogeneous network,  
 8553 where the group ID might not.

8554 For current implementations, the cost of having a separate **gid\_t** will be only  
 8555 lexical.

8556 **mode\_t** This type was chosen so that implementations could choose the appropriate  
 8557 integer type, and for compatibility with the ISO C standard. 4.3 BSD uses  
 8558 **unsigned short** and the SVID uses **ushort**, which is the same. Historically, only the  
 8559 low-order sixteen bits are significant.

8560 **nlink\_t** This type was introduced in place of **short** for *st\_nlink* (see the **<sys/stat.h>** header)  
 8561 in response to an objection that **short** was too small.

8562 **off\_t** This type is used only in *lseek()*, *fcntl()*, and **<sys/stat.h>**. Many implementations  
 8563 would have difficulties if it were defined as anything other than **long**. Requiring  
 8564 an integer type limits the capabilities of *lseek()* to four gigabytes. The ISO C  
 8565 standard supplies routines that use larger types; see *fgetpos()* and *fsetpos()*. XSI-  
 8566 conformant systems provide the *fseeko()* and *ftello()* functions that use larger  
 8567 types.

8568 **pid\_t** The inclusion of this symbol was controversial because it is tied to the issue of the  
 8569 representation of a process ID as a number. From the point of view of a  
 8570 conforming application, process IDs should be “magic cookies”<sup>1</sup> that are produced  
 8571 by calls such as *fork()*, used by calls such as *waitpid()* or *kill()*, and not otherwise  
 8572 analyzed (except that the sign is used as a flag for certain operations).

8573 The concept of a {PID\_MAX} value interacted with this in early proposals. Treating  
 8574 process IDs as an opaque type both removes the requirement for {PID\_MAX} and  
 8575 allows systems to be more flexible in providing process IDs that span a large range  
 8576 of values, or a small one.

8577 Since the values in **uid\_t**, **gid\_t**, and **pid\_t** will be numbers generally, and  
 8578 potentially both large in magnitude and sparse, applications that are based on

8579

---

8580 1. An historical term meaning: “An opaque object, or token, of determinate size, whose significance is known only to the entity  
 8581 which created it. An entity receiving such a token from the generating entity may only make such use of the ‘cookie’ as is defined  
 8582 and permitted by the supplying entity.”

|      |                |                                                                                                                                    |
|------|----------------|------------------------------------------------------------------------------------------------------------------------------------|
| 8583 |                | arrays of objects of this type are unlikely to be fully portable in any case. Solutions                                            |
| 8584 |                | that treat them as magic cookies will be portable.                                                                                 |
| 8585 |                | {CHILD_MAX} precludes the possibility of a “toy implementation”, where there                                                       |
| 8586 |                | would only be one process.                                                                                                         |
| 8587 | <b>ssize_t</b> | This is intended to be a signed analog of <b>size_t</b> . The wording is such that an                                              |
| 8588 |                | implementation may either choose to use a longer type or simply to use the signed                                                  |
| 8589 |                | version of the type that underlies <b>size_t</b> . All functions that return <b>ssize_t</b> ( <i>read()</i>                        |
| 8590 |                | and <i>write()</i> ) describe as “implementation-defined” the result of an input exceeding                                         |
| 8591 |                | {SSIZE_MAX}. It is recognized that some implementations might have <b>ints</b> that                                                |
| 8592 |                | are smaller than <b>size_t</b> . A conforming application would be constrained not to                                              |
| 8593 |                | perform I/O in pieces larger than {SSIZE_MAX}, but a conforming application                                                        |
| 8594 |                | using extensions would be able to use the full range if the implementation                                                         |
| 8595 |                | provided an extended range, while still having a single type-compatible interface.                                                 |
| 8596 |                | The symbols <b>size_t</b> and <b>ssize_t</b> are also required in <b>&lt;unistd.h&gt;</b> to minimize the                          |
| 8597 |                | changes needed for calls to <i>read()</i> and <i>write()</i> . Implementors are reminded that it                                   |
| 8598 |                | must be possible to include both <b>&lt;sys/types.h&gt;</b> and <b>&lt;unistd.h&gt;</b> in the same                                |
| 8599 |                | program (in either order) without error.                                                                                           |
| 8600 | <b>uid_t</b>   | Before the addition of this type, the data types used to represent these values                                                    |
| 8601 |                | varied throughout early proposals. The <b>&lt;sys/stat.h&gt;</b> header defined these values as                                    |
| 8602 |                | type <b>short</b> , the <b>&lt;passwd.h&gt;</b> file (now <b>&lt;pwd.h&gt;</b> and <b>&lt;grp.h&gt;</b> ) used an <b>int</b> , and |
| 8603 |                | <i>getuid()</i> returned an <b>int</b> . In response to a strong objection to the inconsistent                                     |
| 8604 |                | definitions, all the types were switched to <b>uid_t</b> .                                                                         |
| 8605 |                | In practice, those historical implementations that use varying types of this sort can                                              |
| 8606 |                | typedef <b>uid_t</b> to <b>short</b> with no serious consequences.                                                                 |
| 8607 |                | The problem associated with this change concerns object compatibility after                                                        |
| 8608 |                | structure size changes. Since most implementations will define <b>uid_t</b> as a short, the                                        |
| 8609 |                | only substantive change will be a reduction in the size of the <b>passwd</b> structure.                                            |
| 8610 |                | Consequently, implementations with an overriding concern for object                                                                |
| 8611 |                | compatibility can pad the structure back to its current size. For that reason, this                                                |
| 8612 |                | problem was not considered critical enough to warrant the addition of a separate                                                   |
| 8613 |                | type to POSIX.1.                                                                                                                   |
| 8614 |                | The types <b>uid_t</b> and <b>gid_t</b> are magic cookies. There is no {UID_MAX} defined by                                        |
| 8615 |                | POSIX.1, and no structure imposed on <b>uid_t</b> and <b>gid_t</b> other than that they be                                         |
| 8616 |                | positive arithmetic types. (In fact, they could be <b>unsigned char</b> .) There is no                                             |
| 8617 |                | maximum or minimum specified for the number of distinct user or group IDs.                                                         |

## 8618 **B.3 System Interfaces**

8619 See the RATIONALE sections on the individual reference pages.

### 8620 **B.3.1 Examples for Spawn**

8621 The following long examples are provided in the Rationale (Informative) volume of  
8622 IEEE Std 1003.1-2001 as a supplement to the reference page for *posix\_spawn()*.

#### 8623 **Example Library Implementation of Spawn**

8624 The *posix\_spawn()* or *posix\_spawnnp()* functions provide the following:

- 8625 • Simply start a process executing a process image. This is the simplest application for process  
8626 creation, and it may cover most executions of *fork()*.
- 8627 • Support I/O redirection, including pipes.
- 8628 • Run the child under a user and group ID in the domain of the parent.
- 8629 • Run the child at any priority in the domain of the parent.

8630 The *posix\_spawn()* or *posix\_spawnnp()* functions do not cover every possible use of the *fork()*  
8631 function, but they do span the common applications: typical use by a shell and a login utility.

8632 The price for an application is that before it calls *posix\_spawn()* or *posix\_spawnnp()*, the parent  
8633 must adjust to a state that *posix\_spawn()* or *posix\_spawnnp()* can map to the desired state for the  
8634 child. Environment changes require the parent to save some of its state and restore it afterwards.  
8635 The effective behavior of a successful invocation of *posix\_spawn()* is as if the operation were  
8636 implemented with POSIX operations as follows:

```

8637 #include <sys/types.h>
8638 #include <stdlib.h>
8639 #include <stdio.h>
8640 #include <unistd.h>
8641 #include <sched.h>
8642 #include <fcntl.h>
8643 #include <signal.h>
8644 #include <errno.h>
8645 #include <string.h>
8646 #include <signal.h>

8647 /* #include <spawn.h> */
8648 /*****
8649 /* Things that could be defined in spawn.h */
8650 *****/
8651 typedef struct
8652 {
8653 short posix_attr_flags;
8654 #define POSIX_SPAWN_SETPGROUP 0x1
8655 #define POSIX_SPAWN_SETSIGMASK 0x2
8656 #define POSIX_SPAWN_SETSIGDEF 0x4
8657 #define POSIX_SPAWN_SETSCHEDULER 0x8
8658 #define POSIX_SPAWN_SETSCHEDPARAM 0x10
8659 #define POSIX_SPAWN_RESETIDS 0x20
8660 pid_t posix_attr_pgroup;
8661 sigset_t posix_attr_sigmask;
8662 sigset_t posix_attr_sigdefault;

```

```

8663 int posix_attr_schedpolicy;
8664 struct sched_param posix_attr_schedparam;
8665 } posix_spawnattr_t;

8666 typedef char *posix_spawn_file_actions_t;

8667 int posix_spawn_file_actions_init(
8668 posix_spawn_file_actions_t *file_actions);
8669 int posix_spawn_file_actions_destroy(
8670 posix_spawn_file_actions_t *file_actions);
8671 int posix_spawn_file_actions_addclose(
8672 posix_spawn_file_actions_t *file_actions, int fildes);
8673 int posix_spawn_file_actions_adddup2(
8674 posix_spawn_file_actions_t *file_actions, int fildes,
8675 int newfildes);
8676 int posix_spawn_file_actions_addopen(
8677 posix_spawn_file_actions_t *file_actions, int fildes,
8678 const char *path, int oflag, mode_t mode);
8679 int posix_spawnattr_init(posix_spawnattr_t *attr);
8680 int posix_spawnattr_destroy(posix_spawnattr_t *attr);
8681 int posix_spawnattr_getflags(const posix_spawnattr_t *attr,
8682 short *lags);
8683 int posix_spawnattr_setflags(posix_spawnattr_t *attr, short flags);
8684 int posix_spawnattr_getpgroup(const posix_spawnattr_t *attr,
8685 pid_t *pgroup);
8686 int posix_spawnattr_setpgroup(posix_spawnattr_t *attr, pid_t pgroup);
8687 int posix_spawnattr_getschedpolicy(const posix_spawnattr_t *attr,
8688 int *schedpolicy);
8689 int posix_spawnattr_setschedpolicy(posix_spawnattr_t *attr,
8690 int schedpolicy);
8691 int posix_spawnattr_getschedparam(const posix_spawnattr_t *attr,
8692 struct sched_param *schedparam);
8693 int posix_spawnattr_setschedparam(posix_spawnattr_t *attr,
8694 const struct sched_param *schedparam);
8695 int posix_spawnattr_getsigmask(const posix_spawnattr_t *attr,
8696 sigset_t *sigmask);
8697 int posix_spawnattr_setsigmask(posix_spawnattr_t *attr,
8698 const sigset_t *sigmask);
8699 int posix_spawnattr_getdefault(const posix_spawnattr_t *attr,
8700 sigset_t *sigdefault);
8701 int posix_spawnattr_setsigdefault(posix_spawnattr_t *attr,
8702 const sigset_t *sigdefault);
8703 int posix_spawn(pid_t *pid, const char *path,

### I/O Redirection with Spawn

I/O redirection with *posix\_spawn()* or *posix\_spawnnp()* is accomplished by crafting a *file\_actions* argument to effect the desired redirection. Such a redirection follows the general outline of the following example:

```

9039 /* To redirect new standard output (fd 1) to a file, */
9040 /* and redirect new standard input (fd 0) from my fd socket_pair[1], */
9041 /* and close my fd socket_pair[0] in the new process. */
9042 posix_spawn_file_actions_t file_actions;
9043 posix_spawn_file_actions_init(&file_actions);
9044 posix_spawn_file_actions_addopen(&file_actions, 1, "newout", ...);
9045 posix_spawn_file_actions_dup2(&file_actions, socket_pair[1], 0);
9046 posix_spawn_file_actions_close(&file_actions, socket_pair[0]);
9047 posix_spawn_file_actions_close(&file_actions, socket_pair[1]);
9048 posix_spawn(..., &file_actions, ...);
9049 posix_spawn_file_actions_destroy(&file_actions);

```

**9050        Spawning a Process Under a New User ID**

9051        Spawning a process under a new user ID follows the outline shown in the following example:

```
9052 Save = getuid();
9053 setuid(newid);
9054 posix_spawn(...);
9055 setuid(Save);
```

# Rationale for Shell and Utilities

9062

## 9063 C.1 Introduction

### 9064 C.1.1 Scope

9065 Refer to Section A.1.1 (on page 3).

### 9066 C.1.2 Conformance

9067 Refer to Section A.2 (on page 9).

### 9068 C.1.3 Normative References

9069 There is no additional rationale provided for this section.

### 9070 C.1.4 Change History

9071 The change history is provided as an informative section, to track changes from previous issues  
9072 of IEEE Std 1003.1-2001.

9073 The following sections describe changes made to the Shell and Utilities volume of  
9074 IEEE Std 1003.1-2001 since Issue 5 of the base document. The CHANGE HISTORY section for  
9075 each utility describes technical changes made to that utility from Issue 5. Changes between  
9076 earlier issues of the base document and Issue 5 are not included.

9077 The change history between Issue 5 and Issue 6 also lists the changes since the  
9078 ISO POSIX-2: 1993 standard.

#### 9079 Changes from Issue 5 to Issue 6 (IEEE Std 1003.1-2001)

9080 The following list summarizes the major changes that were made in the Shell and Utilities  
9081 volume of IEEE Std 1003.1-2001 from Issue 5 to Issue 6:

- 9082 • This volume of IEEE Std 1003.1-2001 is extensively revised so that it can be both an IEEE  
9083 POSIX Standard and an Open Group Technical Standard.
- 9084 • The terminology has been reworked to meet the style requirements.
- 9085 • Shading notation and margin codes are introduced for identification of options within the  
9086 volume.
- 9087 • This volume of IEEE Std 1003.1-2001 is updated to mandate support of FIPS 151-2. The  
9088 following changes were made:
  - 9089 — Support is mandated for the capabilities associated with the following symbolic  
9090 constants:

9091        \_POSIX\_CHOWN\_RESTRICTED  
9092        \_POSIX\_JOB\_CONTROL  
9093        \_POSIX\_SAVED\_IDS

- 9094 — In the environment for the login shell, the environment variables *LOGNAME* and *HOME*  
9095 shall be defined and have the properties described in the Base Definitions volume of

- 9096 IEEE Std 1003.1-2001, Chapter 7, Locale.
- 9097 • This volume of IEEE Std 1003.1-2001 is updated to align with some features of the Single  
9098 UNIX Specification.
- 9099 • A new section on Utility Limits is added.
- 9100 • A section on the Relationships to Other Documents is added.
- 9101 • Concepts and definitions have been moved to a separate volume.
- 9102 • A RATIONALE section is added to each reference page.
- 9103 • The *c99* utility is added as a replacement for *c89*, which is withdrawn in this issue.
- 9104 • IEEE Std 1003.2d-1994 is incorporated, adding the *qalter*, *qdel*, *qhold*, *qmove*, *qmsg*, *qrerun*, *qrls*,  
9105 *qselect*, *qsig*, *qstat*, and *qsub* utilities.
- 9106 • IEEE P1003.2b draft standard is incorporated, making extensive updates and adding the *iconv*  
9107 utility.
- 9108 • IEEE PASC Interpretations are applied.
- 9109 • The Open Group's corrigenda and resolutions are applied.

#### 9110 **New Features in Issue 6**

9111 The following table lists the new utilities introduced since the ISO POSIX-2:1993 standard (as  
9112 modified by IEEE Std 1003.2d-1994). Apart from the *c99* and *iconv* utilities, these are all part of  
9113 the XSI extension.

| New Utilities in Issue 6 |                 |               |              |             |                   |               |             |
|--------------------------|-----------------|---------------|--------------|-------------|-------------------|---------------|-------------|
| 9116 <i>admin</i>        | <i>compress</i> | <i>gencat</i> | <i>ipcrm</i> | <i>nl</i>   | <i>tsort</i>      | <i>unlink</i> | <i>val</i>  |
| 9117 <i>c99</i>          | <i>cxref</i>    | <i>get</i>    | <i>ipcs</i>  | <i>prs</i>  | <i>ulimit</i>     | <i>uucp</i>   | <i>what</i> |
| 9118 <i>cal</i>          | <i>delta</i>    | <i>hash</i>   | <i>link</i>  | <i>sact</i> | <i>uncompress</i> | <i>uustat</i> | <i>zcat</i> |
| 9119 <i>cflow</i>        | <i>fuser</i>    | <i>iconv</i>  | <i>m4</i>    | <i>sccs</i> | <i>unget</i>      | <i>uux</i>    |             |

#### 9120 **C.1.5 Terminology**

9121 Refer to Section A.1.4 (on page 5).

#### 9122 **C.1.6 Definitions**

9123 Refer to Section A.3 (on page 13).

#### 9124 **C.1.7 Relationship to Other Documents**

##### 9125 *C.1.7.1 System Interfaces*

9126 It has been pointed out that the Shell and Utilities volume of IEEE Std 1003.1-2001 assumes that  
9127 a great deal of functionality from the System Interfaces volume of IEEE Std 1003.1-2001 is  
9128 present, but never states exactly how much (and strictly does not need to since both are  
9129 mandated on a conforming system). This section is an attempt to clarify the assumptions.

9130 **File Removal**

9131 This is intended to be a summary of the *unlink()* and *rmdir()* requirements. Note that it is  
9132 possible using the *unlink()* function for item 4. to occur.

9133 *C.1.7.2 Concepts Derived from the ISO C Standard*

9134 This section was introduced to address the issue that there was insufficient detail presented by  
9135 such utilities as *awk* or *sh* about their procedural control statements and their methods of  
9136 performing arithmetic functions.

9137 The ISO C standard was selected as a model because most historical implementations of the  
9138 standard utilities were written in C. Thus, it was more likely that they would act in the desired  
9139 manner without modification.

9140 Using the ISO C standard is primarily a notational convenience so that the many procedural  
9141 languages in the Shell and Utilities volume of IEEE Std 1003.1-2001 would not have to be  
9142 rigorously described in every aspect. Its selection does not require that the standard utilities be  
9143 written in Standard C; they could be written in Common Usage C, Ada, Pascal, assembler  
9144 language, or anything else.

9145 The sizes of the various numeric values refer to C-language data types that are allowed to be  
9146 different sizes by the ISO C standard. Thus, like a C-language application, a shell application  
9147 cannot rely on their exact size. However, it can rely on their minimum sizes expressed in the  
9148 ISO C standard, such as {LONG\_MAX} for a **long** type.

9149 The behavior on overflow is undefined for ISO C standard arithmetic. Therefore, the standard  
9150 utilities can use “bignum” representation for integers so that there is no fixed maximum unless  
9151 otherwise stated in the utility description. Similarly, standard utilities can use infinite-precision  
9152 representations for floating-point arithmetic, as long as these representations exceed the ISO C  
9153 standard requirements.

9154 This section addresses only the issue of semantics; it is not intended to specify syntax. For  
9155 example, the ISO C standard requires that 0L be recognized as an integer constant equal to zero,  
9156 but utilities such as *awk* and *sh* are not required to recognize 0L (though they are allowed to, as  
9157 an extension).

9158 The ISO C standard requires that a C compiler must issue a diagnostic for constants that are too  
9159 large to represent. Most standard utilities are not required to issue these diagnostics; for  
9160 example, the command:

9161 `diff -C 2147483648 file1 file2`

9162 has undefined behavior, and the *diff* utility is not required to issue a diagnostic even if the  
9163 number 2 147 483 648 cannot be represented.

9164 **C.1.8 Portability**

9165 Refer to Section A.1.5 (on page 8).

9166 *C.1.8.1 Codes*

9167 Refer to Section A.1.5.1 (on page 8).

### 9168 C.1.9 Utility Limits

9169 This section grew out of an idea that originated with the original POSIX.1, in the tables of system  
 9170 limits for the `sysconf()` and `pathconf()` functions. The idea being that a conforming application  
 9171 can be written to use the most restrictive values that a minimal system can provide, but it should  
 9172 not have to. The values provided represent compromises so that some vendors can use  
 9173 historically limited versions of UNIX system utilities. They are the highest values that a strictly  
 9174 conforming application can assume, given no other information.

9175 However, by using the `getconf` utility or the `sysconf()` function, the elegant application can be  
 9176 tailored to more liberal values on some of the specific instances of specific implementations.

9177 There is no explicitly stated requirement that an implementation provide finite limits for any of  
 9178 these numeric values; the implementation is free to provide essentially unbounded capabilities  
 9179 (where it makes sense), stopping only at reasonable points such as `{ULONG_MAX}` (from the  
 9180 ISO C standard). Therefore, applications desiring to tailor themselves to the values on a  
 9181 particular implementation need to be ready for possibly huge values; it may not be a good idea  
 9182 to allocate blindly a buffer for an input line based on the value of `{LINE_MAX}`, for instance.  
 9183 However, unlike the System Interfaces volume of IEEE Std 1003.1-2001, there is no set of limits  
 9184 that return a special indication meaning “unbounded”. The implementation should always  
 9185 return an actual number, even if the number is very large.

9186 The statement:

9187 “It is not guaranteed that the application ...”

9188 is an indication that many of these limits are designed to ensure that implementors design their  
 9189 utilities without arbitrary constraints related to unimaginative programming. There are certainly  
 9190 conditions under which combinations of options can cause failures that would not render an  
 9191 implementation non-conforming. For example, `{EXPR_NEST_MAX}` and `{ARG_MAX}` could  
 9192 collide when expressions are large; combinations of `{BC_SCALE_MAX}` and `{BC_DIM_MAX}`  
 9193 could exceed virtual memory.

9194 In the Shell and Utilities volume of IEEE Std 1003.1-2001, the notion of a limit being guaranteed  
 9195 for the process lifetime, as it is in the System Interfaces volume of IEEE Std 1003.1-2001, is not as  
 9196 useful to a shell script. The `getconf` utility is probably a process itself, so the guarantee would be  
 9197 without value. Therefore, the Shell and Utilities volume of IEEE Std 1003.1-2001 requires the  
 9198 guarantee to be for the session lifetime. This will mean that many vendors will either return very  
 9199 conservative values or possibly implement `getconf` as a built-in.

9200 It may seem confusing to have limits that apply only to a single utility grouped into one global  
 9201 section. However, the alternative, which would be to disperse them out into their utility  
 9202 description sections, would cause great difficulty when `sysconf()` and `getconf` were described.  
 9203 Therefore, the standard developers chose the global approach.

9204 Each language binding could provide symbol names that are slightly different from those shown  
 9205 here. For example, the C-Language Binding option adds a leading underscore to the symbols as a  
 9206 prefix.

9207 The following comments describe selection criteria for the symbols and their values:

9208 `{ARG_MAX}`

9209 This is defined by the System Interfaces volume of IEEE Std 1003.1-2001. Unfortunately, it is  
 9210 very difficult for a conforming application to deal with this value, as it does not know how  
 9211 much of its argument space is being consumed by the environment variables of the user.

9212 {BC\_BASE\_MAX}  
 9213 {BC\_DIM\_MAX}  
 9214 {BC\_SCALE\_MAX}  
 9215 These were originally one value, {BC\_SCALE\_MAX}, but it was unreasonable to link all  
 9216 three concepts into one limit.

9217 {CHILD\_MAX}  
 9218 This is defined by the System Interfaces volume of IEEE Std 1003.1-2001.

9219 {COLL\_WEIGHTS\_MAX}  
 9220 The weights assigned to **order** can be considered as “passes” through the collation  
 9221 algorithm.

9222 {EXPR\_NEST\_MAX}  
 9223 The value for expression nesting was borrowed from the ISO C standard.

9224 {LINE\_MAX}  
 9225 This is a global limit that affects all utilities, unless otherwise noted. The {MAX\_CANON}  
 9226 value from the System Interfaces volume of IEEE Std 1003.1-2001 may further limit input  
 9227 lines from terminals. The {LINE\_MAX} value was the subject of much debate and is a  
 9228 compromise between those who wished to have unlimited lines and those who understood  
 9229 that many historical utilities were written with fixed buffers. Frequently, utility writers  
 9230 selected the UNIX system constant BUFSIZ to allocate these buffers; therefore, some utilities  
 9231 were limited to 512 bytes for I/O lines, while others achieved 4096 bytes or greater.

9232 It should be noted that {LINE\_MAX} applies only to input line length; there is no  
 9233 requirement in IEEE Std 1003.1-2001 that limits the length of output lines. Utilities such as  
 9234 *awk*, *sed*, and *paste* could theoretically construct lines longer than any of the input lines they  
 9235 received, depending on the options used or the instructions from the application. They are  
 9236 not required to truncate their output to {LINE\_MAX}. It is the responsibility of the  
 9237 application to deal with this. If the output of one of those utilities is to be piped into another  
 9238 of the standard utilities, line length restrictions will have to be considered; the *fold* utility,  
 9239 among others, could be used to ensure that only reasonable line lengths reach utilities or  
 9240 applications.

9241 {LINK\_MAX}  
 9242 This is defined by the System Interfaces volume of IEEE Std 1003.1-2001.

9243 {MAX\_CANON}  
 9244 {MAX\_INPUT}  
 9245 {NAME\_MAX}  
 9246 {NGROUPS\_MAX}  
 9247 {OPEN\_MAX}  
 9248 {PATH\_MAX}  
 9249 {PIPE\_BUF}  
 9250 These limits are defined by the System Interfaces volume of IEEE Std 1003.1-2001. Note that  
 9251 the byte lengths described by some of these values continue to represent bytes, even if the  
 9252 applicable character set uses a multi-byte encoding.

9253 {RE\_DUP\_MAX}  
 9254 The value selected is consistent with historical practice. Although the name implies that it  
 9255 applies to all REs, only BREs use the interval notation `\{m,n\}` addressed by this limit.

9256 {POSIX2\_SYMLINKS}  
 9257 The {POSIX2\_SYMLINKS} variable indicates that the underlying operating system supports  
 9258 the creation of symbolic links in specific directories. Many of the utilities defined in  
 9259 IEEE Std 1003.1-2001 that deal with symbolic links do not depend on this value. For

example, a utility that follows symbolic links (or does not, as the case may be) will only be affected by a symbolic link if it encounters one. Presumably, a file system that does not support symbolic links will not contain any. This variable does affect such utilities as *ln -s* and *pax* that attempt to create symbolic links.

{POSIX2\_SYMLINKS} was developed even though there is no comparable configuration value for the system interfaces.

There are different limits associated with command lines and input to utilities, depending on the method of invocation. In the case of a C program *exec*-ing a utility, {ARG\_MAX} is the underlying limit. In the case of the shell reading a script and *exec*-ing a utility, {LINE\_MAX} limits the length of lines the shell is required to process, and {ARG\_MAX} will still be a limit. If a user is entering a command on a terminal to the shell, requesting that it invoke the utility, {MAX\_INPUT} may restrict the length of the line that can be given to the shell to a value below {LINE\_MAX}.

When an option is supported, *getconf* returns a value of 1. For example, when C development is supported:

```
if ["$(getconf POSIX2_C_DEV)" -eq 1]; then
 echo C supported
fi
```

The *sysconf()* function in the C-Language Binding option would return 1.

The following comments describe selection criteria for the symbols and their values:

POSIX2\_C\_BIND  
 POSIX2\_C\_DEV  
 POSIX2\_FORT\_DEV  
 POSIX2\_FORT\_RUN  
 POSIX2\_SW\_DEV  
 POSIX2\_UPE

It is possible for some (usually privileged) operations to remove utilities that support these options or otherwise to render these options unsupported. The header files, the *sysconf()* function, or the *getconf* utility will not necessarily detect such actions, in which case they should not be considered as rendering the implementation non-conforming. A test suite should not attempt tests such as:

```
rm /usr/bin/c99
getconf POSIX2_C_DEV
```

POSIX2\_LOCALEDEF

This symbol was introduced to allow implementations to restrict supported locales to only those supplied by the implementation.

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/2 is applied, deleting the entry for {POSIX2\_VERSION} since it is not a utility limit minimum value.

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/3 is applied, changing the text in Utility Limits from: “utility (see *getconf*) through the *sysconf()* function defined in the System Interfaces volume of IEEE Std 1003.1-2001. The literal names shown in Table 1-3 apply only to the *getconf* utility; the high-level language binding describes the exact form of each name to be used by the interfaces in that binding.” to: “utility (see *getconf*).”.

9303 **C.1.10 Grammar Conventions**

9304 There is no additional rationale provided for this section.

9305 **C.1.11 Utility Description Defaults**9306 This section is arranged with headings in the same order as all the utility descriptions. It is a  
9307 collection of related and unrelated information concerning:

9308 1. The default actions of utilities

9309 2. The meanings of notations used in IEEE Std 1003.1-2001 that are specific to individual  
9310 utility sections9311 Although this material may seem out of place here, it is important that this information appear  
9312 before any of the utilities to be described later.9313 **NAME**

9314 There is no additional rationale provided for this section.

9315 **SYNOPSIS**

9316 There is no additional rationale provided for this section.

9317 **DESCRIPTION**

9318 There is no additional rationale provided for this section.

9319 **OPTIONS**9320 Although it has not always been possible, the standard developers tried to avoid repeating  
9321 information to reduce the risk that duplicate explanations could each be modified differently.9322 The need to recognize `--` is required because conforming applications need to shield their  
9323 operands from any arbitrary options that the implementation may provide as an extension. For  
9324 example, if the standard utility *foo* is listed as taking no options, and the application needed to  
9325 give it a pathname with a leading hyphen, it could safely do it as:9326 `foo -- -myfile`9327 and avoid any problems with `-m` used as an extension.9328 **OPERANDS**9329 The usage of `-` is never shown in the SYNOPSIS. Similarly, the usage of `--` is never shown.9330 The requirement for processing operands in command-line order is to avoid a “WeirdNIX”  
9331 utility that might choose to sort the input files alphabetically, by size, or by directory order.  
9332 Although this might be acceptable for some utilities, in general the programmer has a right to  
9333 know exactly what order will be chosen.9334 Some of the standard utilities take multiple *file* operands and act as if they were processing the  
9335 concatenation of those files. For example:9336 `asa file1 file2`

9337 and:

9338 `cat file1 file2 | asa`

have similar results when questions of file access, errors, and performance are ignored. Other utilities such as *grep* or *wc* have completely different results in these two cases. This latter type of utility is always identified in its DESCRIPTION or OPERANDS sections, whereas the former is not. Although it might be possible to create a general assertion about the former case, the following points must be addressed:

- Access times for the files might be different in the operand case *versus* the *cat* case.
- The utility may have error messages that are cognizant of the input filename, and this added value should not be suppressed. (As an example, *awk* sets a variable with the filename at each file boundary.)

## STDIN

There is no additional rationale provided for this section.

## INPUT FILES

A conforming application cannot assume the following three commands are equivalent:

```
tail -n +2 file
(sed -n 1q; cat) < file
cat file | (sed -n 1q; cat)
```

The second command is equivalent to the first only when the file is seekable. In the third command, if the file offset in the open file description were not unspecified, *sed* would have to be implemented so that it read from the pipe 1 byte at a time or it would have to employ some method to seek backwards on the pipe. Such functionality is not defined currently in POSIX.1 and does not exist on all historical systems. Other utilities, such as *head*, *read*, and *sh*, have similar properties, so the restriction is described globally in this section.

The definition of “text file” is strictly enforced for input to the standard utilities; very few of them list exceptions to the undefined results called for here. (Of course, “undefined” here does not mean that historical implementations necessarily have to change to start indicating error conditions. Conforming applications cannot rely on implementations succeeding or failing when non-text files are used.)

The utilities that allow line continuation are generally those that accept input languages, rather than pure data. It would be unusual for an input line of this type to exceed {LINE\_MAX} bytes and unreasonable to require that the implementation allow unlimited accumulation of multiple lines, each of which could reach {LINE\_MAX}. Thus, for a conforming application the total of all the continued lines in a set cannot exceed {LINE\_MAX}.

The format description is intended to be sufficiently rigorous to allow other applications to generate these input files. However, since <blank>s can legitimately be included in some of the fields described by the standard utilities, particularly in locales other than the POSIX locale, this intent is not always realized.

## ENVIRONMENT VARIABLES

There is no additional rationale provided for this section.

**ASYNCHRONOUS EVENTS**

Because there is no language prohibiting it, a utility is permitted to catch a signal, perform some additional processing (such as deleting temporary files), restore the default signal action (or action inherited from the parent process), and resignal itself.

**STDOUT**

The format description is intended to be sufficiently rigorous to allow post-processing of output by other programs, particularly by an *awk* or *lex* parser.

**STDERR**

This section does not describe error messages that refer to incorrect operation of the utility. Consider a utility that processes program source code as its input. This section is used to describe messages produced by a correctly operating utility that encounters an error in the program source code on which it is processing. However, a message indicating that the utility had insufficient memory in which to operate would not be described.

Some utilities have traditionally produced warning messages without returning a non-zero exit status; these are specifically noted in their sections. Other utilities shall not write to standard error if they complete successfully, unless the implementation provides some sort of extension to increase the verbosity or debugging level.

The format descriptions are intended to be sufficiently rigorous to allow post-processing of output by other programs.

**OUTPUT FILES**

The format description is intended to be sufficiently rigorous to allow post-processing of output by other programs, particularly by an *awk* or *lex* parser.

Receipt of the SIGQUIT signal should generally cause termination (unless in some debugging mode) that would bypass any attempted recovery actions.

**EXTENDED DESCRIPTION**

There is no additional rationale provided for this section.

**EXIT STATUS**

Note the additional discussion of exit values in *Exit Status for Commands* in the *sh* utility. It describes requirements for returning exit values greater than 125.

A utility may list zero as a successful return, 1 as a failure for a specific reason, and greater than 1 as “an error occurred”. In this case, unspecified conditions may cause a 2 or 3, or other value, to be returned. A strictly conforming application should be written so that it tests for successful exit status values (zero in this case), rather than relying upon the single specific error value listed in IEEE Std 1003.1-2001. In that way, it will have maximum portability, even on implementations with extensions.

The standard developers are aware that the general non-enumeration of errors makes it difficult to write test suites that test the *incorrect* operation of utilities. There are some historical implementations that have expended effort to provide detailed status messages and a helpful environment to bypass or explain errors, such as prompting, retrying, or ignoring unimportant syntax errors; other implementations have not. Since there is no realistic way to mandate system behavior in cases of undefined application actions or system problems—in a manner acceptable to all cultures and environments—attention has been limited to the correct operation of utilities

9419 by the conforming application. Furthermore, the conforming application does not need detailed  
 9420 information concerning errors that it caused through incorrect usage or that it cannot correct.

9421 There is no description of defaults for this section because all of the standard utilities specify  
 9422 something (or explicitly state “Unspecified”) for exit status.

#### 9423 **CONSEQUENCES OF ERRORS**

9424 Several actions are possible when a utility encounters an error condition, depending on the  
 9425 severity of the error and the state of the utility. Included in the possible actions of various  
 9426 utilities are: deletion of temporary or intermediate work files; deletion of incomplete files; and  
 9427 validity checking of the file system or directory.

9428 The text about recursive traversing is meant to ensure that utilities such as *find* process as many  
 9429 files in the hierarchy as they can. They should not abandon all of the hierarchy at the first error  
 9430 and resume with the next command-line operand, but should attempt to keep going.

#### 9431 **APPLICATION USAGE**

9432 This section provides additional caveats, issues, and recommendations to the developer.

#### 9433 **EXAMPLES**

9434 This section provides sample usage.

#### 9435 **RATIONALE**

9436 There is no additional rationale provided for this section.

#### 9437 **FUTURE DIRECTIONS**

9438 FUTURE DIRECTIONS sections act as pointers to related work that may impact the interface in  
 9439 the future, and often cautions the developer to architect the code to account for a change in this  
 9440 area. Note that a future directions statement should not be taken as a commitment to adopt a  
 9441 feature or interface in the future.

#### 9442 **SEE ALSO**

9443 There is no additional rationale provided for this section.

#### 9444 **CHANGE HISTORY**

9445 There is no additional rationale provided for this section.

### 9446 **C.1.12 Considerations for Utilities in Support of Files of Arbitrary Size**

9447 This section is intended to clarify the requirements for utilities in support of large files.

9448 The utilities listed in this section are utilities which are used to perform administrative tasks  
 9449 such as to create, move, copy, remove, change the permissions, or measure the resources of a  
 9450 file. They are useful both as end-user tools and as utilities invoked by applications during  
 9451 software installation and operation.

9452 The *chgrp*, *chmod*, *chown*, *ln*, and *rm* utilities probably require use of large file-capable versions of  
 9453 *stat()*, *lstat()*, *ftw()*, and the **stat** structure.

9454 The *cat*, *cksum*, *cmp*, *cp*, *dd*, *mv*, *sum*, and *touch* utilities probably require use of large file-capable  
 9455 versions of *creat()*, *open()*, and *fopen()*.

The *cat*, *cksum*, *cmp*, *dd*, *df*, *du*, *ls*, and *sum* utilities may require writing large integer values. For example:

- The *cat* utility might have a **-n** option which counts <newline>s.
- The *cksum* and *ls* utilities report file sizes.
- The *cmp* utility reports the line number at which the first difference occurs, and also has a **-l** option which reports file offsets.
- The *dd*, *df*, *du*, *ls*, and *sum* utilities report block counts.

The *dd*, *find*, and *test* utilities may need to interpret command arguments that contain 64-bit values. For *dd*, the arguments include *skip=n*, *seek=n*, and *count=n*. For *find*, the arguments include **-sizen**. For *test*, the arguments are those associated with algebraic comparisons.

The *df* utility might need to access large file systems with *statvfs()*.

The *ulimit* utility will need to use large file-capable versions of *getrlimit()* and *setrlimit()* and be able to read and write large integer values.

### C.1.13 Built-In Utilities

All of these utilities can be *exec*-ed. There is no requirement that these utilities are actually built into the shell itself, but many shells need the capability to do so because the Shell and Utilities volume of IEEE Std 1003.1-2001, Section 2.9.1.1, Command Search and Execution requires that they be found prior to the *PATH* search. The shell could satisfy its requirements by keeping a list of the names and directly accessing the file-system versions regardless of *PATH*. Providing all of the required functionality for those such as *cd* or *read* would be more difficult.

There were originally three justifications for allowing the omission of *exec*-able versions:

1. It would require wasting space in the file system, at the expense of very small systems. However, it has been pointed out that all 16 utilities in the table can be provided with 16 links to a single-line shell script:

```
$0 "$@"
```

2. It is not logical to require invocation of utilities such as *cd* because they have no value outside the shell environment or cannot be useful in a child process. However, counter-examples always seemed to be available for even the most unusual cases:

```
find . -type d -exec cd {} \; -exec foo {} \;
 (which invokes "foo" on accessible directories)
```

```
ps ... | sed ... | xargs kill
```

```
find . -exec true \; -a ...
 (where "true" is used for temporary debugging)
```

3. It is confusing to have a utility such as *kill* that can easily be in the file system in the base standard, but that requires built-in status for the User Portability Utilities option (for the % job control job ID notation). It was decided that it was more appropriate to describe the required functionality (rather than the implementation) to the system implementors and let them decide how to satisfy it.

On the other hand, it was realized that any distinction like this between utilities was not useful to applications, and that the cost to correct it was small. These arguments were ultimately the most effective.

|      |                                                                                                                     |
|------|---------------------------------------------------------------------------------------------------------------------|
| 9497 | There were varying reasons for including utilities in the table of built-ins:                                       |
| 9498 | <i>alias, fc, unalias</i>                                                                                           |
| 9499 | The functionality of these utilities is performed more simply within the shell itself and that                      |
| 9500 | is the model most historical implementations have used.                                                             |
| 9501 | <i>bg, fg, jobs</i>                                                                                                 |
| 9502 | All of the job control-related utilities are eligible for built-in status because that is the model                 |
| 9503 | most historical implementations have used.                                                                          |
| 9504 | <i>cd, getopts, newgrp, read, umask, wait</i>                                                                       |
| 9505 | The functionality of these utilities is performed more simply within the context of the                             |
| 9506 | current process. An example can be taken from the usage of the <i>cd</i> utility. The purpose of                    |
| 9507 | the <i>cd</i> utility is to change the working directory for subsequent operations. The actions of <i>cd</i>        |
| 9508 | affect the process in which <i>cd</i> is executed and all subsequent child processes of that process.               |
| 9509 | Based on the POSIX standard process model, changes in the process environment of a child                            |
| 9510 | process have no effect on the parent process. If the <i>cd</i> utility were executed from a child                   |
| 9511 | process, the working directory change would be effective only in the child process. Child                           |
| 9512 | processes initiated subsequent to the child process that executed the <i>cd</i> utility would not                   |
| 9513 | have a changed working directory relative to the parent process.                                                    |
| 9514 | <i>command</i>                                                                                                      |
| 9515 | This utility was placed in the table primarily to protect scripts that are concerned about                          |
| 9516 | their <i>PATH</i> being manipulated. The “secure” shell script example in the <i>command</i> utility in             |
| 9517 | the Shell and Utilities volume of IEEE Std 1003.1-2001 would not be possible if a <i>PATH</i>                       |
| 9518 | change retrieved an alien version of <i>command</i> . (An alternative would have been to                            |
| 9519 | implement <i>getconf</i> as a built-in, but the standard developers considered that it carried too                  |
| 9520 | many changing configuration strings to require in the shell.)                                                       |
| 9521 | <i>kill</i> Since <i>kill</i> provides optional job control functionality using shell notation (%1, %2, and so on), |
| 9522 | some implementations would find it extremely difficult to provide this outside the shell.                           |
| 9523 | <i>true, false</i>                                                                                                  |
| 9524 | These are in the table as a courtesy to programmers who wish to use the "while true"                                |
| 9525 | shell construct without protecting <i>true</i> from <i>PATH</i> searches. (It is acknowledged that                  |
| 9526 | "while :" also works, but the idiom with <i>true</i> is historically pervasive.)                                    |
| 9527 | All utilities, including those in the table, are accessible via the <i>system()</i> and <i>popen()</i> functions in |
| 9528 | the System Interfaces volume of IEEE Std 1003.1-2001. There are situations where the return                         |
| 9529 | functionality of <i>system()</i> and <i>popen()</i> is not desirable. Applications that require the exit status of  |
| 9530 | the invoked utility will not be able to use <i>system()</i> or <i>popen()</i> , since the exit status returned is   |
| 9531 | that of the command language interpreter rather than that of the invoked utility. The alternative                   |
| 9532 | for such applications is the use of the <i>exec</i> family.                                                         |

## 9533 C.2 Shell Command Language

### 9534 C.2.1 Shell Introduction

9535 The System V shell was selected as the starting point for the Shell and Utilities volume of  
 9536 IEEE Std 1003.1-2001. The BSD C shell was excluded from consideration for the following  
 9537 reasons:

- 9538 • Most historically portable shell scripts assume the Version 7 Bourne shell, from which the  
 9539 System V shell is derived.
- 9540 • The majority of tutorial materials on shell programming assume the System V shell.

9541 The construct "#!" is reserved for implementations wishing to provide that extension. If it were  
 9542 not reserved, the Shell and Utilities volume of IEEE Std 1003.1-2001 would disallow it by forcing  
 9543 it to be a comment. As it stands, a strictly conforming application must not use "#!" as the first  
 9544 two characters of the file.

### 9545 C.2.2 Quoting

9546 There is no additional rationale provided for this section.

#### 9547 C.2.2.1 Escape Character (Backslash)

9548 There is no additional rationale provided for this section.

#### 9549 C.2.2.2 Single-Quotes

9550 A backslash cannot be used to escape a single-quote in a single-quoted string. An embedded  
 9551 quote can be created by writing, for example: "'a'\''b'", which yields "a'b". (See the Shell  
 9552 and Utilities volume of IEEE Std 1003.1-2001, Section 2.6.5, Field Splitting for a better  
 9553 understanding of how portions of words are either split into fields or remain concatenated.) A  
 9554 single token can be made up of concatenated partial strings containing all three kinds of quoting  
 9555 or escaping, thus permitting any combination of characters.

#### 9556 C.2.2.3 Double-Quotes

9557 The escaped <newline> used for line continuation is removed entirely from the input and is not  
 9558 replaced by any white space. Therefore, it cannot serve as a token separator.

9559 In double-quoting, if a backslash is immediately followed by a character that would be  
 9560 interpreted as having a special meaning, the backslash is deleted and the subsequent character is  
 9561 taken literally. If a backslash does not precede a character that would have a special meaning, it  
 9562 is left in place unmodified and the character immediately following it is also left unmodified.  
 9563 Thus, for example:

9564       "\\$" → \$

9565       "a" → \a

9566 It would be desirable to include the statement “The characters from an enclosed "\${" to the  
 9567 matching '}' shall not be affected by the double quotes”, similar to the one for "\$()".  
 9568 However, historical practice in the System V shell prevents this.

9569 The requirement that double-quotes be matched inside "\${...}" within double-quotes and the  
 9570 rule for finding the matching '}' in the Shell and Utilities volume of IEEE Std 1003.1-2001,  
 9571 Section 2.6.2, Parameter Expansion eliminate several subtle inconsistencies in expansion for  
 9572 historical shells in rare cases; for example:

9573           `"${foo-bar}"`

9574           yields **bar** when **foo** is not defined, and is an invalid substitution when **foo** is defined, in many  
 9575           historical shells. The differences in processing the `"${...}"` form have led to inconsistencies  
 9576           between historical systems. A consequence of this rule is that single-quotes cannot be used to  
 9577           quote the `' '` within `"${...}"`; for example:

9578           `unset bar`  
 9579           `foo="${bar-' }'"`

9580           is invalid because the `"${...}"` substitution contains an unpaired unescaped single-quote. The  
 9581           backslash can be used to escape the `' '` in this example to achieve the desired result:

9582           `unset bar`  
 9583           `foo="${bar-\ }"`

9584           The differences in processing the `"${...}"` form have led to inconsistencies between the  
 9585           historical System V shell, BSD, and KornShells, and the text in the Shell and Utilities volume of  
 9586           IEEE Std 1003.1-2001 is an attempt to converge them without breaking too many applications.  
 9587           The only alternative to this compromise between shells would be to make the behavior  
 9588           unspecified whenever the literal characters `' '`, `'{'`, `' '`, and `'"'` appear within `"${...}"`.  
 9589           To write a portable script that uses these values, a user would have to assign variables; for  
 9590           example:

9591           `squote=\' dquote=\" lbrace='{ ' rbrace='}'`  
 9592           `${foo-$squote$rbrace$squote}`

9593           rather than:

9594           `${foo-"'"'"' }`

9595           Some implementations have allowed the end of the word to terminate the backquoted command  
 9596           substitution, such as in:

9597           `"`echo hello`"`

9598           This usage is undefined; the matching backquote is required by the Shell and Utilities volume of  
 9599           IEEE Std 1003.1-2001. The other undefined usage can be illustrated by the example:

9600           `sh -c '` echo "foo`'`

9601           The description of the recursive actions involving command substitution can be illustrated with  
 9602           an example. Upon recognizing the introduction of command substitution, the shell parses input  
 9603           (in a new context), gathering the source for the command substitution until an unbalanced `' ) '`  
 9604           or `' '`` is located. For example, in the following:

9605           `echo "$(date; echo "`  
 9606           `one" )"`

9607           the double-quote following the *echo* does not terminate the first double-quote; it is part of the  
 9608           command substitution script. Similarly, in:

9609           `echo "$(echo *)"`

9610           the asterisk is not quoted since it is inside command substitution; however:

9611           `echo "$(echo "*)"`

9612           is quoted (and represents the asterisk character itself).

### 9613 C.2.3 Token Recognition

9614 The " ( ( " and " ) ) " symbols are control operators in the KornShell, used for an alternative  
 9615 syntax of an arithmetic expression command. A conforming application cannot use " ( ( " as a  
 9616 single token (with the exception of the "\$ ( ( " form for shell arithmetic).

9617 On some implementations, the symbol " ( ( " is a control operator; its use produces unspecified  
 9618 results. Applications that wish to have nested subshells, such as:

```
9619 ((echo Hello);(echo World))
```

9620 must separate the " ( ( " characters into two tokens by including white space between them.  
 9621 Some systems may treat these as invalid arithmetic expressions instead of subshells.

9622 Certain combinations of characters are invalid in portable scripts, as shown in the grammar.  
 9623 Implementations may use these combinations (such as " | & ") as valid control operators. Portable  
 9624 scripts cannot rely on receiving errors in all cases where this volume of IEEE Std 1003.1-2001  
 9625 indicates that a syntax is invalid.

9626 The (3) rule about combining characters to form operators is not meant to preclude systems from  
 9627 extending the shell language when characters are combined in otherwise invalid ways.  
 9628 Conforming applications cannot use invalid combinations, and test suites should not penalize  
 9629 systems that take advantage of this fact. For example, the unquoted combination " | & " is not  
 9630 valid in a POSIX script, but has a specific KornShell meaning.

9631 The (10) rule about ' #' as the current character is the first in the sequence in which a new token  
 9632 is being assembled. The ' #' starts a comment only when it is at the beginning of a token. This  
 9633 rule is also written to indicate that the search for the end-of-comment does not consider escaped  
 9634 <newline> specially, so that a comment cannot be continued to the next line.

#### 9635 C.2.3.1 Alias Substitution

9636 The alias capability was added in the User Portability Utilities option because it is widely used in  
 9637 historical implementations by interactive users.

9638 The definition of "alias name" precludes an alias name containing a slash character. Since the  
 9639 text applies to the command words of simple commands, reserved words (in their proper  
 9640 places) cannot be confused with aliases.

9641 The placement of alias substitution in token recognition makes it clear that it precedes all of the  
 9642 word expansion steps.

9643 An example concerning trailing <blank>s and reserved words follows. If the user types:

```
9644 $ alias foo="/bin/ls "

 9645 $ alias while="/"
```

9646 The effect of executing:

```
9647 $ while true

 9648 > do

 9649 > echo "Hello, World"

 9650 > done
```

9651 is a never-ending sequence of "Hello, World" strings to the screen. However, if the user  
 9652 types:

```
9653 $ foo while
```

9654 the result is an *ls* listing of /. Since the alias substitution for **foo** ends in a <space>, the next word  
 9655 is checked for alias substitution. The next word, **while**, has also been aliased, so it is substituted

9656 as well. Since it is not in the proper position as a command word, it is not recognized as a  
 9657 reserved word.

9658 If the user types:

9659 `$ foo; while`

9660 **while** retains its normal reserved-word properties.

#### 9661 C.2.4 Reserved Words

9662 All reserved words are recognized syntactically as such in the contexts described. However, note  
 9663 that **in** is the only meaningful reserved word after a **case** or **for**; similarly, **in** is not meaningful as  
 9664 the first word of a simple command.

9665 Reserved words are recognized only when they are delimited (that is, meet the definition of the  
 9666 Base Definitions volume of IEEE Std 1003.1-2001, Section 3.435, Word), whereas operators are  
 9667 themselves delimiters. For instance, ' ( ' and ' ) ' are control operators, so that no <space> is  
 9668 needed in (*list*). However, ' { ' and ' } ' are reserved words in { *list*; }, so that in this case the  
 9669 leading <space> and semicolon are required.

9670 The list of unspecified reserved words is from the KornShell, so conforming applications cannot  
 9671 use them in places a reserved word would be recognized. This list contained **time** in early  
 9672 proposals, but it was removed when the *time* utility was selected for the Shell and Utilities  
 9673 volume of IEEE Std 1003.1-2001.

9674 There was a strong argument for promoting braces to operators (instead of reserved words), so  
 9675 they would be syntactically equivalent to subshell operators. Concerns about compatibility  
 9676 outweighed the advantages of this approach. Nevertheless, conforming applications should  
 9677 consider quoting ' { ' and ' } ' when they represent themselves.

9678 The restriction on ending a name with a colon is to allow future implementations that support  
 9679 named labels for flow control; see the RATIONALE for the *break* built-in utility.

9680 It is possible that a future version of the Shell and Utilities volume of IEEE Std 1003.1-2001 may  
 9681 require that ' { ' and ' } ' be treated individually as control operators, although the token " { } "  
 9682 will probably be a special-case exemption from this because of the often-used *find*{ } construct.

#### 9683 C.2.5 Parameters and Variables

##### 9684 C.2.5.1 Positional Parameters

9685 There is no additional rationale provided for this section.

##### 9686 C.2.5.2 Special Parameters

9687 Most historical implementations implement subshells by forking; thus, the special parameter  
 9688 ' \$ ' does not necessarily represent the process ID of the shell process executing the commands  
 9689 since the subshell execution environment preserves the value of ' \$ '.

9690 If a subshell were to execute a background command, the value of " \$ ! " for the parent would  
 9691 not change. For example:

```
9692 (
9693 date &
9694 echo $!
9695)
9696 echo $!
```

9697 would echo two different values for "\$!".

9698 The "\$-" special parameter can be used to save and restore *set* options:

```
9699 Save=$(echo $- | sed 's/[ics]//g')
9700 ...
9701 set +aCefnuvx
9702 if [-n "$Save"]; then
9703 set -$Save
9704 fi
```

9705 The three options are removed using *sed* in the example because they may appear in the value of  
9706 "\$-" (from the *sh* command line), but are not valid options to *set*.

9707 The descriptions of parameters '\*' and '@' assume the reader is familiar with the field splitting  
9708 discussion in the Shell and Utilities volume of IEEE Std 1003.1-2001, Section 2.6.5, Field Splitting  
9709 and understands that portions of the word remain concatenated unless there is some reason to  
9710 split them into separate fields.

9711 Some examples of the '\*' and '@' properties, including the concatenation aspects:

```
9712 set "abc" "def ghi" "jkl"
9713 echo $* => "abc" "def" "ghi" "jkl"
9714 echo "$*" => "abc def ghi jkl"
9715 echo $@ => "abc" "def" "ghi" "jkl"
```

9716 but:

```
9717 echo "$@" => "abc" "def ghi" "jkl"
9718 echo "xx$@yy" => "xxabc" "def ghi" "jkl"
9719 echo "$@$@" => "abc" "def ghi" "jklabc" "def ghi" "jkl"
```

9720 In the preceding examples, the double-quote characters that appear after the "=>" do not appear  
9721 in the output and are used only to illustrate word boundaries.

9722 The following example illustrates the effect of setting *IFS* to a null string:

```
9723 $ IFS=''
9724 $ set foo bar bam
9725 $ echo "$@"
9726 foo bar bam
9727 $ echo "$*"
9728 foobarbam
9729 $ unset IFS
9730 $ echo "$*"
9731 foo bar bam
```

### 9732 C.2.5.3 Shell Variables

9733 See the discussion of *IFS* in Section C.2.6.5 (on page 241) and the RATIONALE for the *sh* utility.

9734 The prohibition on *LC\_CTYPE* changes affecting lexical processing protects the shell  
9735 implementor (and the shell programmer) from the ill effects of changing the definition of  
9736 <blank> or the set of alphabetic characters in the current environment. It would probably not be  
9737 feasible to write a compiled version of a shell script without this rule. The rule applies only to  
9738 the current invocation of the shell and its subshells—invoking a shell script or performing *exec sh*  
9739 would subject the new shell to the changes in *LC\_CTYPE*.

|      |                |                                                                                                   |
|------|----------------|---------------------------------------------------------------------------------------------------|
| 9740 |                | Other common environment variables used by historical shells are not specified by the Shell and   |
| 9741 |                | Utilities volume of IEEE Std 1003.1-2001, but they should be reserved for the historical uses.    |
| 9742 |                | Tilde expansion for components of <i>PATH</i> in an assignment such as:                           |
| 9743 |                | <code>PATH=~hlj/bin:~dwc/bin:\$PATH</code>                                                        |
| 9744 |                | is a feature of some historical shells and is allowed by the wording of the Shell and Utilities   |
| 9745 |                | volume of IEEE Std 1003.1-2001, Section 2.6.1, Tilde Expansion. Note that the tildes are expanded |
| 9746 |                | during the assignment to <i>PATH</i> , not when <i>PATH</i> is accessed during command search.    |
| 9747 |                | The following entries represent additional information about variables included in the Shell and  |
| 9748 |                | Utilities volume of IEEE Std 1003.1-2001, or rationale for common variables in use by shells that |
| 9749 |                | have been excluded:                                                                               |
| 9750 | —              | (Underscore.) While underscore is historical practice, its overloaded usage in                    |
| 9751 |                | the KornShell is confusing, and it has been omitted from the Shell and Utilities                  |
| 9752 |                | volume of IEEE Std 1003.1-2001.                                                                   |
| 9753 | <i>ENV</i>     | This variable can be used to set aliases and other items local to the invocation                  |
| 9754 |                | of a shell. The file referred to by <i>ENV</i> differs from <b>\$HOME/.profile</b> in that        |
| 9755 |                | <b>.profile</b> is typically executed at session start-up, whereas the <i>ENV</i> file is         |
| 9756 |                | executed at the beginning of each shell invocation. The <i>ENV</i> value is                       |
| 9757 |                | interpreted in a manner similar to a dot script, in that the commands are                         |
| 9758 |                | executed in the current environment and the file needs to be readable, but not                    |
| 9759 |                | executable. However, unlike dot scripts, no <i>PATH</i> searching is performed.                   |
| 9760 |                | This is used as a guard against Trojan Horse security breaches.                                   |
| 9761 | <i>ERRNO</i>   | This variable was omitted from the Shell and Utilities volume of                                  |
| 9762 |                | IEEE Std 1003.1-2001 because the values of error numbers are not defined in                       |
| 9763 |                | IEEE Std 1003.1-2001 in a portable manner.                                                        |
| 9764 | <i>FCEDIT</i>  | Since this variable affects only the <i>fc</i> utility, it has been omitted from this more        |
| 9765 |                | global place. The value of <i>FCEDIT</i> does not affect the command-line editing                 |
| 9766 |                | mode in the shell; see the description of <i>set -o vi</i> in the <i>set</i> built-in utility.    |
| 9767 | <i>PS1</i>     | This variable is used for interactive prompts. Historically, the “superuser”                      |
| 9768 |                | has had a prompt of ‘#’. Since privileges are not required to be monolithic, it                   |
| 9769 |                | is difficult to define which privileges should cause the alternate prompt.                        |
| 9770 |                | However, a sufficiently powerful user should be reminded of that power by                         |
| 9771 |                | having an alternate prompt.                                                                       |
| 9772 | <i>PS3</i>     | This variable is used by the KornShell for the <i>select</i> command. Since the POSIX             |
| 9773 |                | shell does not include <i>select</i> , <i>PS3</i> was omitted.                                    |
| 9774 | <i>PS4</i>     | This variable is used for shell debugging. For example, the following script:                     |
| 9775 |                | <code>PS4='[\${LINENO}] + '</code>                                                                |
| 9776 |                | <code>set -x</code>                                                                               |
| 9777 |                | <code>echo Hello</code>                                                                           |
| 9778 |                | writes the following to standard error:                                                           |
| 9779 |                | <code>[3]+ echo Hello</code>                                                                      |
| 9780 | <i>RANDOM</i>  | This pseudo-random number generator was not seen as being useful to                               |
| 9781 |                | interactive users.                                                                                |
| 9782 | <i>SECONDS</i> | Although this variable is sometimes used with <i>PS1</i> to allow the display of the              |
| 9783 |                | current time in the prompt of the user, it is not one that would be manipulated                   |

9784 frequently enough by an interactive user to include in the Shell and Utilities  
 9785 volume of IEEE Std 1003.1-2001.

## 9786 C.2.6 Word Expansions

9787 Step (2) refers to the “portions of fields generated by step (1)”. For example, if the word being  
 9788 expanded were "\$x+\$y" and *IFS*=+, the word would be split only if "\$x" or "\$y" contained  
 9789 '+'; the '+' in the original word was not generated by step (1).

9790 *IFS* is used for performing field splitting on the results of parameter and command substitution;  
 9791 it is not used for splitting all fields. Previous versions of the shell used it for splitting all fields  
 9792 during field splitting, but this has severe problems because the shell can no longer parse its own  
 9793 script. There are also important security implications caused by this behavior. All useful  
 9794 applications of *IFS* use it for parsing input of the *read* utility and for splitting the results of  
 9795 parameter and command substitution.

9796 The rule concerning expansion to a single field requires that if **foo=abc** and **bar=def**, that:

9797 "\$foo"\$bar"

9798 expands to the single field:

9799 abcdef

9800 The rule concerning empty fields can be illustrated by:

```
9801 $ unset foo
9802 $ set $foo bar ' ' xyz "$foo" abc
9803 $ for i
9804 > do
9805 > echo "-$i-"
9806 > done
9807 -bar-
9808 --
9809 -xyz-
9810 --
9811 -abc-
```

9812 Step (1) indicates that parameter expansion, command substitution, and arithmetic expansion  
 9813 are all processed simultaneously as they are scanned. For example, the following is valid  
 9814 arithmetic:

```
9815 x=1
9816 echo $(($(echo 3)+$x))
```

9817 An early proposal stated that tilde expansion preceded the other steps, but this is not the case in  
 9818 known historical implementations; if it were, and if a referenced home directory contained a '\$'  
 9819 character, expansions would result within the directory name.

### 9820 C.2.6.1 Tilde Expansion

9821 Tilde expansion generally occurs only at the beginning of words, but an exception based on  
 9822 historical practice has been included:

```
9823 PATH=/posix/bin:~dgg/bin
```

9824 This is eligible for tilde expansion because tilde follows a colon and none of the relevant  
 9825 characters is quoted. Consideration was given to prohibiting this behavior because any of the  
 9826 following are reasonable substitutes:

```

9827 PATH=$(printf %s ~karels/bin : ~bostic/bin)
9828 for Dir in ~maat/bin ~srb/bin ...
9829 do
9830 PATH=${PATH:+$PATH:}$Dir
9831 done

```

9832 In the first command, explicit colons are used for each directory. In all cases, the shell performs  
 9833 tilde expansion on each directory because all are separate words to the shell.

9834 Note that expressions in operands such as:

```

9835 make -k mumble LIBDIR=~chet/lib

```

9836 do not qualify as shell variable assignments, and tilde expansion is not performed (unless the  
 9837 command does so itself, which *make* does not).

9838 Because of the requirement that the word is not quoted, the following are not equivalent; only  
 9839 the last causes tilde expansion:

```

9840 \~hlj/ ~h\lj/ ~"hlj"/ ~hlj\ / ~hlj/

```

9841 In an early proposal, tilde expansion occurred following any unquoted equals sign or colon, but  
 9842 this was removed because of its complexity and to avoid breaking commands such as:

```

9843 rcp hostname:~marc/.profile .

```

9844 A suggestion was made that the special sequence "\$~" should be allowed to force tilde  
 9845 expansion anywhere. Since this is not historical practice, it has been left for future  
 9846 implementations to evaluate. (The description in the Shell and Utilities volume of  
 9847 IEEE Std 1003.1-2001, Section 2.2, Quoting requires that a dollar sign be quoted to represent  
 9848 itself, so the "\$~" combination is already unspecified.)

9849 The results of giving tilde with an unknown login name are undefined because the KornShell  
 9850 "~+" and "~-" constructs make use of this condition, but in general it is an error to give an  
 9851 incorrect login name with tilde. The results of having *HOME* unset are unspecified because some  
 9852 historical shells treat this as an error.

#### 9853 C.2.6.2 Parameter Expansion

9854 The rule for finding the closing '}' in "\${...}" is the one used in the KornShell and is  
 9855 upwardly-compatible with the Bourne shell, which does not determine the closing '}' until the  
 9856 word is expanded. The advantage of this is that incomplete expansions, such as:

```

9857 ${foo

```

9858 can be determined during tokenization, rather than during expansion.

9859 The string length and substring capabilities were included because of the demonstrated need for  
 9860 them, based on their usage in other shells, such as C shell and KornShell.

9861 Historical versions of the KornShell have not performed tilde expansion on the word part of  
 9862 parameter expansion; however, it is more consistent to do so.

## 9863 C.2.6.3 Command Substitution

9864 The "\$ ( )" form of command substitution solves a problem of inconsistent behavior when using  
 9865 backquotes. For example:

| 9866 | Command             | Output |
|------|---------------------|--------|
| 9867 | echo '\$x'          | \$x    |
| 9868 | echo `echo '\$x'`   | \$x    |
| 9869 | echo \$(echo '\$x') | \$x    |

9870 Additionally, the backquoted syntax has historical restrictions on the contents of the embedded  
 9871 command. While the newer "\$ ( )" form can process any kind of valid embedded script, the  
 9872 backquoted form cannot handle some valid scripts that include backquotes. For example, these  
 9873 otherwise valid embedded scripts do not work in the left column, but do work on the right:

|      |                             |                             |
|------|-----------------------------|-----------------------------|
| 9874 | echo `                      | echo \$(                    |
| 9875 | cat <<\eof                  | cat <<\eof                  |
| 9876 | a here-doc with `           | a here-doc with )           |
| 9877 | eof                         | eof                         |
| 9878 | `                           | )                           |
| 9879 | echo `                      | echo \$(                    |
| 9880 | echo abc # a comment with ` | echo abc # a comment with ) |
| 9881 | `                           | )                           |
| 9882 | echo `                      | echo \$(                    |
| 9883 | echo ` `                    | echo ` `                    |
| 9884 | `                           | )                           |

9885 Because of these inconsistent behaviors, the backquoted variety of command substitution is not  
 9886 recommended for new applications that nest command substitutions or attempt to embed  
 9887 complex scripts.

9888 The KornShell feature:

9889 If *command* is of the form *<word*, *word* is expanded to generate a pathname, and the value of  
 9890 the command substitution is the contents of this file with any trailing *<newline>*s deleted.

9891 was omitted from the Shell and Utilities volume of IEEE Std 1003.1-2001 because \$(*cat word*) is  
 9892 an appropriate substitute. However, to prevent breaking numerous scripts relying on this  
 9893 feature, it is unspecified to have a script within "\$ ( )" that has only redirections.

9894 The requirement to separate "\$ (" and ' (' when a single subshell is command-substituted is to  
 9895 avoid any ambiguities with arithmetic expansion.

9896 IEEE Std 1003.1-2001 / Cor 1-2002, item XCU / TC1 / D6 / 4 is applied, changing the text from: "If a  
 9897 command substitution occurs inside double-quotes, it shall not be performed on the results of  
 9898 the substitution." to: "If a command substitution occurs inside double-quotes, field splitting and  
 9899 pathname expansion shall not be performed on the results of the substitution.". The  
 9900 replacement text taken from the ISO POSIX-2:1993 standard is clearer about the items that are  
 9901 not performed.

## 9902 C.2.6.4 Arithmetic Expansion

9903 The "`(( ))`" form of KornShell arithmetic in early proposals was omitted. The standard  
 9904 developers concluded that there was a strong desire for some kind of arithmetic evaluator to  
 9905 replace *expr*, and that relating it to '`$`' makes it work well with the standard shell language, and  
 9906 it provides access to arithmetic evaluation in places where accessing a utility would be  
 9907 inconvenient.

9908 The syntax and semantics for arithmetic were changed for the ISO/IEC 9945-2:1993 standard.  
 9909 The language is essentially a pure arithmetic evaluator of constants and operators (excluding  
 9910 assignment) and represents a simple subset of the previous arithmetic language (which was  
 9911 derived from the KornShell "`(( ))`" construct). The syntax was changed from that of a  
 9912 command denoted by `((expression))` to an expansion denoted by `$(expression)`. The new form is  
 9913 a dollar expansion ('`$`') that evaluates the expression and substitutes the resulting value.  
 9914 Objections to the previous style of arithmetic included that it was too complicated, did not fit in  
 9915 well with the use of variables in the shell, and its syntax conflicted with subshells. The  
 9916 justification for the new syntax is that the shell is traditionally a macro language, and if a new  
 9917 feature is to be added, it should be accomplished by extending the capabilities presented by the  
 9918 current model of the shell, rather than by inventing a new one outside the model; adding a new  
 9919 dollar expansion was perceived to be the most intuitive and least destructive way to add such a  
 9920 new capability.

9921 In early proposals, a form `$(expression)` was used. It was functionally equivalent to the "`$(( ))`"  
 9922 of the current text, but objections were lodged that the 1988 KornShell had already implemented  
 9923 "`$(( ))`" and there was no compelling reason to invent yet another syntax. Furthermore, the  
 9924 "`$[ ]`" syntax had a minor incompatibility involving the patterns in **case** statements.

9925 The portion of the ISO C standard arithmetic operations selected corresponds to the operations  
 9926 historically supported in the KornShell.

9927 It was concluded that the *test* command (**I**) was sufficient for the majority of relational arithmetic  
 9928 tests, and that tests involving complicated relational expressions within the shell are rare, yet  
 9929 could still be accommodated by testing the value of "`$(( ))`" itself. For example:

```
9930 # a complicated relational expression
9931 while [$(((($x + $y)/($a * $b)) < ($foo*$bar))) -ne 0]
```

9932 or better yet, the rare script that has many complex relational expressions could define a  
 9933 function like this:

```
9934 val() {
9935 return $((!$1))
9936 }
```

9937 and complicated tests would be less intimidating:

```
9938 while val $(((($x + $y)/($a * $b)) < ($foo*$bar)))
9939 do
9940 # some calculations
9941 done
```

9942 A suggestion that was not adopted was to modify *true* and *false* to take an optional argument,  
 9943 and *true* would exit true only if the argument was non-zero, and *false* would exit false only if the  
 9944 argument was non-zero:

```
9945 while true $((($x > 5 && $y <= 25))
```

9946 There is a minor portability concern with the new syntax. The example "`$((2+2))`" could have  
 9947 been intended to mean a command substitution of a utility named "`2+2`" in a subshell. The

standard developers considered this to be obscure and isolated to some KornShell scripts (because "\$()" command substitution existed previously only in the KornShell). The text on command substitution requires that the "\$(" and '((' be separate tokens if this usage is needed.

An example such as:

```
echo $((echo hi);(echo there))
```

should not be misinterpreted by the shell as arithmetic because attempts to balance the parentheses pairs would indicate that they are subshells. However, as indicated by the Base Definitions volume of IEEE Std 1003.1-2001, Section 3.112, Control Operator, a conforming application must separate two adjacent parentheses with white space to indicate nested subshells.

Although the ISO/IEC 9899:1999 standard now requires support for **long long** and allows extended integer types with higher ranks, IEEE Std 1003.1-2001 only requires arithmetic expansions to support **signed long** integer arithmetic. Implementations are encouraged to support signed integer values at least as large as the size of the largest file allowed on the implementation.

Implementations are also allowed to perform floating-point evaluations as long as an application won't see different results for expressions that would not overflow **signed long** integer expression evaluation. (This includes appropriate truncation of results to integer values.)

Changes made in response to IEEE PASC Interpretation 1003.2 #208 removed the requirement that the integer constant suffixes `l` and `L` had to be recognized. The ISO POSIX-2:1993 standard did not require the `u`, `ul`, `uL`, `U`, `Ul`, `UL`, `lu`, `lU`, `Lu`, and `LU` suffixes since only signed integer arithmetic was required. Since all arithmetic expressions were treated as handling **signed long** integer types anyway, the `l` and `L` suffixes were redundant. No known scripts used them and some historic shells did not support them. When the ISO/IEC 9899:1999 standard was used as the basis for the description of arithmetic processing, the `ll` and `LL` suffixes and combinations were also not required. Implementations are still free to accept any or all of these suffixes, but are not required to do so.

There was also some confusion as to whether the shell was required to recognize character constants. Syntactically, character constants were required to be recognized, but the requirements for the handling of backslash ('\\') and quote ('''') characters (needed to specify character constants) within an arithmetic expansion were ambiguous. Furthermore, no known shells supported them. Changes made in response to IEEE PASC Interpretation 1003.2 #208 removed the requirement to support them (if they were indeed required before). IEEE Std 1003.1-2001 clearly does not require support for character constants.

#### C.2.6.5 Field Splitting

The operation of field splitting using *IFS*, as described in early proposals, was based on the way the KornShell splits words, but it is incompatible with other common versions of the shell. However, each has merit, and so a decision was made to allow both. If the *IFS* variable is unset or is `<space><tab><newline>`, the operation is equivalent to the way the System V shell splits words. Using characters outside the `<space><tab><newline>` set yields the KornShell behavior, where each of the non-`<space><tab><newline>`s is significant. This behavior, which affords the most flexibility, was taken from the way the original *awk* handled field splitting.

Rule (3) can be summarized as a pseudo-ERE:

```
(s*nS*|s+)
```

where *s* is an *IFS* white space character and *n* is a character in the *IFS* that is not white space. Any string matching that ERE delimits a field, except that the *s+* form does not delimit fields at

9994 the beginning or the end of a line. For example, if *IFS* is <space>/<comma>/<tab>, the string:  
 9995 <space><space>red<space><space>, <space>white<space>blue  
 9996 yields the three colors as the delimited fields.

#### 9997 C.2.6.6 Pathname Expansion

9998 There is no additional rationale provided for this section.

#### 9999 C.2.6.7 Quote Removal

10000 There is no additional rationale provided for this section.

### 10001 C.2.7 Redirection

10002 In the System Interfaces volume of IEEE Std 1003.1-2001, file descriptors are integers in the range  
 10003 0–({OPEN\_MAX}–1). The file descriptors discussed in the Shell and Utilities volume of  
 10004 IEEE Std 1003.1-2001, Section 2.7, Redirection are that same set of small integers.

10005 Having multi-digit file descriptor numbers for I/O redirection can cause some obscure  
 10006 compatibility problems. Specifically, scripts that depend on an example command:

```
10007 echo 22>/dev/null
```

10008 echoing "2" to standard error or "22" to standard output are no longer portable. However, the  
 10009 file descriptor number must still be delimited from the preceding text. For example:

```
10010 cat file2>foo
```

10011 writes the contents of **file2**, not the contents of **file**.

10012 The ">|" format of output redirection was adopted from the KornShell. Along with the  
 10013 *noclobber* option, set **-C**, it provides a safety feature to prevent inadvertent overwriting of  
 10014 existing files. (See the RATIONALE for the *pathchk* utility for why this step was taken.) The  
 10015 restriction on regular files is historical practice.

10016 The System V shell and the KornShell have differed historically on pathname expansion of *word*;  
 10017 the former never performed it, the latter only when the result was a single field (file). As a  
 10018 compromise, it was decided that the KornShell functionality was useful, but only as a shorthand  
 10019 device for interactive users. No reasonable shell script would be written with a command such  
 10020 as:

```
10021 cat foo > a*
```

10022 Thus, shell scripts are prohibited from doing it, while interactive users can select the shell with  
 10023 which they are most comfortable.

10024 The construct "2>&1" is often used to redirect standard error to the same file as standard  
 10025 output. Since the redirections take place beginning to end, the order of redirections is significant.  
 10026 For example:

```
10027 ls > foo 2>&1
```

10028 directs both standard output and standard error to file **foo**. However:

```
10029 ls 2>&1 > foo
```

10030 only directs standard output to file **foo** because standard error was duplicated as standard  
 10031 output before standard output was directed to file **foo**.

10032 The "<>" operator could be useful in writing an application that worked with several terminals,  
 10033 and occasionally wanted to start up a shell. That shell would in turn be unable to run  
 10034 applications that run from an ordinary controlling terminal unless it could make use of "<>"  
 10035 redirection. The specific example is a historical version of the pager *more*, which reads from  
 10036 standard error to get its commands, so standard input and standard output are both available  
 10037 for their usual usage. There is no way of saying the following in the shell without "<>":

```
10038 cat food | more - >/dev/tty03 2<>/dev/tty03
```

10039 Another example of "<>" is one that opens **/dev/tty** on file descriptor 3 for reading and writing:

```
10040 exec 3<> /dev/tty
```

10041 An example of creating a lock file for a critical code region:

```
10042 set -C
10043 until 2> /dev/null > lockfile
10044 do sleep 30
10045 done
10046 set +C
10047 perform critical function
10048 rm lockfile
```

10049 Since **/dev/null** is not a regular file, no error is generated by redirecting to it in *noclobber* mode.

10050 Tilde expansion is not performed on a here-document because the data is treated as if it were  
 10051 enclosed in double quotes.

#### 10052 C.2.7.1 *Redirecting Input*

10053 There is no additional rationale provided for this section.

#### 10054 C.2.7.2 *Redirecting Output*

10055 There is no additional rationale provided for this section.

#### 10056 C.2.7.3 *Appending Redirected Output*

10057 Note that when a file is opened (even with the O\_APPEND flag set), the initial file offset for that  
 10058 file is set to the beginning of the file. Some historic shells set the file offset to the current end-of-  
 10059 file when **append** mode shell redirection was used, but this is not allowed by  
 10060 IEEE Std 1003.1-2001.

#### 10061 C.2.7.4 *Here-Document*

10062 There is no additional rationale provided for this section.

#### 10063 C.2.7.5 *Duplicating an Input File Descriptor*

10064 There is no additional rationale provided for this section.

#### 10065 C.2.7.6 *Duplicating an Output File Descriptor*

10066 There is no additional rationale provided for this section.

10067 C.2.7.7 *Open File Descriptors for Reading and Writing*

10068 There is no additional rationale provided for this section.

10069 **C.2.8 Exit Status and Errors**10070 C.2.8.1 *Consequences of Shell Errors*

10071 There is no additional rationale provided for this section.

10072 C.2.8.2 *Exit Status for Commands*

10073 There is a historical difference in *sh* and *ksh* non-interactive error behavior. When a command  
 10074 named in a script is not found, some implementations of *sh* exit immediately, but *ksh* continues  
 10075 with the next command. Thus, the Shell and Utilities volume of IEEE Std 1003.1-2001 says that  
 10076 the shell “may” exit in this case. This puts a small burden on the programmer, who has to test  
 10077 for successful completion following a command if it is important that the next command not be  
 10078 executed if the previous command was not found. If it is important for the command to have  
 10079 been found, it was probably also important for it to complete successfully. The test for successful  
 10080 completion would not need to change.

10081 Historically, shells have returned an exit status of  $128+n$ , where  $n$  represents the signal number.  
 10082 Since signal numbers are not standardized, there is no portable way to determine which signal  
 10083 caused the termination. Also, it is possible for a command to exit with a status in the same range  
 10084 of numbers that the shell would use to report that the command was terminated by a signal.  
 10085 Implementations are encouraged to choose exit values greater than 256 to indicate programs  
 10086 that terminate by a signal so that the exit status cannot be confused with an exit status generated  
 10087 by a normal termination.

10088 Historical shells make the distinction between “utility not found” and “utility found but cannot  
 10089 execute” in their error messages. By specifying two seldomly used exit status values for these  
 10090 cases, 127 and 126 respectively, this gives an application the opportunity to make use of this  
 10091 distinction without having to parse an error message that would probably change from locale to  
 10092 locale. The *command*, *env*, *nohup*, and *xargs* utilities in the Shell and Utilities volume of  
 10093 IEEE Std 1003.1-2001 have also been specified to use this convention.

10094 When a command fails during word expansion or redirection, most historical implementations  
 10095 exit with a status of 1. However, there was some sentiment that this value should probably be  
 10096 much higher so that an application could distinguish this case from the more normal exit status  
 10097 values. Thus, the language “greater than zero” was selected to allow either method to be  
 10098 implemented.

10099 **C.2.9 Shell Commands**

10100 A description of an “empty command” was removed from an early proposal because it is only  
 10101 relevant in the cases of *sh -c " "*, *system(" ")*, or an empty shell-script file (such as the  
 10102 implementation of *true* on some historical systems). Since it is no longer mentioned in the Shell  
 10103 and Utilities volume of IEEE Std 1003.1-2001, it falls into the silently unspecified category of  
 10104 behavior where implementations can continue to operate as they have historically, but  
 10105 conforming applications do not construct empty commands. (However, note that *sh* does  
 10106 explicitly state an exit status for an empty string or file.) In an interactive session or a script with  
 10107 other commands, extra <newline>s or semicolons, such as:

```

10108 $ false
10109 $
10110 $ echo $?
10111 1

```

10112 would not qualify as the empty command described here because they would be consumed by  
 10113 other parts of the grammar.

#### 10114 C.2.9.1 Simple Commands

10115 The enumerated list is used only when the command is actually going to be executed. For  
 10116 example, in:

```

10117 true || $foo *

```

10118 no expansions are performed.

10119 The following example illustrates both how a variable assignment without a command name  
 10120 affects the current execution environment, and how an assignment with a command name only  
 10121 affects the execution environment of the command:

```

10122 $ x=red
10123 $ echo $x
10124 red
10125 $ export x
10126 $ sh -c 'echo $x'
10127 red
10128 $ x=blue sh -c 'echo $x'
10129 blue
10130 $ echo $x
10131 red

```

10132 This next example illustrates that redirections without a command name are still performed:

```

10133 $ ls foo
10134 ls: foo: no such file or directory
10135 $ > foo
10136 $ ls foo
10137 foo

```

10138 A command without a command name, but one that includes a command substitution, has an  
 10139 exit status of the last command substitution that the shell performed. For example:

```

10140 if x=$(command)
10141 then ...
10142 fi

```

10143 An example of redirections without a command name being performed in a subshell shows that  
 10144 the here-document does not disrupt the standard input of the **while** loop:

```

10145 IFS=:
10146 while read a b
10147 do echo $a
10148 <<-eof
10149 Hello
10150 eof
10151 done </etc/passwd

```

10152       Following are examples of commands without command names in AND-OR lists:

```
10153 > foo || {
10154 echo "error: foo cannot be created" >&2
10155 exit 1
10156 }

10157 # set saved if /vmunix.save exists
10158 test -f /vmunix.save && saved=1
```

10159       Command substitution and redirections without command names both occur in subshells, but  
10160       they are not necessarily the same ones. For example, in:

```
10161 exec 3> file
10162 var=$(echo foo >&3) 3>&1
```

10163       it is unspecified whether **foo** is echoed to the file or to standard output.

## 10164       **Command Search and Execution**

10165       This description requires that the shell can execute shell scripts directly, even if the underlying  
10166       system does not support the common "#!" interpreter convention. That is, if file **foo** contains  
10167       shell commands and is executable, the following executes **foo**:

```
10168 ./foo
```

10169       The command search shown here does not match all historical implementations. A more typical  
10170       sequence has been:

- 10171       • Any built-in (special or regular)
- 10172       • Functions
- 10173       • Path search for executable files

10174       But there are problems with this sequence. Since the programmer has no idea in advance which  
10175       utilities might have been built into the shell, a function cannot be used to override portably a  
10176       utility of the same name. (For example, a function named *cd* cannot be written for many  
10177       historical systems.) Furthermore, the *PATH* variable is partially ineffective in this case, and only  
10178       a pathname with a slash can be used to ensure a specific executable file is invoked.

10179       After the *execve()* failure described, the shell normally executes the file as a shell script. Some  
10180       implementations, however, attempt to detect whether the file is actually a script and not an  
10181       executable from some other architecture. The method used by the KornShell is allowed by the  
10182       text that indicates non-text files may be bypassed.

10183       The sequence selected for the Shell and Utilities volume of IEEE Std 1003.1-2001 acknowledges  
10184       that special built-ins cannot be overridden, but gives the programmer full control over which  
10185       versions of other utilities are executed. It provides a means of suppressing function lookup (via  
10186       the *command* utility) for the user's own functions and ensures that any regular built-ins or  
10187       functions provided by the implementation are under the control of the path search. The  
10188       mechanisms for associating built-ins or functions with executable files in the path are not  
10189       specified by the Shell and Utilities volume of IEEE Std 1003.1-2001, but the wording requires that  
10190       if either is implemented, the application is not able to distinguish a function or built-in from an  
10191       executable (other than in terms of performance, presumably). The implementation ensures that  
10192       all effects specified by the Shell and Utilities volume of IEEE Std 1003.1-2001 resulting from the  
10193       invocation of the regular built-in or function (interaction with the environment, variables, traps,  
10194       and so on) are identical to those resulting from the invocation of an executable file.

**Examples**

Consider three versions of the *ls* utility:

1. The application includes a shell function named *ls*.
2. The user writes a utility named *ls* and puts it in **/fred/bin**.
3. The example implementation provides *ls* as a regular shell built-in that is invoked (either by the shell or directly by *exec*) when the path search reaches the directory **/posix/bin**.

If *PATH*=**/posix/bin**, various invocations yield different versions of *ls*:

| Invocation                                             | Version of <i>ls</i> |
|--------------------------------------------------------|----------------------|
| <i>ls</i> (from within application script)             | (1) function         |
| <i>command ls</i> (from within application script)     | (3) built-in         |
| <i>ls</i> (from within makefile called by application) | (3) built-in         |
| <i>system("ls")</i>                                    | (3) built-in         |
| <i>PATH="/fred/bin:\$PATH" ls</i>                      | (2) user's version   |

**C.2.9.2 Pipelines**

Because pipeline assignment of standard input or standard output or both takes place before redirection, it can be modified by redirection. For example:

```
$ command1 2>&1 | command2
```

sends both the standard output and standard error of *command1* to the standard input of *command2*.

The reserved word **!** allows more flexible testing using AND and OR lists.

It was suggested that it would be better to return a non-zero value if any command in the pipeline terminates with non-zero status (perhaps the bitwise-inclusive OR of all return values). However, the choice of the last-specified command semantics are historical practice and would cause applications to break if changed. An example of historical behavior:

```
$ sleep 5 | (exit 4)
$ echo $?
4
$ (exit 4) | sleep 5
$ echo $?
0
```

**C.2.9.3 Lists**

The equal precedence of "&&" and "||" is historical practice. The standard developers evaluated the model used more frequently in high-level programming languages, such as C, to allow the shell logical operators to be used for complex expressions in an unambiguous way, but they could not allow historical scripts to break in the subtle way unequal precedence might cause. Some arguments were posed concerning the "{" or "(" groupings that are required historically. There are some disadvantages to these groupings:

- The "(" can be expensive, as they spawn other processes on some implementations. This performance concern is primarily an implementation issue.
- The "{" braces are not operators (they are reserved words) and require a trailing space after each '{', and a semicolon before each '}'. Most programmers (and certainly

10237 interactive users) have avoided braces as grouping constructs because of the problematic  
 10238 syntax required. Braces were not changed to operators because that would generate  
 10239 compatibility issues even greater than the precedence question; braces appear outside the  
 10240 context of a keyword in many shell scripts.

10241 IEEE PASC Interpretation 1003.2 #204 is applied, clarifying that the operators "&&" and "| |"  
 10242 are evaluated with left associativity.

### 10243 **Asynchronous Lists**

10244 The grammar treats a construct such as:

```
10245 foo & bar & bam &
```

10246 as one “asynchronous list”, but since the status of each element is tracked by the shell, the term  
 10247 “element of an asynchronous list” was introduced to identify just one of the **foo**, **bar**, or **bam**  
 10248 portions of the overall list.

10249 Unless the implementation has an internal limit, such as {CHILD\_MAX}, on the retained process  
 10250 IDs, it would require unbounded memory for the following example:

```
10251 while true
10252 do foo & echo $!
10253 done
```

10254 The treatment of the signals SIGINT and SIGQUIT with asynchronous lists is described in the  
 10255 Shell and Utilities volume of IEEE Std 1003.1-2001, Section 2.11, Signals and Error Handling.

10256 Since the connection of the input to the equivalent of **/dev/null** is considered to occur before  
 10257 redirections, the following script would produce no output:

```
10258 exec < /etc/passwd
10259 cat <&0 &
10260 wait
```

### 10261 **Sequential Lists**

10262 There is no additional rationale provided for this section.

### 10263 **AND Lists**

10264 There is no additional rationale provided for this section.

### 10265 **OR Lists**

10266 There is no additional rationale provided for this section.

## 10267 C.2.9.4 Compound Commands

10268 **Grouping Commands**

10269 The semicolon shown in `{compound-list;}` is an example of a control operator delimiting the `}`  
 10270 reserved word. Other delimiters are possible, as shown in the Shell and Utilities volume of  
 10271 IEEE Std 1003.1-2001, Section 2.10, Shell Grammar; `<newline>` is frequently used.

10272 A proposal was made to use the **<do-done>** construct in all cases where command grouping in  
 10273 the current process environment is performed, identifying it as a construct for the grouping  
 10274 commands, as well as for shell functions. This was not included because the shell already has a  
 10275 grouping construct for this purpose ("`{ }`"), and changing it would have been counter-  
 10276 productive.

10277 **For Loop**

10278 The format is shown with generous usage of `<newline>`s. See the grammar in the Shell and  
 10279 Utilities volume of IEEE Std 1003.1-2001, Section 2.10, Shell Grammar for a precise description of  
 10280 where `<newline>`s and semicolons can be interchanged.

10281 Some historical implementations support '`{`' and '`}`' as substitutes for **do** and **done**. The  
 10282 standard developers chose to omit them, even as an obsolescent feature. (Note that these  
 10283 substitutes were only for the **for** command; the **while** and **until** commands could not use them  
 10284 historically because they are followed by compound-lists that may contain "`{ ... }`" grouping  
 10285 commands themselves.)

10286 The reserved word pair **do ... done** was selected rather than **do ... od** (which would have  
 10287 matched the spirit of **if ... fi** and **case ... esac**) because *od* is already the name of a standard  
 10288 utility.

10289 PASC Interpretation 1003.2 #169 has been applied changing the grammar.

10290 **Case Conditional Construct**

10291 An optional left parenthesis before *pattern* was added to allow numerous historical KornShell  
 10292 scripts to conform. At one time, using the leading parenthesis was required if the **case** statement  
 10293 was to be embedded within a "`$ ( )`" command substitution; this is no longer the case with the  
 10294 POSIX shell. Nevertheless, many historical scripts use the left parenthesis, if only because it  
 10295 makes matching-parenthesis searching easier in *vi* and other editors. This is a relatively simple  
 10296 implementation change that is upwards-compatible for all scripts.

10297 Consideration was given to requiring *break* inside the *compound-list* to prevent falling through to  
 10298 the next pattern action list. This was rejected as being nonexistent practice. An interesting  
 10299 undocumented feature of the KornShell is that using "`;&`" instead of "`;;`" as a terminator  
 10300 causes the exact opposite behavior—the flow of control continues with the next *compound-list*.

10301 The pattern '`*`', given as the last pattern in a **case** construct, is equivalent to the default case in  
 10302 a C-language **switch** statement.

10303 The grammar shows that reserved words can be used as patterns, even if one is the first word on  
 10304 a line. Obviously, the reserved word **esac** cannot be used in this manner.

10305 **If Conditional Construct**

10306 The precise format for the command syntax is described in the Shell and Utilities volume of  
 10307 IEEE Std 1003.1-2001, Section 2.10, Shell Grammar.

10308 **While Loop**

10309 The precise format for the command syntax is described in the Shell and Utilities volume of  
 10310 IEEE Std 1003.1-2001, Section 2.10, Shell Grammar.

10311 **Until Loop**

10312 The precise format for the command syntax is described in the Shell and Utilities volume of  
 10313 IEEE Std 1003.1-2001, Section 2.10, Shell Grammar.

10314 C.2.9.5 *Function Definition Command*

10315 The description of functions in an early proposal was based on the notion that functions should  
 10316 behave like miniature shell scripts; that is, except for sharing variables, most elements of an  
 10317 execution environment should behave as if they were a new execution environment, and  
 10318 changes to these should be local to the function. For example, traps and options should be reset  
 10319 on entry to the function, and any changes to them do not affect the traps or options of the caller.  
 10320 There were numerous objections to this basic idea, and the opponents asserted that functions  
 10321 were intended to be a convenient mechanism for grouping common commands that were to be  
 10322 executed in the current execution environment, similar to the execution of the *dot* special  
 10323 built-in.

10324 It was also pointed out that the functions described in that early proposal did not provide a local  
 10325 scope for everything a new shell script would, such as the current working directory, or *umask*,  
 10326 but instead provided a local scope for only a few select properties. The basic argument was that  
 10327 if a local scope is needed for the execution environment, the mechanism already existed: the  
 10328 application can put the commands in a new shell script and call that script. All historical shells  
 10329 that implemented functions, other than the KornShell, have implemented functions that operate  
 10330 in the current execution environment. Because of this, traps and options have a global scope  
 10331 within a shell script. Local variables within a function were considered and included in another  
 10332 early proposal (controlled by the special built-in *local*), but were removed because they do not fit  
 10333 the simple model developed for functions and because there was some opposition to adding yet  
 10334 another new special built-in that was not part of historical practice. Implementations should  
 10335 reserve the identifier *local* (as well as *typeset*, as used in the KornShell) in case this local variable  
 10336 mechanism is adopted in a future version of IEEE Std 1003.1-2001.

10337 A separate issue from the execution environment of a function is the availability of that function  
 10338 to child shells. A few objectors maintained that just as a variable can be shared with child shells  
 10339 by exporting it, so should a function. In early proposals, the *export* command therefore had a *-f*  
 10340 flag for exporting functions. Functions that were exported were to be put into the environment  
 10341 as *name()*=*value* pairs, and upon invocation, the shell would scan the environment for these and  
 10342 automatically define these functions. This facility was strongly opposed and was omitted. Some  
 10343 of the arguments against exportable functions were as follows:

- 10344 • There was little historical practice. The Ninth Edition shell provided them, but there was  
 10345 controversy over how well it worked.
- 10346 • There are numerous security problems associated with functions appearing in the  
 10347 environment of a user and overriding standard utilities or the utilities owned by the  
 10348 application.

- There was controversy over requiring *make* to import functions, where it has historically used an *exec* function for many of its command line executions.

- Functions can be big and the environment is of a limited size. (The counter-argument was that functions are no different from variables in terms of size: there can be big ones, and there can be small ones—and just as one does not export huge variables, one does not export huge functions. However, this might not apply to the average shell-function writer, who typically writes much larger functions than variables.)

As far as can be determined, the functions in the Shell and Utilities volume of IEEE Std 1003.1-2001 match those in System V. Earlier versions of the KornShell had two methods of defining functions:

```
function fname { compound-list }
```

and:

```
fname() { compound-list }
```

The latter used the same definition as the Shell and Utilities volume of IEEE Std 1003.1-2001, but differed in semantics, as described previously. The current edition of the KornShell aligns the latter syntax with the Shell and Utilities volume of IEEE Std 1003.1-2001 and keeps the former as is.

The name space for functions is limited to that of a *name* because of historical practice. Complications in defining the syntactic rules for the function definition command and in dealing with known extensions such as the "@()" usage in the KornShell prevented the name space from being widened to a *word*. Using functions to support synonyms such as the "!!" and '% ' usage in the C shell is thus disallowed to conforming applications, but acceptable as an extension. For interactive users, the aliasing facilities in the Shell and Utilities volume of IEEE Std 1003.1-2001 should be adequate for this purpose. It is recognized that the name space for utilities in the file system is wider than that currently supported for functions, if the portable filename character set guidelines are ignored, but it did not seem useful to mandate extensions in systems for so little benefit to conforming applications.

The "()" in the function definition command consists of two operators. Therefore, intermixing <blank>s with the *fname*, '(', and ')' is allowed, but unnecessary.

An example of how a function definition can be used wherever a simple command is allowed:

```
If variable i is equal to "yes",
define function foo to be ls -l
#
["$i" = yes] && foo() {
 ls -l
}
```

## C.2.10 Shell Grammar

There are several subtle aspects of this grammar where conventional usage implies rules about the grammar that in fact are not true.

For *compound\_list*, only the forms that end in a *separator* allow a reserved word to be recognized, so usually only a *separator* can be used where a compound list precedes a reserved word (such as **Then**, **Else**, **Do**, and **Rbrace**). Explicitly requiring a separator would disallow such valid (if rare) statements as:

```
if (false) then (echo x) else (echo y) fi
```

- 10393 See the Note under special grammar rule (1).
- 10394 Concerning the third sentence of rule (1) (“Also, if the parser ...”):
- 10395 • This sentence applies rather narrowly: when a compound list is terminated by some clear  
10396 delimiter (such as the closing **fi** of an inner **if\_clause**) then it would apply; where the  
10397 compound list might continue (as in after a ‘;’), rule (7a) (and consequently the first  
10398 sentence of rule (1)) would apply. In many instances the two conditions are identical, but this  
10399 part of rule (1) does not give license to treating a **WORD** as a reserved word unless it is in a  
10400 place where a reserved word has to appear.
  - 10401 • The statement is equivalent to requiring that when the LR(1) lookahead set contains exactly  
10402 one reserved word, it must be recognized if it is present. (Here “LR(1)” refers to the  
10403 theoretical concepts, not to any real parser generator.)
- 10404 For example, in the construct below, and when the parser is at the point marked with ‘^’,  
10405 the only next legal token is **then** (this follows directly from the grammar rules):
- ```
10406     if if...fi then ... fi
10407         ^
```
- 10408 At that point, the **then** must be recognized as a reserved word.
- 10409 (Depending on the parser generator actually used, “extra” reserved words may be in some
10410 lookahead sets. It does not really matter if they are recognized, or even if any possible
10411 reserved word is recognized in that state, because if it is recognized and is not in the
10412 (theoretical) LR(1) lookahead set, an error is ultimately detected. In the example above, if
10413 some other reserved word (for example, **while**) is also recognized, an error occurs later.
- 10414 This is approximately equivalent to saying that reserved words are recognized after other
10415 reserved words (because it is after a reserved word that this condition occurs), but avoids the
10416 “except for ...” list that would be required for **case**, **for**, and so on. (Reserved words are of
10417 course recognized anywhere a *simple_command* can appear, as well. Other rules take care of
10418 the special cases of non-recognition, such as rule (4) for **case** statements.)
- 10419 Note that the body of here-documents are handled by token recognition (see the Shell and
10420 Utilities volume of IEEE Std 1003.1-2001, Section 2.3, Token Recognition) and do not appear in
10421 the grammar directly. (However, the here-document I/O redirection operator is handled as part
10422 of the grammar.)
- 10423 The start symbol of the grammar (**complete_command**) represents either input from the
10424 command line or a shell script. It is repeatedly applied by the interpreter to its input and
10425 represents a single “chunk” of that input as seen by the interpreter.

10426 C.2.10.1 Shell Grammar Lexical Conventions

10427 There is no additional rationale provided for this section.

10428 C.2.10.2 Shell Grammar Rules

10429 There is no additional rationale provided for this section.

10430 **C.2.11 Signals and Error Handling**

10431 There is no additional rationale provided for this section.

10432 **C.2.12 Shell Execution Environment**

10433 Some implementations have implemented the last stage of a pipeline in the current environment
10434 so that commands such as:

10435 `command | read foo`

10436 set variable **foo** in the current environment. This extension is allowed, but not required;
10437 therefore, a shell programmer should consider a pipeline to be in a subshell environment, but
10438 not depend on it.

10439 In early proposals, the description of execution environment failed to mention that each
10440 command in a multiple command pipeline could be in a subshell execution environment. For
10441 compatibility with some historical shells, the wording was phrased to allow an implementation
10442 to place any or all commands of a pipeline in the current environment. However, this means that
10443 a POSIX application must assume each command is in a subshell environment, but not depend
10444 on it.

10445 The wording about shell scripts is meant to convey the fact that describing “trap actions” can
10446 only be understood in the context of the shell command language. Outside of this context, such
10447 as in a C-language program, signals are the operative condition, not traps.

10448 **C.2.13 Pattern Matching Notation**

10449 Pattern matching is a simpler concept and has a simpler syntax than REs, as the former is
10450 generally used for the manipulation of filenames, which are relatively simple collections of
10451 characters, while the latter is generally used to manipulate arbitrary text strings of potentially
10452 greater complexity. However, some of the basic concepts are the same, so this section points
10453 liberally to the detailed descriptions in the Base Definitions volume of IEEE Std 1003.1-2001,
10454 Chapter 9, Regular Expressions.

10455 *C.2.13.1 Patterns Matching a Single Character*

10456 Both quoting and escaping are described here because pattern matching must work in three
10457 separate circumstances:

1. Calling directly upon the shell, such as in pathname expansion or in a **case** statement. All
10459 of the following match the string or file **abc**:

10460 `abc "abc" a"b" c a\bc a[b] c a["b"] c a[\b] c a["\b"] c a?c a*c`

10461 The following do not:

10462 `"a?c" a*c a\[b] c`

2. Calling a utility or function without going through a shell, as described for *find* and the
10464 *fnmatch()* function defined in the System Interfaces volume of IEEE Std 1003.1-2001.

3. Calling utilities such as *find*, *cpio*, *tar*, or *pax* through the shell command line. In this case,
10466 shell quote removal is performed before the utility sees the argument. For example, in:

10467 `find /bin -name "e\c[\h]o" -print`

10468 after quote removal, the backslashes are presented to *find* and it treats them as escape
10469 characters. Both precede ordinary characters, so the *c* and *h* represent themselves and *echo*
10470 would be found on many historical systems (that have it in **/bin**). To find a filename that

10471 contained shell special characters or pattern characters, both quoting and escaping are
10472 required, such as:

10473 `pax -r . . . "*a\(\?"`

10474 to extract a filename ending with "a(?".

10475 Conforming applications are required to quote or escape the shell special characters (sometimes
10476 called metacharacters). If used without this protection, syntax errors can result or
10477 implementation extensions can be triggered. For example, the KornShell supports a series of
10478 extensions based on parentheses in patterns.

10479 The restriction on a circumflex in a bracket expression is to allow implementations that support
10480 pattern matching using the circumflex as the negation character in addition to the exclamation
10481 mark. A conforming application must use something like "[\^!]" to match either character.

10482 C.2.13.2 Patterns Matching Multiple Characters

10483 Since each asterisk matches zero or more occurrences, the patterns "a*b" and "a**b" have
10484 identical functionality.

10485 Examples

10486 `a[bc]` Matches the strings "ab" and "ac".

10487 `a*d` Matches the strings "ad", "abd", and "abcd", but not the string "abc".

10488 `a*d*` Matches the strings "ad", "abcd", "abcdef", "aaaad", and "adddd".

10489 `*a*d` Matches the strings "ad", "abcd", "efabcd", "aaaad", and "adddd".

10490 C.2.13.3 Patterns Used for Filename Expansion

10491 The caveat about a slash within a bracket expression is derived from historical practice. The
10492 pattern "a[b/c]d" does not match such pathnames as **abd** or **a/d**. On some implementations
10493 (including those conforming to the Single UNIX Specification), it matched a pathname of
10494 literally "a[b/c]d". On other systems, it produced an undefined condition (an unescaped '['
10495 used outside a bracket expression). In this version, the XSI behavior is now required.

10496 Filenames beginning with a period historically have been specially protected from view on
10497 UNIX systems. A proposal to allow an explicit period in a bracket expression to match a leading
10498 period was considered; it is allowed as an implementation extension, but a conforming
10499 application cannot make use of it. If this extension becomes popular in the future, it will be
10500 considered for a future version of the Shell and Utilities volume of IEEE Std 1003.1-2001.

10501 Historical systems have varied in their permissions requirements. To match **f*/bar** has required
10502 read permissions on the **f*** directories in the System V shell, but the Shell and Utilities volume of
10503 IEEE Std 1003.1-2001, the C shell, and KornShell require only search permissions.

10504 **C.2.14 Special Built-In Utilities**

10505 See the RATIONALE sections on the individual reference pages.

10506 **C.3 Batch Environment Services and Utilities**10507 **Scope of the Batch Environment Services and Utilities Option**

10508 This section summarizes the deliberations of the IEEE P1003.15 (Batch Environment) working
 10509 group in the development of the Batch Environment Services and Utilities option, which covers
 10510 a set of services and utilities defining a batch processing system.

10511 This informative section contains historical information concerning the contents of the
 10512 amendment and describes why features were included or discarded by the working group.

10513 **History of Batch Systems**

10514 The supercomputing technical committee began as a “Birds Of a Feather” (BOF) at the January
 10515 1987 Usenix meeting. There was enough general interest to form a supercomputing attachment
 10516 to the /usr/group working groups. Several subgroups rapidly formed. Of those subgroups, the
 10517 batch group was the most ambitious. The first early meetings were spent evaluating user needs
 10518 and existing batch implementations.

10519 To evaluate user needs, individuals from the supercomputing community came and presented
 10520 their needs. Common requests were flexibility, interoperability, control of resources, and ease-
 10521 of-use. Backward-compatibility was not an issue. The working group then evaluated some
 10522 existing systems. The following different systems were evaluated:

- 10523 • PROD
- 10524 • Convex Distributed Batch
- 10525 • NQS
- 10526 • CTSS
- 10527 • MDQS from Ballistics Research Laboratory (BRL)

10528 Finally, NQS was chosen as a model because it satisfied not only the most user requirements, but
 10529 because it was public domain, already implemented on a variety of hardware platforms, and
 10530 network-based.

10531 **Historical Implementations of Batch Systems**

10532 Deferred processing of work under the control of a scheduler has been a feature of most
 10533 proprietary operating systems from the earliest days of multi-user systems in order to maximize
 10534 utilization of the computer.

10535 The arrival of UNIX systems proved to be a dilemma to many hardware providers and users
 10536 because it did not include the sophisticated batch facilities offered by the proprietary systems.
 10537 This omission was rectified in 1986 by NASA Ames Research Center who developed the
 10538 Network Queuing System (NQS) as a portable UNIX application that allowed the routing and
 10539 processing of batch “jobs” in a network. To encourage its usage, the product was later put into
 10540 the public domain. It was promptly picked up by UNIX hardware providers, and ported and
 10541 developed for their respective hardware and UNIX implementations.

Many major vendors, who traditionally offer a batch-dominated environment, ported the public-domain product to their systems, customized it to support the capabilities of their systems, and added many customer-requested features.

Due to the strong hardware provider and customer acceptance of NQS, it was decided to use NQS as the basis for the POSIX Batch Environment amendment in 1987. Other batch systems considered at the time included CTSS, MDQS (a forerunner of NQS from the Ballistics Research Laboratory), and PROD (a Los Alamos Labs development). None were thought to have both the functionality and acceptability of NQS.

10550 **NQS Differences from the *at* utility**

The base standard *at* and *batch* utilities are not sufficient to meet the batch processing needs in a supercomputing environment and additional functionality in the areas of resource management, job scheduling, system management, and control of output is required.

10554 **Batch Environment Services and Utilities Option Definitions**

The concept of a batch job is closely related to a session with a session leader. The main difference is that a batch job does not have a controlling terminal. There has been much debate over whether to use the term “request” or “job”. Job was the final choice because of the historical use of this term in the batch environment.

The current definition for job identifiers is not sufficient with the model of destinations. The current definition is:

```
sequence_number.originating_host
```

Using the model of destination, a host may include multiple batch nodes, the location of which is identified uniquely by a name or directory service. If the current definition is used, batch nodes running on the same host would have to coordinate their use of sequence numbers, as sequence numbers are assigned by the originating host. The alternative is to use the originating batch node name instead of the originating host name.

The reasons for wishing to run more than one batch system per host could be the following.

A test and production batch system are maintained on a single host. This is most likely in a development facility, but could also arise when a site is moving from one version to another. The new batch system could be installed as a test version that is completely separate from the production batch system, so that problems can be isolated to the test system. Requiring the batch nodes to coordinate their use of sequence numbers creates a dependency between the two nodes, and that defeats the purpose of running two nodes.

A site has multiple departments using a single host, with different management policies. An example of contention might be in job selection algorithms. One group might want a FIFO type of selection, while another group wishes to use a more complex algorithm based on resource availability. Again, requiring the batch nodes to coordinate is an unnecessary binding.

The proposal eventually accepted was to replace originating host with originating batch node. This supplies sufficient granularity to ensure unique job identifiers. If more than one batch node is on a particular host, they each have their own unique name.

The queue portion of a destination is not part of the job identifier as these are not required to be unique between batch nodes. For instance, two batch nodes may both have queues called small, medium, and large. It is only the batch node name that is uniquely identifiable throughout the batch system. The queue name has no additional function in this context.

10585 Assume there are three batch nodes, each of which has its own name server. On batch node one,
10586 there are no queues. On batch node two, there are fifty queues. On batch node three, there are
10587 forty queues. The system administrator for batch node one does not have to configure queues,
10588 because there are none implemented. However, if a user wishes to send a job to either batch
10589 node two or three, the system administrator for batch node one must configure a destination
10590 that maps to the appropriate batch node and queue. If every queue is to be made accessible from
10591 batch node one, the system administrator has to configure ninety destinations.

10592 To avoid requiring this, there should be a mechanism to allow a user to separate the destination
10593 into a batch node name and a queue name. Then, an implementation that is configured to get to
10594 all the batch nodes does not need any more configuration to allow a user to get to all of the
10595 queues on all of the batch nodes. The node name is used to locate the batch node, while the
10596 queue name is sent unchanged to that batch node.

10597 The following are requirements that a destination identifier must be capable of providing:

- 10598 • The ability to direct a job to a queue in a particular batch node.
- 10599 • The ability to direct a job to a particular batch node.
- 10600 • The ability to group at a higher level than just one queue. This includes grouping similar
10601 queues across multiple batch nodes (this is a pipe queue).
- 10602 • The ability to group batch nodes. This allows a user to submit a job to a group name with no
10603 knowledge of the batch node configuration. This also provides aliasing as a special case.
10604 Aliasing is a group containing only one batch node name. The group name is the alias.

10605 In addition, the administrator has the following requirements:

- 10606 • The ability to control access to the queues.
- 10607 • The ability to control access to the batch nodes.
- 10608 • The ability to control access to groups of queues (pipe queues).
- 10609 • The ability to configure retry time intervals and durations.

10610 The requirements of the user are met by destination as explained in the following.

10611 The user has the ability to specify a queue name, which is known only to the batch node
10612 specified. There is no configuration of these queues required on the submitting node.

10613 The user has the ability to specify a batch node whose name is network-unique. The
10614 configuration required is that the batch node be defined as an application, just as other
10615 applications such as FTP are configured.

10616 Once a job reaches a queue, it can again become a user of the batch system. The batch node can
10617 choose to send the job to another batch node or queue or both. In other words, the routing is at
10618 an application level, and it is up to the batch system to choose where the job will be sent.
10619 Configuration is up to the batch node where the queue resides. This provides grouping of
10620 queues across batch nodes or within a batch node. The user submits the job to a queue, which by
10621 definition routes the job to other queues or nodes or both.

10622 A node name may be given to a naming service, which returns multiple addresses as opposed to
10623 just one. This provides grouping at a batch node level. This is a local issue, meaning that the
10624 batch node must choose only one of these addresses. The list of addresses is not sent with the
10625 job, and once the job is accepted on another node, there is no connection between the list and the
10626 job. The requirements of the administrator are met by destination as explained in the following.

10627 The control of queues is a batch system issue, and will be done using the batch administrative
10628 utilities.

10629 The control of nodes is a network issue, and will be done through whatever network facilities
10630 are available.

10631 The control of access to groups of queues (pipe queues) is covered by the control of any other
10632 queue. The fact that the job may then be sent to another destination is not relevant.

10633 The propagation of a job across more than one point-to-point connection was dropped because
10634 of its complexity and because all of the issues arising from this capability could not be resolved.
10635 It could be provided as additional functionality at some time in the future.

10636 The addition of *network* as a defined term was done to clarify the difference between a network
10637 of batch nodes as opposed to a network of hosts. A network of batch nodes is referred to as a
10638 batch system. The network refers to the actual host configuration. A single host may have
10639 multiple batch nodes.

10640 In the absence of a standard network naming convention, this option establishes its own
10641 convention for the sake of consistency and expediency. This is subject to change, should a future
10642 working group develop a standard naming convention for network pathnames.

10643 C.3.1 Batch General Concepts

10644 During the development of the Batch Environment Services and Utilities option, a number of
10645 topics were discussed at length which influenced the wording of the normative text but could
10646 not be included in the final text. The following items are some of the most significant terms and
10647 concepts of those discussed:

- 10648 • Small and Consistent Command Set

10649 Often, conventional utilities from UNIX systems have a very complicated utility syntax and
10650 usage. This can often result in confusion and errors when trying to use them. The Batch
10651 Environment Services and Utilities option utility set, on the other hand, has been paired to a
10652 small set of robust utilities with an orthogonal calling sequence.

- 10653 • Checkpoint/Restart

10654 This feature permits an already executing process to checkpoint or save its contents. Some
10655 implementations permit this at both the batch utility level (for example, checkpointing this
10656 job upon its abnormal termination) or from within the job itself via a system call. Support of
10657 checkpoint/restart is optional. A conscious, careful effort was made to make the *qsub* utility
10658 consistently refer to checkpoint/restart as optional functionality.

- 10659 • Rerunability

10660 When a user submits a job for batch processing, they can designate it “rerunnable” in that it
10661 will automatically resume execution from the start of the job if the machine on which it was
10662 executing crashes for some reason. The decision on whether the job will be rerun or not is
10663 entirely up to the submitter of the job and no decisions will be made within the batch system.
10664 A job that is rerunnable and has been submitted with the proper checkpoint/restart switch
10665 will first be checkpointed and execution begun from that point. Furthermore, use of the
10666 implementation-defined checkpoint/restart feature will not be defined in this context.

- 10667 • Error Codes

10668 All utilities exit with error status zero (0) if successful, one (1) if a user error occurred, and
10669 two (2) for an internal Batch Environment Services and Utilities option error.

- 10670 • Level of Portability

10671 Portability is specified at both the user, operator, and administrator levels. A conforming
10672 batch implementation prevents identical functionality and behavior at all these levels.

10673	Additionally, portable batch shell scripts with embedded Batch Environment Services and	
10674	Utilities option utilities add an additional level of portability.	
10675	• Resource Specification	
10676	A small set of globally understood resources, such as memory and CPU time, is specified. All	
10677	conforming batch implementations are able to process them in a manner consistent with the	
10678	yet-to-be-developed resource management model. Resources not in this amendment set are	
10679	ignored and passed along as part of the argument stream of the utility.	
10680	• Queue Position	
10681	Queue position is the place a job occupies in a queue. It is dependent on a variety of factors	
10682	such as submission time and priority. Since priority may be affected by the implementation	
10683	of fair share scheduling, the definition of queue position is implementation-defined.	
10684	• Queue ID	
10685	A numerical queue ID is an external requirement for purposes of accounting. The	
10686	identification number was chosen over queue name for processing convenience.	
10687	• Job ID	
10688	A common notion of “jobs” is a collection of processes whose process group cannot be	
10689	altered and is used for resource management and accounting. This concept is	
10690	implementation-defined and, as such, has been omitted from the batch amendment.	
10691	• Bytes <i>versus</i> Words	
10692	Except for one case, bytes are used as the standard unit for memory size. Furthermore, the	
10693	definition of a word varies from machine to machine. Therefore, bytes will be the default unit	
10694	of memory size.	
10695	• Regular Expressions	
10696	The standard definition of regular expressions is much too broad to be used in the batch	
10697	utility syntax. All that is needed is a simple concept of “all”; for example, delete all my jobs	
10698	from the named queue. For this reason, regular expressions have been eliminated from the	
10699	batch amendment.	
10700	• Display Privacy	
10701	How much data should be displayed locally through functions? Local policy dictates the	
10702	amount of privacy. Library functions must be used to create and enforce local policy.	
10703	Network and local <i>qstats</i> must reflect the policy of the server machine.	
10704	• Remote Host Naming Convention	
10705	It was decided that host names would be a maximum of 255 characters in length, with at	
10706	most 15 characters being shown in displays. The 255 character limit was chosen because it is	
10707	consistent with BSD. The 15-character limit was an arbitrary decision.	
10708	• Network Administration	
10709	Network administration is important, but is outside the scope of the batch amendment.	
10710	Network administration could be done with <i>rsh</i> . However, authentication becomes two-	
10711	sided.	
10712	• Network Administration Philosophy	
10713	Keep it simple. Centralized management should be possible. For example, Los Alamos needs	
10714	a dumb set of CPUs to be managed by a central system <i>versus</i> several independently-	

10715 managed systems as is the general case for the Batch Environment Services and Utilities
10716 option.

- 10717 • Operator Utility Defaults (that is, Default Host, User, Account, and so on)

10718 It was decided that usability would override orthogonality and syntactic consistency.

- 10719 • The Batch System Manager and Operator Distinction

10720 The distinction between manager and operator is that operators can only control the flow of
10721 jobs. A manager can alter the batch system configuration in addition to job flow. POSIX
10722 makes a distinction between user and system administrator but goes no further. The
10723 concepts of manager and operator privileges fall under local policy. The distinction between
10724 manager and operator is historical in batch environments, and the Batch Environment
10725 Services and Utilities option has continued that distinction.

- 10726 • The Batch System Administrator

10727 An administrator is equivalent to a batch system manager.

10728 C.3.2 Batch Services

10729 This rationale is provided as informative rather than normative text, to avoid placing
10730 requirements on implementors regarding the use of symbolic constants, but at the same time to
10731 give implementors a preferred practice for assigning values to these constants to promote
10732 interoperability.

10733 The *Checkpoint* and *Minimum_Cpu_Interval* attributes induce a variety of behavior depending
10734 upon their values. Some jobs cannot or should not be checkpointed. Other users will simply
10735 need to ensure job continuation across planned downtimes; for example, scheduled preventive
10736 maintenance. For users consuming expensive resources, or for jobs that run longer than the
10737 mean time between failures, however, periodic checkpointing may be essential. However,
10738 system administrators must be able to set minimum checkpoint intervals on a queue-by-queue
10739 basis to guard against, for example, naive users specifying interval values too small on
10740 memory-intensive jobs. Otherwise, system overhead would adversely affect performance.

10741 The use of symbolic constants, such as `NO_CHECKPOINT`, was introduced to lend a degree of
10742 formalism and portability to this option.

10743 Support for checkpointing is optional for servers. However, clients must provide for the `-c`
10744 option, since in a distributed environment the job may run on a server that does provide such
10745 support, even if the host of the client does not support the checkpoint feature.

10746 If the user does not specify the `-c` option, the default action is left unspecified by this option.
10747 Some implementations may wish to do checkpointing by default; others may wish to checkpoint
10748 only under an explicit request from the user.

10749 The *Priority* attribute has been made non-optional. All clients already had been required to
10750 support the `-p` option. The concept of prioritization is common in historical implementations.
10751 The default priority is left to the server to establish.

10752 The *Hold_Types* attribute has been modified to allow for implementation-defined hold types to
10753 be passed to a batch server.

10754 It was the intent of the IEEE P1003.15 working group to mandate the support for the
10755 *Resource_List* attribute in this option by referring to another amendment, specifically the
10756 IEEE P1003.1a draft standard. However, during the development of the IEEE P1003.1a draft
10757 standard this was excluded. As such this requirement has been removed from the normative
10758 text.

10759 The *Shell_Path* attribute has been modified to accept a list of shell paths that are associated with
 10760 a host. The name of the attribute has been changed to *Shell_Path_List*.

10761 **C.3.3 Common Behavior for Batch Environment Utilities**

10762 This section was defined to meet the goal of a “Small and Consistent Command Set” for this
 10763 option.

10764 **C.4 Utilities**

10765 For the utilities included in IEEE Std 1003.1-2001, see the RATIONALE sections on the individual
 10766 reference pages.

10767 **Exclusion of Utilities**

10768 The set of utilities contained in IEEE Std 1003.1-2001 is drawn from the base documents, with
 10769 one addition: the *c99* utility. This section contains rationale for some of the deliberations that led
 10770 to this set of utilities, and why certain utilities were excluded.

10771 Many utilities were evaluated by the standard developers; more historical utilities were
 10772 excluded from the base documents than included. The following list contains many common
 10773 UNIX system utilities that were not included as mandatory utilities, in the User Portability
 10774 Utilities option, in the XSI extension, or in one of the software development groups. It is
 10775 logistically difficult for this rationale to distribute correctly the reasons for not including a utility
 10776 among the various utility options. Therefore, this section covers the reasons for all utilities not
 10777 included in IEEE Std 1003.1-2001.

10778 This rationale is limited to a discussion of only those utilities actively or indirectly evaluated by
 10779 the standard developers of the base documents, rather than the list of all known UNIX utilities
 10780 from all its variants.

10781 *adb* The intent of the various software development utilities was to assist in the
 10782 installation (rather than the actual development and debugging) of applications.
 10783 This utility is primarily a debugging tool. Furthermore, many useful aspects of *adb*
 10784 are very hardware-specific.

10785 *as* Assemblers are hardware-specific and are included implicitly as part of the
 10786 compilers in IEEE Std 1003.1-2001.

10787 *banner* The only known use of this command is as part of the *lp* printer header pages. It
 10788 was decided that the format of the header is implementation-defined, so this utility
 10789 is superfluous to application portability.

10790 *calendar* This reminder service program is not useful to conforming applications.

10791 *cancel* The *lp* (line printer spooling) system specified is the most basic possible and did
 10792 not need this level of application control.

10793 *chroot* This is primarily of administrative use, requiring superuser privileges.

10794 *col* No utilities defined in IEEE Std 1003.1-2001 produce output requiring such a filter.
 10795 The *nroff* text formatter is present on many historical systems and will continue to
 10796 remain as an extension; *col* is expected to be shipped by all the systems that ship
 10797 *nroff*.

10798 *cpio* This has been replaced by *pax*, for reasons explained in the rationale for that utility.

10799	<i>cpp</i>	This is subsumed by <i>c99</i> .
10800	<i>cu</i>	This utility is terminal-oriented and is not useful from shell scripts or typical application programs.
10801		
10802	<i>dc</i>	
10803		The functionality of this utility can be provided by the <i>bc</i> utility; <i>bc</i> was selected because it was easier to use and had superior functionality. Although the historical versions of <i>bc</i> are implemented using <i>dc</i> as a base, IEEE Std 1003.1-2001 prescribes the interface and not the underlying mechanism used to implement it.
10804		
10805		
10806	<i>dircmp</i>	
10807		Although a useful concept, the historical output of this directory comparison program is not suitable for processing in application programs. Also, the <i>diff -r</i> command gives equivalent functionality.
10808		
10809	<i>dis</i>	Disassemblers are hardware-specific.
10810	<i>emacs</i>	The community of <i>emacs</i> editing enthusiasts was adamant that the full <i>emacs</i> editor not be included in the base documents because they were concerned that an attempt to standardize this very powerful environment would encourage vendors to ship versions conforming strictly to the standard, but lacking the extensibility required by the community. The author of the original <i>emacs</i> program also expressed his desire to omit the program. Furthermore, there were a number of historical UNIX systems that did not include <i>emacs</i> , or included it without supporting it, but there were very few that did not include and support <i>vi</i> .
10811		
10812		
10813		
10814		
10815		
10816		
10817		
10818	<i>ld</i>	This is subsumed by <i>c99</i> .
10819	<i>line</i>	The functionality of <i>line</i> can be provided with <i>read</i> .
10820	<i>lint</i>	This technology is partially subsumed by <i>c99</i> . It is also hard to specify the degree of checking for possible error conditions in programs in any compiler, and specifying what <i>lint</i> would do in these cases is equally difficult.
10821		
10822		It is fairly easy to specify what a compiler does. It requires specifying the language, what it does with that language, and stating that the interpretation of any incorrect program is unspecified. Unfortunately, any description of <i>lint</i> is required to specify what to do with erroneous programs. Since the number of possible errors and questionable programming practices is infinite, one cannot require <i>lint</i> to detect all errors of any given class.
10823		
10824		
10825		
10826		
10827		
10828		
10829		Additionally, some vendors complained that since many compilers are distributed in a binary form without a <i>lint</i> facility (because the ISO C standard does not require one), implementing the standard as a stand-alone product will be much harder. Rather than being able to build upon a standard compiler component (simply by providing <i>c99</i> as an interface), source to that compiler would most likely need to be modified to provide the <i>lint</i> functionality. This was considered a major burden on system providers for a very small gain to developers (users).
10830		
10831		
10832		
10833		
10834		
10835		
10836	<i>login</i>	This utility is terminal-oriented and is not useful from shell scripts or typical application programs.
10837		
10838	<i>lorder</i>	This utility is an aid in creating an implementation-defined detail of object libraries that the standard developers did not feel required standardization.
10839		
10840	<i>lpstat</i>	The <i>lp</i> system specified is the most basic possible and did not need this level of application control.
10841		
10842	<i>mail</i>	This utility was omitted in favor of <i>mailx</i> because there was a considerable functionality overlap between the two.
10843		

10844	<i>mknod</i>	This was omitted in favor of <i>mkfifo</i> , as <i>mknod</i> has too many implementation-defined functions.
10845		
10846	<i>news</i>	This utility is terminal-oriented and is not useful from shell scripts or typical application programs.
10847		
10848	<i>pack</i>	This compression program was considered inferior to <i>compress</i> .
10849	<i>passwd</i>	This utility was proposed in a historical draft of the base documents but met with too many objections to be included. There were various reasons: • Changing a password should not be viewed as a command, but as part of the login sequence. Changing a password should only be done while a trusted path is in effect. • Even though the text in early drafts was intended to allow a variety of implementations to conform, the security policy for one site may differ from another site running with identical hardware and software. One site might use password authentication while the other did not. Vendors could not supply a <i>passwd</i> utility that would conform to IEEE Std 1003.1-2001 for all sites using their system. • This is really a subject for a system administration working group or a security working group.
10850		
10851		
10852		
10853		
10854		
10855		
10856		
10857		
10858		
10859		
10860		
10861		
10862	<i>pcat</i>	This compression program was considered inferior to <i>zcat</i> .
10863	<i>pg</i>	This duplicated many of the features of the <i>more</i> pager, which was preferred by the standard developers.
10864		
10865	<i>prof</i>	The intent of the various software development utilities was to assist in the installation (rather than the actual development and debugging) of applications. This utility is primarily a debugging tool.
10866		
10867		
10868	RCS	RCS was originally considered as part of a version control utilities portion of the scope. However, this aspect was abandoned by the standard developers. SCCS is now included as an optional part of the XSI extension.
10869		
10870		
10871	<i>red</i>	Restricted editor. This was not considered by the standard developers because it never provided the level of security restriction required.
10872		
10873	<i>rsh</i>	Restricted shell. This was not considered by the standard developers because it does not provide the level of security restriction that is implied by historical documentation.
10874		
10875		
10876	<i>sdb</i>	The intent of the various software development utilities was to assist in the installation (rather than the actual development and debugging) of applications. This utility is primarily a debugging tool. Furthermore, some useful aspects of <i>sdb</i> are very hardware-specific.
10877		
10878		
10879		
10880	<i>sdiff</i>	The “side-by-side <i>diff</i> ” utility from System V was omitted because it is used infrequently, and even less so by conforming applications. Despite being in System V, it is not in the SVID or XPG.
10881		
10882		
10883	<i>shar</i>	Any of the numerous “shell archivers” were excluded because they did not meet the requirement of existing practice.
10884		
10885	<i>shl</i>	This utility is terminal-oriented and is not useful from shell scripts or typical application programs. The job control aspects of the shell command language are generally more useful.
10886		
10887		

10888	<i>size</i>	The intent of the various software development utilities was to assist in the installation (rather than the actual development and debugging) of applications. This utility is primarily a debugging tool.
10889		
10890		
10891	<i>spell</i>	This utility is not useful from shell scripts or typical application programs. The <i>spell</i> utility was considered, but was omitted because there is no known technology that can be used to make it recognize general language for user-specified input without providing a complete dictionary along with the input file.
10892		
10893		
10894		
10895	<i>su</i>	This utility is not useful from shell scripts or typical application programs. (There was also sentiment to avoid security-related utilities.)
10896		
10897	<i>sum</i>	This utility was renamed <i>cksum</i> .
10898	<i>tar</i>	This has been replaced by <i>pax</i> , for reasons explained in the rationale for that utility.
10899	<i>unpack</i>	This compression program was considered inferior to <i>uncompress</i> .
10900	<i>wall</i>	This utility is terminal-oriented and is not useful in shell scripts or typical applications. It is generally used only by system administrators.
10901

The Institute of Electrical and Electronics Engineers, Inc.

Portability Considerations (Informative)

This section contains information to satisfy various international requirements:

- Section D.1 describes perceived user requirements.
- Section D.2 (on page 270) indicates how the facilities of IEEE Std 1003.1-2001 satisfy those requirements.
- Section D.3 (on page 277) offers guidance to writers of profiles on how the configurable options, limits, and optional behavior of IEEE Std 1003.1-2001 should be cited in profiles.

D.1 User Requirements

This section describes the user requirements that were perceived by the developers of IEEE Std 1003.1-2001. The primary source for these requirements was an analysis of historical practice in widespread use, as typified by the base documents listed in Section A.1.1 (on page 3).

IEEE Std 1003.1-2001 addresses the needs of users requiring open systems solutions for source code portability of applications. It currently addresses users requiring open systems solutions for source-code portability of applications involving multi-programming and process management (creating processes, signaling, and so on); access to files and directories in a hierarchy of file systems (opening, reading, writing, deleting files, and so on); access to asynchronous communications ports and other special devices; access to information about other users of the system; facilities supporting applications requiring bounded (realtime) response.

The following users are identified for IEEE Std 1003.1-2001:

- Those employing applications written in high-level languages, such as C, Ada, or FORTRAN.
- Users who desire conforming applications that do not necessarily require the characteristics of high-level languages (for example, the speed of execution of compiled languages or the relative security of source code intellectual property inherent in the compilation process).
- Users who desire conforming applications that can be developed quickly and can be modified readily without the use of compilers and other system components that may be unavailable on small systems or those without special application development capabilities.
- Users who interact with a system to achieve general-purpose time-sharing capabilities common to most business or government offices or academic environments: editing, filing, inter-user communications, printing, and so on.
- Users who develop applications for POSIX-conformant systems.
- Users who develop applications for UNIX systems.

An acknowledged restriction on applicable users is that they are limited to the group of individuals who are familiar with the style of interaction characteristic of historically-derived systems based on one of the UNIX operating systems (as opposed to other historical systems with different models, such as MS/DOS, Macintosh, VMS, MVS, and so on). Typical users would include program developers, engineers, or general-purpose time-sharing users.

The requirements of users of IEEE Std 1003.1-2001 can be summarized as a single goal: *application source portability*. The requirements of the user are stated in terms of the requirements

10947 of portability of applications. This in turn becomes a requirement for a standardized set of
10948 syntax and semantics for operations commonly found on many operating systems.

10949 The following sections list the perceived requirements for application portability.

10950 **D.1.1 Configuration Interrogation**

10951 An application must be able to determine whether and how certain optional features are
10952 provided and to identify the system upon which it is running, so that it may appropriately adapt
10953 to its environment.

10954 Applications must have sufficient information to adapt to varying behaviors of the system.

10955 **D.1.2 Process Management**

10956 An application must be able to manage itself, either as a single process or as multiple processes.
10957 Applications must be able to manage other processes when appropriate.

10958 Applications must be able to identify, control, create, and delete processes, and there must be
10959 communication of information between processes and to and from the system.

10960 Applications must be able to use multiple flows of control with a process (threads) and
10961 synchronize operations between these flows of control.

10962 **D.1.3 Access to Data**

10963 Applications must be able to operate on the data stored on the system, access it, and transmit it
10964 to other applications. Information must have protection from unauthorized or accidental access
10965 or modification.

10966 **D.1.4 Access to the Environment**

10967 Applications must be able to access the external environment to communicate their input and
10968 results.

10969 **D.1.5 Access to Determinism and Performance Enhancements**

10970 Applications must have sufficient control of resource allocation to ensure the timeliness of
10971 interactions with external objects.

10972 **D.1.6 Operating System-Dependent Profile**

10973 The capabilities of the operating system may make certain optional characteristics of the base
10974 language in effect no longer optional, and this should be specified.

10975 **D.1.7 I/O Interaction**

10976 The interaction between the C language I/O subsystem (*stdio*) and the I/O subsystem of
10977 IEEE Std 1003.1-2001 must be specified.

10978 D.1.8 Internationalization Interaction

10979 The effects of the environment of IEEE Std 1003.1-2001 on the internationalization facilities of the
10980 C language must be specified.

10981 D.1.9 C-Language Extensions

10982 Certain functions in the C language must be extended to support the additional capabilities
10983 provided by IEEE Std 1003.1-2001.

10984 D.1.10 Command Language

10985 Users should be able to define procedures that combine simple tools and/or applications into
10986 higher-level components that perform to the specific needs of the user. The user should be able
10987 to store, recall, use, and modify these procedures. These procedures should employ a powerful
10988 command language that is used for recurring tasks in conforming applications (scripts) in the
10989 same way that it is used interactively to accomplish one-time tasks. The language and the
10990 utilities that it uses must be consistent between systems to reduce errors and retraining.

10991 D.1.11 Interactive Facilities

10992 Use the system to accomplish individual tasks at an interactive terminal. The interface should be
10993 consistent, intuitive, and offer usability enhancements to increase the productivity of terminal
10994 users, reduce errors, and minimize retraining costs. Online documentation or usage assistance
10995 should be available.

10996 D.1.12 Accomplish Multiple Tasks Simultaneously

10997 Access applications and interactive facilities from a single terminal without requiring serial
10998 execution: switch between multiple interactive tasks; schedule one-time or periodic background
10999 work; display the status of all work in progress or scheduled; influence the priority scheduling of
11000 work, when authorized.

11001 D.1.13 Complex Data Manipulation

11002 Manipulate data in files in complex ways: sort, merge, compare, translate, edit, format, pattern
11003 match, select subsets (strings, columns, fields, rows, and so on). These facilities should be
11004 available to both conforming applications and interactive users.

11005 D.1.14 File Hierarchy Manipulation

11006 Create, delete, move/rename, copy, backup/archive, and display files and directories. These
11007 facilities should be available to both conforming applications and interactive users.

11008 D.1.15 Locale Configuration

11009 Customize applications and interactive sessions for the cultural and language conventions of the
11010 user. Employ a wide variety of standard character encodings. These facilities should be available
11011 to both conforming applications and interactive users.

11012 D.1.16 Inter-User Communication

11013 Send messages or transfer files to other users on the same system or other systems on a network.
 11014 These facilities should be available to both conforming applications and interactive users.

11015 D.1.17 System Environment

11016 Display information about the status of the system (activities of users and their interactive and
 11017 background work, file system utilization, system time, configuration, and presence of optional
 11018 facilities) and the environment of the user (terminal characteristics, and so on). Inform the
 11019 system operator/administrator of problems. Control access to user files and other resources.

11020 D.1.18 Printing

11021 Output files on a variety of output device classes, accessing devices on local or network-
 11022 connected systems. Control (or influence) the formatting, priority scheduling, and output
 11023 distribution of work. These facilities should be available to both conforming applications and
 11024 interactive users.

11025 D.1.19 Software Development

11026 Develop (create and manage source files, compile/interpret, debug) portable open systems
 11027 applications and package them for distribution to, and updating of, other systems.

11028 D.2 Portability Capabilities

11029 This section describes the significant portability capabilities of IEEE Std 1003.1-2001 and
 11030 indicates how the user requirements listed in Section D.1 (on page 267) are addressed. The
 11031 capabilities are listed in the same format as the preceding user requirements; they are
 11032 summarized below:

- 11033 • Configuration Interrogation
- 11034 • Process Management
- 11035 • Access to Data
- 11036 • Access to the Environment
- 11037 • Access to Determinism and Performance Enhancements
- 11038 • Operating System-Dependent Profile
- 11039 • I/O Interaction
- 11040 • Internationalization Interaction
- 11041 • C-Language Extensions
- 11042 • Command Language
- 11043 • Interactive Facilities
- 11044 • Accomplish Multiple Tasks Simultaneously
- 11045 • Complex Data Manipulation
- 11046 • File Hierarchy Manipulation

- 11047 • Locale Configuration
- 11048 • Inter-User Communication
- 11049 • System Environment
- 11050 • Printing
- 11051 • Software Development

11052 D.2.1 Configuration Interrogation

11053 The *uname()* operation provides basic identification of the system. The *sysconf()*, *pathconf()*, and
 11054 *fpathconf()* functions and the *getconf* utility provide means to interrogate the implementation to
 11055 determine how to adapt to the environment in which it is running. These values can be either
 11056 static (indicating that all instances of the implementation have the same value) or dynamic
 11057 (indicating that different instances of the implementation have the different values, or that the
 11058 value may vary for other reasons, such as reconfiguration).

11059 Unsatisfied Requirements

11060 None directly. However, as new areas are added, there will be a need for additional capability in
 11061 this area.

11062 D.2.2 Process Management

11063 The *fork()*, *exec* family, *posix_spawn()*, and *posix_spawnnp()* functions provide for the creation of
 11064 new processes or the insertion of new applications into existing processes. The *_Exit()*, *_exit()*,
 11065 *exit()*, and *abort()* functions allow for the termination of a process by itself. The *wait()* and
 11066 *waitpid()* functions allow one process to deal with the termination of another.

11067 The *times()* function allows for basic measurement of times used by a process. Various
 11068 functions, including *fstat()*, *getegid()*, *geteuid()*, *getgid()*, *getgrgid()*, *getgrnam()*, *getlogin()*,
 11069 *getpid()*, *getppid()*, *getpwnam()*, *getpwuid()*, *getuid()*, *lstat()*, and *stat()*, provide for access to the
 11070 identifiers of processes and the identifiers and names of owners of processes (and files).

11071 The various functions operating on environment variables provide for communication of
 11072 information (primarily user-configurable defaults) from a parent to child processes.

11073 The operations on the current working directory control and interrogate the directory from
 11074 which relative filename searches start. The *umask()* function controls the default protections
 11075 applied to files created by the process.

11076 The *alarm()*, *pause()*, *sleep()*, *ualarm()*, and *usleep()* operations allow the process to suspend until
 11077 a timer has expired or to be notified when a period of time has elapsed. The *time()* operation
 11078 interrogates the current time and date.

11079 The signal mechanism provides for communication of events either from other processes or
 11080 from the environment to the application, and the means for the application to control the effect
 11081 of these events. The mechanism provides for external termination of a process and for a process
 11082 to suspend until an event occurs. The mechanism also provides for a value to be associated with
 11083 an event.

11084 Job control provides a means to group processes and control them as groups, and to control their
 11085 access to the function between the user and the system (the “controlling terminal”). It also
 11086 provides the means to suspend and resume processes.

11087 The Process Scheduling option provides control of the scheduling and priority of a process.

11088 The Message Passing option provides a means for interprocess communication involving small
11089 amounts of data.

11090 The Memory Management facilities provide control of memory resources and for the sharing of
11091 memory. This functionality is mandatory on XSI-conformant systems.

11092 The Threads facilities provide multiple flows of control with a process (threads),
11093 synchronization between threads, association of data with threads, and controlled cancellation
11094 of threads.

11095 The XSI interprocess communications functionality provide an alternate set of facilities to
11096 manipulate semaphores, message queues, and shared memory. These are provided on XSI-
11097 conformant systems to support conforming applications developed to run on UNIX systems.

11098 **D.2.3 Access to Data**

11099 The *open()*, *close()*, *fclose()*, *fopen()*, and *pipe()* functions provide for access to files and data.
11100 Such files may be regular files, interprocess data channels (pipes), or devices. Additional types
11101 of objects in the file system are permitted and are being contemplated for standardization.

11102 The *access()*, *chmod()*, *chown()*, *dup()*, *dup2()*, *fchmod()*, *fcntl()*, *fstat()*, *ftruncate()*, *lstat()*,
11103 *readlink()*, *realpath()*, *stat()*, and *utime()* functions allow for control and interrogation of file and
11104 file-related objects (including symbolic links), and their ownership, protections, and timestamps.

11105 The *fgetc()*, *fputc()*, *fread()*, *fseek()*, *fsetpos()*, *fwrite()*, *getc()*, *getchar()*, *lseek()*, *putchar()*, *putc()*,
11106 *read()*, and *write()* functions provide for data transfer from the application to files (in all their
11107 forms).

11108 The *closedir()*, *link()*, *mkdir()*, *opendir()*, *readdir()*, *rename()*, *rmdir()*, *rewinddir()*, and *unlink()*
11109 functions provide for a complete set of operations on directories. Directories can arbitrarily
11110 contain other directories, and a single file can be mentioned in more than one directory.

11111 The file-locking mechanism provides for advisory locking (protection during transactions) of
11112 ranges of bytes (in effect, records) in a file.

11113 The *confstr()*, *fpathconf()*, *pathconf()*, and *sysconf()* functions provide for enquiry as to the
11114 behavior of the system where variability is permitted.

11115 The Synchronized Input and Output option provides for assured commitment of data to media.

11116 The Asynchronous Input and Output option provides for initiation and control of asynchronous
11117 data transfers.

11118 **D.2.4 Access to the Environment**

11119 The operations and types in the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 11,
11120 General Terminal Interface are provided for access to asynchronous serial devices. The primary
11121 intended use for these is the controlling terminal for the application (the interaction point
11122 between the user and the system). They are general enough to be used to control any
11123 asynchronous serial device. The functions are also general enough to be used with many other
11124 device types as a user interface when some emulation is provided.

11125 Less detailed access is provided for other device types, but in many instances an application
11126 need not know whether an object in the file system is a device or a regular file to operate
11127 correctly.

11128 **Unsatisfied Requirements**

11129 Detailed control of common device classes, specifically magnetic tape, is not provided.

11130 **D.2.5 Bounded (Realtime) Response**

11131 The Realtime Signals Extension provides queued signals and the prioritization of the handling of
 11132 signals. The SCHED_FIFO, SCHED_SPORADIC, and SCHED_RR scheduling policies provide
 11133 control over processor allocation. The Semaphores option provides high-performance
 11134 synchronization. The Memory Management functions provide memory locking for control of
 11135 memory allocation, file mapping for high-performance, and shared memory for high-
 11136 performance interprocess communication. The Message Passing option provides for interprocess
 11137 communication without being dependent on shared memory.

11138 The Timers option provides a high resolution function called *nanosleep()* with a finer resolution
 11139 than the *sleep()* function.

11140 The Typed Memory Objects option, the Monotonic Clock option, and the Timeouts option
 11141 provide further facilities for applications to use to obtain predictable bounded response.

11142 **D.2.6 Operating System-Dependent Profile**

11143 IEEE Std 1003.1-2001 makes no distinction between text and binary files. The values of
 11144 EXIT_SUCCESS and EXIT_FAILURE are further defined.

11145 **Unsatisfied Requirements**

11146 None known, but the ISO C standard may contain some additional options that could be
 11147 specified.

11148 **D.2.7 I/O Interaction**

11149 IEEE Std 1003.1-2001 defines how each of the ISO C standard *stdio* functions interact with the
 11150 POSIX.1 operations, typically specifying the behavior in terms of POSIX.1 operations.

11151 **Unsatisfied Requirements**

11152 None.

11153 **D.2.8 Internationalization Interaction**

11154 The IEEE Std 1003.1-2001 environment operations provide a means to define the environment
 11155 for *setlocale()* and time functions such as *ctime()*. The *tzset()* function is provided to set time
 11156 conversion information.

11157 The *nl_langinfo()* function is provided as an XSI extension to query locale-specific cultural
 11158 settings.

11159 **Unsatisfied Requirements**

11160 None.

11161 D.2.9 C-Language Extensions

11162 The *setjmp()* and *longjmp()* functions are not defined to be cognizant of the signal masks defined
 11163 for POSIX.1. The *sigsetjmp()* and *siglongjmp()* functions are provided to fill this gap.

11164 The *_setjmp()* and *_longjmp()* functions are provided as XSI extensions to support historic
 11165 practice.

11166 Unsatisfied Requirements

11167 None.

11168 D.2.10 Command Language

11169 The shell command language, as described in the Shell and Utilities volume of
 11170 IEEE Std 1003.1-2001, Chapter 2, Shell Command Language, is a common language useful in
 11171 batch scripts, through an API to high-level languages (for the C-Language Binding option,
 11172 *system()* and *popen()*) and through an interactive terminal (see the *sh* utility). The shell language
 11173 has many of the characteristics of a high-level language, but it has been designed to be more
 11174 suitable for user terminal entry and includes interactive debugging facilities. Through the use of
 11175 pipelining, many complex commands can be constructed from combinations of data filters and
 11176 other common components. Shell scripts can be created, stored, recalled, and modified by the
 11177 user with simple editors.

11178 In addition to the basic shell language, the following utilities offer features that simplify and
 11179 enhance programmatic access to the utilities and provide features normally found only in high-
 11180 level languages: *basename*, *bc*, *command*, *dirname*, *echo*, *env*, *expr*, *false*, *printf*, *read*, *sleep*, *tee*, *test*,
 11181 *time**,² *true*, *wait*, *xargs*, and all of the special built-in utilities in the Shell and Utilities volume of
 11182 IEEE Std 1003.1-2001, Section 2.14, Special Built-In Utilities.

11183 Unsatisfied Requirements

11184 None.

11185 D.2.11 Interactive Facilities

11186 The utilities offer a common style of command-line interface through conformance to the Utility
 11187 Syntax Guidelines (see the Base Definitions volume of IEEE Std 1003.1-2001, Section 12.2, Utility
 11188 Syntax Guidelines) and the common utility defaults (see the Shell and Utilities volume of
 11189 IEEE Std 1003.1-2001, Section 1.11, Utility Description Defaults). The *sh* utility offers an
 11190 interactive command-line history and editing facility. The following utilities in the User
 11191 Portability Utilities option have been customized for interactive use: *alias*, *ex*, *fc*, *mailx*, *more*, *talk*,
 11192 *vi*, *unalias*, and *write*; the *man* utility offers online access to system documentation.

11193 _____

11194 2. The utilities listed with an asterisk here and later in this section are present only on systems which support the User Portability
 11195 Utilities option. There may be further restrictions on the utilities offered with various configuration option combinations; see the
 11196 individual utility descriptions.

11197 **Unsatisfied Requirements**

11198 The command line interface to individual utilities is as intuitive and consistent as historical
 11199 practice allows. Work underway based on graphical user interfaces may be more suitable for
 11200 novice or occasional users of the system.

11201 **D.2.12 Accomplish Multiple Tasks Simultaneously**

11202 The shell command language offers background processing through the asynchronous list
 11203 command form; see the Shell and Utilities volume of IEEE Std 1003.1-2001, Section 2.9, Shell
 11204 Commands. The *nohup* utility makes background processing more robust and usable. The *kill*
 11205 utility can terminate background jobs. When the User Portability Utilities option is supported,
 11206 the following utilities allow manipulation of jobs: *bg*, *fg*, and *jobs*. Also, if the User Portability
 11207 Utilities option is supported, the following can support periodic job scheduling, control, and
 11208 display: *at*, *batch*, *crontab*, *nice*, *ps*, and *renice*.

11209 **Unsatisfied Requirements**

11210 Terminals with multiple windows may be more suitable for some multi-tasking interactive uses
 11211 than the job control approach in IEEE Std 1003.1-2001. See the comments on graphical user
 11212 interfaces in Section D.2.11 (on page 274). The *nice* and *renice* utilities do not necessarily take
 11213 advantage of complex system scheduling algorithms that are supported by the realtime options
 11214 within IEEE Std 1003.1-2001.

11215 **D.2.13 Complex Data Manipulation**

11216 The following utilities address user requirements in this area: *asa*, *awk*, *bc*, *cmp*, *comm*, *csplit**, *cut*,
 11217 *dd*, *diff*, *ed*, *ex**, *expand**, *expr*, *find*, *fold*, *grep*, *head*, *join*, *od*, *paste*, *pr*, *printf*, *sed*, *sort*, *split**, *tabs**, *tail*,
 11218 *tr*, *unexpand**, *uniq*, *uudecode**, *uuencode**, and *wc*.

11219 **Unsatisfied Requirements**

11220 Sophisticated text formatting utilities, such as *troff* or *TeX*, are not included. Standards work in
 11221 the area of SGML may satisfy this.

11222 **D.2.14 File Hierarchy Manipulation**

11223 The following utilities address user requirements in this area: *basename*, *cd*, *chgrp*, *chmod*, *chown*,
 11224 *cksum*, *cp*, *dd*, *df**, *diff*, *dirname*, *du**, *find*, *ls*, *ln*, *mkdir*, *mkfifo*, *mv*, *patch**, *pathchk*, *pax*, *pwd*, *rm*, *rmdir*,
 11225 *test*, and *touch*.

11226 **Unsatisfied Requirements**

11227 Some graphical user interfaces offer more intuitive file manager components that allow file
 11228 manipulation through the use of icons for novice users.

11229 D.2.15 Locale Configuration

11230 The standard utilities are affected by the various *LC_* variables to achieve locale-dependent
 11231 operation: character classification, collation sequences, regular expressions and shell pattern
 11232 matching, date and time formats, numeric formatting, and monetary formatting. When the
 11233 POSIX2_LOCALEDEF option is supported, applications can provide their own locale definition
 11234 files. The following utilities address user requirements in this area: *date*, *ed*, *ex**, *find*, *grep*, *locale*,
 11235 *localedef*, *more**, *sed*, *sh*, *sort*, *tr*, *uniq*, and *vi**.

11236 The *iconv()*, *iconv_close()*, and *iconv_open()* functions are available to allow an application to
 11237 convert character data between supported character sets.

11238 The *gencat* utility and the *catopen()*, *catclose()*, and *catgets()* functions for message catalog
 11239 manipulation are available on XSI-conformant systems.

11240 Unsatisfied Requirements

11241 Some aspects of multi-byte character and state-encoded character encodings have not yet been
 11242 addressed. The C-language functions, such as *getopt()*, are generally limited to single-byte
 11243 characters. The effect of the *LC_MESSAGES* variable on message formats is only suggested at
 11244 this time.

11245 D.2.16 Inter-User Communication

11246 The following utilities address user requirements in this area: *cksum*, *mailx**, *mesg**, *patch**, *pax*,
 11247 *talk**, *uudecode**, *uuencode**, *who**, and *write**.

11248 The historical UUCP utilities are included on XSI-conformant systems.

11249 Unsatisfied Requirements

11250 None.

11251 D.2.17 System Environment

11252 The following utilities address user requirements in this area: *chgrp*, *chmod*, *chown*, *df**, *du**, *env*,
 11253 *getconf*, *id*, *logger*, *logname*, *mesg**, *newgrp**, *ps**, *stty*, *tput**, *tty*, *umask*, *uname*, and *who**.

11254 The *closelog()*, *openlog()*, *setlogmask()*, and *syslog()* functions provide System Logging facilities
 11255 on XSI-conformant systems; these are analogous to the *logger* utility.

11256 Unsatisfied Requirements

11257 None.

11258 D.2.18 Printing

11259 The following utilities address user requirements in this area: *pr* and *lp*.

11260 Unsatisfied Requirements

11261 There are no features to control the formatting or scheduling of the print jobs.

11262 D.2.19 Software Development

11263 The following utilities address user requirements in this area: *ar*, *asa*, *awk*, *c99*, *ctags**, *fort77*,
 11264 *getconf*, *getopts*, *lex*, *localedef*, *make*, *nm**, *od*, *patch**, *pax*, *strings**, *strip*, *time**, and *yacc*.

11265 The *system()*, *popen()*, *pclose()*, *regcomp()*, *regex()*, *regerror()*, *regfree()*, *fnmatch()*, *getopt()*,
 11266 *glob()*, *globfree()*, *wordexp()*, and *wordfree()* functions allow C-language programmers to access
 11267 some of the interfaces used by the utilities, such as argument processing, regular expressions,
 11268 and pattern matching.

11269 The SCCS source-code control system utilities are available on systems supporting the XSI
 11270 Development option.

11271 Unsatisfied Requirements

11272 There are no language-specific development tools related to languages other than C and
 11273 FORTRAN. The C tools are more complete and varied than the FORTRAN tools. There is no
 11274 data dictionary or other CASE-like development tools.

11275 D.2.20 Future Growth

11276 It is arguable whether or not all functionality to support applications is potentially within the
 11277 scope of IEEE Std 1003.1-2001. As a simple matter of practicality, it cannot be. Areas such as
 11278 graphics, application domain-specific functionality, windowing, and so on, should be in unique
 11279 standards. As such, they are properly “Unsatisfied Requirements” in terms of providing fully
 11280 conforming applications, but ones which are outside the scope of IEEE Std 1003.1-2001.

11281 However, as the standards evolve, certain functionality once considered “exotic” enough to be
 11282 part of a separate standard become common enough to be included in a core standard such as
 11283 this. Realtime and networking, for example, have both moved from separate standards (with
 11284 much difficult cross-referencing) into IEEE Std 1003.1 over time, and although no specific areas
 11285 have been identified for inclusion in future revisions, such inclusions seem likely.

11286 D.3 Profiling Considerations

11287 This section offers guidance to writers of profiles on how the configurable options, limits, and
 11288 optional behavior of IEEE Std 1003.1-2001 should be cited in profiles. Profile writers should
 11289 consult the general guidance in POSIX.0 when writing POSIX Standardized Profiles.

11290 The information in this section is an inclusive list of features that should be considered by profile
 11291 writers. Subsetting of IEEE Std 1003.1-2001 should follow the Base Definitions volume of
 11292 IEEE Std 1003.1-2001, Section 2.1.5.1, Subprofiling Considerations. A set of profiling options is
 11293 described in Appendix E (on page 291).

11294 D.3.1 Configuration Options

11295 There are two set of options suggested by IEEE Std 1003.1-2001: those for POSIX-conforming
 11296 systems and those for X/Open System Interface (XSI) conformance. The requirements for XSI
 11297 conformance are documented in the Base Definitions volume of IEEE Std 1003.1-2001 and not
 11298 discussed further here, as they superset the POSIX conformance requirements.

11299 D.3.2 Configuration Options (Shell and Utilities)

11300 There are three broad optional configurations for the Shell and Utilities volume of
 11301 IEEE Std 1003.1-2001: basic execution system, development system, and user portability
 11302 interactive system. The options to support these, and other minor configuration options, are
 11303 listed in the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 2, Conformance. Profile
 11304 writers should consult the following list and the comments concerning user requirements
 11305 addressed by various components in Section D.2 (on page 270).

11306 POSIX2_UPE

11307 The system supports the User Portability Utilities option.

11308 This option is a requirement for a user portability interactive system. It is required
 11309 frequently except for those systems, such as embedded realtime or dedicated application
 11310 systems, that support little or no interactive time-sharing work by users or operators. XSI-
 11311 conformant systems support this option.

11312 POSIX2_SW_DEV

11313 The system supports the Software Development Utilities option.

11314 This option is required by many systems, even those in which actual software development
 11315 does not occur. The *make* utility, in particular, is required by many application software
 11316 packages as they are installed onto the system. If POSIX2_C_DEV is supported,
 11317 POSIX2_SW_DEV is almost a mandatory requirement because of *ar* and *make*.

11318 POSIX2_C_BIND

11319 The system supports the C-Language Bindings option.

11320 This option is required on some implementations developing complex C applications or on
 11321 any system installing C applications in source form that require the functions in this option.
 11322 The *system()* and *popen()* functions, in particular, are widely used by applications; the
 11323 others are rather more specialized.

11324 POSIX2_C_DEV

11325 The system supports the C-Language Development Utilities option.

11326 This option is required by many systems, even those in which actual C-language software
 11327 development does not occur. The *c99* utility, in particular, is required by many application
 11328 software packages as they are installed onto the system. The *lex* and *yacc* utilities are used
 11329 less frequently.

11330 POSIX2_FORT_DEV

11331 The system supports the FORTRAN Development Utilities option

11332 As with C, this option is needed on any system developing or installing FORTRAN
 11333 applications in source form.

11334 POSIX2_FORT_RUN

11335 The system supports the FORTRAN Runtime Utilities option.

11336 This option is required for some FORTRAN applications that need the *asa* utility to convert
 11337 Hollerith printing statement output. It is unknown how frequently this occurs.

11338 POSIX2_LOCALEDEF

11339 The system supports the creation of locales.

11340 This option is needed if applications require their own customized locale definitions to
 11341 operate. It is presently unknown whether many applications are dependent on this.
 11342 However, the option is virtually mandatory for systems in which internationalized
 11343 applications are developed.

11344	XSI-conformant systems support this option.	
11345	POSIX2_PBS	
11346	The system supports the Batch Environment Services and Utilities option.	
11347	POSIX2_PBS_ACCOUNTING	
11348	The system supports the optional feature of accounting within the Batch Environment	
11349	Services and Utilities option. It will be required in servers that implement the optional	
11350	feature of accounting.	
11351	POSIX2_PBS_CHECKPOINT	
11352	The system supports the optional feature of checkpoint/restart within the Batch	
11353	Environment Services and Utilities option.	
11354	POSIX2_PBS_LOCATE	
11355	The system supports the optional feature of locating batch jobs within the Batch	
11356	Environment Services and Utilities option.	
11357	POSIX2_PBS_MESSAGE	
11358	The system supports the optional feature of sending messages to batch jobs within the	
11359	Batch Environment Services and Utilities option.	
11360	POSIX2_PBS_TRACK	
11361	The system supports the optional feature of tracking batch jobs within the Batch	
11362	Environment Services and Utilities option.	
11363	POSIX2_CHAR_TERM	
11364	The system supports at least one terminal type capable of all operations described in	
11365	IEEE Std 1003.1-2001.	
11366	On systems with POSIX2_UPE, this option is almost always required. It was developed	
11367	solely to allow certain specialized vendors and user applications to bypass the requirement	
11368	for general-purpose asynchronous terminal support. For example, an application and	
11369	system that was suitable for block-mode terminals, such as IBM 3270s, would not need this	
11370	option.	
11371	XSI-conformant systems support this option.	

11372 **D.3.3 Configurable Limits**

11373	Very few of the limits need to be increased for profiles. No profile can cite lower values.	
11374	{POSIX2_BC_BASE_MAX}	
11375	{POSIX2_BC_DIM_MAX}	
11376	{POSIX2_BC_SCALE_MAX}	
11377	{POSIX2_BC_STRING_MAX}	
11378	No increase is anticipated for any of these <i>bc</i> values, except for very specialized applications	
11379	involving huge numbers.	
11380	{POSIX2_COLL_WEIGHTS_MAX}	
11381	Some natural languages with complex collation requirements require an increase from the	
11382	default 2 to 4; no higher numbers are anticipated.	
11383	{POSIX2_EXPR_NEST_MAX}	
11384	No increase is anticipated.	
11385	{POSIX2_LINE_MAX}	
11386	This number is much larger than most historical applications have been able to use. At some	
11387	future time, applications may be rewritten to take advantage of even larger values.	

11388 {POSIX2_RE_DUP_MAX}
 11389 No increase is anticipated.

11390 {POSIX2_VERSION}
 11391 This is actually not a limit, but a standard version stamp. Generally, a profile should specify
 11392 the Shell and Utilities volume of IEEE Std 1003.1-2001, Chapter 2, Shell Command Language
 11393 by name in the normative references section, not this value.

11394 **D.3.4 Configuration Options (System Interfaces)**

11395 {NGROUPS_MAX}
 11396 A non-zero value indicates that the implementation supports supplementary groups.

11397 This option is needed where there is a large amount of shared use of files, but where a
 11398 certain amount of protection is needed. Many profiles³ are known to require this option; it
 11399 should only be required if needed, but it should never be prohibited.

11400 _POSIX_ADVISORY_INFO
 11401 The system provides advisory information for file management.

11402 This option allows the application to specify advisory information that can be used to
 11403 achieve better or even deterministic response time in file manager or input and output
 11404 operations.

11405 _POSIX_ASYNCHRONOUS_IO
 11406 The system provides concurrent process execution and input and output transfers.

11407 This option was created to support historical systems that did not provide the feature. It
 11408 should only be required if needed, but it should never be prohibited.

11409 _POSIX_BARRIERS
 11410 The system supports barrier synchronization.

11411 This option was created to allow efficient synchronization of multiple parallel threads in
 11412 multi-processor systems in which the operation is supported in part by the hardware
 11413 architecture.

11414 _POSIX_CHOWN_RESTRICTED
 11415 The system restricts the right to “give away” files to other users.

11416 This option should be carefully investigated before it is required. Some applications expect
 11417 that they can change the ownership of files in this way. It is provided where either security
 11418 or system account requirements cause this ability to be a problem. It is also known to be
 11419 specified in many profiles.

11420 _POSIX_CLOCK_SELECTION
 11421 The system supports the Clock Selection option.

11422 This option allows applications to request a high resolution sleep in order to suspend a
 11423 thread during a relative time interval, or until an absolute time value, using the desired
 11424 clock. It also allows the application to select the clock used in a *pthread_cond_timedwait()*
 11425 function call.

11426 _____

11427 3. There are no formally approved profiles of IEEE Std 1003.1-2001 at the time of publication; the reference here is to various
 11428 profiles generated by private bodies or governments.

11429 `_POSIX_CPUTIME`

11430 The system supports the Process CPU-Time Clocks option.

11431 This option allows applications to use a new clock that measures the execution times of
 11432 processes or threads, and the possibility to create timers based upon these clocks, for
 11433 runtime detection (and treatment) of execution time overruns.

11434 `_POSIX_FSYNC`

11435 The system supports file synchronization requests.

11436 This option was created to support historical systems that did not provide the feature.
 11437 Applications that are expecting guaranteed completion of their input and output operations
 11438 should require the `_POSIX_SYNC_IO` option. This option should never be prohibited.

11439 XSI-conformant systems support this option.

11440 `_POSIX_IPV6`

11441 The system supports facilities related to Internet Protocol Version 6 (IPv6).

11442 This option was created to allow systems to transition to IPv6.

11443 `_POSIX_JOB_CONTROL`

11444 Job control facilities are mandatory in IEEE Std 1003.1-2001.

11445 The option was created primarily to support historical systems that did not provide the
 11446 feature. Many existing profiles now require it; it should only be required if needed, but it
 11447 should never be prohibited. Most applications that use it can run when it is not present,
 11448 although with a degraded level of user convenience.

11449 `_POSIX_MAPPED_FILES`

11450 The system supports the mapping of regular files into the process address space.

11451 XSI-conformant systems support this option.

11452 Both this option and the Shared Memory Objects option provide shared access to memory
 11453 objects in the process address space. The functions defined under this option provide the
 11454 functionality of existing practice for mapping regular files. This functionality was deemed
 11455 unnecessary, if not inappropriate, for embedded systems applications and, hence, is
 11456 provided under this option. It should only be required if needed, but it should never be
 11457 prohibited.

11458 `_POSIX_MEMLOCK`

11459 The system supports the locking of the address space.

11460 This option was created to support historical systems that did not provide the feature. It
 11461 should only be required if needed, but it should never be prohibited.

11462 `_POSIX_MEMLOCK_RANGE`

11463 The system supports the locking of specific ranges of the address space.

11464 For applications that have well-defined sections that need to be locked and others that do
 11465 not, IEEE Std 1003.1-2001 supports an optional set of functions to lock or unlock a range of
 11466 process addresses. The following are two reasons for having a means to lock down a
 11467 specific range:

- 11468 1. An asynchronous event handler function that must respond to external events in a
 11469 deterministic manner such that page faults cannot be tolerated
- 11470 2. An input/output “buffer” area that is the target for direct-to-process I/O, and the
 11471 overhead of implicit locking and unlocking for each I/O call cannot be tolerated

- 11472 It should only be required if needed, but it should never be prohibited.
- 11473 _posix_memory_protection
- 11474 The system supports memory protection.
- 11475 XSI-conformant systems support this option.
- 11476 The provision of this option typically imposes additional hardware requirements. It should
- 11477 never be prohibited.
- 11478 _posix_prioritized_io
- 11479 The system provides prioritization for input and output operations.
- 11480 The use of this option may interfere with the ability of the system to optimize input and
- 11481 output throughput. It should only be required if needed, but it should never be prohibited.
- 11482 _posix_message_passing
- 11483 The system supports the passing of messages between processes.
- 11484 This option was created to support historical systems that did not provide the feature. The
- 11485 functionality adds a high-performance XSI interprocess communication facility for local
- 11486 communication. It should only be required if needed, but it should never be prohibited.
- 11487 _posix_monotonic_clock
- 11488 The system supports the Monotonic Clock option.
- 11489 This option allows realtime applications to rely on a monotonically increasing clock that
- 11490 does not jump backwards, and whose value does not change except for the regular ticking
- 11491 of the clock.
- 11492 _posix_priority_scheduling
- 11493 The system provides priority-based process scheduling.
- 11494 Support of this option provides predictable scheduling behavior, allowing applications to
- 11495 determine the order in which processes that are ready to run are granted access to a
- 11496 processor. It should only be required if needed, but it should never be prohibited.
- 11497 _posix_realtime_signals
- 11498 The system provides prioritized, queued signals with associated data values.
- 11499 This option was created to support historical systems that did not provide the features. It
- 11500 should only be required if needed, but it should never be prohibited.
- 11501 _posix_regexp
- 11502 Support for regular expression facilities is mandatory in IEEE Std 1003.1-2001.
- 11503 _posix_saved_ids
- 11504 Support for this feature is mandatory in IEEE Std 1003.1-2001.
- 11505 Certain classes of applications rely on it for proper operation, and there is no alternative
- 11506 short of giving the application root privileges on most implementations that did not provide
- 11507 _posix_saved_ids.
- 11508 _posix_semaphores
- 11509 The system provides counting semaphores.
- 11510 This option was created to support historical systems that did not provide the feature. It
- 11511 should only be required if needed, but it should never be prohibited.
- 11512 _posix_shared_memory_objects
- 11513 The system supports the mapping of shared memory objects into the process address space.

- 11514 Both this option and the Memory Mapped Files option provide shared access to memory
 11515 objects in the process address space. The functions defined under this option provide the
 11516 functionality of existing practice for shared memory objects. This functionality was deemed
 11517 appropriate for embedded systems applications and, hence, is provided under this option. It
 11518 should only be required if needed, but it should never be prohibited.
- 11519 `_POSIX_SHELL`
 11520 Support for the *sh* utility command line interpreter is mandatory in IEEE Std 1003.1-2001.
- 11521 `_POSIX_SPAWN`
 11522 The system supports the spawn option.
- 11523 This option provides applications with an efficient mechanism to spawn execution of a new
 11524 process.
- 11525 `_POSIX_SPINLOCKS`
 11526 The system supports spin locks.
- 11527 This option was created to support a simple and efficient synchronization mechanism for
 11528 threads executing in multi-processor systems.
- 11529 `_POSIX_SPORADIC_SERVER`
 11530 The system supports the sporadic server scheduling policy.
- 11531 This option provides applications with a new scheduling policy for scheduling aperiodic
 11532 processes or threads in hard realtime applications.
- 11533 `_POSIX_SYNCHRONIZED_IO`
 11534 The system supports guaranteed file synchronization.
- 11535 This option was created to support historical systems that did not provide the feature.
 11536 Applications that are expecting guaranteed completion of their input and output operations
 11537 should require this option, rather than the File Synchronization option. It should only be
 11538 required if needed, but it should never be prohibited.
- 11539 `_POSIX_THREADS`
 11540 The system supports multiple threads of control within a single process.
- 11541 This option was created to support historical systems that did not provide the feature.
 11542 Applications written assuming a multi-threaded environment would be expected to require
 11543 this option. It should only be required if needed, but it should never be prohibited.
- 11544 XSI-conformant systems support this option.
- 11545 `_POSIX_THREAD_ATTR_STACKADDR`
 11546 The system supports specification of the stack address for a created thread.
- 11547 Applications may take advantage of support of this option for performance benefits, but
 11548 dependence on this feature should be minimized. This option should never be prohibited.
- 11549 XSI-conformant systems support this option.
- 11550 `_POSIX_THREAD_ATTR_STACKSIZE`
 11551 The system supports specification of the stack size for a created thread.
- 11552 Applications may require this option in order to ensure proper execution, but such usage
 11553 limits portability and dependence on this feature should be minimized. It should only be
 11554 required if needed, but it should never be prohibited.
- 11555 XSI-conformant systems support this option.

11556 `_POSIX_THREAD_PRIORITY_SCHEDULING`
11557 The system provides priority-based thread scheduling.

11558 Support of this option provides predictable scheduling behavior, allowing applications to
11559 determine the order in which threads that are ready to run are granted access to a processor.
11560 It should only be required if needed, but it should never be prohibited.

11561 `_POSIX_THREAD_PRIO_INHERIT`
11562 The system provides mutual-exclusion operations with priority inheritance.

11563 Support of this option provides predictable scheduling behavior, allowing applications to
11564 determine the order in which threads that are ready to run are granted access to a processor.
11565 It should only be required if needed, but it should never be prohibited.

11566 `_POSIX_THREAD_PRIO_PROTECT`
11567 The system supports a priority ceiling emulation protocol for mutual-exclusion operations.

11568 Support of this option provides predictable scheduling behavior, allowing applications to
11569 determine the order in which threads that are ready to run are granted access to a processor.
11570 It should only be required if needed, but it should never be prohibited.

11571 `_POSIX_THREAD_PROCESS_SHARED`
11572 The system provides shared access among multiple processes to synchronization objects.

11573 This option was created to support historical systems that did not provide the feature. It
11574 should only be required if needed, but it should never be prohibited.

11575 XSI-conformant systems support this option.

11576 `_POSIX_THREAD_SAFE_FUNCTIONS`
11577 The system provides thread-safe versions of all of the POSIX.1 functions.

11578 This option is required if the Threads option is supported. This is a separate option because
11579 thread-safe functions are useful in implementations providing other mechanisms for
11580 concurrency. It should only be required if needed, but it should never be prohibited.

11581 XSI-conformant systems support this option.

11582 `_POSIX_THREAD_SPORADIC_SERVER`
11583 The system supports the thread sporadic server scheduling policy.

11584 Support for this option provides applications with a new scheduling policy for scheduling
11585 aperiodic threads in hard realtime applications.

11586 `_POSIX_TIMEOUTS`
11587 The system provides timeouts for some blocking services.

11588 This option was created to provide a timeout capability to system services, thus allowing
11589 applications to include better error detection, and recovery capabilities.

11590 `_POSIX_TIMERS`
11591 The system provides higher resolution clocks with multiple timers per process.

11592 This option was created to support historical systems that did not provide the features. This
11593 option is appropriate for applications requiring higher resolution timestamps or needing to
11594 control the timing of multiple activities. It should only be required if needed, but it should
11595 never be prohibited.

11596 `_POSIX_TRACE`
11597 The system supports the Trace option.

11598 This option was created to allow applications to perform tracing.

11599 _posix_trace_event_filter

11600 The system supports the Trace Event Filter option.

11601 This option is dependent on support of the Trace option.

11602 _posix_trace_inherit

11603 The system supports the Trace Inherit option.

11604 This option is dependent on support of the Trace option.

11605 _posix_trace_log

11606 The system supports the Trace Log option.

11607 This option is dependent on support of the Trace option.

11608 _posix_typed_memory_objects

11609 The system supports the Typed Memory Objects option.

11610 This option was created to allow realtime applications to access different kinds of physical

11611 memory, and allow processes in these applications to share portions of this memory.

11612 **D.3.5 Configurable Limits**

11613 In general, the configurable limits in the **<limits.h>** header defined in the Base Definitions

11614 volume of IEEE Std 1003.1-2001 have been set to minimal values; many applications or

11615 implementations may require larger values. No profile can cite lower values.

11616 {AIO_LISTIO_MAX}

11617 The current minimum is likely to be inadequate for most applications. It is expected that

11618 this value will be increased by profiles requiring support for list input and output

11619 operations.

11620 {AIO_MAX}

11621 The current minimum is likely to be inadequate for most applications. It is expected that

11622 this value will be increased by profiles requiring support for asynchronous input and

11623 output operations.

11624 {AIO_PRIO_DELTA_MAX}

11625 The functionality associated with this limit is needed only by sophisticated applications. It

11626 is not expected that this limit would need to be increased under a general-purpose profile.

11627 {ARG_MAX}

11628 The current minimum is likely to need to be increased for profiles, particularly as larger

11629 amounts of information are passed through the environment. Many implementations are

11630 believed to support larger values.

11631 {CHILD_MAX}

11632 The current minimum is suitable only for systems where a single user is not running

11633 applications in parallel. It is significantly too low for any system also requiring windows,

11634 and if _POSIX_JOB_CONTROL is specified, it should be raised.

11635 {CLOCKRES_MIN}

11636 It is expected that profiles will require a finer granularity clock, perhaps as fine as 1 μ s,

11637 represented by a value of 1 000 for this limit.

11638 {DELAYTIMER_MAX}

11639 It is believed that most implementations will provide larger values.

11640	{LINK_MAX}
11641	For most applications and usage, the current minimum is adequate. Many implementations
11642	have a much larger value, but this should not be used as a basis for raising the value unless
11643	the applications to be used require it.
11644	{LOGIN_NAME_MAX}
11645	This is not actually a limit, but an implementation parameter. No profile should impose a
11646	requirement on this value.
11647	{MAX_CANON}
11648	For most purposes, the current minimum is adequate. Unless high-speed burst serial
11649	devices are used, it should be left as is.
11650	{MAX_INPUT}
11651	See {MAX_CANON}.
11652	{MQ_OPEN_MAX}
11653	The current minimum should be adequate for most profiles.
11654	{MQ_PRIO_MAX}
11655	The current minimum corresponds to the required number of process scheduling priorities.
11656	Many realtime practitioners believe that the number of message priority levels ought to be
11657	the same as the number of execution scheduling priorities.
11658	{NAME_MAX}
11659	Many implementations now support larger values, and many applications and users
11660	assume that larger names can be used. Many existing profiles also specify a larger value.
11661	Specifying this value will reduce the number of conforming implementations, although this
11662	might not be a significant consideration over time. Values greater than 255 should not be
11663	required.
11664	{NGROUPS_MAX}
11665	The value selected will typically be 8 or larger.
11666	{OPEN_MAX}
11667	The historically common value for this has been 20. Many implementations support larger
11668	values. If applications that use larger values are anticipated, an appropriate value should be
11669	specified.
11670	{PAGESIZE}
11671	This is not actually a limit, but an implementation parameter. No profile should impose a
11672	requirement on this value.
11673	{PATH_MAX}
11674	Historically, the minimum has been either 1024 or indefinite, depending on the
11675	implementation. Few applications actually require values larger than 256, but some users
11676	may create file hierarchies that must be accessed with longer paths. This value should only
11677	be changed if there is a clear requirement.
11678	{PIPE_BUF}
11679	The current minimum is adequate for most applications. Historically, it has been larger. If
11680	applications that write single transactions larger than this are anticipated, it should be
11681	increased. Applications that write lines of text larger than this probably do not need it
11682	increased, as the text line is delimited by a <newline>.
11683	{POSIX_VERSION}
11684	This is actually not a limit, but a standard version stamp. Generally, a profile should specify
11685	IEEE Std 1003.1-2001 by a name in the normative references section, not this value.

11686	{PTHREAD_DESTRUCTOR_ITERATIONS}
11687	It is unlikely that applications will need larger values to avoid loss of memory resources.
11688	{PTHREAD_KEYS_MAX}
11689	The current value should be adequate for most profiles.
11690	{PTHREAD_STACK_MIN}
11691	This should not be treated as an actual limit, but as an implementation parameter. No
11692	profile should impose a requirement on this value.
11693	{PTHREAD_THREADS_MAX}
11694	It is believed that most implementations will provide larger values.
11695	{RTSIG_MAX}
11696	The current limit was chosen so that the set of POSIX.1 signal numbers can fit within a 32-
11697	bit field. It is recognized that most existing implementations define many more signals than
11698	are specified in POSIX.1 and, in fact, many implementations have already exceeded 32
11699	signals (including the “null signal”). Support of {_POSIX_RTSIG_MAX} additional signals
11700	may push some implementations over the single 32-bit word line, but is unlikely to push
11701	any implementations that are already over that line beyond the 64 signal line.
11702	{SEM_NSEMS_MAX}
11703	The current value should be adequate for most profiles.
11704	{SEM_VALUE_MAX}
11705	The current value should be adequate for most profiles.
11706	{SSIZE_MAX}
11707	This limit reflects fundamental hardware characteristics (the size of an integer), and should
11708	not be specified unless it is clearly required. Extreme care should be taken to assure that
11709	any value that might be specified does not unnecessarily eliminate implementations
11710	because of accidents of hardware design.
11711	{STREAM_MAX}
11712	This limit is very closely related to {OPEN_MAX}. It should never be larger than
11713	{OPEN_MAX}, but could reasonably be smaller for application areas where most files are
11714	not accessed through <i>stdio</i> . Some implementations may limit {STREAM_MAX} to 20 but
11715	allow {OPEN_MAX} to be considerably larger. Such implementations should be allowed for
11716	if the applications permit.
11717	{TIMER_MAX}
11718	The current limit should be adequate for most profiles, but it may need to be larger for
11719	applications with a large number of asynchronous operations.
11720	{TTY_NAME_MAX}
11721	This is not actually a limit, but an implementation parameter. No profile should impose a
11722	requirement on this value.
11723	{TZNAME_MAX}
11724	The minimum has been historically adequate, but if longer timezone names are anticipated
11725	(particularly such values as UTC−1), this should be increased.

11726 D.3.6 Optional Behavior

11727 In IEEE Std 1003.1-2001, there are no instances of the terms unspecified, undefined,
11728 implementation-defined, or with the verbs “may” or “need not”, that the developers of
11729 IEEE Std 1003.1-2001 anticipate or sanction as suitable for profile or test method citation. All of
11730 these are merely warnings to conforming applications to avoid certain areas that can vary from
11731 system to system, and even over time on the same system. In many cases, these terms are used
11732 explicitly to support extensions, but profiles should not anticipate and require such extensions;
11733 future versions of IEEE Std 1003.1 may do so.

11734 / *Rationale (Informative)*

11735 **Part E:**

11736 **Subprofiling Considerations**

11737 *The Open Group*

11738 *The Institute of Electrical and Electronics Engineers, Inc.*

Subprofiling Considerations (Informative)

This section contains further information to satisfy the requirement that the project scope enable subprofiling of IEEE Std 1003.1-2001. The original intent was to have included a set of options similar to the “Units of Functionality” contained in IEEE Std 1003.13-1998. However, as the development of IEEE Std 1003.1-2001 continued, the standard developers felt it premature to fix these in normative text. The approach instead has been to include a general requirement in normative text regarding subprofiling and to include an informative section (here) containing a proposed set of subprofiling options.

E.1 Subprofiling Option Groups

The following Option Groups⁴ are defined to support profiling. Systems claiming support to IEEE Std 1003.1-2001 need not implement these options apart from the requirements stated in the Base Definitions volume of IEEE Std 1003.1-2001, Section 2.1.3, POSIX Conformance. These Option Groups allow profiles to subset the System Interfaces volume of IEEE Std 1003.1-2001 by collecting sets of related functions.
