Abstract

This standard defines a standard operating system interface and environment, including a command interpreter (or “shell”), and common utility programs to support applications portability at the source code level. This standard is intended to be used by both applications developers and system implementors and comprises four major components (each in an associated volume):

• General terms, concepts, and interfaces common to all volumes of this standard, including utility conventions and C-language header definitions, are included in the Base Definitions volume.
• Definitions for system service functions and subroutines, language-specific system services for the C programming language, function issues, including portability, error handling, and error recovery, are included in the System Interfaces volume.
• Definitions for a standard source code-level interface to command interpretation services (a “shell”) and common utility programs for application programs are included in the Shell and Utilities volume.
• Extended rationale that did not fit well into the rest of the document structure, which contains historical information concerning the contents of this standard and why features were included or discarded by the standard developers, is included in the Rationale (Informative) volume.

The following areas are outside the scope of this standard:

• Graphics interfaces
• Database management system interfaces
• Record I/O considerations
• Object or binary code portability
• System configuration and resource availability

This standard describes the external characteristics and facilities that are of importance to applications developers, rather than the internal construction techniques employed to achieve these capabilities. Special emphasis is placed on those functions and facilities that are needed in a wide variety of commercial applications.

Keywords

application program interface (API), argument, asynchronous, basic regular expression (BRE), batch job, batch system, built-in utility, byte, child, command language interpreter, CPU, extended regular expression (ERE), FIFO, file access control mechanism, input/output (I/O), job control, network, portable operating system interface (POSIX®), parent, shell, stream, string, synchronous, system, thread, X/Open System Interface (XSI)
IEEE Standards documents are developed within the IEEE Societies and the Standards Coordinating Committees of the IEEE Standards Association (IEEE-SA) Standards Board. The IEEE develops its standards through a consensus development process, approved by the American National Standards Institute, which brings together volunteers representing varied viewpoints and interests to achieve the final product. Volunteers are not necessarily members of the Institute and serve without compensation. While the IEEE administers the process and establishes rules to promote fairness in the consensus development process, the IEEE does not independently evaluate, test, or verify the accuracy of any of the information contained in its standards.

Use of an IEEE Standard is wholly voluntary. The IEEE disclaims liability for any personal injury, property, or other damage, of any nature whatsoever, whether special, indirect, consequential, or compensatory, directly or indirectly resulting from the publication, use of, or reliance upon this, or any other IEEE Standard document.

The IEEE does not warrant or represent the accuracy or content of the material contained herein, and expressly disclaims any express or implied warranty, including any implied warranty of merchantability or fitness for a specific purpose, or that the use of the material contained herein is free from patent infringement. IEEE Standards documents are supplied "AS IS".

The existence of an IEEE Standard does not imply that there are no other ways to produce, test, measure, purchase, market, or provide other goods and services related to the scope of the IEEE Standard. Furthermore, the viewpoint expressed at the time a standard is approved and issued is subject to change brought about through developments in the state of the art and comments received from users of the standard. Every IEEE Standard is subjected to review at least every five years for revision or reaffirmation. When a document is more than five years old and has not been reaffirmed, it is reasonable to conclude that its contents, although still of some value, do not wholly reflect the present state of the art. Users are cautioned to check to determine that they have the latest edition of any IEEE Standard.

In publishing and making this document available, the IEEE is not suggesting or rendering professional or other services for, or on behalf of, any person or entity. Nor is the IEEE undertaking to perform any duty owed by any other person or entity to another. Any person utilizing this, and any other IEEE Standards document, should rely upon the advice of a competent professional in determining the exercise of reasonable care in any given circumstances.

Interpretations: Occasionally questions may arise regarding the meaning of portions of standards as they relate to specific applications. When the need for interpretations is brought to the attention of the IEEE, the Institute will initiate action to prepare appropriate responses. Since IEEE Standards represent a consensus of concerned interests, it is important to ensure that any interpretation has also received the concurrence of a balance of interests. For this reason, IEEE and the members of its societies and Standards Coordinating Committees are not able to provide an instant response to interpretation requests except in those cases where the matter has previously received formal consideration.

Comments for revision of IEEE Standards are welcome from any interested party, regardless of membership affiliation with the IEEE. Suggestions for changes in documents should be in the form of a proposed change of text, together with appropriate supporting comments. Comments on standards and requests for interpretations should be addressed to:

Secretary, IEEE-SA Standards Board, 445 Hoes Lane, P.O. Box 1331, Piscataway, NJ 08855-1331, U.S.A.

---

Attention is called to the possibility that implementation of this standard may require use of subject matter covered by patent rights. By publication of this standard, no position is taken with respect to the existence or validity of any patent rights in connection therewith. The IEEE shall not be responsible for identifying patents for which a license may be required by an IEEE Standard or for conducting inquiries into the legal validity or scope of those patents that are brought to its attention.

A patent holder has filed a statement of assurance that it will grant licenses under these rights without compensation or under reasonable rates and non-discriminatory, reasonable terms and conditions to all applicants desiring to obtain such licenses. The IEEE makes no representation as to the reasonableness of rates and/or terms and conditions of the license agreements offered by patent holders. Further information may be obtained from the IEEE Standards Department.

Authorization to photocopy portions of any individual standard for internal or personal use is granted in the U.S. by the Institute of Electrical and Electronics Engineers, Inc., provided that the appropriate fee is paid to the Copyright Clearance Center. Permission to photocopy portions of any individual standard for educational classroom use can also be obtained through the Copyright Clearance Center. To arrange for payment of the licensing fee, please contact:

Copyright Clearance Center, Customer Service, 222 Rosewood Drive, Danvers, MA 01923, U.S.A., Tel.: +1 978 750 8400

Amendments, corrigenda, and interpretations for this standard, or information about the IEEE standards development process, may be found at http://standards.ieee.org.

Full catalog and ordering information on all IEEE publications is available from the IEEE Online Catalog & Store at http://shop.ieee.org/store.

---

1. For this standard, please send comments via the Austin Group as requested on page iii.
2. Please refer to the special provisions for this standard on page iii concerning permissions from both copyright holders and arrangements to cover photocopying and reproduction across the world, as well as by commercial organizations wishing to license the material for use in product documentation.
The Open Group

The Open Group, a vendor and technology-neutral consortium, is committed to delivering greater business efficiency by bringing together buyers and suppliers of information technology to lower the time, cost, and risks associated with integrating new technology across the enterprise.

The Open Group’s mission is to offer all organizations concerned with open information infrastructures a forum to share knowledge, integrate open initiatives, and certify approved products and processes in a manner in which they continue to trust our impartiality.

In the global eCommerce world of today, no single economic entity can achieve independence while still ensuring interoperability. The assurance that products will interoperate with each other across differing systems and platforms is essential to the success of eCommerce and business workflow. The Open Group, with its proven testing and certification program, is the international guarantor of interoperability in the new century.

The Open Group provides opportunities to exchange information and shape the future of IT. The Open Group’s members include some of the largest and most influential organizations in the world. The flexible structure of The Open Groups membership allows for almost any organization, no matter what their size, to join and have a voice in shaping the future of the IT world.

More information is available on The Open Group web site at http://www.opengroup.org.

The Open Group has over 15 years’ experience in developing and operating certification programs and has extensive experience developing and facilitating industry adoption of test suites used to validate conformance to an open standard or specification. The Open Group portfolio of test suites includes the Westwood family of tests for this standard and the associated certification program for Version 3 of the Single UNIX Specification, as well tests for CDE, CORBA, Motif, Linux, LDAP, POSIX.1, POSIX.2, POSIX Realtime, Sockets, UNIX, XPG4, XNFS, XTI, and X11. The Open Group test tools are essential for proper development and maintenance of standards-based products, ensuring conformance of products to industry-standard APIs, applications portability, and interoperability. In-depth testing identifies defects at the earliest possible point in the development cycle, saving costs in development and quality assurance.

More information is available at http://www.opengroup.org/testing.

The Open Group publishes a wide range of technical documentation, the main part of which is focused on development of Technical and Product Standards and Guides, but which also includes white papers, technical studies, branding and testing documentation, and business titles. Full details and a catalog are available at http://www.opengroup.org/pubs.

As with all live documents, Technical Standards and Specifications require revision to align with new developments and associated international standards. To distinguish between revised specifications which are fully backwards compatible and those which are not:

- A new Version indicates there is no change to the definitive information contained in the previous publication of that title, but additions/extensions are included. As such, it replaces the previous publication.

- A new Issue indicates there is substantive change to the definitive information contained in the previous publication of that title, and there may also be additions/extensions. As such, both previous and new documents are maintained as current publications.

Readers should note that Corrigenda may apply to any publication. Corrigenda information is published at http://www.opengroup.org/corrigenda.

Full catalog and ordering information on all Open Group publications is available at http://www.opengroup.org/pubs.

Structure of the Standard

This standard was originally developed by the Austin Group, a joint working group of members of the IEEE, members of The Open Group, and members of ISO/IEC Joint Technical Committee 1, as one of the four volumes of IEEE Std 1003.1-2001. The standard was approved by ISO and IEC and published in four parts, correlating to the original volumes.

A mapping of the parts to the volumes is shown below:

<table>
<thead>
<tr>
<th>ISO/IEC 9945 Part</th>
<th>IEEE Std 1003.1 Volume</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>9945-1</td>
<td>Base Definitions</td>
<td>Includes general terms, concepts, and interfaces common to all parts of ISO/IEC 9945, including utility conventions and C-language header definitions.</td>
</tr>
<tr>
<td>9945-2</td>
<td>System Interfaces</td>
<td>Includes definitions for system service functions and subroutines, language-specific system services for the C programming language, function issues, including portability, error handling, and error recovery.</td>
</tr>
<tr>
<td>9945-3</td>
<td>Shell and Utilities</td>
<td>Includes definitions for a standard source code-level interface to command interpretation services (a “shell”) and common utility programs for application programs.</td>
</tr>
<tr>
<td>9945-4</td>
<td>Rationale</td>
<td>Includes extended rationale that did not fit well into the rest of the document structure, containing historical information concerning the contents of ISO/IEC 9945 and why features were included or discarded by the standard developers.</td>
</tr>
</tbody>
</table>

All four parts comprise the entire standard, and are intended to be used together to accommodate significant internal referencing among them. POSIX-conforming systems are required to support all four parts.
Introduction

Note: This introduction is not part of IEEE Std 1003.1-2001, Standard for Information Technology — Portable Operating System Interface (POSIX).

This standard has been jointly developed by the IEEE and The Open Group. It is simultaneously an IEEE Standard, an ISO/IEC Standard, and an Open Group Technical Standard.

The Austin Group

This standard was developed, and is maintained, by a joint working group of members of the IEEE Portable Applications Standards Committee, members of The Open Group, and members of ISO/IEC Joint Technical Committee 1. This joint working group is known as the Austin Group.\(^3\) The Austin Group arose out of discussions amongst the parties which started in early 1998, leading to an initial meeting and formation of the group in September 1998. The purpose of the Austin Group has been to revise, combine, and update the following standards: ISO/IEC 9945-1, ISO/IEC 9945-2, IEEE Std 1003.1, IEEE Std 1003.2, and the Base Specifications of The Open Group Single UNIX Specification.

After two initial meetings, an agreement was signed in July 1999 between The Open Group and the Institute of Electrical and Electronics Engineers (IEEE), Inc., to formalize the project with the first draft of the revised specifications being made available at the same time. Under this agreement, The Open Group and IEEE agreed to share joint copyright of the resulting work. The Open Group has provided the chair and secretariat for the Austin Group.

The base document for the revision was The Open Group’s Base volumes of its Single UNIX Specification, Version 2. These were selected since they were a superset of the existing POSIX.1 and POSIX.2 specifications and had some organizational aspects that would benefit the audience for the new revision.

The approach to specification development has been one of “write once, adopt everywhere”, with the deliverables being a set of specifications that carry the IEEE POSIX designation, The Open Group's Technical Standard designation, and an ISO/IEC designation. This set of specifications forms the core of the Single UNIX Specification, Version 3.

This unique development has combined both the industry-led efforts and the formal standardization activities into a single initiative, and included a wide spectrum of participants. The Austin Group continues as the maintenance body for this document.

Anyone wishing to participate in the Austin Group should contact the chair with their request. There are no fees for participation or membership. You may participate as an observer or as a contributor. You do not have to attend face-to-face meetings to participate; electronic participation is most welcome. For more information on the Austin Group and how to participate, see http://www.opengroup.org/austin.

---

\(^3\) The Austin Group is named after the location of the inaugural meeting held at the IBM facility in Austin, Texas in September 1998.
Background
The developers of this standard represent a cross section of hardware manufacturers, vendors of operating systems and other software development tools, software designers, consultants, academics, authors, applications programmers, and others.

Conceptually, this standard describes a set of fundamental services needed for the efficient construction of application programs. Access to these services has been provided by defining an interface, using the C programming language, a command interpreter, and common utility programs that establish standard semantics and syntax. Since this interface enables application writers to write portable applications—it was developed with that goal in mind—it has been designated POSIX,\(^4\) an acronym for Portable Operating System Interface.

Although originated to refer to the original IEEE Std 1003.1-1988, the name POSIX more correctly refers to a family of related standards: IEEE Std 1003.n and the parts of ISO/IEC 9945. In earlier editions of the IEEE standard, the term POSIX was used as a synonym for IEEE Std 1003.1-1988. A preferred term, POSIX.1, emerged. This maintained the advantages of readability of the symbol “POSIX” without being ambiguous with the POSIX family of standards.

Audience
The intended audience for this standard is all persons concerned with an industry-wide standard operating system based on the UNIX system. This includes at least four groups of people:

1. Persons buying hardware and software systems
2. Persons managing companies that are deciding on future corporate computing directions
3. Persons implementing operating systems, and especially
4. Persons developing applications where portability is an objective

Purpose
Several principles guided the development of this standard:

- Application-Oriented
  The basic goal was to promote portability of application programs across UNIX system environments by developing a clear, consistent, and unambiguous standard for the interface specification of a portable operating system based on the UNIX system documentation. This standard codifies the common, existing definition of the UNIX system.

- Interface, Not Implementation
  This standard defines an interface, not an implementation. No distinction is made between library functions and system calls; both are referred to as functions. No details of the implementation of any function are given (although historical practice is sometimes indicated in the RATIONALE section). Symbolic names are given for constants (such as signals and error numbers) rather than numbers.

---

\(^4\) The name POSIX was suggested by Richard Stallman. It is expected to be pronounced pahz-icks, as in positive, not poh-six, or other variations. The pronunciation has been published in an attempt to promulgate a standardized way of referring to a standard operating system interface.
• Source, Not Object, Portability

This standard has been written so that a program written and translated for execution on one conforming implementation may also be translated for execution on another conforming implementation. This standard does not guarantee that executable (object or binary) code will execute under a different conforming implementation than that for which it was translated, even if the underlying hardware is identical.

• The C Language

The system interfaces and header definitions are written in terms of the standard C language as specified in the ISO C standard.

• No Superuser, No System Administration

There was no intention to specify all aspects of an operating system. System administration facilities and functions are excluded from this standard, and functions usable only by the superuser have not been included. Still, an implementation of the standard interface may also implement features not in this standard. This standard is also not concerned with hardware constraints or system maintenance.

• Minimal Interface, Minimally Defined

In keeping with the historical design principles of the UNIX system, the mandatory core facilities of this standard have been kept as minimal as possible. Additional capabilities have been added as optional extensions.

• Broadly Implementable

The developers of this standard endeavored to make all specified functions implementable across a wide range of existing and potential systems, including:

1. All of the current major systems that are ultimately derived from the original UNIX system code (Version 7 or later)
2. Compatible systems that are not derived from the original UNIX system code
3. Emulations hosted on entirely different operating systems
4. Networked systems
5. Distributed systems
6. Systems running on a broad range of hardware

No direct references to this goal appear in this standard, but some results of it are mentioned in the Rationale (Informative) volume.

• Minimal Changes to Historical Implementations

When the original version of IEEE Std 1003.1 was published, there were no known historical implementations that did not have to change. However, there was a broad consensus on a set of functions, types, definitions, and concepts that formed an interface that was common to most historical implementations.

The adoption of the 1988 and 1990 IEEE system interface standards, the 1992 IEEE shell and utilities standard, the various Open Group (formerly X/Open) specifications, and the subsequent revisions and addenda to all of them have consolidated this consensus, and this revision reflects the significantly increased level of consensus arrived at since the original versions. The earlier standards and their modifications specified a number of areas where consensus had not been reached before, and these are now reflected in this revision. The authors of the original versions tried, as much as possible, to follow the principles below
when creating new specifications:

1. By standardizing an interface like one in an historical implementation; for example, directories

2. By specifying an interface that is readily implementable in terms of, and backwards-compatible with, historical implementations, such as the extended tar format defined in the pax utility

3. By specifying an interface that, when added to an historical implementation, will not conflict with it; for example, the sigaction() function

This revision tries to minimize the number of changes required to implementations which conform to the earlier versions of the approved standards to bring them into conformance with the current standard. Specifically, the scope of this work excluded doing any "new" work, but rather collecting into a single document what had been spread across a number of documents, and presenting it in what had been proven in practice to be a more effective way. Some changes to prior conforming implementations were unavoidable, primarily as a consequence of resolving conflicts found in prior revisions, or which became apparent when bringing the various pieces together.

However, since it references the 1999 version of the ISO C standard, and no longer supports "Common Usage C", there are a number of unavoidable changes. Applications portability is similarly affected.

This standard is specifically not a codification of a particular vendor's product.

It should be noted that implementations will have different kinds of extensions. Some will reflect "historical usage" and will be preserved for execution of pre-existing applications. These functions should be considered "obsolescent" and the standard functions used for new applications. Some extensions will represent functions beyond the scope of this standard. These need to be used with careful management to be able to adapt to future extensions of this standard and/or port to implementations that provide these services in a different manner.

• Minimal Changes to Existing Application Code

A goal of this standard was to minimize additional work for the developers of applications. However, because every known historical implementation will have to change at least slightly to conform, some applications will have to change.

This Standard

This standard defines the Portable Operating System Interface (POSIX) requirements and consists of the following volumes:

• Base Definitions (this volume)

• Shell and Utilities

• System Interfaces

• Rationale (Informative)
This Volume

The Base Definitions volume provides common definitions for this standard, therefore readers should be familiar with it before using the other volumes.

This volume is structured as follows:

- Chapter 1 is an introduction.
- Chapter 2 defines the conformance requirements.
- Chapter 3 defines general terms used.
- Chapter 4 describes general concepts used.
- Chapter 5 describes the notation used to specify file input and output formats in this volume and the Shell and Utilities volume.
- Chapter 6 describes the portable character set and the process of character set definition.
- Chapter 7 describes the syntax for defining internationalization locales as well as the POSIX locale provided on all systems.
- Chapter 8 describes the use of environment variables for internationalization and other purposes.
- Chapter 9 describes the syntax of pattern matching using regular expressions employed by many utilities and matched by the `regcomp()` and `regexec()` functions.
- Chapter 10 describes files and devices found on all systems.
- Chapter 11 describes the asynchronous terminal interface for many of the functions in the System Interfaces volume and the `stty` utility in the Shell and Utilities volume.
- Chapter 12 describes the policies for command line argument construction and parsing.
- Chapter 13 defines the contents of headers which declare constants, macros, and data structures that are needed by programs using the services provided by the System Interfaces volume.

Comprehensive references are available in the index.

Typographical Conventions

The following typographical conventions are used throughout this standard. In the text, this standard is referred to as IEEE Std 1003.1-2001, which is technically identical to The Open Group Base Specifications, Issue 6.

The typographical conventions listed here are for ease of reading only. Editorial inconsistencies in the use of typography are unintentional and have no normative meaning in this standard.

## Notes:

1. Conversion specifications, specifier characters, and modifier characters are used primarily in date-related functions and utilities and the `fprintf` and `fscanf` formatting functions.

2. Unless otherwise noted, the quotes shall not be used as input or output. When used in a list item, the quotes are omitted. For literal characters, `\` (or any of the other sequences such as `''`) is the same as the C constant `\` (or `''`).

3. The style selected for some of the special characters, such as `<newline>`, matches the form of the input given to the `localedef` utility. Generally, the characters selected for this special treatment are those that are not visually distinct, such as the control characters `<tab>` or `<newline>`.

4. Names surrounded by braces represent symbolic limits or configuration values which may be declared in appropriate headers by means of the C `#define` construct.

5. Brackets shown in this font, "[ ]", are part of the syntax and do not indicate optional items. In syntax the `|` symbol is used to separate alternatives, and ellipses ("...") are used to show that additional arguments are optional.

Shading is used to identify extensions and options; see Section 1.5.1 (on page 6).

Footnotes and notes within the body of the normative text are for information only (informative).

Informative sections (such as Rationale, Change History, Application Usage, and so on) are denoted by continuous shading bars in the margins.
Ranges of values are indicated with parentheses or brackets as follows:

- \((a,b)\) means the range of all values from \(a\) to \(b\), including neither \(a\) nor \(b\).
- \([a,b]\) means the range of all values from \(a\) to \(b\), including \(a\) and \(b\).
- \([a,b)\) means the range of all values from \(a\) to \(b\), including \(a\), but not \(b\).
- \((a,b]\) means the range of all values from \(a\) to \(b\), including \(b\), but not \(a\).

Note: A symbolic limit beginning with POSIX is treated differently, depending on context. In a C-language header, the symbol \(\text{POSIX}\text{string}\) (where \text{string} may contain underscores) is represented by the C identifier \_POSIX\text{string}, with a leading underscore required to prevent ISO C standard name space pollution. However, in other contexts, such as languages other than C, the leading underscore is not used because this requirement does not exist.
Participants

IEEE Std 1003.1-2001 was prepared by the Austin Group, sponsored by the Portable Applications Standards Committee of the IEEE Computer Society, The Open Group, and ISO/SC22 WG15.

The Austin Group

At the time of approval, the membership of the Austin Group was as follows:

Andrew Josey, Chair
Donald W. Cragun, Organizational Representative, IEEE PASC
Nicholas Stoughton, Organizational Representative, ISO/SC22 WG15
Mark Brown, Organizational Representative, The Open Group
Cathy Hughes, Technical Editor

Participants

IEEE-SA Standards Board

When the IEEE-SA Standards Board approved IEEE Std 1003.1-2001 on 6 December 2001, it had the following membership:

Donald N. Heirman, Chair
James T. Carlo, Vice-Chair
Judith Gorman, Secretary

Satish K. Aggarwal  James H. Gurney  James W. Moore
Mark D. Bowman  Richard J. Holleman  Robert F. Munzner
Gary R. Engmann  Lowell G. Johnson  Ronald C. Petersen
Harold E. Epstein  Robert J. Kennelly  Gerald H. Peterson
H. Landis Floyd  Joseph L. Koepfinger*  John B. Posey
Jay Forster*  Peter H. Lips  Gary S. Robinson
Howard M. Frazier  L. Bruce McClung  Akio Tojo
Ruben D. Garzon  Daleep C. Mohla  Donald W. Zipse

Also included are the following non-voting IEEE-SA Standards Board liaisons:

Alan Cookson, NIST Representative
Donald R. Volzka, TAB Representative
Yvette Ho Sang, Don Messina, Savoula Amanatidis, IEEE Project Editors

* Member Emeritus
IEEE Std 1003.1-2001/Cor 1-2002 was prepared by the Austin Group, sponsored by the Portable Applications Standards Committee of the IEEE Computer Society, The Open Group, and ISO/IEC JTC 1/SC22/WG15.

The Austin Group
At the time of approval, the membership of the Austin Group was as follows:

**Andrew Josey**, Chair
**Donald W. Cragun**, Organizational Representative, IEEE PASC
**Nicholas Stoughton**, Organizational Representative, ISO/IEC JTC 1/SC22/WG15
**Mark Brown**, Organizational Representative, The Open Group
**Cathy Fox**, Technical Editor

**Austin Group Technical Reviewers**

The Open Group

When The Open Group approved the Base Specifications, Issue 6, Technical Corrigendum 1 on 7 February 2003, the membership of The Open Group Base Working Group was as follows:

Andrew Josey, Chair
Finnbarr P. Murphy, Vice-Chair
Mark Brown, Austin Group Liaison
Cathy Fox, Technical Editor

Base Working Group Members

Mark Brown, Joanna Farley, Curtis Royster Jr.
Dave Butenhof, Andrew Gollan, Nicholas Stoughton
Donald W. Cragun, Finnbarr P. Murphy, Kenjiro Tsuji
Larry Dwyer, Frank Prindle
Ulrich Drepper, Andrew K. Roach
IEEE

When the IEEE Standards Board approved IEEE Std 1003.1-2001/Cor 1-2002 on 11 December 2002, the membership of the committees was as follows:

Portable Applications Standards Committee (PASC)

Lowell G. Johnson, Chair
Joseph M. Gwinn, Vice-Chair
Jay Ashford, Functional Chair
Andrew Josey, Functional Chair
Curtis Royster Jr., Functional Chair
Nicholas Stoughton, Secretary

Balloting Committee

The following members of the balloting committee voted on IEEE Std 1003.1-2001/Cor 1-2002. Balloters may have voted for approval, disapproval, or abstention:

Alejandro Alonso  Michael Gonzalez  Charles Ngethe
Jay Ashford  Scott Gudgel  Peter Petrov
David J. Blackwood  Charles E. Hammons  Frank Prindle
Julian Blake  Bryan Harold  Vikram Punj
Mitchell Bonnett  Barry Hedquist  Francois Riche
Mark Brown  Karl Heubaum  Curtis Royster Jr.
Dave Butenhof  Lowell G. Johnson  Diane Schleicher
Keith Chow  Andrew Josey  Stephen C. Schwarm
Luis Cordova  Kenneth Lang  Gil Shultz
Donald W. Cragun  Pi-Cheng Law  Nicholas Stoughton
Steven J. Dovich  George Miao  Donn S. Terry
Dr. Sourav Dutta  Roger J. Martin  Oren Yuen
Yaakov Fenster  Finnbarr P. Murphy  Juan A. de la Puente
IEEE-SA Standards Board

When the IEEE-SA Standards Board approved IEEE Std 1003.1-2001/Cor 1-2002 on 11 December 2002, the membership was as follows:

James T. Carlo, Chair
James H. Gurney, Vice-Chair
Judith Gorman, Secretary

Sid Bennett                      Arnold M. Greenspan                      Daleep C. Mohla
H. Stephen Berger                Raymond Hapeman                           William J. Moylan
Clyde R. Camp                    Donald M. Heirman                         Malcolm V. Thaden
Richard DeBlasio                 Richard H. Hulett                          Geoffrey O. Thompson
Harold E. Epstein                Lowell G. Johnson                         Howard L. Wolfman
Julian Forster*                  Joseph L. Koepfinger*                      Don Wright
Howard M. Frazier                 Peter H. Lips                            
Toshio Fukuda                    Nader Mehravari

Also included are the following non-voting IEEE-SA Standards Board liaisons:

Alan Cookson, NIST Representative
Satish K. Aggarwal, NRC Representative
Savoula Amanatidis, IEEE Standards Managing Editor

Source Documents

Parts of the following documents were used to create the base documents for this standard:

AIX 3.2 Manual

OSF/1

OSF AES

System V Release 2.0

System V Release 4.2
1.1 Scope

IEEE Std 1003.1-2001 defines a standard operating system interface and environment, including a command interpreter (or “shell”), and common utility programs to support applications portability at the source code level. It is intended to be used by both applications developers and system implementors.

IEEE Std 1003.1-2001 comprises four major components (each in an associated volume):

1. General terms, concepts, and interfaces common to all volumes of IEEE Std 1003.1-2001, including utility conventions and C-language header definitions, are included in the Base Definitions volume of IEEE Std 1003.1-2001.

2. Definitions for system service functions and subroutines, language-specific system services for the C programming language, function issues, including portability, error handling, and error recovery, are included in the System Interfaces volume of IEEE Std 1003.1-2001.

3. Definitions for a standard source code-level interface to command interpretation services (a “shell”) and common utility programs for application programs are included in the Shell and Utilities volume of IEEE Std 1003.1-2001.

4. Extended rationale that did not fit well into the rest of the document structure, containing historical information concerning the contents of IEEE Std 1003.1-2001 and why features were included or discarded by the standard developers, is included in the Rationale (Informative) volume of IEEE Std 1003.1-2001.

The following areas are outside of the scope of IEEE Std 1003.1-2001:

- Graphics interfaces
- Database management system interfaces
- Record I/O considerations
- Object or binary code portability
- System configuration and resource availability

IEEE Std 1003.1-2001 describes the external characteristics and facilities that are of importance to applications developers, rather than the internal construction techniques employed to achieve these capabilities. Special emphasis is placed on those functions and facilities that are needed in a wide variety of commercial applications.

The facilities provided in IEEE Std 1003.1-2001 are drawn from the following base documents:

- The following amendments to the POSIX.1-1990 standard:
  - IEEE P1003.1a draft standard (Additional System Services)
  - IEEE Std 1003.1d-1999 (Additional Realtime Extensions)
IEEE Std 1003.1g-2000 (Protocol-Independent Interfaces (PII))
IEEE Std 1003.1j-2000 (Advanced Realtime Extensions)
IEEE Std 1003.1q-2000 (Tracing)
IEEE Std 1003.2-1992 (POSIX-2) (includes IEEE Std 1003.2a-1992)
The following amendments to the ISO POSIX-2: 1993 standard:
IEEE P1003.2b draft standard (Additional Utilities)
IEEE Std 1003.2d-1994 (Batch Environment)
Note: XBD5, XCU5, and XSH5 are collectively referred to as the Base Specifications.
ISO/IEC 9899: 1999, Programming Languages — C.
IEEE Std 1003.1-2001 uses the Base Specifications as its organizational basis and adds the following additional functionality to them, drawn from the base documents above:
The amendments to the POSIX.1-1990 standard and the ISO POSIX-2: 1993 standard listed above, except for parts of IEEE Std 1003.1g-2000
Portability Considerations
Additional rationale and notes
The following features, marked legacy or obsolescent in the base documents, are not carried forward into IEEE Std 1003.1-2001. Other features from the base documents marked legacy or obsolescent are carried forward unless otherwise noted.
From XSH5, the following legacy interfaces, headers, and external variables are not carried forward:

```c
advance(), brk(), chroot(), compile(), cuserid(), gamma(), getdtablesize(), getpagesize(), getpass(), getw(), putw(), re_comp(), re_exec(), regcmp(), regex(), sbrk(), sigstack(), step(), ttyslot(), valloc(), wait3(), <re_comp.h>, <regexp.h>, <varargs.h>, loc1, loc2, loc3
```

From XCU5, the following legacy utilities are not carried forward:

calendar, cancel, cc, col, cpio, cu, dircmp, dis, egrep, fgrep, line, lint, lpstat, mail, pack, pcat, pg, spell, sum, tar, unpack, ualog, uuname, uupick, auto

In addition, legacy features within non-legacy reference pages (for example, headers) are not carried forward.

From the ISO POSIX-1:1996 standard, the following obsolescent features are not carried forward:
From the ISO POSIX-2: 1993 standard, obsolescent features within the following pages are not carried forward:

- Page 75, zero-length prefix within `PATH`
- Page 156, 159 `set`
- Page 178, `awk`, use of no argument and no parentheses with length
- Page 259, `ed`
- Page 272, `env`
- Page 282, `find -perm[-]onum`
- Page 295-296, `egrep`
- Page 299-300, `head`
- Page 305-306, `join`
- Page 309-310, `kill`
- Page 431-433, 435-436, `sort`
- Page 444-445, `tail`
- Page 453, 455-456, `touch`
- Page 464-465, `tty`
- Page 472, `uniq`
- Page 515-516, `ex`
- Page 542-543, `expand`
- Page 563-565, `more`
- Page 574-576, `newgrp`
- Page 578, `nice`
- Page 594-596, `renice`
- Page 597-598, `split`
- Page 600-601, `strings`
- Page 624-625, `vi`
- Page 693, `lex`

The `c89` utility (which specified a compiler for the C Language specified by the ISO/IEC 9899:1990 standard) has been replaced by a `c99` utility (which specifies a compiler for the C Language specified by the ISO/IEC 9899:1999 standard).

From XSH5, text marked OH (Optional Header) has been reviewed on a case-by-case basis and removed where appropriate. The XCU5 text marked OF (Output Format Incompletely Specified) and UN (Possibly Unsupportable Feature) has been reviewed on a case-by-case basis and removed where appropriate.

For the networking interfaces, the base document is the XNS, Issue 5.2 specification. The following parts of the XNS, Issue 5.2 specification are out of scope and not included in IEEE Std 1003.1-2001:

- Part 3 (XTI)
- Part 4 (Appendixes)

Since there is much duplication between the XNS, Issue 5.2 specification and IEEE Std 1003.1g-2000, material only from the following sections of IEEE Std 1003.1g-2000 has been included:

- General terms related to sockets (Section 2.2.2)
- Socket concepts (Sections 5.1 through 5.3, inclusive)
Scope

1. Introduction

- The `pselect()` function (Sections 6.2.2.1 and 6.2.3)
- The `sockatmark()` function (Section 5.4.13)
- The `<sys/select.h>` header (Section 6.2)

Emphasis is placed on standardizing existing practice for existing users, with changes and additions limited to correcting deficiencies in the following areas:

- Issues raised by IEEE or ISO/IEC Interpretations against IEEE Std 1003.1 and IEEE Std 1003.2
- Issues raised in corrigenda for the Base Specifications and working group resolutions from The Open Group
- Corrigenda and resolutions passed by The Open Group for the XNS, Issue 5.2 specification
- Changes to make the text self-consistent with the additional material merged
- A reorganization of the options in order to facilitate profiling, both for smaller profiles such as IEEE Std 1003.13, and larger profiles such as the Single UNIX Specification
- Alignment with the ISO/IEC 9899:1999 standard

1.2 Conformance

Conformance requirements for IEEE Std 1003.1-2001 are defined in Chapter 2 (on page 17).

1.3 Normative References

The following standards contain provisions which, through references in IEEE Std 1003.1-2001, constitute provisions of IEEE Std 1003.1-2001. At the time of publication, the editions indicated were valid. All standards are subject to revision, and parties to agreements based on IEEE Std 1003.1-2001 are encouraged to investigate the possibility of applying the most recent editions of the standards listed below. Members of IEC and ISO maintain registers of currently valid International Standards.

2. ISO/IEC documents can be obtained from the ISO office: 1 Rue de Varembé, Case Postale 56, CH-1211, Genève 20, Switzerland/Suisse
1.4 Terminology

For the purposes of IEEE Std 1003.1-2001, the following terminology definitions apply:

can
Describes a permissible optional feature or behavior available to the user or application. The feature or behavior is mandatory for an implementation that conforms to IEEE Std 1003.1-2001. An application can rely on the existence of the feature or behavior.

implementation-defined
Describes a value or behavior that is not defined by IEEE Std 1003.1-2001 but is selected by an implementor. The value or behavior may vary among implementations that conform to IEEE Std 1003.1-2001. An application should not rely on the existence of the value or behavior. An application that relies on such a value or behavior cannot be assured to be portable across conforming implementations.

The implementor shall document such a value or behavior so that it can be used correctly by an application.

legacy
Describes a feature or behavior that is being retained for compatibility with older applications, but which has limitations which make it inappropriate for developing portable applications. New applications should use alternative means of obtaining equivalent functionality.

may
Describes a feature or behavior that is optional for an implementation that conforms to IEEE Std 1003.1-2001. An application should not rely on the existence of the feature or behavior. An application that relies on such a feature or behavior cannot be assured to be portable across conforming implementations.

To avoid ambiguity, the opposite of may is expressed as need not, instead of may not.

shall
For an implementation that conforms to IEEE Std 1003.1-2001, describes a feature or behavior that is mandatory. An application can rely on the existence of the feature or behavior.

For an application or user, describes a behavior that is mandatory.

should
For an implementation that conforms to IEEE Std 1003.1-2001, describes a feature or behavior that is recommended but not mandatory. An application should not rely on the existence of the feature or behavior. An application that relies on such a feature or behavior cannot be assured to be portable across conforming implementations.

For an application, describes a feature or behavior that is recommended programming practice for optimum portability.
undefined

Describes the nature of a value or behavior not defined by IEEE Std 1003.1-2001 which results from use of an invalid program construct or invalid data input.

The value or behavior may vary among implementations that conform to IEEE Std 1003.1-2001. An application should not rely on the existence or validity of the value or behavior. An application that relies on any particular value or behavior cannot be assured to be portable across conforming implementations.

unspecified

Describes the nature of a value or behavior not specified by IEEE Std 1003.1-2001 which results from use of a valid program construct or valid data input.

The value or behavior may vary among implementations that conform to IEEE Std 1003.1-2001. An application should not rely on the existence or validity of the value or behavior. An application that relies on any particular value or behavior cannot be assured to be portable across conforming implementations.

1.5 Portability

Some of the utilities in the Shell and Utilities volume of IEEE Std 1003.1-2001 and functions in the System Interfaces volume of IEEE Std 1003.1-2001 describe functionality that might not be fully portable to systems meeting the requirements for POSIX conformance (see the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 2, Conformance).

Where optional, enhanced, or reduced functionality is specified, the text is shaded and a code in the margin identifies the nature of the option, extension, or warning (see Section 1.5.1). For maximum portability, an application should avoid such functionality.

Unless the primary task of a utility is to produce textual material on its standard output, application developers should not rely on the format or content of any such material that may be produced. Where the primary task is to provide such material, but the output format is incompletely specified, the description is marked with the OF margin code and shading. Application developers are warned not to expect that the output of such an interface on one system is any guide to its behavior on another system.

1.5.1 Codes

The codes and their meanings are as follows. See also Section 1.5.2 (on page 14).

ADV

Advisory Information

The functionality described is optional. The functionality described is also an extension to the ISO C standard.

Where applicable, functions are marked with the ADV margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the ADV margin legend.

AIO

Asynchronous Input and Output

The functionality described is optional. The functionality described is also an extension to the ISO C standard.

Where applicable, functions are marked with the AIO margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the AIO margin legend.
Introduction

246 BAR  Barriers
The functionality described is optional. The functionality described is also an extension to the
ISO C standard.
Where applicable, functions are marked with the BAR margin legend in the SYNOPSIS section.
Where additional semantics apply to a function, the material is identified by use of the BAR
margin legend.

252 BE  Batch Environment Services and Utilities
The functionality described is optional.
Where applicable, utilities are marked with the BE margin legend in the SYNOPSIS section.
Where additional semantics apply to a utility, the material is identified by use of the BE margin
legend.

257 CD  C-Language Development Utilities
The functionality described is optional.
Where applicable, utilities are marked with the CD margin legend in the SYNOPSIS section.
Where additional semantics apply to a utility, the material is identified by use of the CD margin
legend.

262 CPT  Process CPU-Time Clocks
The functionality described is optional. The functionality described is also an extension to the
ISO C standard.
Where applicable, functions are marked with the CPT margin legend in the SYNOPSIS section.
Where additional semantics apply to a function, the material is identified by use of the CPT
margin legend.

268 CS  Clock Selection
The functionality described is optional. The functionality described is also an extension to the
ISO C standard.
Where applicable, functions are marked with the CS margin legend in the SYNOPSIS section.
Where additional semantics apply to a function, the material is identified by use of the CS
margin legend.

274 CX  Extension to the ISO C standard
The functionality described is an extension to the ISO C standard. Application writers may make
use of an extension as it is supported on all IEEE Std 1003.1-2001-conforming systems.
With each function or header from the ISO C standard, a statement to the effect that “any
conflict is unintentional” is included. That is intended to refer to a direct conflict.
IEEE Std 1003.1-2001 acts in part as a profile of the ISO C standard, and it may choose to further
constrain behaviors allowed to vary by the ISO C standard. Such limitations are not considered
conflicts.
Where additional semantics apply to a function or header, the material is identified by use of the
CX margin legend.

284 FD  FORTRAN Development Utilities
The functionality described is optional.
Where applicable, utilities are marked with the FD margin legend in the SYNOPSIS section.
Where additional semantics apply to a utility, the material is identified by use of the FD margin
legend.

289 FR  FORTRAN Runtime Utilities
The functionality described is optional.
Portability

Introduction

Where applicable, utilities are marked with the FR margin legend in the SYNOPSIS section. Where additional semantics apply to a utility, the material is identified by use of the FR margin legend.

File Synchronization
The functionality described is optional. The functionality described is also an extension to the ISO C standard.
Where applicable, functions are marked with the FSC margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the FSC margin legend.

IPV6
The functionality described is optional. The functionality described is also an extension to the ISO C standard.
Where applicable, functions are marked with the IP6 margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the IP6 margin legend.

Advisory Information and either Memory Mapped Files or Shared Memory Objects
The functionality described is optional. The functionality described is also an extension to the ISO C standard.
This is a shorthand notation for combinations of multiple option codes.
Where applicable, functions are marked with the MC1 margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the MC1 margin legend.
Refer to Section 1.5.2 (on page 14).

Memory Mapped Files, Shared Memory Objects, or Memory Protection
The functionality described is optional. The functionality described is also an extension to the ISO C standard.
This is a shorthand notation for combinations of multiple option codes.
Where applicable, functions are marked with the MC2 margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the MC2 margin legend.
Refer to Section 1.5.2 (on page 14).

Memory Mapped Files, Shared Memory Objects, or Typed Memory Objects
The functionality described is optional. The functionality described is also an extension to the ISO C standard.
This is a shorthand notation for combinations of multiple option codes.
Where applicable, functions are marked with the MC3 margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the MC3 margin legend.
Refer to Section 1.5.2 (on page 14).

Memory Mapped Files
The functionality described is optional. The functionality described is also an extension to the ISO C standard.
Where applicable, functions are marked with the MF margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the MF margin legend.

**Process Memory Locking**
The functionality described is optional. The functionality described is also an extension to the ISO C standard. Where applicable, functions are marked with the ML margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the ML margin legend.

**Range Memory Locking**
The functionality described is optional. The functionality described is also an extension to the ISO C standard. Where applicable, functions are marked with the MLR margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the MLR margin legend.

**Monotonic Clock**
The functionality described is optional. The functionality described is also an extension to the ISO C standard. Where applicable, functions are marked with the MON margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the MON margin legend.

**Memory Protection**
The functionality described is optional. The functionality described is also an extension to the ISO C standard. Where applicable, functions are marked with the MPR margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the MPR margin legend.

**Message Passing**
The functionality described is optional. The functionality described is also an extension to the ISO C standard. Where applicable, functions are marked with the MSG margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the MSG margin legend.

**IEC 60559 Floating-Point Option**
The functionality described is optional. The functionality described is also an extension to the ISO C standard. Where applicable, functions are marked with the MX margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the MX margin legend.

**Obsolescent**
The functionality described may be withdrawn in a future version of this volume of IEEE Std 1003.1-2001. Strictly Conforming POSIX Applications and Strictly Conforming XSI Applications shall not use obsolescent features. Where applicable, the material is identified by use of the OB margin legend.
Output Format Incompletely Specified

The functionality described is an XSI extension. The format of the output produced by the utility is not fully specified. It is therefore not possible to post-process this output in a consistent fashion. Typical problems include unknown length of strings and unspecified field delimiters.

Where applicable, the material is identified by use of the OF margin legend.

Optional Header

In the SYNOPSIS section of some interfaces in the System Interfaces volume of IEEE Std 1003.1-2001 an included header is marked as in the following example:

```
#include <sys/types.h>
#include <grp.h>
struct group *getgrnam(const char *name);
```

The OH margin legend indicates that the marked header is not required on XSI-conformant systems.

Prioritized Input and Output

The functionality described is optional. The functionality described is also an extension to the ISO C standard.

Where applicable, functions are marked with the PIO margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the PIO margin legend.

Process Scheduling

The functionality described is optional. The functionality described is also an extension to the ISO C standard.

Where applicable, functions are marked with the PS margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the PS margin legend.

Raw Sockets

The functionality described is optional. The functionality described is also an extension to the ISO C standard.

Where applicable, functions are marked with the RS margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the RS margin legend.

Realtime Signals Extension

The functionality described is optional. The functionality described is also an extension to the ISO C standard.

Where applicable, functions are marked with the RTS margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the RTS margin legend.

Software Development Utilities

The functionality described is optional.

Where applicable, utilities are marked with the SD margin legend in the SYNOPSIS section. Where additional semantics apply to a utility, the material is identified by use of the SD margin legend.

Semaphores

The functionality described is optional. The functionality described is also an extension to the ISO C standard.
Introduction

Where applicable, functions are marked with the SEM margin legend in the SYNOPSIS section.
Where additional semantics apply to a function, the material is identified by use of the SEM margin legend.

SHM

The functionality described is optional. The functionality described is also an extension to the ISO C standard.
Where applicable, functions are marked with the SHM margin legend in the SYNOPSIS section.
Where additional semantics apply to a function, the material is identified by use of the SHM margin legend.

SIO

The functionality described is optional. The functionality described is also an extension to the ISO C standard.
Where applicable, functions are marked with the SIO margin legend in the SYNOPSIS section.
Where additional semantics apply to a function, the material is identified by use of the SIO margin legend.

SPI

The functionality described is optional. The functionality described is also an extension to the ISO C standard.
Where applicable, functions are marked with the SPI margin legend in the SYNOPSIS section.
Where additional semantics apply to a function, the material is identified by use of the SPI margin legend.

SPN

The functionality described is optional. The functionality described is also an extension to the ISO C standard.
Where applicable, functions are marked with the SPN margin legend in the SYNOPSIS section.
Where additional semantics apply to a function, the material is identified by use of the SPN margin legend.

SS

The functionality described is optional. The functionality described is also an extension to the ISO C standard.
Where applicable, functions are marked with the SS margin legend in the SYNOPSIS section.
Where additional semantics apply to a function, the material is identified by use of the SS margin legend.

TCT

The functionality described is optional. The functionality described is also an extension to the ISO C standard.
Where applicable, functions are marked with the TCT margin legend in the SYNOPSIS section.
Where additional semantics apply to a function, the material is identified by use of the TCT margin legend.

TEF

The functionality described is optional. The functionality described is also an extension to the ISO C standard.
Where applicable, functions are marked with the TEF margin legend in the SYNOPSIS section.
Where additional semantics apply to a function, the material is identified by use of the TEF margin legend.
Portability

467 THR Threads
468 The functionality described is optional. The functionality described is also an extension to the
469 ISO C standard.
470
471 Where applicable, functions are marked with the THR margin legend in the SYNOPSIS section.
472 Where additional semantics apply to a function, the material is identified by use of the THR
473 margin legend.

474 TMO Timeouts
475 The functionality described is optional. The functionality described is also an extension to the
476 ISO C standard.
477
478 Where applicable, functions are marked with the TMO margin legend in the SYNOPSIS section.
479 Where additional semantics apply to a function, the material is identified by use of the TMO
480 margin legend.

481 TMR Timers
482 The functionality described is optional. The functionality described is also an extension to the
483 ISO C standard.
484
485 Where applicable, functions are marked with the TMR margin legend in the SYNOPSIS section.
486 Where additional semantics apply to a function, the material is identified by use of the TMR
487 margin legend.

488 TPI Thread Priority Inheritance
489 The functionality described is optional. The functionality described is also an extension to the
490 ISO C standard.
491
492 Where applicable, functions are marked with the TPI margin legend in the SYNOPSIS section.
493 Where additional semantics apply to a function, the material is identified by use of the TPI
494 margin legend.

495 TPP Thread Priority Protection
496 The functionality described is optional. The functionality described is also an extension to the
497 ISO C standard.
498
499 Where applicable, functions are marked with the TPP margin legend in the SYNOPSIS section.
500 Where additional semantics apply to a function, the material is identified by use of the TPP
501 margin legend.

502 TPS Thread Execution Scheduling
503 The functionality described is optional. The functionality described is also an extension to the
504 ISO C standard.
505
506 Where applicable, functions are marked with the TPS margin legend for the SYNOPSIS section.
507 Where additional semantics apply to a function, the material is identified by use of the TPS
508 margin legend.

509 TRC Trace
510 The functionality described is optional. The functionality described is also an extension to the
511 ISO C standard.
512
12 Base Definitions, Issue 6 — Copyright © 2001-2003, IEEE and The Open Group. All rights reserved.
Where applicable, functions are marked with the TRI margin legend in the SYNOPSIS section.
Where additional semantics apply to a function, the material is identified by use of the TRI margin legend.

TRL Trace Log
The functionality described is optional. The functionality described is also an extension to the ISO C standard.
Where applicable, functions are marked with the TRL margin legend in the SYNOPSIS section.
Where additional semantics apply to a function, the material is identified by use of the TRL margin legend.

TSA Thread Stack Address Attribute
The functionality described is optional. The functionality described is also an extension to the ISO C standard.
Where applicable, functions are marked with the TSA margin legend for the SYNOPSIS section.
Where additional semantics apply to a function, the material is identified by use of the TSA margin legend.

TSF Thread-Safe Functions
The functionality described is optional. The functionality described is also an extension to the ISO C standard.
Where applicable, functions are marked with the TSF margin legend in the SYNOPSIS section.
Where additional semantics apply to a function, the material is identified by use of the TSF margin legend.

TSH Thread Process-Shared Synchronization
The functionality described is optional. The functionality described is also an extension to the ISO C standard.
Where applicable, functions are marked with the TSH margin legend in the SYNOPSIS section.
Where additional semantics apply to a function, the material is identified by use of the TSH margin legend.

TSP Thread Sporadic Server
The functionality described is optional. The functionality described is also an extension to the ISO C standard.
Where applicable, functions are marked with the TSP margin legend in the SYNOPSIS section.
Where additional semantics apply to a function, the material is identified by use of the TSP margin legend.

TSS Thread Stack Size Attribute
The functionality described is optional. The functionality described is also an extension to the ISO C standard.
Where applicable, functions are marked with the TSS margin legend in the SYNOPSIS section.
Where additional semantics apply to a function, the material is identified by use of the TSS margin legend.

TYM Typed Memory Objects
The functionality described is optional. The functionality described is also an extension to the ISO C standard.
Where applicable, functions are marked with the TYM margin legend in the SYNOPSIS section.
Where additional semantics apply to a function, the material is identified by use of the TYM margin legend.
Portability

Introduction

557  UP  User Portability Utilities
558  The functionality described is optional.
559  Where applicable, utilities are marked with the UP margin legend in the SYNOPSIS section.
560  Where additional semantics apply to a utility, the material is identified by use of the UP margin
561  legend.

562  XSI  Extension
563  The functionality described is an XSI extension. Functionality marked XSI is also an extension to
564  the ISO C standard. Application writers may confidently make use of an extension on all
565  systems supporting the X/Open System Interfaces Extension.
566  If an entire SYNOPSIS section is shaded and marked XSI, all the functionality described in that
567  reference page is an extension. See Section 2.1.4 (on page 21).

568  XSR  XSI STREAMS
569  The functionality described is optional. The functionality described is also an extension to the
570  ISO C standard.
571  Where applicable, functions are marked with the XSR margin legend in the SYNOPSIS section.
572  Where additional semantics apply to a function, the material is identified by use of the XSR
573  margin legend.

1.5.2  Margin Code Notation

574  Some of the functionality described in IEEE Std 1003.1-2001 depends on support of more than
575  one option, or independently may depend on several options. The following notation for margin
576  codes is used to denote the following cases.

578  A Feature Dependent on One or Two Options
579  In this case, margin codes have a <space> separator; for example:
580  MF
581  This feature requires support for only the Memory Mapped Files option.
582  MF SHM This feature requires support for both the Memory Mapped Files and the Shared Memory
583  Objects options; that is, an application which uses this feature is portable only between
584  implementations that provide both options.

584  A Feature Dependent on Either of the Options Denoted
585  In this case, margin codes have a ‘ | ’ separator to denote the logical OR, for example:
586  MF|SHM This feature is dependent on support for either the Memory Mapped Files option or the Shared
587  Memory Objects option; that is, an application which uses this feature is portable between
588  implementations that provide any (or all) of the options.

589  A Feature Dependent on More than Two Options
590  The following shorthand notations are used:
591  MC1 The MC1 margin code is shorthand for ADV (MF|SHM). Features which are shaded with this
592  margin code require support of the Advisory Information option and either the Memory
593  Mapped Files or Shared Memory Objects option.
594  MC2 The MC2 margin code is shorthand for MF|SHM|MPR. Features which are shaded with this
595  margin code require support of either the Memory Mapped Files, Shared Memory Objects, or
596  Memory Protection options.
The MC3 margin code is shorthand for MF|SHM|TYM. Features which are shaded with this margin code require support of either the Memory Mapped Files, Shared Memory Objects, or Typed Memory Objects options.

**Large Sections Dependent on an Option**

Where large sections of text are dependent on support for an option, a lead-in text block is provided and shaded accordingly; for example:

This section describes extensions to support tracing of user applications. This functionality is dependent on support of the Trace option (and the rest of this section is not further shaded for this option).
2.1 Implementation Conformance

2.1.1 Requirements

A conforming implementation shall meet all of the following criteria:

1. The system shall support all utilities, functions, and facilities defined within IEEE Std 1003.1-2001 that are required for POSIX conformance (see Section 2.1.3 (on page 18)). These interfaces shall support the functional behavior described herein.

2. The system may support one or more options as described under Section 2.1.5 (on page 22). When an implementation claims that an option is supported, all of its constituent parts shall be provided.

3. The system may support the X/Open System Interface Extension (XSI) as described under Section 2.1.4 (on page 21).

4. The system may provide additional utilities, functions, or facilities not required by IEEE Std 1003.1-2001. Non-standard extensions of the utilities, functions, or facilities specified in IEEE Std 1003.1-2001 should be identified as such in the system documentation. Non-standard extensions, when used, may change the behavior of utilities, functions, or facilities defined by IEEE Std 1003.1-2001. The conformance document shall define an environment in which an application can be run with the behavior specified by IEEE Std 1003.1-2001. In no case shall such an environment require modification of a Strictly Conforming POSIX Application (see Section 2.2.1 (on page 31)).

2.1.2 Documentation

A conformance document with the following information shall be available for an implementation claiming conformance to IEEE Std 1003.1-2001. The conformance document shall have the same structure as IEEE Std 1003.1-2001, with the information presented in the appropriate sections and subsections. Sections and subsections that consist solely of subordinate section titles, with no other information, are not required. The conformance document shall not contain information about extended facilities or capabilities outside the scope of IEEE Std 1003.1-2001.

The conformance document shall contain a statement that indicates the full name, number, and date of the standard that applies. The conformance document may also list international software standards that are available for use by a Conforming POSIX Application. Applicable characteristics where documentation is required by one of these standards, or by standards of government bodies, may also be included.

The conformance document shall describe the limit values found in the headers <limits.h> (on page 249) and <unistd.h> (on page 400), stating values, the conditions under which those values may change, and the limits of such variations, if any.

The conformance document shall describe the behavior of the implementation for all implementation-defined features defined in IEEE Std 1003.1-2001. This requirement shall be met by listing these features and providing either a specific reference to the system documentation or providing full syntax and semantics of these features. When the value or behavior in the
Implementation Conformance

The implementation is designed to be variable or customized on each instantiation of the system, the implementation provider shall document the nature and permissible ranges of this variation.

The conformance document may specify the behavior of the implementation for those features where IEEE Std 1003.1-2001 states that implementations may vary or where features are identified as undefined or unspecified.

The conformance document shall not contain documentation other than that specified in the preceding paragraphs except where such documentation is specifically allowed or required by other provisions of IEEE Std 1003.1-2001.

The phrases “shall document” or “shall be documented” in IEEE Std 1003.1-2001 mean that documentation of the feature shall appear in the conformance document, as described previously, unless there is an explicit reference in the conformance document to show where the information can be found in the system documentation.

The system documentation should also contain the information found in the conformance document.

2.1.3 POSIX Conformance

A conforming implementation shall meet the following criteria for POSIX conformance.

2.1.3.1 POSIX System Interfaces

- The system shall support all the mandatory functions and headers defined in IEEE Std 1003.1-2001, and shall set the symbolic constant _POSIX_VERSION to the value 200112L.
- Although all implementations conforming to IEEE Std 1003.1-2001 support all the features described below, there may be system-dependent or file system-dependent configuration procedures that can remove or modify any or all of these features. Such configurations should not be made if strict compliance is required.

The following symbolic constants shall either be undefined or defined with a value other than −1. If a constant is undefined, an application should use the `sysconf()`, `pathconf()`, or `fpathconf()` functions, or the `getconf` utility, to determine which features are present on the system at that time or for the particular pathname in question.

- _POSIX_CHOWN_RESTRICTED
  The use of `chown()` is restricted to a process with appropriate privileges, and to changing the group ID of a file only to the effective group ID of the process or to one of its supplementary group IDs.
- _POSIX_NO_TRUNC

- The following symbolic constants shall be defined as follows:
  - _POSIX_JOB_CONTROL shall have a value greater than zero.
  - _POSIX_SAVED_IDS shall have a value greater than zero.
  - _POSIX_VDISABLE shall have a value other than −1.

Note: The symbols above represent historical options that are no longer allowed as options, but are retained here for backwards-compatibility of applications.
• The system may support one or more options (see Section 2.1.6 (on page 28)) denoted by the following symbolic constants:
  — _POSIX_ADVISORY_INFO
  — _POSIX_ASYNCHRONOUS_IO
  — _POSIX_BARRIERS
  — _POSIX_CLOCK_SELECTION
  — _POSIX_CPUTIME
  — _POSIX_FSYNC
  — _POSIX_IPV6
  — _POSIX_MAPPED_FILES
  — _POSIX_MEMLOCK
  — _POSIX_MEMLOCK_RANGE
  — _POSIX_MEMORY_PROTECTION
  — _POSIX_MESSAGE_PASSING
  — _POSIX_MONOTONIC_CLOCK
  — _POSIX_PRIORITIZED_IO
  — _POSIX_PRIORITY_SCHEDULING
  — _POSIX_RAW_SOCKETS
  — _POSIX_REALTIME_SIGNALS
  — _POSIX_SEMAPHORES
  — _POSIX_SHARED_MEMORY_OBJECTS
  — _POSIX_SPAWN
  — _POSIX_SPIN_LOCKS
  — _POSIX_SPORADIC_SERVER
  — _POSIX_SYNCHRONIZED_IO
  — _POSIX_THREAD_ATTR_STACKADDR
  — _POSIX_THREAD_CPUTIME
  — _POSIX_THREAD_ATTR_STACKSIZE
  — _POSIX_THREAD_PRIO_INHERIT
  — _POSIX_THREAD_PRIO_PROTECT
  — _POSIX_THREAD_PRIORITY_SCHEDULING
  — _POSIX_THREAD_PROCESS_SHARED
  — _POSIX_THREAD_SAFE_FUNCTIONS
  — _POSIX_THREAD_SPORADIC_SERVER
  — _POSIX_THREADS
— _POSIX_TIMEOUTS
— _POSIX_TIMERS
— _POSIX_TRACE
— _POSIX_TRACE_EVENT_FILTER
— _POSIX_TRACE_INHERIT
— _POSIX_TRACE_LOG
— _POSIX_TYPED_MEMORY_OBJECTS

If any of the symbolic constants _POSIX_TRACE_EVENT_FILTER, _POSIX_TRACE_LOG, or _POSIX_TRACE_INHERIT is defined to have a value other than −1, then the symbolic constant _POSIX_TRACE shall also be defined to have a value other than −1.

xsi

• The system may support the XSI extensions (see Section 2.1.5.2 (on page 24)) denoted by the following symbolic constants:

— _XOPEN_CRYPT
— _XOPEN_LEGACY
— _XOPEN_REALTIME
— _XOPEN_REALTIME_THREADS
— _XOPEN_UNIX

2.1.3.2 POSIX Shell and Utilities

• The system shall provide all the mandatory utilities in the Shell and Utilities volume of IEEE Std 1003.1-2001 with all the functional behavior described therein.

• The system shall support the Large File capabilities described in the Shell and Utilities volume of IEEE Std 1003.1-2001.

• The system may support one or more options (see Section 2.1.6 (on page 28)) denoted by the following symbolic constants. (The literal names below apply to the getconf utility.)

— POSIX2_C_DEV
— POSIX2_CHAR_TERM
— POSIX2_FORT_DEV
— POSIX2_FORT_RUN
— POSIX2_LOCALEDEF
— POSIX2 PBS
— POSIX2 PBS_ACCOUNTING
— POSIX2 PBS_LOCATE
— POSIX2 PBS_MESSAGE
— POSIX2 PBS_TRACK
— POSIX2 SW_DEV
— POSIX2 UPE
• The system may support the XSI extensions (see Section 2.1.4).

Additional language bindings and development utility options may be provided in other related standards or in a future version of IEEE Std 1003.1-2001. In the former case, additional symbolic constants of the same general form as shown in this subsection should be defined by the related standard document and made available to the application without requiring IEEE Std 1003.1-2001 to be updated.

2.1.4 XSI Conformance

This section describes the criteria for implementations conforming to the XSI extension (see Section 3.439 (on page 96)). This functionality is dependent on the support of the XSI extension (and the rest of this section is not further shaded).

IEEE Std 1003.1-2001 describes utilities, functions, and facilities offered to application programs by the X/Open System Interface (XSI). An XSI-conforming implementation shall meet the criteria for POSIX conformance and the following requirements.

2.1.4.1 XSI System Interfaces

• The system shall support all the functions and headers defined in IEEE Std 1003.1-2001 as part of the XSI extension denoted by the symbolic constant _XOPEN_UNIX and any extensions marked with the XSI extension marking (see Section 1.5.1 (on page 6)).

• The system shall support the mmap(), munmap(), and msync() functions.

• The system shall support the following options defined within IEEE Std 1003.1-2001 (see Section 2.1.6 (on page 28)):

  — _POSIX_FSYNC
  — _POSIX_MAPPED_FILES
  — _POSIX_MEMORY_PROTECTION
  — _POSIX_THREAD_ATTR_STACKADDR
  — _POSIX_THREAD_ATTR_STACKSIZE
  — _POSIX_THREAD_PROCESS_SHARED
  — _POSIX_THREAD_SAFE_FUNCTIONS
  — _POSIX_THREADS

• The system may support the following XSI Option Groups (see Section 2.1.5.2 (on page 24)) defined within IEEE Std 1003.1-2001:

  — Encryption
  — Realtime
  — Advanced Realtime
  — Realtime Threads
  — Advanced Realtime Threads
  — Tracing
  — XSI STREAMS
  — Legacy
2.1.4.2 XSI Shell and Utilities Conformance

- The system shall support all the utilities defined in the Shell and Utilities volume of IEEE Std 1003.1-2001 as part of the XSI extension denoted by the XSI marking in the SYNOPSIS section, and any extensions marked with the XSI extension marking (see Section 1.5.1 (on page 6)) within the text.
- The system shall support the User Portability Utilities option.
- The system shall support creation of locales (see Chapter 7 (on page 123)).
- The C-language Development utility `c99` shall be supported.
- The XSI Development Utilities option may be supported. It consists of the following software development utilities:

  ```
  admin  delta  prs  unget  |
  cflow  get  rmdel  val  |
  ctags  m4  sact  what  |
  cxref  nm  sccs  |
  ```

- Within the utilities that are provided, functionality marked by the code OF (see Section 1.5.1 (on page 6)) need not be provided.

2.1.5 Option Groups

An Option Group is a group of related functions or options defined within the System Interfaces volume of IEEE Std 1003.1-2001.

If an implementation supports an Option Group, then the system shall support the functional behavior described herein.

If an implementation does not support an Option Group, then the system need not support the functional behavior described herein.

2.1.5.1 Subprofiling Considerations

Profiling standards supporting functional requirements less than that required in IEEE Std 1003.1-2001 may subset both mandatory and optional functionality required for POSIX Conformance (see Section 2.1.3 (on page 18)) or XSI Conformance (see Section 2.1.4 (on page 21)). Such profiles shall organize the subsets into Subprofiling Option Groups.

The Rationale (Informative) volume of IEEE Std 1003.1-2001, Appendix E, Subprofiling Considerations (Informative) describes a representative set of such Subprofiling Option Groups for use by profiles applicable to specialized realtime systems. IEEE Std 1003.1-2001 does not require that the presence of Subprofiling Option Groups be testable at compile-time (as symbols defined in any header) or at runtime (via `sysconf()` or `getconf`).

A Subprofiling Option Group may provide basic system functionality that other Subprofiling Option Groups and other options depend upon. If a profile of IEEE Std 1003.1-2001 does not

---

3. As an example, the File System profiling option group provides underlying support for pathname resolution and file creation which are needed by any interface in IEEE Std 1003.1-2001 that parses a `path` argument. If a profile requires support for the Device Input and Output profiling option group but does not require support for the File System profiling option group, the profile must specify how pathname resolution is to behave in that profile, how the O_CREAT flag to `open()` is to be handled (and the use of the character `a` in the `mode` argument of `fopen()` when a filename argument names a file that does not exist), and specify lots of other details.
require an implementation to provide a Subprofiling Option Group that provides features utilized by a required Subprofiling Option Group (or option),\textsuperscript{4} the profile shall specify\textsuperscript{5} all of the following:

- Restricted or altered behavior of interfaces defined in IEEE Std 1003.1-2001 that may differ on an implementation of the profile
- Additional behaviors that may produce undefined or unspecified results
- Additional implementation-defined behavior that implementations shall be required to document in the profile's conformance document

if any of the above is a result of the profile not requiring an interface required by IEEE Std 1003.1-2001.

The following additional rules shall apply to all profiles of IEEE Std 1003.1-2001:

- Any application that conforms to that profile shall also conform to IEEE Std 1003.1-2001 (that is, a profile shall not require restricted, altered, or extended behaviors of an implementation of IEEE Std 1003.1-2001).
- Profiles are permitted to add additional requirements to the limits defined in <limits.h> and <stdint.h>, subject to the following:
  - For the limits in <limits.h> and <stdint.h>:
    - If the limit is specified as having a fixed value, it shall not be changed by a profile.
    - If a limit is specified as having a minimum or maximum acceptable value, it may be changed by a profile as follows:
      - A profile may increase a minimum acceptable value, but shall not make a minimum acceptable value smaller.
      - A profile may reduce a maximum acceptable value, but shall not make a maximum acceptable value larger.
    - A profile shall not change a limit specified as having a minimum or maximum value into a limit specified as having a fixed value.
  - A profile shall not create new limits.
  - Any implementation that conforms to IEEE Std 1003.1-2001 (including all options and extended limits required by the profile) shall also conform to that profile.

\textsuperscript{4} As an example, IEEE Std 1003.1-2001 requires that implementations claiming to support the Range Memory Locking option also support the Process Memory Locking option. A profile could require that the Range Memory Locking option had to be supplied without requiring that the Process Memory Locking option be supplied as long as the profile specifies everything an application writer or system implementor would have to know to build an application or implementation conforming to the profile.

\textsuperscript{5} Note that the profile could just specify that any use of the features not specified by the profile would produce undefined or unspecified results.
2.1.5.2 XSI Option Groups

This section describes Option Groups to support the definition of XSI conformance within the System Interfaces volume of IEEE Std 1003.1-2001. This functionality is dependent on the support of the XSI extension (and the rest of this section is not further shaded).

The following Option Groups are defined.

**Encryption**

The Encryption Option Group is denoted by the symbolic constant _XOPEN_CRYPT. It includes the following functions:

- `crypt()`, `encrypt()`, `setkey()`

These functions are marked CRYPT.

Due to export restrictions on the decoding algorithm in some countries, implementations may be restricted in making these functions available. All the functions in the Encryption Option Group may therefore return [ENOSYS] or, alternatively, `encrypt()` shall return [ENOSYS] for the decryption operation.

An implementation that claims conformance to this Option Group shall set _XOPEN_CRYPT to a value other than −1.

**Realtime**

The Realtime Option Group is denoted by the symbolic constant _XOPEN_REALTIME.

This Option Group includes a set of realtime functions drawn from options within IEEE Std 1003.1-2001 (see Section 2.1.6 (on page 28)).

Where entire functions are included in the Option Group, the NAME section is marked with REALTIME. Where additional semantics have been added to existing pages, the new material is identified by use of the appropriate margin legend for the underlying option defined within IEEE Std 1003.1-2001.

An implementation that claims conformance to this Option Group shall set _XOPEN_REALTIME to a value other than −1.

This Option Group consists of the set of the following options from within IEEE Std 1003.1-2001 (see Section 2.1.6 (on page 28)):

- _POSIX_ASYNCHRONOUS_IO
- _POSIX_FSYNC
- _POSIX_MAPPED_FILES
- _POSIX_MEMLOCK
- _POSIX_MEMLOCK_RANGE
- _POSIX_MEMORY_PROTECTION
- _POSIX_MESSAGE_PASSING
- _POSIX_PRIORITIZED_IO
- _POSIX_PRIORITY_SCHEDULING
- _POSIX_REALTIME_SIGNALS
- _POSIX_SEMAPHORES
- _POSIX_SHARED_MEMORY_OBJECTS
- _POSIX_SYNCHRONIZED_IO
- _POSIX_TIMERS
If the symbolic constant \_XOPEN_REALTIME is defined to have a value other than \-1, then the following symbolic constants shall be defined by the implementation to have the value 200112L:

\begin{verbatim}
\_POSIX_ASYNCHRONOUS_IO
\_POSIX_MEMLOCK
\_POSIX_MEMLOCK_RANGE
\_POSIX_MESSAGE_PASSING
\_POSIX_PRIORITY_SCHEDULING
\_POSIX_REALTIME_SIGNALS
\_POSIX_SEMAPHORES
\_POSIX_SHARED_MEMORY_OBJECTS
\_POSIX_SYNCHRONIZED_IO
\_POSIX_TIMERS
\end{verbatim}

The functionality associated with \_POSIX_MAPPED_FILES, \_POSIX_MEMORY_PROTECTION, and \_POSIX_FSYNC is always supported on XSI-conformant systems.

Support of \_POSIX_PRIORITIZED_IO on XSI-conformant systems is optional. If this functionality is supported, then \_POSIX_PRIORITIZED_IO shall be set to a value other than \-1. Otherwise, it shall be undefined.

If \_POSIX_PRIORITIZED_IO is supported, then asynchronous I/O operations performed by \textit{aio_read()}, \textit{aio_write()}, and \textit{lio_listio()} shall be submitted at a priority equal to the scheduling priority of the process minus \textit{aiocbp->aio_reqprio}. The implementation shall also document for which files I/O prioritization is supported.

### Advanced Realtime

An implementation that claims conformance to this Option Group shall also support the Realtime Option Group.

Where entire functions are included in the Option Group, the NAME section is marked with ADVANCED REALTIME. Where additional semantics have been added to existing pages, the new material is identified by use of the appropriate margin legend for the underlying option defined within IEEE Std 1003.1-2001.

This Option Group consists of the set of the following options from within IEEE Std 1003.1-2001 (see Section 2.1.6 (on page 28)):

\begin{verbatim}
\_POSIX_ADVISORY_INFO
\_POSIX_CLOCK_SELECTION
\_POSIX_CPUTIME
\_POSIX_MONOTONIC_CLOCK
\_POSIX_SPAWN
\_POSIX_SPORADIC_SERVER
\_POSIX_TIMEOUTS
\_POSIX_TYPED_MEMORY_OBJECTS
\end{verbatim}

If the implementation supports the Advanced Realtime Option Group, then the following symbolic constants shall be defined by the implementation to have the value 200112L:
If the symbolic constant _POSIX_SPAWN is defined, then the symbolic constant _POSIX_PRIORITY_SCHEDULING shall also be defined by the implementation to have the value 200112L.

If the symbolic constant _POSIX_CPUTIME is defined, then the symbolic constant _POSIX_TIMERS shall also be defined by the implementation to have the value 200112L.

If the symbolic constant _POSIX_MONOTONIC_CLOCK is defined, then the symbolic constant _POSIX_TIMERS shall also be defined by the implementation to have the value 200112L.

If the symbolic constant _POSIX_CLOCK_SELECTION is defined, then the symbolic constant _POSIX_TIMERS shall also be defined by the implementation to have the value 200112L.

Realtime Threads

The Realtime Threads Option Group is denoted by the symbolic constant _XOPEN_REALTIME_THREADS.

This Option Group consists of the set of the following options from within IEEE Std 1003.1-2001 (see Section 2.1.6 (on page 28)):

- _POSIX_THREAD_PRIO_INHERIT
- _POSIX_THREAD_PRIO_PROTECT
- _POSIX_THREAD_PRIORITY_SCHEDULING

Where applicable, whole pages are marked REALTIME THREADS, together with the appropriate option margin legend for the SYNOPSIS section (see Section 1.5.1 (on page 6)).

An implementation that claims conformance to this Option Group shall set _XOPEN_REALTIME_THREADS to a value other than −1.

If the symbol _XOPEN_REALTIME_THREADS is defined to have a value other than −1, then the following options shall also be defined by the implementation to have the value 200112L:

- _POSIX_THREAD_PRIO_INHERIT
- _POSIX_THREAD_PRIO_PROTECT
- _POSIX_THREAD_PRIORITY_SCHEDULING

Advanced Realtime Threads

An implementation that claims conformance to this Option Group shall also support the Realtime Threads Option Group.

Where entire functions are included in the Option Group, the NAME section is marked with ADVANCED REALTIME THREADS. Where additional semantics have been added to existing pages, the new material is identified by use of the appropriate margin legend for the underlying option defined within IEEE Std 1003.1-2001.

This Option Group consists of the set of the following options from within IEEE Std 1003.1-2001 (see Section 2.1.6 (on page 28)):
If the symbolic constant \_POSIX_THREAD_SPORADIC_SERVER is defined to have the value 200112L, then the symbolic constant \_POSIX_THREAD_PRIORITY_SCHEDULING shall also be defined by the implementation to have the value 200112L.

If the symbolic constant \_POSIX_THREAD_CPUTIME is defined to have the value 200112L, then the symbolic constant \_POSIX_TIMERS shall also be defined by the implementation to have the value 200112L.

If the symbolic constant \_POSIX_BARRIERS is defined to have the value 200112L, then the symbolic constants \_POSIX_THREADS and \_POSIX_THREAD_SAFE_FUNCTIONS shall also be defined by the implementation to have the value 200112L.

If the symbolic constant \_POSIX_SPIN_LOCKS is defined to have the value 200112L, then the symbolic constants \_POSIX_THREADS and \_POSIX_THREAD_SAFE_FUNCTIONS shall also be defined by the implementation to have the value 200112L.

If the implementation supports the Advanced Realtime Threads Option Group, then the following symbolic constants shall be defined by the implementation to have the value 200112L:

\_POSIX_BARRIERS
\_POSIX_SPIN_LOCKS
\_POSIX_THREAD_CPUTIME
\_POSIX_THREAD_SPORADIC_SERVER

Tracing

This Option Group includes a set of tracing functions drawn from options within IEEE Std 1003.1-2001 (see Section 2.1.6 (on page 28)).

Where entire functions are included in the Option Group, the NAME section is marked with TRACING. Where additional semantics have been added to existing pages, the new material is identified by use of the appropriate margin legend for the underlying option defined within IEEE Std 1003.1-2001.

This Option Group consists of the set of the following options from within IEEE Std 1003.1-2001 (see Section 2.1.6 (on page 28)):

\_POSIX_TRACE
\_POSIX_TRACE_EVENT_FILTER
\_POSIX_TRACE_LOG
\_POSIX_TRACE_INHERIT

If the implementation supports the Tracing Option Group, then the following symbolic constants shall be defined by the implementation to have the value 200112L:

\_POSIX_TRACE
\_POSIX_TRACE_EVENT_FILTER
\_POSIX_TRACE_LOG
\_POSIX_TRACE_INHERIT
**XSI STREAMS**

The XSI STREAMS Option Group is denoted by the symbolic constant \_XOPEN_STREAMS.

This Option Group includes functionality related to STREAMS, a uniform mechanism for implementing networking services and other character-based I/O as described in the System Interfaces volume of IEEE Std 1003.1-2001, Section 2.6, STREAMS.

It includes the following functions:

- fattach()
- fdetach()
- getmsg()
- getpmsg()
- ioctl()
- isastream()
- putmsg()
- putpmsg()

and the `<stropts.h>` header.

Where applicable, whole pages are marked STREAMS, together with the appropriate option margin legend for the SYNOPSIS section (see Section 1.5.1 (on page 6)). Where additional semantics have been added to existing pages, the new material is identified by use of the appropriate margin legend for the underlying option defined within IEEE Std 1003.1-2001.

An implementation that claims conformance to this Option Group shall set \_XOPEN_STREAMS to a value other than −1.

**Legacy**

The Legacy Option Group is denoted by the symbolic constant \_XOPEN_LEGACY.

The Legacy Option Group includes the functions and headers which were mandatory in previous versions of IEEE Std 1003.1-2001 but are optional in this version.

These functions and headers are retained in IEEE Std 1003.1-2001 because of their widespread use. Application writers should not rely on the existence of these functions or headers in new applications, but should follow the migration path detailed in the APPLICATION USAGE sections of the relevant pages.

Various factors may have contributed to the decision to mark a function or header LEGACY. In all cases, the specific reasons for the withdrawal of a function or header are documented on the relevant pages.

Once a function or header is marked LEGACY, no modifications are made to the specifications of such functions or headers other than to the APPLICATION USAGE sections of the relevant pages.

The functions and headers which form this Option Group are as follows:

- bcmp()
- bcopy()
- bzero()
- ecvt()
- fcvt()
- ftime()
- gcvt()
- getwd()
- index()
- mktemp()
- rindex()
- utimes()
- wcscs()

An implementation that claims conformance to this Option Group shall set \_XOPEN_LEGACY to a value other than −1.

### 2.1.6 Options

The symbolic constants defined in `<unistd.h>`, *Constants for Options and Option Groups* (on page 400) reflect implementation options for IEEE Std 1003.1-2001. These symbols can be used by the application to determine which optional facilities are present on the implementation. The `sysconf()` function defined in the System Interfaces volume of IEEE Std 1003.1-2001 or the `getconf` utility defined in the Shell and Utilities volume of IEEE Std 1003.1-2001 can be used to retrieve the value of each symbol on each specific implementation to determine whether the option is supported.
Where an option is not supported, the associated utilities, functions, or facilities need not be present.

Margin codes are defined for each option (see Section 1.5.1 (on page 6)).

### 2.1.6.1 System Interfaces

Refer to `<unistd.h>`, *Constants for Options and Option Groups* (on page 400) for the list of options.

### 2.1.6.2 Shell and Utilities

Each of these symbols shall be considered valid names by the implementation. Refer to `<unistd.h>`, *Constants for Options and Option Groups* (on page 400).

The literal names shown below apply only to the `getconf` utility.

- **CD**
  - POSIX2_C_DEV
    - The system supports the C-Language Development Utilities option.
    - The utilities in the C-Language Development Utilities option are used for the development of C-language applications, including compilation or translation of C source code and complex program generators for simple lexical tasks and processing of context-free grammars.
    - The utilities listed below may be provided by a conforming system; however, any system claiming conformance to the C-Language Development Utilities option shall provide all of the utilities listed.
      - `c99`
      - `lex`
      - `yacc`

- **POSIX2_CHAR_TERM**
  - The system supports the Terminal Characteristics option. This value need not be present on a system not supporting the User Portability Utilities option.
  - Where applicable, the dependency is noted within the description of the utility.
  - This option applies only to systems supporting the User Portability Utilities option. If supported, then the system supports at least one terminal type capable of all operations described in IEEE Std 1003.1-2001; see Section 10.2 (on page 185).

- **FD**
  - POSIX2_FORT_DEV
    - The system supports the FORTRAN Development Utilities option.
    - The `fort77` FORTRAN compiler is the only utility in the FORTRAN Development Utilities option. This is used for the development of FORTRAN language applications, including compilation or translation of FORTRAN source code.
    - The `fort77` utility may be provided by a conforming system; however, any system claiming conformance to the FORTRAN Development Utilities option shall provide the `fort77` utility.

- **FR**
  - POSIX2_FORT_RUN
    - The system supports the FORTRAN Runtime Utilities option.
    - The `asa` utility is the only utility in the FORTRAN Runtime Utilities option.
    - The `asa` utility may be provided by a conforming system; however, any system claiming conformance to the FORTRAN Runtime Utilities option shall provide the `asa` utility.
POSIX2_LOCALEDEF
The system supports the Locale Creation Utilities option.

If supported, the system supports the creation of locales as described in the localedef utility.

The localedef utility may be provided by a conforming system; however, any system claiming conformance to the Locale Creation Utilities option shall provide the localedef utility.

POSIX2_PBS
The system supports the Batch Environment Services and Utilities option (see the Shell and Utilities volume of IEEE Std 1003.1-2001, Chapter 3, Batch Environment Services).

Note: The Batch Environment Services and Utilities option is a combination of mandatory and optional batch services and utilities. The POSIX_PBS symbolic constant implies the system supports all the mandatory batch services and utilities.

POSIX2_PBS_ACCOUNTING
The system supports the Batch Accounting option.

POSIX2_PBS_CHECKPOINT
The system supports the Batch Checkpoint/Restart option.

POSIX2_PBS_LOCATE
The system supports the Locate Batch Job Request option.

POSIX2_PBS_MESSAGE
The system supports the Batch Job Message Request option.

POSIX2_PBS_TRACK
The system supports the Track Batch Job Request option.

POSIX2_SW_DEV
The system supports the Software Development Utilities option.

The utilities in the Software Development Utilities option are used for the development of applications, including compilation or translation of source code, the creation and maintenance of library archives, and the maintenance of groups of inter-dependent programs.

The utilities listed below may be provided by the conforming system; however, any system claiming conformance to the Software Development Utilities option shall provide all of the utilities listed here.

    ar
    make
    nm
    strip

POSIX2_UPE
The system supports the User Portability Utilities option.

The utilities in the User Portability Utilities option shall be implemented on all systems that claim conformance to this option. Certain utilities are noted as having features that cannot be implemented on all terminal types; if the POSIX2_CHAR_TERM option is supported, the system shall support all such features on at least one terminal type; see Section 10.2 (on page 185).

Some of the utilities are required only on systems that also support the Software Development Utilities option, or the character-at-a-time terminal option (see Section 10.2 (on page 185)); such utilities have this noted in their DESCRIPTION sections. All of the
other utilities listed are required only on systems that claim conformance to the User Portability Utilities option.

alias expand nm unalias
at fc patch unexpand
batch fg ps uudecode
bg file renice uuencode
crontab jobs split vi
df man strings who
ctags mesg tabs write
du newgrp time
ex nice put

2.2 Application Conformance

All applications claiming conformance to IEEE Std 1003.1-2001 shall use only language-dependent services for the C programming language described in Section 2.3 (on page 33), shall use only the utilities and facilities defined in the Shell and Utilities volume of IEEE Std 1003.1-2001, and shall fall within one of the following categories.

2.2.1 Strictly Conforming POSIX Application

A Strictly Conforming POSIX Application is an application that requires only the facilities described in IEEE Std 1003.1-2001. Such an application:

1. Shall accept any implementation behavior that results from actions it takes in areas described in IEEE Std 1003.1-2001 as implementation-defined or unspecified, or where IEEE Std 1003.1-2001 indicates that implementations may vary

2. Shall not perform any actions that are described as producing undefined results

3. For symbolic constants, shall accept any value in the range permitted by IEEE Std 1003.1-2001, but shall not rely on any value in the range being greater than the minimums listed or being less than the maximums listed in IEEE Std 1003.1-2001

4. Shall not use facilities designated as obsolescent

5. Is required to tolerate and permitted to adapt to the presence or absence of optional facilities whose availability is indicated by Section 2.1.3 (on page 18)

6. For the C programming language, shall not produce any output dependent on any behavior described in the ISO/IEC 9899:1999 standard as unspecified, undefined, or implementation-defined, unless the System Interfaces volume of IEEE Std 1003.1-2001 specifies the behavior

7. For the C programming language, shall not exceed any minimum implementation limit defined in the ISO/IEC 9899:1999 standard, unless the System Interfaces volume of IEEE Std 1003.1-2001 specifies a higher minimum implementation limit

8. For the C programming language, shall define _POSIX_C_SOURCE to be 200112L before any header is included

Within IEEE Std 1003.1-2001, any restrictions placed upon a Conforming POSIX Application shall restrict a Strictly Conforming POSIX Application.
2.2.2 Conforming POSIX Application

2.2.2.1 ISO/IEC Conforming POSIX Application

An ISO/IEC Conforming POSIX Application is an application that uses only the facilities described in IEEE Std 1003.1-2001 and approved Conforming Language bindings for any ISO or IEC standard. Such an application shall include a statement of conformance that documents all options and limit dependencies, and all other ISO or IEC standards used.

2.2.2.2 <National Body> Conforming POSIX Application

A <National Body> Conforming POSIX Application differs from an ISO/IEC Conforming POSIX Application in that it also may use specific standards of a single ISO/IEC member body referred to here as <National Body>. Such an application shall include a statement of conformance that documents all options and limit dependencies, and all other <National Body> standards used.

2.2.3 Conforming POSIX Application Using Extensions

A Conforming POSIX Application Using Extensions is an application that differs from a Conforming POSIX Application only in that it uses non-standard facilities that are consistent with IEEE Std 1003.1-2001. Such an application shall fully document its requirements for these extended facilities, in addition to the documentation required of a Conforming POSIX Application. A Conforming POSIX Application Using Extensions shall be either an ISO/IEC Conforming POSIX Application Using Extensions or a <National Body> Conforming POSIX Application Using Extensions (see Section 2.2.2.1 and Section 2.2.2.2).

2.2.4 Strictly Conforming XSI Application

A Strictly Conforming XSI Application is an application that requires only the facilities described in IEEE Std 1003.1-2001. Such an application:

1. Shall accept any implementation behavior that results from actions it takes in areas described in IEEE Std 1003.1-2001 as implementation-defined or unspecified, or where IEEE Std 1003.1-2001 indicates that implementations may vary

2. Shall not perform any actions that are described as producing undefined results

3. For symbolic constants, shall accept any value in the range permitted by IEEE Std 1003.1-2001, but shall not rely on any value in the range being greater than the minimums listed or being less than the maximums listed in IEEE Std 1003.1-2001

4. Shall not use facilities designated as obsolescent

5. Is required to tolerate and permitted to adapt to the presence or absence of optional facilities whose availability is indicated by Section 2.1.4 (on page 21)

6. For the C programming language, shall not produce any output dependent on any behavior described in the ISO C standard as unspecified, undefined, or implementation-defined, unless the System Interfaces volume of IEEE Std 1003.1-2001 specifies the behavior

7. For the C programming language, shall not exceed any minimum implementation limit defined in the ISO C standard, unless the System Interfaces volume of IEEE Std 1003.1-2001 specifies a higher minimum implementation limit

8. For the C programming language, shall define _XOPEN_SOURCE to be 600 before any header is included
Within IEEE Std 1003.1-2001, any restrictions placed upon a Conforming POSIX Application shall restrict a Strictly Conforming XSI Application.

2.2.5 Conforming XSI Application Using Extensions
A Conforming XSI Application Using Extensions is an application that differs from a Strictly Conforming XSI Application only in that it uses non-standard facilities that are consistent with IEEE Std 1003.1-2001. Such an application shall fully document its requirements for these extended facilities, in addition to the documentation required of a Strictly Conforming XSI Application.

2.3 Language-Dependent Services for the C Programming Language
Implementors seeking to claim conformance using the ISO C standard shall claim POSIX conformance as described in Section 2.1.3 (on page 18).

2.4 Other Language-Related Specifications
IEEE Std 1003.1-2001 is currently specified in terms of the shell command language and ISO C. Bindings to other programming languages are being developed.

If conformance to IEEE Std 1003.1-2001 is claimed for implementation of any programming language, the implementation of that language shall support the use of external symbols distinct to at least 31 bytes in length in the source program text. (That is, identifiers that differ at or before the thirty-first byte shall be distinct.) If a national or international standard governing a language defines a maximum length that is less than this value, the language-defined maximum shall be supported. External symbols that differ only by case shall be distinct when the character set in use distinguishes uppercase and lowercase characters and the language permits (or requires) uppercase and lowercase characters to be distinct in external symbols.
Definitions

For the purposes of IEEE Std 1003.1-2001, the terms and definitions given in Chapter 3 apply.

Note: No shading to denote extensions or options occurs in this chapter. Where the terms and definitions given in this chapter are used elsewhere in text related to extensions and options, they are shaded as appropriate.

3.1 Abortive Release
An abrupt termination of a network connection that may result in the loss of data.

3.2 Absolute Pathname
A pathname beginning with a single or more than two slashes; see also Section 3.266 (on page 72).

Note: Pathname Resolution is defined in detail in Section 4.11 (on page 102).

3.3 Access Mode
A particular form of access permitted to a file.

3.4 Additional File Access Control Mechanism
An implementation-defined mechanism that is layered upon the access control mechanisms defined here, but which do not grant permissions beyond those defined herein, although they may further restrict them.

Note: File Access Permissions are defined in detail in Section 4.4 (on page 99).

3.5 Address Space
The memory locations that can be referenced by a process or the threads of a process.

3.6 Advisory Information
An interface that advises the implementation on (portable) application behavior so that it can optimize the system.
3.7 Affirmative Response

An input string that matches one of the responses acceptable to the \texttt{LC\_MESSAGES} category keyword \texttt{yesexpr}, matching an extended regular expression in the current locale.

\textbf{Note:} The \texttt{LC\_MESSAGES} category is defined in detail in Section 7.3.6 (on page 152).

3.8 Alert

To cause the user’s terminal to give some audible or visual indication that an error or some other event has occurred. When the standard output is directed to a terminal device, the method for alerting the terminal user is unspecified. When the standard output is not directed to a terminal device, the alert is accomplished by writing the \texttt{<alert>} to standard output (unless the utility description indicates that the use of standard output produces undefined results in this case).

3.9 Alert Character (\texttt{<alert>})

A character that in the output stream should cause a terminal to alert its user via a visual or audible notification. It is the character designated by ‘\texttt{\a}’ in the C language. It is unspecified whether this character is the exact sequence transmitted to an output device by the system to accomplish the alert function.

3.10 Alias Name

In the shell command language, a word consisting solely of underscores, digits, and alphabetics from the portable character set and any of the following characters: ‘!’, ‘\%', ‘,’ ‘@’. Implementations may allow other characters within alias names as an extension.

\textbf{Note:} The Portable Character Set is defined in detail in Section 6.1 (on page 115).

3.11 Alignment

A requirement that objects of a particular type be located on storage boundaries with addresses that are particular multiples of a byte address.

\textbf{Note:} See also the ISO C standard, Section B3.

3.12 Alternate File Access Control Mechanism

An implementation-defined mechanism that is independent of the access control mechanisms defined herein, and which if enabled on a file may either restrict or extend the permissions of a given user. IEEE Std 1003.1-2001 defines when such mechanisms can be enabled and when they are disabled.

\textbf{Note:} File Access Permissions are defined in detail in Section 4.4 (on page 99).
3.13 **Alternate Signal Stack**

Memory associated with a thread, established upon request by the implementation for a thread, separate from the thread signal stack, in which signal handlers responding to signals sent to that thread may be executed.

3.14 **Ancillary Data**

Protocol-specific, local system-specific, or optional information. The information can be both local or end-to-end significant, header information, part of a data portion, protocol-specific, and implementation or system-specific.

3.15 **Angle Brackets**

The characters ‘<’ (left-angle-bracket) and ‘>’ (right-angle-bracket). When used in the phrase “enclosed in angle brackets”, the symbol ‘<’ immediately precedes the object to be enclosed, and ‘>’ immediately follows it. When describing these characters in the portable character set, the names <less-than-sign> and <greater-than-sign> are used.

3.16 **Application**

A computer program that performs some desired function.

3.17 **Application Address**

Endpoint address of a specific application.

3.18 **Application Program Interface (API)**

The definition of syntax and semantics for providing computer system services.

3.19 **Appropriate Privileges**

An implementation-defined means of associating privileges with a process with regard to the function calls, function call options, and the commands that need special privileges. There may be zero or more such means. These means (or lack thereof) are described in the conformance document.

**Note:** Function calls are defined in the System Interfaces volume of IEEE Std 1003.1-2001, and commands are defined in the Shell and Utilities volume of IEEE Std 1003.1-2001.

3.20 **Argument**

In the shell command language, a parameter passed to a utility as the equivalent of a single string in the `argv` array created by one of the `exec` functions. An argument is one of the options, option-arguments, or operands following the command name.

**Note:** The Utility Argument Syntax is defined in detail in Section 12.1 (on page 201) and the Shell and Utilities volume of IEEE Std 1003.1-2001, Section 2.9.1.1, Command Search and Execution.

In the C language, an expression in a function call expression or a sequence of preprocessing tokens in a function-like macro invocation.

3.21 **Arm (a Timer)**

To start a timer measuring the passage of time, enabling notifying a process when the specified time or time interval has passed.

3.22 **Asterisk**

The character `'*'`.

3.23 **Async-Cancel-Safe Function**

A function that may be safely invoked by an application while the asynchronous form of cancellation is enabled. No function is async-cancel-safe unless explicitly described as such.

3.24 **Asynchronous Events**

Events that occur independently of the execution of the application.

3.25 **Asynchronous Input and Output**

A functionality enhancement to allow an application process to queue data input and output commands with asynchronous notification of completion.

3.26 **Async-Signal-Safe Function**

A function that may be invoked, without restriction, from signal-catching functions. No function is async-signal-safe unless explicitly described as such.
3.27 Asynchronously-Generated Signal

A signal that is not attributable to a specific thread. Examples are signals sent via `kill()`, signals sent from the keyboard, and signals delivered to process groups. Being asynchronous is a property of how the signal was generated and not a property of the signal number. All signals may be generated asynchronously.

Note: The `kill()` function is defined in detail in the System Interfaces volume of IEEE Std 1003.1-2001.

3.28 Asynchronous I/O Completion

For an asynchronous read or write operation, when a corresponding synchronous read or write would have completed and when any associated status fields have been updated.

3.29 Asynchronous I/O Operation

An I/O operation that does not of itself cause the thread requesting the I/O to be blocked from further use of the processor.

This implies that the process and the I/O operation may be running concurrently.

3.30 Authentication

The process of validating a user or process to verify that the user or process is not a counterfeit.

3.31 Authorization

The process of verifying that a user or process has permission to use a resource in the manner requested.

To ensure security, the user or process would also need to be authenticated before granting access.

3.32 Background Job

See Background Process Group in Section 3.34.

3.33 Background Process

A process that is a member of a background process group.

3.34 Background Process Group (or Background Job)

Any process group, other than a foreground process group, that is a member of a session that has established a connection with a controlling terminal.
3.35 Backquote
The character ‘\’’, also known as a grave accent.

3.36 Backslash
The character ‘\’’, also known as a reverse solidus.

3.37 Backspace Character (<backspace>)
A character that, in the output stream, should cause printing (or displaying) to occur one column position previous to the position about to be printed. If the position about to be printed is at the beginning of the current line, the behavior is unspecified. It is the character designated by ‘\b’ in the C language. It is unspecified whether this character is the exact sequence transmitted to an output device by the system to accomplish the backspace function. The <backspace> defined here is not necessarily the ERASE special character.

Note: Special Characters are defined in detail in Section 11.1.9 (on page 191).

3.38 Barrier
A synchronization object that allows multiple threads to synchronize at a particular point in their execution.

3.39 Base Character
One of the set of characters defined in the Latin alphabet. In Western European languages other than English, these characters are commonly used with diacritical marks (accents, cedilla, and so on) to extend the range of characters in an alphabet.

3.40 Basename
The final, or only, filename in a pathname.

3.41 Basic Regular Expression (BRE)
A regular expression (see Section 3.316 (on page 79)) used by the majority of utilities that select strings from a set of character strings.

Note: Basic Regular Expressions are described in detail in Section 9.3 (on page 171).

3.42 Batch Access List
A list of user IDs and group IDs of those users and groups authorized to place batch jobs in a batch queue.

A batch access list is associated with a batch queue. A batch server uses the batch access list of a batch queue as one of the criteria in deciding to put a batch job in a batch queue.
3.43 **Batch Administrator**

A user that is authorized to modify all the attributes of queues and jobs and to change the status of a batch server.

3.44 **Batch Client**

A computational entity that utilizes batch services by making requests of batch servers.

Batch clients often provide the means by which users access batch services, although a batch server may act as a batch client by virtue of making requests of another batch server.

3.45 **Batch Destination**

The batch server in a batch system to which a batch job should be sent for processing.

Acceptance of a batch job at a batch destination is the responsibility of a receiving batch server.

A batch destination may consist of a batch server-specific portion, a network-wide portion, or both. The batch server-specific portion is referred to as the "batch queue". The network-wide portion is referred to as a "batch server name".

3.46 **Batch Destination Identifier**

A string that identifies a specific batch destination.

A string of characters in the portable character set used to specify a particular batch destination.

**Note:** The Portable Character Set is defined in detail in Section 6.1 (on page 115).

3.47 **Batch Directive**

A line from a file that is interpreted by the batch server. The line is usually in the form of a comment and is an additional means of passing options to the *qsub* utility.

**Note:** The *qsub* utility is defined in detail in the Shell and Utilities volume of IEEE Std 1003.1-2001.

3.48 **Batch Job**

A set of computational tasks for a computing system.

Batch jobs are managed by batch servers.

Once created, a batch job may be executing or pending execution. A batch job that is executing has an associated session leader (a process) that initiates and monitors the computational tasks of the batch job.
**Batch Job Attribute**

A named data type whose value affects the processing of a batch job. The values of the attributes of a batch job affect the processing of that job by the batch server that manages the batch job.

**Batch Job Identifier**

A unique name for a batch job. A name that is unique among all other batch job identifiers in a batch system and that identifies the batch server to which the batch job was originally submitted.

**Batch Job Name**

A label that is an attribute of a batch job. The batch job name is not necessarily unique.

**Batch Job Owner**

The `username@hostname` of the user submitting the batch job, where `username` is a user name (see also Section 3.426 (on page 94)) and `hostname` is a network host name.

**Batch Job Priority**

A value specified by the user that may be used by an implementation to determine the order in which batch jobs are selected to be executed. Job priority has a numeric value in the range $-1024$ to $1023$.

*Note:* The batch job priority is not the execution priority (nice value) of the batch job.

**Batch Job State**

An attribute of a batch job which determines the types of requests that the batch server that manages the batch job can accept for the batch job. Valid states include QUEUED, RUNNING, HELD, WAITING, EXITING, and TRANSITING.

**Batch Name Service**

A service that assigns batch names that are unique within the batch name space, and that can translate a unique batch name into the location of the named batch entity.

**Batch Name Space**

The environment within which a batch name is known to be unique.
3.57 **Batch Node**

A host containing part or all of a batch system.

A batch node is a host meeting at least one of the following conditions:

- Capable of executing a batch client
- Contains a routing batch queue
- Contains an execution batch queue

3.58 **Batch Operator**

A user that is authorized to modify some, but not all, of the attributes of jobs and queues, and may change the status of the batch server.

3.59 **Batch Queue**

A manageable object that represents a set of batch jobs and is managed by a single batch server.

**Note:** A set of batch jobs is called a batch queue largely for historical reasons. Jobs are selected from the batch queue for execution based on attributes such as priority, resource requirements, and hold conditions. See also the Shell and Utilities volume of IEEE Std 1003.1-2001, Section 3.1.2, Batch Queues.

3.60 **Batch Queue Attribute**

A named data type whose value affects the processing of all batch jobs that are members of the batch queue.

A batch queue has attributes that affect the processing of batch jobs that are members of the batch queue.

3.61 **Batch Queue Position**

The place, relative to other jobs in the batch queue, occupied by a particular job in a batch queue. This is defined in part by submission time and priority; see also Section 3.62.

3.62 **Batch Queue Priority**

The maximum job priority allowed for any batch job in a given batch queue.

The batch queue priority is set and may be changed by users with appropriate privilege. The priority is bounded in an implementation-defined manner.

3.63 **Batch Rerunability**

An attribute of a batch job indicating that it may be rerun after an abnormal termination from the beginning without affecting the validity of the results.
3.64 **Batch Restart**

The action of resuming the processing of a batch job from the point of the last checkpoint. Typically, this is done if the batch job has been interrupted because of a system failure.

3.65 **Batch Server**

A computational entity that provides batch services.

3.66 **Batch Server Name**

A string of characters in the portable character set used to specify a particular server in a network.

**Note:** The Portable Character Set is defined in detail in Section 6.1 (on page 115).

3.67 **Batch Service**

Computational and organizational services performed by a batch system on behalf of batch jobs.

Batch services are of two types: requested and deferred.

**Note:** Batch Services are listed in the Shell and Utilities volume of IEEE Std 1003.1-2001, Table 3-5, Batch Services Summary.

3.68 **Batch Service Request**

A solicitation of services from a batch client to a batch server.

A batch service request may entail the exchange of any number of messages between the batch client and the batch server.

When naming specific types of service requests, the term “request” is qualified by the type of request, as in Queue Batch Job Request and Delete Batch Job Request.

3.69 **Batch Submission**

The process by which a batch client requests that a batch server create a batch job via a Queue Job Request to perform a specified computational task.

3.70 **Batch System**

A collection of one or more batch servers.
3.71 **Batch Target User**
The name of a user on the batch destination batch server.
The target user is the user name under whose account the batch job is to execute on the destination batch server.

3.72 **Batch User**
A user who is authorized to make use of batch services.

3.73 **Bind**
The process of assigning a network address to an endpoint.

3.74 **Blank Character (<blank>)**
One of the characters that belong to the blank character class as defined via the LC_CTYPE category in the current locale. In the POSIX locale, a <blank> is either a <tab> or a <space>.

3.75 **Blank Line**
A line consisting solely of zero or more <blank>s terminated by a <newline>; see also Section 3.144 (on page 55).

3.76 **Blocked Process (or Thread)**
A process (or thread) that is waiting for some condition (other than the availability of a processor) to be satisfied before it can continue execution.

3.77 **Blocking**
A property of an open file description that causes function calls associated with it to wait for the requested action to be performed before returning.

3.78 **Block-Mode Terminal**
A terminal device operating in a mode incapable of the character-at-a-time input and output operations described by some of the standard utilities.

**Note:** Output Devices and Terminal Types are defined in detail in Section 10.2 (on page 185).
3.79 Block Special File

A file that refers to a device. A block special file is normally distinguished from a character special file by providing access to the device in a manner such that the hardware characteristics of the device are not visible.

3.80 Braces

The characters '{' (left brace) and '}' (right brace), also known as curly braces. When used in the phrase "enclosed in (curly) braces" the symbol '{' immediately precedes the object to be enclosed, and '}' immediately follows it. When describing these characters in the portable character set, the names <left-brace> and <right-brace> are used.

3.81 Brackets

The characters '[' (left-bracket) and ']' (right-bracket), also known as square brackets. When used in the phrase "enclosed in (square) brackets" the symbol '[' immediately precedes the object to be enclosed, and ']' immediately follows it. When describing these characters in the portable character set, the names <left-square-bracket> and <right-square-bracket> are used.

3.82 Broadcast

The transfer of data from one endpoint to several endpoints, as described in RFC 919 and RFC 922.

3.83 Built-In Utility (or Built-In)

A utility implemented within a shell. The utilities referred to as special built-ins have special qualities. Unless qualified, the term "built-in" includes the special built-in utilities. Regular built-ins are not required to be actually built into the shell on the implementation, but they do have special command-search qualities.

Note: Special Built-In Utilities are defined in detail in the Shell and Utilities volume of IEEE Std 1003.1-2001, Section 2.14, Special Built-In Utilities.

Regular Built-In Utilities are defined in detail in the Shell and Utilities volume of IEEE Std 1003.1-2001, Section 2.9.1.1, Command Search and Execution.

3.84 Byte

An individually addressable unit of data storage that is exactly an octet, used to store a character or a portion of a character; see also Section 3.87 (on page 47). A byte is composed of a contiguous sequence of 8 bits. The least significant bit is called the "low-order" bit; the most significant is called the "high-order" bit.

Note: The definition of byte from the ISO C standard is broader than the above and might accommodate hardware architectures with different sized addressable units than octets.
Definitions

3.85 Byte Input/Output Functions

The functions that perform byte-oriented input from streams or byte-oriented output to streams:

fgetc(), fgets(), fprintf(), fputc(), fputs(), fread(), fscanf(), fwrite(), getc(), getchar(), gets(), printf(), putc(), putchar(), puts(), scanf(), ungetc(), vfprintf(), and vprintf().

Note: Functions are defined in detail in the System Interfaces volume of IEEE Std 1003.1-2001.

3.86 Carriage-Return Character (<carriage-return>)

A character that in the output stream indicates that printing should start at the beginning of the same physical line in which the <carriage-return> occurred. It is the character designated by ‘\r’ in the C language. It is unspecified whether this character is the exact sequence transmitted to an output device by the system to accomplish the movement to the beginning of the line.

3.87 Character

A sequence of one or more bytes representing a single graphic symbol or control code.

Note: This term corresponds to the ISO C standard term multi-byte character, where a single-byte character is a special case of a multi-byte character. Unlike the usage in the ISO C standard, character here has no necessary relationship with storage space, and byte is used when storage space is discussed.

See the definition of the portable character set in Section 6.1 (on page 115) for a further explanation of the graphical representations of (abstract) characters, as opposed to character encodings.

3.88 Character Array

An array of elements of type char.

3.89 Character Class

A named set of characters sharing an attribute associated with the name of the class. The classes and the characters that they contain are dependent on the value of the LC_CTYPE category in the current locale.

Note: The LC_CTYPE category is defined in detail in Section 7.3.1 (on page 126).

3.90 Character Set

A finite set of different characters used for the representation, organization, or control of data.
3.91 Character Special File
A file that refers to a device. One specific type of character special file is a terminal device file.

Note: The General Terminal Interface is defined in detail in Chapter 11 (on page 187).

3.92 Character String
A contiguous sequence of characters terminated by and including the first null byte.

3.93 Child Process
A new process created (by fork(), posix_spawn(), or posix_spawnp()) by a given process. A child process remains the child of the creating process as long as both processes continue to exist.

Note: The fork(), posix_spawn(), and posix_spawnp() functions are defined in detail in the System Interfaces volume of IEEE Std 1003.1-2001.

3.94 Circumflex
The character ‘ˆ’.

3.95 Clock
A software or hardware object that can be used to measure the apparent or actual passage of time.

The current value of the time measured by a clock can be queried and, possibly, set to a value within the legal range of the clock.

3.96 Clock Jump
The difference between two successive distinct values of a clock, as observed from the application via one of the ‘get time’ operations.

3.97 Clock Tick
An interval of time; an implementation-defined number of these occur each second. Clock ticks are one of the units that may be used to express a value found in type clock_t.

3.98 Coded Character Set
A set of unambiguous rules that establishes a character set and the one-to-one relationship between each character of the set and its bit representation.
3.99 Codeset

The result of applying rules that map a numeric code value to each element of a character set. An element of a character set may be related to more than one numeric code value but the reverse is not true. However, for state-dependent encodings the relationship between numeric code values and elements of a character set may be further controlled by state information. The character set may contain fewer elements than the total number of possible numeric code values; that is, some code values may be unassigned.

Note: Character Encoding is defined in detail in Section 6.2 (on page 118).

3.100 Collating Element

The smallest entity used to determine the logical ordering of character or wide-character strings; see also Section 3.102. A collating element consists of either a single character, or two or more characters collating as a single entity. The value of the LC_COLLATE category in the current locale determines the current set of collating elements.

3.101 Collation

The logical ordering of character or wide-character strings according to defined precedence rules. These rules identify a collation sequence between the collating elements, and such additional rules that can be used to order strings consisting of multiple collating elements.

3.102 Collation Sequence

The relative order of collating elements as determined by the setting of the LC_COLLATE category in the current locale. The collation sequence is used for sorting and is determined from the collating weights assigned to each collating element. In the absence of weights, the collation sequence is the order in which collating elements are specified between order_start and order_end keywords in the LC_COLLATE category.

Multi-level sorting is accomplished by assigning elements one or more collation weights, up to the limit {COLL_WEIGHTS_MAX}. On each level, elements may be given the same weight (at the primary level, called an equivalence class; see also Section 3.150 (on page 55)) or be omitted from the sequence. Strings that collate equally using the first assigned weight (primary ordering) are then compared using the next assigned weight (secondary ordering), and so on.

Note: {COLL_WEIGHTS_MAX} is defined in detail in <limits.h>.

3.103 Column Position

A unit of horizontal measure related to characters in a line.

It is assumed that each character in a character set has an intrinsic column width independent of any output device. Each printable character in the portable character set has a column width of one. The standard utilities, when used as described in IEEE Std 1003.1-2001, assume that all characters have integral column widths. The column width of a character is not necessarily related to the internal representation of the character (numbers of bits or bytes).

The column position of a character in a line is defined as one plus the sum of the column widths of the preceding characters in the line. Column positions are numbered starting from 1.
3.104 Command

A directive to the shell to perform a particular task.

Note: Shell Commands are defined in detail in the Shell and Utilities volume of IEEE Std 1003.1-2001, Section 2.9, Shell Commands.

3.105 Command Language Interpreter

An interface that interprets sequences of text input as commands. It may operate on an input stream or it may interactively prompt and read commands from a terminal. It is possible for applications to invoke utilities through a number of interfaces, which are collectively considered to act as command interpreters. The most obvious of these are the *sh* utility and the *system()* function, although *popen()* and the various forms of *exec* may also be considered to behave as interpreters.

3.106 Composite Graphic Symbol

A graphic symbol consisting of a combination of two or more other graphic symbols in a single character position, such as a diacritical mark and a base character.

3.107 Condition Variable

A synchronization object which allows a thread to suspend execution, repeatedly, until some associated predicate becomes true. A thread whose execution is suspended on a condition variable is said to be blocked on the condition variable.

3.108 Connection

An association established between two or more endpoints for the transfer of data

3.109 Connection Mode

The transfer of data in the context of a connection; see also Section 3.110.

3.110 Connectionless Mode

The transfer of data other than in the context of a connection; see also Section 3.109 and Section 3.123 (on page 52).
3.111 **Control Character**

A character, other than a graphic character, that affects the recording, processing, transmission, or interpretation of text.

3.112 **Control Operator**

In the shell command language, a token that performs a control function. It is one of the following symbols:

&& & (); ; newline | |

The end-of-input indicator used internally by the shell is also considered a control operator.

*Note:* Token Recognition is defined in detail in the Shell and Utilities volume of IEEE Std 1003.1-2001, Section 2.3, Token Recognition.

3.113 **Controlling Process**

The session leader that established the connection to the controlling terminal. If the terminal subsequently ceases to be a controlling terminal for this session, the session leader ceases to be the controlling process.

3.114 **Controlling Terminal**

A terminal that is associated with a session. Each session may have at most one controlling terminal associated with it, and a controlling terminal is associated with exactly one session. Certain input sequences from the controlling terminal cause signals to be sent to all processes in the process group associated with the controlling terminal.

*Note:* The General Terminal Interface is defined in detail in Chapter 11 (on page 187).

3.115 **Conversion Descriptor**

A per-process unique value used to identify an open codeset conversion.

3.116 **Core File**

A file of unspecified format that may be generated when a process terminates abnormally.

3.117 **CPU Time (Execution Time)**

The time spent executing a process or thread, including the time spent executing system services on behalf of that process or thread. If the Threads option is supported, then the value of the CPU-time clock for a process is implementation-defined. With this definition the sum of all the execution times of all the threads in a process might not equal the process execution time, even in a single-threaded process, because implementations may differ in how they account for time during context switches or for other reasons.
3.118 **CPU-Time Clock**
A clock that measures the execution time of a particular process or thread.

3.119 **CPU-Time Timer**
A timer attached to a CPU-time clock.

3.120 **Current Job**
In the context of job control, the job that will be used as the default for the `fg` or `bg` utilities. There is at most one current job; see also Section 3.203 (on page 63).

3.121 **Current Working Directory**
See *Working Directory* in Section 3.436 (on page 96).

3.122 **Cursor Position**
The line and column position on the screen denoted by the terminal’s cursor.

3.123 **Datagram**
A unit of data transferred from one endpoint to another in connectionless mode service.

3.124 **Data Segment**
Memory associated with a process, that can contain dynamically allocated data.

3.125 **Deferred Batch Service**
A service that is performed as a result of events that are asynchronous with respect to requests.

Note: Once a batch job has been created, it is subject to deferred services.

3.126 **Device**
A computer peripheral or an object that appears to the application as such.

3.127 **Device ID**
A non-negative integer used to identify a device.
3.128 **Directory**

A file that contains directory entries. No two directory entries in the same directory have the same name.

3.129 **Directory Entry (or Link)**

An object that associates a filename with a file. Several directory entries can associate names with the same file.

3.130 **Directory Stream**

A sequence of all the directory entries in a particular directory. An open directory stream may be implemented using a file descriptor.

3.131 **Disarm (a Timer)**

To stop a timer from measuring the passage of time, disabling any future process notifications (until the timer is armed again).

3.132 **Display**

To output to the user’s terminal. If the output is not directed to a terminal, the results are undefined.

3.133 **Display Line**

A line of text on a physical device or an emulation thereof. Such a line will have a maximum number of characters which can be presented.

Note: This may also be written as “line on the display”.

3.134 **Dollar Sign**

The character ‘$’.

3.135 **Dot**

In the context of naming files, the filename consisting of a single dot character (‘.’).

Note: In the context of shell special built-in utilities, see *dot* in the Shell and Utilities volume of IEEE Std 1003.1-2001, Section 2.14, Special Built-In Utilities.

Pathname Resolution is defined in detail in Section 4.11 (on page 102).
3.136 **Dot-Dot**

The filename consisting solely of two dot characters (". . ").

**Note:** Pathname Resolution is defined in detail in Section 4.11 (on page 102).

3.137 **Double-Quote**

The character ‘“’, also known as quotation-mark.

**Note:** The “double” adjective in this term refers to the two strokes in the character glyph.

IEEE Std 1003.1-2001 never uses the term “double-quote” to refer to two apostrophes or quotation marks.

3.138 **Downshifting**

The conversion of an uppercase character that has a single-character lowercase representation into this lowercase representation.

3.139 **Driver**

A module that controls data transferred to and received from devices.

**Note:** Drivers are traditionally written to be a part of the system implementation, although they are frequently written separately from the writing of the implementation. A driver may contain processor-specific code, and therefore be non-portable.

3.140 **Effective Group ID**

An attribute of a process that is used in determining various permissions, including file access permissions; see also Section 3.188 (on page 61).

3.141 **Effective User ID**

An attribute of a process that is used in determining various permissions, including file access permissions; see also Section 3.425 (on page 94).

3.142 **Eight-Bit Transparency**

The ability of a software component to process 8-bit characters without modifying or utilizing any part of the character in a way that is inconsistent with the rules of the current coded character set.

3.143 **Empty Directory**

A directory that contains, at most, directory entries for dot and dot-dot, and has exactly one link to it, in dot-dot. No other links to the directory may exist. It is unspecified whether an implementation can ever consider the root directory to be empty.
3.144 Empty Line
A line consisting of only a <newline>; see also Section 3.75 (on page 45).

3.145 Empty String (or Null String)
A string whose first byte is a null byte.

3.146 Empty Wide-Character String
A wide-character string whose first element is a null wide-character code.

3.147 Encoding Rule
The rules used to convert between wide-character codes and multi-byte character codes.

Note: Stream Orientation and Encoding Rules are defined in detail in the System Interfaces volume of IEEE Std 1003.1-2001, Section 2.5.2, Stream Orientation and Encoding Rules.

3.148 Entire Regular Expression
The concatenated set of one or more basic regular expressions or extended regular expressions that make up the pattern specified for string selection.

Note: Regular Expressions are defined in detail in Chapter 9 (on page 169).

3.149 Epoch
The time zero hours, zero minutes, zero seconds, on January 1, 1970 Coordinated Universal Time (UTC).

Note: See also Seconds Since the Epoch defined in Section 4.14 (on page 104).

3.150 Equivalence Class
A set of collating elements with the same primary collation weight.
Elements in an equivalence class are typically elements that naturally group together, such as all accented letters based on the same base letter.
The collation order of elements within an equivalence class is determined by the weights assigned on any subsequent levels after the primary weight.

3.151 Era
A locale-specific method for counting and displaying years.

Note: The LC_TIME category is defined in detail in Section 7.3.5 (on page 147).
**Era Definitions**

3.152 **Event Management**

The mechanism that enables applications to register for and be made aware of external events such as data becoming available for reading.

3.153 **Executable File**

A regular file acceptable as a new process image file by the equivalent of the `exec` family of functions, and thus usable as one form of a utility. The standard utilities described as compilers can produce executable files, but other unspecified methods of producing executable files may also be provided. The internal format of an executable file is unspecified, but a conforming application cannot assume an executable file is a text file.

3.154 **Execute**

To perform command search and execution actions, as defined in the Shell and Utilities volume of IEEE Std 1003.1-2001; see also Section 3.200 (on page 62).

Note: Command Search and Execution is defined in detail in the Shell and Utilities volume of IEEE Std 1003.1-2001, Section 2.9.1.1, Command Search and Execution.

3.155 **Execution Time**

See CPU Time in Section 3.117 (on page 51).

3.156 **Execution Time Monitoring**

A set of execution time monitoring primitives that allow online measuring of thread and process execution times.

3.157 **Expand**

In the shell command language, when not qualified, the act of applying word expansions.

Note: Word Expansions are defined in detail in the Shell and Utilities volume of IEEE Std 1003.1-2001, Section 2.6, Word Expansions.

3.158 **Extended Regular Expression (ERE)**

A regular expression (see also Section 3.316 (on page 79)) that is an alternative to the Basic Regular Expression using a more extensive syntax, occasionally used by some utilities.

Note: Extended Regular Expressions are described in detail in Section 9.4 (on page 175).
3.159 Extended Security Controls

Implementation-defined security controls allowed by the file access permission and appropriate privilege (see also Section 3.19 (on page 37)) mechanisms, through which an implementation can support different security policies from those described in IEEE Std 1003.1-2001.

Note: See also Extended Security Controls defined in Section 4.3 (on page 99).

File Access Permissions are defined in detail in Section 4.4 (on page 99).

3.160 Feature Test Macro

A macro used to determine whether a particular set of features is included from a header.

Note: See also the System Interfaces volume of IEEE Std 1003.1-2001, Section 2.2, The Compilation Environment.

3.161 Field

In the shell command language, a unit of text that is the result of parameter expansion, arithmetic expansion, command substitution, or field splitting. During command processing, the resulting fields are used as the command name and its arguments.

Note: Parameter Expansion is defined in detail in the Shell and Utilities volume of IEEE Std 1003.1-2001, Section 2.6.2, Parameter Expansion.

Arithmetic Expansion is defined in detail in the Shell and Utilities volume of IEEE Std 1003.1-2001, Section 2.6.4, Arithmetic Expansion.

Command Substitution is defined in detail in the Shell and Utilities volume of IEEE Std 1003.1-2001, Section 2.6.3, Command Substitution.

Field Splitting is defined in detail in the Shell and Utilities volume of IEEE Std 1003.1-2001, Section 2.6.5, Field Splitting.

For further information on command processing, see the Shell and Utilities volume of IEEE Std 1003.1-2001, Section 2.9.1, Simple Commands.

3.162 FIFO Special File (or FIFO)

A type of file with the property that data written to such a file is read on a first-in-first-out basis.

Note: Other characteristics of FIFOs are described in the System Interfaces volume of IEEE Std 1003.1-2001, lseek(), open(), read(), and write().

3.163 File

An object that can be written to, or read from, or both. A file has certain attributes, including access permissions and type. File types include regular file, character special file, block special file, FIFO special file, symbolic link, socket, and directory. Other types of files may be supported by the implementation.
3.164 **File Description**

See *Open File Description* in Section 3.253 (on page 70).

3.165 **File Descriptor**

A per-process unique, non-negative integer used to identify an open file for the purpose of file access. The value of a file descriptor is from zero to |OPEN_MAX|. A process can have no more than |OPEN_MAX| file descriptors open simultaneously. File descriptors may also be used to implement message catalog descriptors and directory streams; see also Section 3.253 (on page 70).

Note: \(|OPEN_MAX|\) is defined in detail in `<limits.h>`.

3.166 **File Group Class**

The property of a file indicating access permissions for a process related to the group identification of a process. A process is in the file group class of a file if the process is not in the file owner class and if the effective group ID or one of the supplementary group IDs of the process matches the group ID associated with the file. Other members of the class may be implementation-defined.

3.167 **File Mode**

An object containing the file mode bits and file type of a file.

Note: File mode bits and file types are defined in detail in `<sys/stat.h>`.

3.168 **File Mode Bits**

A file's file permission bits: set-user-ID-on-execution bit (S_ISUID), set-group-ID-on-execution bit (S_ISGID), and, on directories, the restricted deletion flag bit (S_ISVTX).

Note: File Mode Bits are defined in detail in `<sys/stat.h>`.

3.169 **Filename**

A name consisting of 1 to |NAME_MAX| bytes used to name a file. The characters composing the name may be selected from the set of all character values excluding the slash character and the null byte. The filenames dot and dot-dot have special meaning. A filename is sometimes referred to as a “pathname component”.

Note: Pathname Resolution is defined in detail in Section 4.11 (on page 102).

3.170 **Filename Portability**

Filenames should be constructed from the portable filename character set because the use of other characters can be confusing or ambiguous in certain contexts. (For example, the use of a colon (’ : ’) in a pathname could cause ambiguity if that pathname were included in a *PATH* definition.)
3.171 File Offset

The byte position in the file where the next I/O operation begins. Each open file description associated with a regular file, block special file, or directory has a file offset. A character special file that does not refer to a terminal device may have a file offset. There is no file offset specified for a pipe or FIFO.

3.172 File Other Class

The property of a file indicating access permissions for a process related to the user and group identification of a process. A process is in the file other class of a file if the process is not in the file owner class or file group class.

3.173 File Owner Class

The property of a file indicating access permissions for a process related to the user identification of a process. A process is in the file owner class of a file if the effective user ID of the process matches the user ID of the file.

3.174 File Permission Bits

Information about a file that is used, along with other information, to determine whether a process has read, write, or execute/search permission to a file. The bits are divided into three parts: owner, group, and other. Each part is used with the corresponding file class of processes. These bits are contained in the file mode.

Note: File modes are defined in detail in `<sys/stat.h>`.

File Access Permissions are defined in detail in Section 4.4 (on page 99).

3.175 File Serial Number

A per-file system unique identifier for a file.

3.176 File System

A collection of files and certain of their attributes. It provides a name space for file serial numbers referring to those files.

3.177 File Type

See File in Section 3.163 (on page 57).
Filter

3.178 Filter
A command whose operation consists of reading data from standard input or a list of input files and writing data to standard output. Typically, its function is to perform some transformation on the data stream.

3.179 First Open (of a File)
When a process opens a file that is not currently an open file within any process.

3.180 Flow Control
The mechanism employed by a communications provider that constrains a sending entity to wait until the receiving entities can safely receive additional data without loss.

3.181 Foreground Job
See Foreground Process Group in Section 3.183.

3.182 Foreground Process
A process that is a member of a foreground process group.

3.183 Foreground Process Group (or Foreground Job)
A process group whose member processes have certain privileges, denied to processes in background process groups, when accessing their controlling terminal. Each session that has established a connection with a controlling terminal has at most one process group of the session as the foreground process group of that controlling terminal.

Note: The General Terminal Interface is defined in detail in Chapter 11.

3.184 Foreground Process Group ID
The process group ID of the foreground process group.

3.185 Form-Feed Character (<form-feed>)
A character that in the output stream indicates that printing should start on the next page of an output device. It is the character designated by ‘\f’ in the C language. If the <form-feed> is not the first character of an output line, the result is unspecified. It is unspecified whether this character is the exact sequence transmitted to an output device by the system to accomplish the movement to the next page.
3.186 Graphic Character
A member of the graph character class of the current locale.

Note: The graph character class is defined in detail in Section 7.3.1 (on page 126).

3.187 Group Database
A system database of implementation-defined format that contains at least the following
information for each group ID:
- Group name
- Numerical group ID
- List of users allowed in the group

The list of users allowed in the group is used by the newgrp utility.

Note: The newgrp utility is defined in detail in the Shell and Utilities volume of IEEE Std 1003.1-2001.

3.188 Group ID
A non-negative integer, which can be contained in an object of type gid_t, that is used to identify
a group of system users. Each system user is a member of at least one group. When the identity
of a group is associated with a process, a group ID value is referred to as a real group ID, an
effective group ID, one of the supplementary group IDs, or a saved set-group-ID.

3.189 Group Name
A string that is used to identify a group; see also Section 3.187. To be portable across conforming
systems, the value is composed of characters from the portable filename character set. The
hyphen should not be used as the first character of a portable group name.

3.190 Hard Limit
A system resource limitation that may be reset to a lesser or greater limit by a privileged process.
A non-privileged process is restricted to only lowering its hard limit.

3.191 Hard Link
The relationship between two directory entries that represent the same file; see also Section 3.129
(on page 53). The result of an execution of the ln utility (without the −s option) or the link() function. This term is contrasted against symbolic link; see also Section 3.372 (on page 86).

3.192 Home Directory
The directory specified by the HOME environment variable.
3.193 Host Byte Order

The arrangement of bytes in any integer type when using a specific machine architecture.

**Note:** Two common methods of byte ordering are big-endian and little-endian. Big-endian is a format for storage of binary data in which the most significant byte is placed first, with the rest in descending order. Little-endian is a format for storage or transmission of binary data in which the least significant byte is placed first, with the rest in ascending order. See also Section 4.8 (on page 101).

3.194 Incomplete Line

A sequence of one or more non-<newline>s at the end of the file.

3.195 Inf

A value representing +infinity or a value representing −infinity that can be stored in a floating type. Not all systems support the Inf values.

3.196 Instrumented Application

An application that contains at least one call to the trace point function `posix_trace_event()`. Each process of an instrumented application has a mapping of trace event names to trace event type identifiers. This mapping is used by the trace stream that is created for that process.

3.197 Interactive Shell

A processing mode of the shell that is suitable for direct user interaction.

3.198 Internationalization

The provision within a computer program of the capability of making itself adaptable to the requirements of different native languages, local customs, and coded character sets.

3.199 Interprocess Communication

A functionality enhancement to add a high-performance, deterministic interprocess communication facility for local communication.

3.200 Invoke

To perform command search and execution actions, except that searching for shell functions and special built-in utilities is suppressed; see also Section 3.154 (on page 56).

**Note:** Command Search and Execution is defined in detail in the Shell and Utilities volume of IEEE Std 1003.1-2001, Section 2.9.1.1, Command Search and Execution.
3.201 Job
A set of processes, comprising a shell pipeline, and any processes descended from it, that are all in the same process group.

Note: See also the Shell and Utilities volume of IEEE Std 1003.1-2001, Section 2.9.2, Pipelines.

3.202 Job Control
A facility that allows users selectively to stop (suspend) the execution of processes and continue (resume) their execution at a later point. The user typically employs this facility via the interactive interface jointly supplied by the terminal I/O driver and a command interpreter.

3.203 Job Control Job ID
A handle that is used to refer to a job. The job control job ID can be any of the forms shown in the following table:

Table 3-1 Job Control Job ID Formats

<table>
<thead>
<tr>
<th>Job Control Job ID</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>%%</td>
<td>Current job.</td>
</tr>
<tr>
<td>%+</td>
<td>Current job.</td>
</tr>
<tr>
<td>%−</td>
<td>Previous job.</td>
</tr>
<tr>
<td>%n</td>
<td>Job number n.</td>
</tr>
<tr>
<td>%string</td>
<td>Job whose command begins with string.</td>
</tr>
<tr>
<td>%?string</td>
<td>Job whose command contains string.</td>
</tr>
</tbody>
</table>

3.204 Last Close (of a File)
When a process closes a file, resulting in the file not being an open file within any process.

3.205 Line
A sequence of zero or more non-<newline>s plus a terminating <newline>.

3.206 Linger
A period of time before terminating a connection, to allow outstanding data to be transferred.

3.207 Link
See Directory Entry in Section 3.129 (on page 53).
3.208  **Link Count**  
The number of directory entries that refer to a particular file.

3.209  **Local Customs**  
The conventions of a geographical area or territory for such things as date, time, and currency formats.

3.210  **Local Interprocess Communication (Local IPC)**  
The transfer of data between processes in the same system.

3.211  **Locale**  
The definition of the subset of a user’s environment that depends on language and cultural conventions.  

*Note:* Locales are defined in detail in Chapter 7 (on page 123).

3.212  **Localization**  
The process of establishing information within a computer system specific to the operation of particular native languages, local customs, and coded character sets.

3.213  **Login**  
The unspecified activity by which a user gains access to the system. Each login is associated with exactly one login name.

3.214  **Login Name**  
A user name that is associated with a login.

3.215  **Map**  
To create an association between a page-aligned range of the address space of a process and some memory object, such that a reference to an address in that range of the address space results in a reference to the associated memory object. The mapped memory object is not necessarily memory-resident.
3.216 **Marked Message**

A STREAMs message on which a certain flag is set. Marking a message gives the application protocol-specific information. An application can use `ioctl()` to determine whether a given message is marked.

*Note:* The `ioctl()` function is defined in detail in the System Interfaces volume of IEEE Std 1003.1-2001.

3.217 **Matched**

A state applying to a sequence of zero or more characters when the characters in the sequence correspond to a sequence of characters defined by a basic regular expression or extended regular expression pattern.

*Note:* Regular Expressions are defined in detail in Chapter 9 (on page 169).

3.218 **Memory Mapped Files**

A facility to allow applications to access files as part of the address space.

3.219 **Memory Object**

One of:

- A file (see Section 3.163 (on page 57))
- A shared memory object (see Section 3.340 (on page 82))
- A typed memory object (see Section 3.418 (on page 93))

When used in conjunction with `mmap()`, a memory object appears in the address space of the calling process.

*Note:* The `mmap()` function is defined in detail in the System Interfaces volume of IEEE Std 1003.1-2001.

3.220 **Memory-Resident**

The process of managing the implementation in such a way as to provide an upper bound on memory access times.

3.221 **Message**

In the context of programmatic message passing, information that can be transferred between processes or threads by being added to and removed from a message queue. A message consists of a fixed-size message buffer.
3.222 Message Catalog

In the context of providing natural language messages to the user, a file or storage area containing program messages, command prompts, and responses to prompts for a particular native language, territory, and codeset.

3.223 Message Catalog Descriptor

In the context of providing natural language messages to the user, a per-process unique value used to identify an open message catalog. A message catalog descriptor may be implemented using a file descriptor.

3.224 Message Queue

In the context of programmatic message passing, an object to which messages can be added and removed. Messages may be removed in the order in which they were added or in priority order.

3.225 Mode

A collection of attributes that specifies a file’s type and its access permissions.

Note: File Access Permissions are defined in detail in Section 4.4 (on page 99).

3.226 Monotonic Clock

A clock whose value cannot be set via clock_settime() and which cannot have negative clock jumps.

3.227 Mount Point

Either the system root directory or a directory for which the st_dev field of structure stat differs from that of its parent directory.

Note: The stat structure is defined in detail in <sys/stat.h>.

3.228 Multi-Character Collating Element

A sequence of two or more characters that collate as an entity. For example, in some coded character sets, an accented character is represented by a non-spacing accent, followed by the letter. Other examples are the Spanish elements ch and ll.

3.229 Mutex

A synchronization object used to allow multiple threads to serialize their access to shared data. The name derives from the capability it provides; namely, mutual-exclusion. The thread that has locked a mutex becomes its owner and remains the owner until that same thread unlocks the mutex.
3.230 Name

In the shell command language, a word consisting solely of underscores, digits, and alphabetics from the portable character set. The first character of a name is not a digit.

Note: The Portable Character Set is defined in detail in Section 6.1 (on page 115).

3.231 Named STREAM

A STREAMS-based file descriptor that is attached to a name in the file system name space. All subsequent operations on the named STREAM act on the STREAM that was associated with the file descriptor until the name is disassociated from the STREAM.

3.232 NaN (Not a Number)

A set of values that may be stored in a floating type but that are neither Inf nor valid floating-point numbers. Not all systems support NaN values.

3.233 Native Language

A computer user’s spoken or written language, such as American English, British English, Danish, Dutch, French, German, Italian, Japanese, Norwegian, or Swedish.

3.234 Negative Response

An input string that matches one of the responses acceptable to the LC_MESSAGES category keyword noexpr, matching an extended regular expression in the current locale.

Note: The LC_MESSAGES category is defined in detail in Section 7.3.6 (on page 152).

3.235 Network

A collection of interconnected hosts.

Note: The term “network” in IEEE Std 1003.1-2001 is used to refer to the network of hosts. The term “batch system” is used to refer to the network of batch servers.

3.236 Network Address

A network-visible identifier used to designate specific endpoints in a network. Specific endpoints on host systems have addresses, and host systems may also have addresses.
3.237 **Network Byte Order**

The way of representing any integer type such that, when transmitted over a network via a network endpoint, the `int` type is transmitted as an appropriate number of octets with the most significant octet first, followed by any other octets in descending order of significance.

*Note:* This order is more commonly known as big-endian ordering. See also Section 4.8 (on page 101).

3.238 **Newline Character (<newline>)**

A character that in the output stream indicates that printing should start at the beginning of the next line. It is the character designated by `\n` in the C language. It is unspecified whether this character is the exact sequence transmitted to an output device by the system to accomplish the movement to the next line.

3.239 **Nice Value**

A number used as advice to the system to alter process scheduling. Numerically smaller values give a process additional preference when scheduling a process to run. Numerically larger values reduce the preference and make a process less likely to run. Typically, a process with a smaller nice value runs to completion more quickly than an equivalent process with a higher nice value. The symbol `{NZERO}` specifies the default nice value of the system.

3.240 **Non-Blocking**

A property of an open file description that causes function calls involving it to return without delay when it is detected that the requested action associated with the function call cannot be completed without unknown delay.

*Note:* The exact semantics are dependent on the type of file associated with the open file description. For data reads from devices such as ttys and FIFOs, this property causes the read to return immediately when no data was available. Similarly, for writes, it causes the call to return immediately when the thread would otherwise be delayed in the write operation; for example, because no space was available. For networking, it causes functions not to await protocol events (for example, acknowledgements) to occur. See also the System Interfaces volume of IEEE Std 1003.1-2001, Section 2.10.7, Socket I/O Mode.

3.241 **Non-Spacing Characters**

A character, such as a character representing a diacritical mark in the ISO/IEC 6937:1994 standard coded character set, which is used in combination with other characters to form composite graphic symbols.

3.242 **NUL**

A character with all bits set to zero.
3.243 Null Byte
A byte with all bits set to zero.

3.244 Null Pointer
The value that is obtained by converting the number 0 into a pointer; for example, (void *) 0. The C language guarantees that this value does not match that of any legitimate pointer, so it is used by many functions that return pointers to indicate an error.

3.245 Null String
See Empty String in Section 3.145 (on page 55).

3.246 Null Wide-Character Code
A wide-character code with all bits set to zero.

3.247 Number Sign
The character ‘#’, also known as hash sign.

3.248 Object File
A regular file containing the output of a compiler, formatted as input to a linkage editor for linking with other object files into an executable form. The methods of linking are unspecified and may involve the dynamic linking of objects at runtime. The internal format of an object file is unspecified, but a conforming application cannot assume an object file is a text file.

3.249 Octet
Unit of data representation that consists of eight contiguous bits.

3.250 Offset Maximum
An attribute of an open file description representing the largest value that can be used as a file offset.

3.251 Opaque Address
An address such that the entity making use of it requires no details about its contents or format.
3.252 Open File
A file that is currently associated with a file descriptor.

3.253 Open File Description
A record of how a process or group of processes is accessing a file. Each file descriptor refers to exactly one open file description, but an open file description can be referred to by more than one file descriptor. The file offset, file status, and file access modes are attributes of an open file description.

3.254 Operand
An argument to a command that is generally used as an object supplying information to a utility necessary to complete its processing. Operands generally follow the options in a command line.

Note: Utility Argument Syntax is defined in detail in Section 12.1 (on page 201).

3.255 Operator
In the shell command language, either a control operator or a redirection operator.

3.256 Option
An argument to a command that is generally used to specify changes in the utility’s default behavior.

Note: Utility Argument Syntax is defined in detail in Section 12.1 (on page 201).

3.257 Option-Argument
A parameter that follows certain options. In some cases an option-argument is included within the same argument string as the option—in most cases it is the next argument.

Note: Utility Argument Syntax is defined in detail in Section 12.1 (on page 201).

3.258 Orientation
A stream has one of three orientations: unoriented, byte-oriented, or wide-oriented.

Note: For further information, see the System Interfaces volume of IEEE Std 1003.1-2001, Section 2.5.2, Stream Orientation and Encoding Rules.

3.259 Orphaned Process Group
A process group in which the parent of every member is either itself a member of the group or is not a member of the group’s session.
The granularity of process memory mapping or locking.

Physical memory and memory objects can be mapped into the address space of a process on page boundaries and in integral multiples of pages. Process address space can be locked into memory (made memory-resident) on page boundaries and in integral multiples of pages.

The size, in bytes, of the system unit of memory allocation, protection, and mapping. On systems that have segment rather than page-based memory architectures, the term "page" means a segment.

In the shell command language, an entity that stores values. There are three types of parameters: variables (named parameters), positional parameters, and special parameters. Parameter expansion is accomplished by introducing a parameter with the "$" character.

In the C language, an object declared as part of a function declaration or definition that acquires a value on entry to the function, or an identifier following the macro name in a function-like macro definition.

When discussing a given directory, the directory that both contains a directory entry for the given directory and is represented by the pathname dot-dot in the given directory.

When discussing other types of files, a directory containing a directory entry for the file under discussion.

This concept does not apply to dot and dot-dot.

The process which created (or inherited) the process under discussion.

An attribute of a new process identifying the parent of the process. The parent process ID of a process is the process ID of its creator, for the lifetime of the creator. After the creator's lifetime has ended, the parent process ID is the process ID of an implementation-defined system process.
3.266 Pathname
A character string that is used to identify a file. In the context of IEEE Std 1003.1-2001, a pathname consists of, at most, \{PATH_MAX\} bytes, including the terminating null byte. It has an optional beginning slash, followed by zero or more filenames separated by slashes. A pathname may optionally contain one or more trailing slashes. Multiple successive slashes are considered to be the same as one slash.

Note: Pathname Resolution is defined in detail in Section 4.11 (on page 102).

3.267 Pathname Component
See Filename in Section 3.169 (on page 58).

3.268 Path Prefix
A pathname, with an optional ending slash, that refers to a directory.

3.269 Pattern
A sequence of characters used either with regular expression notation or for pathname expansion, as a means of selecting various character strings or pathnames, respectively.

Note: Regular Expressions are defined in detail in Chapter 9 (on page 169).

See also the Shell and Utilities volume of IEEE Std 1003.1-2001, Section 2.6.6, Pathname Expansion.

The syntaxes of the two types of patterns are similar, but not identical; IEEE Std 1003.1-2001 always indicates the type of pattern being referred to in the immediate context of the use of the term.

3.270 Period
The character ".". The term "period" is contrasted with dot (see also Section 3.135 (on page 53)), which is used to describe a specific directory entry.

3.271 Permissions
Attributes of an object that determine the privilege necessary to access or manipulate the object.

Note: File Access Permissions are defined in detail in Section 4.4 (on page 99).

3.272 Persistence
A mode for semaphores, shared memory, and message queues requiring that the object and its state (including data, if any) are preserved after the object is no longer referenced by any process.

Persistence of an object does not imply that the state of the object is maintained across a system crash or a system reboot.
3.273 Pipe
An object accessed by one of the pair of file descriptors created by the *pipe()* function. Once created, the file descriptors can be used to manipulate it, and it behaves identically to a FIFO special file when accessed in this way. It has no name in the file hierarchy.

*Note:* The *pipe()* function is defined in detail in the System Interfaces volume of IEEE Std 1003.1-2001.

3.274 Polling
A scheduling scheme whereby the local process periodically checks until the pre-specified events (for example, read, write) have occurred.

3.275 Portable Character Set
The collection of characters that are required to be present in all locales supported by conforming systems.

*Note:* The Portable Character Set is defined in detail in Section 6.1 (on page 115).
This term is contrasted against the smaller portable filename character set; see also Section 3.276.

3.276 Portable Filename Character Set
The set of characters from which portable filenames are constructed.

```
ABCDEFGHIJKLMNOPQRSTUVWXYZ
abcdefghijklmnopqrstuvwxyz
0123456789._-
```

The last three characters are the period, underscore, and hyphen characters, respectively.

3.277 Positional Parameter
In the shell command language, a parameter denoted by a single digit or one or more digits in curly braces.

*Note:* For further information, see the Shell and Utilities volume of IEEE Std 1003.1-2001, Section 2.5.1, Positional Parameters.

3.278 Preallocation
The reservation of resources in a system for a particular use.

Preallocation does not imply that the resources are immediately allocated to that use, but merely indicates that they are guaranteed to be available in bounded time when needed.
3.279 **Preempted Process (or Thread)**

A running thread whose execution is suspended due to another thread becoming runnable at a higher priority.

3.280 **Previous Job**

In the context of job control, the job that will be used as the default for the `fg` or `bg` utilities if the current job exits. There is at most one previous job; see also Section 3.203 (on page 63).

3.281 **Printable Character**

One of the characters included in the `print` character classification of the `LC_CTYPE` category in the current locale.

**Note:** The `LC_CTYPE` category is defined in detail in Section 7.3.1 (on page 126).

3.282 **Printable File**

A text file consisting only of the characters included in the `print` and `space` character classifications of the `LC_CTYPE` category and the `<backspace>`, all in the current locale.

**Note:** The `LC_CTYPE` category is defined in detail in Section 7.3.1 (on page 126).

3.283 **Priority**

A non-negative integer associated with processes or threads whose value is constrained to a range defined by the applicable scheduling policy. Numerically higher values represent higher priorities.

3.284 **Priority Band**

The queuing order applied to normal priority STREAMS messages. High priority STREAMS messages are not grouped by priority bands. The only differentiation made by the STREAMS mechanism is between zero and non-zero bands, but specific protocol modules may differentiate between priority bands.

3.285 **Priority Inversion**

A condition in which a thread that is not voluntarily suspended (waiting for an event or time delay) is not running while a lower priority thread is running. Such blocking of the higher priority thread is often caused by contention for a shared resource.

3.286 **Priority Scheduling**

A performance and determinism improvement facility to allow applications to determine the order in which threads that are ready to run are granted access to processor resources.
3.287 **Priority-Based Scheduling**
Scheduling in which the selection of a running thread is determined by the priorities of the runnable processes or threads.

3.288 **Privilege**
See *Appropriate Privileges* in Section 3.19 (on page 37).

3.289 **Process**
An address space with one or more threads executing within that address space, and the required system resources for those threads.

**Note:** Many of the system resources defined by IEEE Std 1003.1-2001 are shared among all of the threads within a process. These include the process ID, the parent process ID, process group ID, session membership, real, effective, and saved set-user-ID, real, effective, and saved set-group-ID, supplementary group IDs, current working directory, root directory, file mode creation mask, and file descriptors.

3.290 **Process Group**
A collection of processes that permits the signaling of related processes. Each process in the system is a member of a process group that is identified by a process group ID. A newly created process joins the process group of its creator.

3.291 **Process Group ID**
The unique positive integer identifier representing a process group during its lifetime.

**Note:** See also Process Group ID Reuse defined in Section 4.12 (on page 103).

3.292 **Process Group Leader**
A process whose process ID is the same as its process group ID.

3.293 **Process Group Lifetime**
A period of time that begins when a process group is created and ends when the last remaining process in the group leaves the group, due either to the end of the last process’ lifetime or to the last remaining process calling the `setsid()` or `setpgid()` functions.

**Note:** The `setsid()` and `setpgid()` functions are defined in detail in the System Interfaces volume of IEEE Std 1003.1-2001.
3.294 Process ID

The unique positive integer identifier representing a process during its lifetime.

Note: See also Process ID Reuse defined in Section 4.12 (on page 103).

3.295 Process Lifetime

The period of time that begins when a process is created and ends when its process ID is returned to the system. After a process is created with a fork() function, it is considered active. At least one thread of control and address space exist until it terminates. It then enters an inactive state where certain resources may be returned to the system, although some resources, such as the process ID, are still in use. When another process executes a wait(), waitid(), or waitpid() function for an inactive process, the remaining resources are returned to the system. The last resource to be returned to the system is the process ID. At this time, the lifetime of the process ends.

Note: The fork(), wait(), waitid(), and waitpid() functions are defined in detail in the System Interfaces volume of IEEE Std 1003.1-2001.

3.296 Process Memory Locking

A performance improvement facility to bind application programs into the high-performance random access memory of a computer system. This avoids potential latencies introduced by the operating system in storing parts of a program that were not recently referenced on secondary memory devices.

3.297 Process Termination

There are two kinds of process termination:

1. Normal termination occurs by a return from main() or when requested with the exit() or _exit() functions.

2. Abnormal termination occurs when requested by the abort() function or when some signals are received.

Note: The _exit(), abort(), and exit() functions are defined in detail in the System Interfaces volume of IEEE Std 1003.1-2001.

3.298 Process-To-Process Communication

The transfer of data between processes.

3.299 Process Virtual Time

The measurement of time in units elapsed by the system clock while a process is executing.
3.300 Program

A prepared sequence of instructions to the system to accomplish a defined task. The term “program” in IEEE Std 1003.1-2001 encompasses applications written in the Shell Command Language, complex utility input languages (for example, awk, lex, sed, and so on), and high-level languages.

3.301 Protocol

A set of semantic and syntactic rules for exchanging information.

3.302 Pseudo-Terminal

A facility that provides an interface that is identical to the terminal subsystem. A pseudo-terminal is composed of two devices: the “master device” and a “slave device”. The slave device provides processes with an interface that is identical to the terminal interface, although there need not be hardware behind that interface. Anything written on the master device is presented to the slave as an input and anything written on the slave device is presented as an input on the master side.

3.303 Radix Character

The character that separates the integer part of a number from the fractional part.

3.304 Read-Only File System

A file system that has implementation-defined characteristics restricting modifications.

Note: File Times Update is described in detail in Section 4.7 (on page 100).

3.305 Read-Write Lock

Multiple readers, single writer (read-write) locks allow many threads to have simultaneous read-only access to data while allowing only one thread to have write access at any given time. They are typically used to protect data that is read-only more frequently than it is changed. Read-write locks can be used to synchronize threads in the current process and other processes if they are allocated in memory that is writable and shared among the cooperating processes and have been initialized for this behavior.

3.306 Real Group ID

The attribute of a process that, at the time of process creation, identifies the group of the user who created the process; see also Section 3.188 (on page 61).
3.307 **Real Time**
Time measured as total units elapsed by the system clock without regard to which thread is executing.

3.308 **Realtime Signal Extension**
A determinism improvement facility to enable asynchronous signal notifications to an application to be queued without impacting compatibility with the existing signal functions.

3.309 **Real User ID**
The attribute of a process that, at the time of process creation, identifies the user who created the process; see also Section 3.425 (on page 94).

3.310 **Record**
A collection of related data units or words which is treated as a unit.

3.311 **Redirection**
In the shell command language, a method of associating files with the input or output of commands.

*Note:* For further information, see the Shell and Utilities volume of IEEE Std 1003.1-2001, Section 2.7, Redirection.

3.312 **Redirection Operator**
In the shell command language, a token that performs a redirection function. It is one of the following symbols:

```
<  >  > |  <<  >>  &  >&  <−  −>
```

3.313 **Reentrant Function**
A function whose effect, when called by two or more threads, is guaranteed to be as if the threads each executed the function one after another in an undefined order, even if the actual execution is interleaved.

3.314 **Referenced Shared Memory Object**
A shared memory object that is open or has one or more mappings defined on it.
3.315 **Refresh**

To ensure that the information on the user’s terminal screen is up-to-date.

3.316 **Regular Expression**

A pattern that selects specific strings from a set of character strings.

**Note:** Regular Expressions are described in detail in Chapter 9 (on page 169).

3.317 **Region**

In the context of the address space of a process, a sequence of addresses.

In the context of a file, a sequence of offsets.

3.318 **Regular File**

A file that is a randomly accessible sequence of bytes, with no further structure imposed by the system.

3.319 **Relative Pathname**

A pathname not beginning with a slash.

**Note:** Pathname Resolution is defined in detail in Section 4.11 (on page 102).

3.320 **Relocatable File**

A file holding code or data suitable for linking with other object files to create an executable or a shared object file.

3.321 **Relocation**

The process of connecting symbolic references with symbolic definitions. For example, when a program calls a function, the associated call instruction transfers control to the proper destination address at execution.

3.322 **Requested Batch Service**

A service that is either rejected or performed prior to a response from the service to the requester.

3.323 **(Time) Resolution**

The minimum time interval that a clock can measure or whose passage a timer can detect.
3.324 Root Directory

A directory, associated with a process, that is used in pathname resolution for pathnames that begin with a slash.

3.325 Runnable Process (or Thread)

A thread that is capable of being a running thread, but for which no processor is available.

3.326 Running Process (or Thread)

A thread currently executing on a processor. On multi-processor systems there may be more than one such thread in a system at a time.

3.327 Saved Resource Limits

An attribute of a process that provides some flexibility in the handling of unrepresentable resource limits, as described in the exec family of functions and setrlimit().

Note: The exec and setrlimit() functions are defined in detail in the System Interfaces volume of IEEE Std 1003.1-2001.

3.328 Saved Set-Group-ID

An attribute of a process that allows some flexibility in the assignment of the effective group ID attribute, as described in the exec family of functions and setgid().

Note: The exec and setgid() functions are defined in detail in the System Interfaces volume of IEEE Std 1003.1-2001.

3.329 Saved Set-User-ID

An attribute of a process that allows some flexibility in the assignment of the effective user ID attribute, as described in the exec family of functions and setuid().

Note: The exec and setuid() functions are defined in detail in the System Interfaces volume of IEEE Std 1003.1-2001.

3.330 Scheduling

The application of a policy to select a runnable process or thread to become a running process or thread, or to alter one or more of the thread lists.

3.331 Scheduling Allocation Domain

The set of processors on which an individual thread can be scheduled at any given time.
A property of a thread that defines the set of threads against which that thread competes for resources.

For example, in a scheduling decision, threads sharing scheduling contention scope compete for processor resources. In IEEE Std 1003.1-2001, a thread has scheduling contention scope of either PTHREAD_SCOPE_SYSTEM or PTHREAD_SCOPE_PROCESS.

A set of rules that is used to determine the order of execution of processes or threads to achieve some goal.

Note: Scheduling Policy is defined in detail in Section 4.13 (on page 103).

A rectangular region of columns and lines on a terminal display. A screen may be a portion of a physical display device or may occupy the entire physical area of the display device.

To move the representation of data vertically or horizontally relative to the terminal screen. There are two types of scrolling:

1. The cursor moves with the data.
2. The cursor remains stationary while the data moves.

A minimum synchronization primitive to serve as a basis for more complex synchronization mechanisms to be defined by the application program.

Note: Semaphores are defined in detail in Section 4.15 (on page 104).

A collection of process groups established for job control purposes. Each process group is a member of a session. A process is considered to be a member of the session of which its process group is a member. A newly created process joins the session of its creator. A process can alter its session membership; see setsid(). There can be multiple process groups in the same session.

Note: The setsid() function is defined in detail in the System Interfaces volume of IEEE Std 1003.1-2001.
3.338 Session Leader
A process that has created a session.

Note: For further information, see the `setsid()` function defined in the System Interfaces volume of IEEE Std 1003.1-2001.

3.339 Session Lifetime
The period between when a session is created and the end of the lifetime of all the process groups that remain as members of the session.

3.340 Shared Memory Object
An object that represents memory that can be mapped concurrently into the address space of more than one process.

3.341 Shell
A program that interprets sequences of text input as commands. It may operate on an input stream or it may interactively prompt and read commands from a terminal.

3.342 Shell, the
The Shell Command Language Interpreter; a specific instance of a shell.

Note: For further information, see the `sh` utility defined in the Shell and Utilities volume of IEEE Std 1003.1-2001.

3.343 Shell Script
A file containing shell commands. If the file is made executable, it can be executed by specifying its name as a simple command. Execution of a shell script causes a shell to execute the commands within the script. Alternatively, a shell can be requested to execute the commands in a shell script by specifying the name of the shell script as the operand to the `sh` utility.

Note: Simple Commands are defined in detail in the Shell and Utilities volume of IEEE Std 1003.1-2001, Section 2.9.1, Simple Commands.

The `sh` utility is defined in detail in the Shell and Utilities volume of IEEE Std 1003.1-2001.

3.344 Signal
A mechanism by which a process or thread may be notified of, or affected by, an event occurring in the system. Examples of such events include hardware exceptions and specific actions by processes. The term signal is also used to refer to the event itself.
3.345 **Signal Stack**
Memory established for a thread, in which signal handlers catching signals sent to that thread are executed.

3.346 **Single-Quote**
The character ‘ ’, also known as apostrophe.

3.347 **Slash**
The character ‘ /’, also known as solidus.

3.348 **Socket**
A file of a particular type that is used as a communications endpoint for process-to-process communication as described in the System Interfaces volume of IEEE Std 1003.1-2001.

3.349 **Socket Address**
An address associated with a socket or remote endpoint, including an address family identifier and addressing information specific to that address family. The address may include multiple parts, such as a network address associated with a host system and an identifier for a specific endpoint.

3.350 **Soft Limit**
A resource limitation established for each process that the process may set to any value less than or equal to the hard limit.

3.351 **Source Code**
When dealing with the Shell Command Language, input to the command language interpreter. The term “shell script” is synonymous with this meaning. When dealing with an ISO/IEC-conforming programming language, source code is input to a compiler conforming to that ISO/IEC standard. Source code also refers to the input statements prepared for the following standard utilities: awk, bc, ed, lex, localedef, make, sed, and yacc. Source code can also refer to a collection of sources meeting any or all of these meanings.

**Note:** The awk, bc, ed, lex, localedef, make, sed, and yacc utilities are defined in detail in the Shell and Utilities volume of IEEE Std 1003.1-2001.
3.352 Space Character (<space>)

The character defined in the portable character set as <space>. The <space> is a member of the space character class of the current locale, but represents the single character, and not all of the possible members of the class; see also Section 3.431 (on page 95).

3.353 Spawn

A process creation primitive useful for systems that have difficulty with fork() and as an efficient replacement for fork()/exec.

3.354 Special Built-In

See Built-In Utility in Section 3.83 (on page 46).

3.355 Special Parameter

In the shell command language, a parameter named by a single character from the following list:

* @ # ? ! - $ 0

Note: For further information, see the Shell and Utilities volume of IEEE Std 1003.1-2001, Section 2.5.2, Special Parameters.

3.356 Spin Lock

A synchronization object used to allow multiple threads to serialize their access to shared data.

3.357 Sporadic Server

A scheduling policy for threads and processes that reserves a certain amount of execution capacity for processing aperiodic events at a given priority level.

3.358 Standard Error

An output stream usually intended to be used for diagnostic messages.

3.359 Standard Input

An input stream usually intended to be used for primary data input.

3.360 Standard Output

An output stream usually intended to be used for primary data output.
3.361 Standard Utilities

3.362 Stream

Appearing in lowercase, a stream is a file access object that allows access to an ordered sequence of characters, as described by the ISO C standard. Such objects can be created by the `fdopen()`, `fopen()`, or `popen()` functions, and are associated with a file descriptor. A stream provides the additional services of user-selectable buffering and formatted input and output; see also Section 3.363.

Note: For further information, see the System Interfaces volume of IEEE Std 1003.1-2001, Section 2.5, Standard I/O Streams.

The `fdopen()`, `fopen()`, or `popen()` functions are defined in detail in the System Interfaces volume of IEEE Std 1003.1-2001.

3.363 STREAM

Appearing in uppercase, STREAM refers to a full-duplex connection between a process and an open device or pseudo-device. It optionally includes one or more intermediate processing modules that are interposed between the process end of the STREAM and the device driver (or pseudo-device driver) end of the STREAM; see also Section 3.362.

Note: For further information, see the System Interfaces volume of IEEE Std 1003.1-2001, Section 2.6, STREAMS.

3.364 STREAM End

The STREAM end is the driver end of the STREAM and is also known as the downstream end of the STREAM.

3.365 STREAM Head

The STREAM head is the beginning of the STREAM and is at the boundary between the system and the application process. This is also known as the upstream end of the STREAM.

3.366 STREAMS Multiplexor

A driver with multiple STREAMS connected to it. Multiplexing with STREAMS connected above is referred to as N-to-1, or “upper multiplexing”. Multiplexing with STREAMS connected below is referred to as 1-to-N or “lower multiplexing”.

3.367 String

A contiguous sequence of bytes terminated by and including the first null byte.
3.368 **Subshell**

A shell execution environment, distinguished from the main or current shell execution environment.

*Note:* For further information, see the Shell and Utilities volume of IEEE Std 1003.1-2001, Section 2.12, Shell Execution Environment.

3.369 **Successfully Transferred**

For a write operation to a regular file, when the system ensures that all data written is readable on any subsequent open of the file (even one that follows a system or power failure) in the absence of a failure of the physical storage medium.

For a read operation, when an image of the data on the physical storage medium is available to the requesting process.

3.370 **Supplementary Group ID**

An attribute of a process used in determining file access permissions. A process has up to \{NGROUPS_MAX\} supplementary group IDs in addition to the effective group ID. The supplementary group IDs of a process are set to the supplementary group IDs of the parent process when the process is created.

3.371 **Suspended Job**

A job that has received a SIGSTOP, SIGTSTP, SIGTIN, or SIGTTOU signal that caused the process group to stop. A suspended job is a background job, but a background job is not necessarily a suspended job.

3.372 **Symbolic Link**

A type of file with the property that when the file is encountered during pathname resolution, a string stored by the file is used to modify the pathname resolution. The stored string has a length of \{SYMLINK_MAX\} bytes or fewer.

*Note:* Pathname Resolution is defined in detail in Section 4.11 (on page 102).

3.373 **Synchronized Input and Output**

A determinism and robustness improvement mechanism to enhance the data input and output mechanisms, so that an application can ensure that the data being manipulated is physically present on secondary mass storage devices.

3.374 **Synchronized I/O Completion**

The state of an I/O operation that has either been successfully transferred or diagnosed as unsuccessful.
3.375 **Synchronized I/O Data Integrity Completion**

For read, when the operation has been completed or diagnosed if unsuccessful. The read is complete only when an image of the data has been successfully transferred to the requesting process. If there were any pending write requests affecting the data to be read at the time that the synchronized read operation was requested, these write requests are successfully transferred prior to reading the data.

For write, when the operation has been completed or diagnosed if unsuccessful. The write is complete only when the data specified in the write request is successfully transferred and all file system information required to retrieve the data is successfully transferred.

File attributes that are not necessary for data retrieval (access time, modification time, status change time) need not be successfully transferred prior to returning to the calling process.

3.376 **Synchronized I/O File Integrity Completion**

Identical to a synchronized I/O data integrity completion with the addition that all file attributes relative to the I/O operation (including access time, modification time, status change time) are successfully transferred prior to returning to the calling process.

3.377 **Synchronized I/O Operation**

An I/O operation performed on a file that provides the application assurance of the integrity of its data and files.

3.378 **Synchronous I/O Operation**

An I/O operation that causes the thread requesting the I/O to be blocked from further use of the processor until that I/O operation completes.

**Note:** A synchronous I/O operation does not imply synchronized I/O data integrity completion or synchronized I/O file integrity completion.

3.379 **Synchronously-Generated Signal**

A signal that is attributable to a specific thread.

For example, a thread executing an illegal instruction or touching invalid memory causes a synchronously-generated signal. Being synchronous is a property of how the signal was generated and not a property of the signal number.

3.380 **System**

3.381 System Crash

An interval initiated by an unspecified circumstance that causes all processes (possibly other than special system processes) to be terminated in an undefined manner, after which any changes to the state and contents of files created or written to by an application prior to the interval are undefined, except as required elsewhere in IEEE Std 1003.1-2001.

3.382 System Console

An implementation-defined device that receives messages sent by the syslog() function, and the fmtmsg() function when the MM_CONSOLE flat is set.

Note: The syslog() and fmtmsg() functions are defined in detail in the System Interfaces volume of IEEE Std 1003.1-2001.

3.383 System Databases

An implementation provides two system databases.

The “group database” contains the following information for each group:
1. Group name
2. Numerical group ID
3. List of all users allowed in the group

The “user database” contains the following information for each user:
1. User name
2. Numerical user ID
3. Numerical group ID
4. Initial working directory
5. Initial user program

If the initial user program field is null, the system default is used. If the initial working directory field is null, the interpretation of that field is implementation-defined. These databases may contain other fields that are unspecified by IEEE Std 1003.1-2001.

3.384 System Documentation

All documentation provided with an implementation except for the conformance document.
Electronically distributed documents for an implementation are considered part of the system documentation.

3.385 System Process

An implementation-defined object, other than a process executing an application, that has a process ID.
3.386 **System Reboot**

An implementation-defined sequence of events that may result in the loss of transitory data; that is, data that is not saved in permanent storage. For example, message queues, shared memory, semaphores, and processes.

3.387 **System Trace Event**

A trace event that is generated by the implementation, in response either to a system-initiated action or to an application-requested action, except for a call to `posix_trace_event()`. When supported by the implementation, a system-initiated action generates a process-independent system trace event and an application-requested action generates a process-dependent system trace event. For a system trace event not defined by IEEE Std 1003.1-2001, the associated trace event type identifier is derived from the implementation-defined name for this trace event, and the associated data is of implementation-defined content and length.

3.388 **System-Wide**

Pertaining to events occurring in all processes existing in an implementation at a given point in time.

3.389 **Tab Character (<tab>)**

A character that in the output stream indicates that printing or displaying should start at the next horizontal tabulation position on the current line. It is the character designated by '\t' in the C language. If the current position is at or past the last defined horizontal tabulation position, the behavior is unspecified. It is unspecified whether this character is the exact sequence transmitted to an output device by the system to accomplish the tabulation.

3.390 **Terminal (or Terminal Device)**

A character special file that obeys the specifications of the general terminal interface.

**Note:** The General Terminal Interface is defined in detail in Chapter 11 (on page 187).

3.391 **Text Column**

A roughly rectangular block of characters capable of being laid out side-by-side next to other text columns on an output page or terminal screen. The widths of text columns are measured in column positions.
Text File

3.392 Text File

A file that contains characters organized into one or more lines. The lines do not contain NUL characters and none can exceed {LINE_MAX} bytes in length, including the <newline>. Although IEEE Std 1003.1-2001 does not distinguish between text files and binary files (see the ISO C standard), many utilities only produce predictable or meaningful output when operating on text files. The standard utilities that have such restrictions always specify "text files" in their STDIN or INPUT FILES sections.

3.393 Thread

A single flow of control within a process. Each thread has its own thread ID, scheduling priority and policy, errno value, thread-specific key/value bindings, and the required system resources to support a flow of control. Anything whose address may be determined by a thread, including but not limited to static variables, storage obtained via malloc(), directly addressable storage obtained through implementation-defined functions, and automatic variables, are accessible to all threads in the same process.

Note: The malloc() function is defined in detail in the System Interfaces volume of IEEE Std 1003.1-2001.

3.394 Thread ID

Each thread in a process is uniquely identified during its lifetime by a value of type pthread_t called a thread ID.

3.395 Thread List

An ordered set of runnable threads that all have the same ordinal value for their priority.

The ordering of threads on the list is determined by a scheduling policy or policies. The set of thread lists includes all runnable threads in the system.

3.396 Thread-Safe

A function that may be safely invoked concurrently by multiple threads. Each function defined in the System Interfaces volume of IEEE Std 1003.1-2001 is thread-safe unless explicitly stated otherwise. Examples are any "pure" function, a function which holds a mutex locked while it is accessing static storage, or objects shared among threads.

3.397 Thread-Specific Data Key

A process global handle of type pthread_key_t which is used for naming thread-specific data.

Although the same key value may be used by different threads, the values bound to the key by pthread_setspecific() and accessed by pthread_getspecific() are maintained on a per-thread basis and persist for the life of the calling thread.

Note: The pthread_getspecific() and pthread_setspecific() functions are defined in detail in the System Interfaces volume of IEEE Std 1003.1-2001.
3.398 Tilde
The character ‘˜’.

3.399 Timeouts
A method of limiting the length of time an interface will block; see also Section 3.76 (on page 45).

3.400 Timer
A mechanism that can notify a thread when the time as measured by a particular clock has reached or passed a specified value, or when a specified amount of time has passed.

3.401 Timer Overrun
A condition that occurs each time a timer, for which there is already an expiration signal queued to the process, expires.

3.402 Token
In the shell command language, a sequence of characters that the shell considers as a single unit when reading input. A token is either an operator or a word.

Note: The rules for reading input are defined in detail in the Shell and Utilities volume of IEEE Std 1003.1-2001, Section 2.3, Token Recognition.

3.403 Trace Analyzer Process
A process that extracts trace events from a trace stream to retrieve information about the behavior of an application.

3.404 Trace Controller Process
A process that creates a trace stream for tracing a process.

3.405 Trace Event
A data object that represents an action executed by the system, and that is recorded in a trace stream.

3.406 Trace Event Type
A data object type that defines a class of trace event.
3.407 Trace Event Type Mapping
A one-to-one mapping between trace event types and trace event names.

3.408 Trace Filter
A filter that allows the trace controller process to specify those trace event types that are to be ignored; that is, not generated.

3.409 Trace Generation Version
A data object that is an implementation-defined character string, generated by the trace system and describing the origin and version of the trace system.

3.410 Trace Log
The flushed image of a trace stream, if the trace stream is created with a trace log.

3.411 Trace Point
An action that may cause a trace event to be generated.

3.412 Trace Stream
An opaque object that contains trace events plus internal data needed to interpret those trace events.

3.413 Trace Stream Identifier
A handle to manage tracing operations in a trace stream.

3.414 Trace System
A system that allows both system and user trace events to be generated into a trace stream. These trace events can be retrieved later.

3.415 Traced Process
A process for which at least one trace stream has been created. A traced process is also called a target process.
3.416 Tracing Status of a Trace Stream
A status that describes the state of an active trace stream. The tracing status of a trace stream can be retrieved from the trace stream attributes. An active trace stream can be in one of two states: running or suspended.

3.417 Typed Memory Name Space
A system-wide name space that contains the names of the typed memory objects present in the system. It is configurable for a given implementation.

3.418 Typed Memory Object
A combination of a typed memory pool and a typed memory port. The entire contents of the pool are accessible from the port. The typed memory object is identified through a name that belongs to the typed memory name space.

3.419 Typed Memory Pool
An extent of memory with the same operational characteristics. Typed memory pools may be contained within each other.

3.420 Typed Memory Port
A hardware access path to one or more typed memory pools.

3.421 Unbind
Remove the association between a network address and an endpoint.

3.422 Unit Data
See Datagram in Section 3.123 (on page 52).

3.423 Upshifting
The conversion of a lowercase character that has a single-character uppercase representation into this uppercase representation.
3.424  **User Database**

A system database of implementation-defined format that contains at least the following information for each user ID:

- User name
- Numerical user ID
- Initial numerical group ID
- Initial working directory
- Initial user program

The initial numerical group ID is used by the `newgrp` utility. Any other circumstances under which the initial values are operative are implementation-defined.

If the initial user program field is null, an implementation-defined program is used.

If the initial working directory field is null, the interpretation of that field is implementation-defined.

**Note:** The `newgrp` utility is defined in detail in the Shell and Utilities volume of IEEE Std 1003.1-2001.

3.425  **User ID**

A non-negative integer that is used to identify a system user. When the identity of a user is associated with a process, a user ID value is referred to as a real user ID, an effective user ID, or a saved set-user-ID.

3.426  **User Name**

A string that is used to identify a user; see also Section 3.424. To be portable across systems conforming to IEEE Std 1003.1-2001, the value is composed of characters from the portable filename character set. The hyphen should not be used as the first character of a portable user name.

3.427  **User Trace Event**

A trace event that is generated explicitly by the application as a result of a call to `posix_trace_event()`.

3.428  **Utility**

A program, excluding special built-in utilities provided as part of the Shell Command Language, that can be called by name from a shell to perform a specific task, or related set of tasks.

**Note:** For further information on special built-in utilities, see the Shell and Utilities volume of IEEE Std 1003.1-2001, Section 2.14, Special Built-In Utilities.
3.429 Variable

In the shell command language, a named parameter.

Note: For further information, see the Shell and Utilities volume of IEEE Std 1003.1-2001, Section 2.5, Parameters and Variables.

3.430 Vertical-Tab Character (<vertical-tab>)

A character that in the output stream indicates that printing should start at the next vertical tabulation position. It is the character designated by ‘\v’ in the C language. If the current position is at or past the last defined vertical tabulation position, the behavior is unspecified. It is unspecified whether this character is the exact sequence transmitted to an output device by the system to accomplish the tabulation.

3.431 White Space

A sequence of one or more characters that belong to the space character class as defined via the $LC_CTYPE$ category in the current locale.

In the POSIX locale, white space consists of one or more <blank>s (<space>s and <tab>s), <newline>s, <carriage-return>s, <form-feed>s, and <vertical-tab>s.

3.432 Wide-Character Code (C Language)

An integer value corresponding to a single graphic symbol or control code.

Note: C Language Wide-Character Codes are defined in detail in Section 6.3 (on page 119).

3.433 Wide-Character Input/Output Functions

The functions that perform wide-oriented input from streams or wide-oriented output to streams: fgetwc(), fgetws(), fputwc(), fputws(), fwpprintf(), fwpscanf(), getwc(), getwchar(), putwc(), putwchar(), ungetwc(), vfwprintf(), vfwscanf(), vwpprintf(), vwpscanf(), wprintf(), and wscanf().

Note: These functions are defined in detail in the System Interfaces volume of IEEE Std 1003.1-2001.

3.434 Wide-Character String

A contiguous sequence of wide-character codes terminated by and including the first null wide-character code.
3.435 **Word**

In the shell command language, a token other than an operator. In some cases a word is also a portion of a word token: in the various forms of parameter expansion, such as ${name=word}$, and variable assignment, such as name=word, the word is the portion of the token depicted by word.

The concept of a word is no longer applicable following word expansions—only fields remain.

**Note:** For further information, see the Shell and Utilities volume of IEEE Std 1003.1-2001, Section 2.6.2, Parameter Expansion and the Shell and Utilities volume of IEEE Std 1003.1-2001, Section 2.6, Word Expansions.

3.436 **Working Directory (or Current Working Directory)**

A directory, associated with a process, that is used in pathname resolution for pathnames that do not begin with a slash.

3.437 **Worldwide Portability Interface**

Functions for handling characters in a codeset-independent manner.

3.438 **Write**

To output characters to a file, such as standard output or standard error. Unless otherwise stated, standard output is the default output destination for all uses of the term “write”; see the distinction between display and write in Section 3.132 (on page 53).

3.439 **XSI**

The X/Open System Interface is the core application programming interface for C and sh programming for systems conforming to the Single UNIX Specification. This is a superset of the mandatory requirements for conformance to IEEE Std 1003.1-2001.

3.440 **XSI-Conformant**

A system which allows an application to be built using a set of services that are consistent across all systems that conform to IEEE Std 1003.1-2001 and that support the XSI extension.

**Note:** See also Chapter 2 (on page 17).

3.441 **Zombie Process**

A process that has terminated and that is deleted when its exit status has been reported to another process which is waiting for that process to terminate.
The algebraic sign provides additional information about any variable that has the value zero when the representation allows the sign to be determined.
Chapter 4

General Concepts

For the purposes of IEEE Std 1003.1-2001, the general concepts given in Chapter 4 apply.

Note: No shading to denote extensions or options occurs in this chapter. Where the terms and definitions given in this chapter are used elsewhere in text related to extensions and options, they are shaded as appropriate.

4.1 Concurrent Execution

Functions that suspend the execution of the calling thread shall not cause the execution of other threads to be indefinitely suspended.

4.2 Directory Protection

If a directory is writable and the mode bit S_ISVTX is set on the directory, a process may remove or rename files within that directory only if one or more of the following is true:

• The effective user ID of the process is the same as that of the owner ID of the file.
• The effective user ID of the process is the same as that of the owner ID of the directory.
• The process has appropriate privileges.

If the S_ISVTX bit is set on a non-directory file, the behavior is unspecified.

4.3 Extended Security Controls

An implementation may provide implementation-defined extended security controls (see Section 3.159 (on page 57)). These permit an implementation to provide security mechanisms to implement different security policies than those described in IEEE Std 1003.1-2001. These mechanisms shall not alter or override the defined semantics of any of the interfaces in IEEE Std 1003.1-2001.

4.4 File Access Permissions

The standard file access control mechanism uses the file permission bits, as described below.

Implementations may provide additional or alternate file access control mechanisms, or both. An additional access control mechanism shall only further restrict the access permissions defined by the file permission bits. An alternate file access control mechanism shall:

• Specify file permission bits for the file owner class, file group class, and file other class of that file, corresponding to the access permissions.
• Be enabled only by explicit user action, on a per-file basis by the file owner or a user with the appropriate privilege.
• Be disabled for a file after the file permission bits are changed for that file with chmod(). The disabling of the alternate mechanism need not disable any additional mechanisms supported
Whenever a process requests file access permission for read, write, or execute/search, if no additional mechanism denies access, access shall be determined as follows:

- If a process has the appropriate privilege:
  - If read, write, or directory search permission is requested, access shall be granted.
  - If execute permission is requested, access shall be granted if execute permission is granted to at least one user by the file permission bits or by an alternate access control mechanism; otherwise, access shall be denied.

- Otherwise:
  - The file permission bits of a file contain read, write, and execute/search permissions for the file owner class, file group class, and file other class.
  - Access shall be granted if an alternate access control mechanism is not enabled and the requested access permission bit is set for the class (file owner class, file group class, or file other class) to which the process belongs, or if an alternate access control mechanism is enabled and it allows the requested access; otherwise, access shall be denied.

4.5 **File Hierarchy**

Files in the system are organized in a hierarchical structure in which all of the non-terminal nodes are directories and all of the terminal nodes are any other type of file. Since multiple directory entries may refer to the same file, the hierarchy is properly described as a "directed graph".

4.6 **Filenames**

For a filename to be portable across implementations conforming to IEEE Std 1003.1-2001, it shall consist only of the portable filename character set as defined in Section 3.276 (on page 73).

The hyphen character shall not be used as the first character of a portable filename. Uppercase and lowercase letters shall retain their unique identities between conforming implementations. In the case of a portable pathname, the slash character may also be used.

4.7 **File Times Update**

Each file has three distinct associated time values: `st_atime`, `st_mtime`, and `st_ctime`. The `st_atime` field is associated with the times that the file data is accessed; `st_mtime` is associated with the times that the file data is modified; and `st_ctime` is associated with the times that the file status is changed. These values are returned in the file characteristics structure, as described in `<sys/stat.h>`.

Each function or utility in IEEE Std 1003.1-2001 that reads or writes data or changes file status indicates which of the appropriate time-related fields shall be "marked for update". If an implementation of such a function or utility marks for update a time-related field not specified by IEEE Std 1003.1-2001, this shall be documented, except that any changes caused by pathname resolution need not be documented. For the other functions or utilities in IEEE Std 1003.1-2001 (those that are not explicitly required to read or write file data or change file status, but that in some implementations happen to do so), the effect is unspecified.
An implementation may update fields that are marked for update immediately, or it may update such fields periodically. At an update point in time, any marked fields shall be set to the current time and the update marks shall be cleared. All fields that are marked for update shall be updated when the file ceases to be open by any process, or when a `stat()`, `fstat()`, or `lstat()` is performed on the file. Other times at which updates are done are unspecified. Marks for update, and updates themselves, are not done for files on read-only file systems; see Section 3.304 (on page 77).

4.8 Host and Network Byte Orders

When data is transmitted over the network, it is sent as a sequence of octets (8-bit unsigned values). If an entity (such as an address or a port number) can be larger than 8 bits, it needs to be stored in several octets. The convention is that all such values are stored with 8 bits in each octet, and with the first (lowest-addressed) octet holding the most-significant bits. This is called “network byte order”.

Network byte order may not be convenient for processing actual values. For this, it is more sensible for values to be stored as ordinary integers. This is known as “host byte order”. In host byte order:

- The most significant bit might not be stored in the first byte in address order.
- Bits might not be allocated to bytes in any obvious order at all.

8-bit values stored in `uint8_t` objects do not require conversion to or from host byte order, as they have the same representation. 16 and 32-bit values can be converted using the `htonl()`, `htons()`, `ntohl()`, and `ntohs()` functions. When reading data that is to be converted to host byte order, it should either be received directly into a `uint16_t` or `uint32_t` object or should be copied from an array of bytes using `memcpy()` or similar. Passing the data through other types could cause the byte order to be changed. Similar considerations apply when sending data.

4.9 Measurement of Execution Time

The mechanism used to measure execution time shall be implementation-defined. The implementation shall also define to whom the CPU time that is consumed by interrupt handlers and system services on behalf of the operating system will be charged. See Section 3.117 (on page 51).
4.10 Memory Synchronization

Applications shall ensure that access to any memory location by more than one thread of control (threads or processes) is restricted such that no thread of control can read or modify a memory location while another thread of control may be modifying it. Such access is restricted using functions that synchronize thread execution and also synchronize memory with respect to other threads. The following functions synchronize memory with respect to other threads:

- `fork()`
- `pthread_barrier_wait()`
- `pthread_cond_broadcast()`
- `pthread_cond_signal()`
- `pthread_cond_timedwait()`
- `pthread_cond_wait()`
- `pthread_create()`
- `pthread_join()`
- `pthread_mutex_lock()`
- `pthread_mutex_timedlock()`
- `pthread_mutex_trylock()`
- `pthread_mutex_unlock()`
- `pthread_rwlock_rdlock()`
- `pthread_rwlock_timedrdlock()`
- `pthread_rwlock_timedwrlock()`
- `pthread_rwlock_tryrdlock()`
- `pthread_rwlock_trywrlock()`
- `pthread_rwlock_unlock()`
- `pthread_rwlock_wrlock()`
- `sem_post()`
- `sem_trywait()`
- `sem_wait()`
- `wait()`
- `waitpid()`

The `pthread_once()` function shall synchronize memory for the first call in each thread for a given `pthread_once_t` object.

Unless explicitly stated otherwise, if one of the above functions returns an error, it is unspecified whether the invocation causes memory to be synchronized.

Applications may allow more than one thread of control to read a memory location simultaneously.

4.11 Pathname Resolution

Pathname resolution is performed for a process to resolve a pathname to a particular file in a file hierarchy. There may be multiple pathnames that resolve to the same file.

Each filename in the pathname is located in the directory specified by its predecessor (for example, in the pathname fragment `a/b`, file `b` is located in directory `a`). Pathname resolution shall fail if this cannot be accomplished. If the pathname begins with a slash, the predecessor of the first filename in the pathname shall be taken to be the root directory of the process (such pathnames are referred to as “absolute pathnames”). If the pathname does not begin with a slash, the predecessor of the first filename of the pathname shall be taken to be the current working directory of the process (such pathnames are referred to as “relative pathnames”).

The interpretation of a pathname component is dependent on the value of `{NAME_MAX}` and `_POSIX_NO_TRUNC` associated with the path prefix of that component. If any pathname component is longer than `{NAME_MAX}`, the implementation shall consider this an error.

A pathname that contains at least one non-slash character and that ends with one or more trailing slashes shall be resolved as if a single dot character (‘.’) were appended to the pathname.

If a symbolic link is encountered during pathname resolution, the behavior shall depend on whether the pathname component is at the end of the pathname and on the function being performed. If all of the following are true, then pathname resolution is complete:

1. This is the last pathname component of the pathname.
2. The pathname has no trailing slash.
3. The function is required to act on the symbolic link itself, or certain arguments direct that
   the function act on the symbolic link itself.

In all other cases, the system shall prefix the remaining pathname, if any, with the contents of the
symbolic link. If the combined length exceeds \{PATH_MAX\}, and the implementation considers
this to be an error, \texttt{errno} shall be set to \texttt{ENAMETOOLONG} and an error indication shall be
returned. Otherwise, the resolved pathname shall be the resolution of the pathname just created.
If the resulting pathname does not begin with a slash, the predecessor of the first filename of the
pathname is taken to be the directory containing the symbolic link.

If the system detects a loop in the pathname resolution process, it shall set \texttt{errno} to \texttt{ELOOP} and
return an error indication. The same may happen if during the resolution process more symbolic
links were followed than the implementation allows. This implementation-defined limit shall
not be smaller than \{SYMLOOP_MAX\}.

The special filename \texttt{dot} shall refer to the directory specified by its predecessor. The special
filename \texttt{dot-dot} shall refer to the parent directory of its predecessor directory. As a special case,
in the root directory, \texttt{dot-dot} may refer to the root directory itself.

A pathname consisting of a single slash shall resolve to the root directory of the process. A null
pathname shall not be successfully resolved. A pathname that begins with two successive
slashes may be interpreted in an implementation-defined manner, although more than two
leading slashes shall be treated as a single slash.

4.12 Process ID Reuse

A process group ID shall not be reused by the system until the process group lifetime ends.

A process ID shall not be reused by the system until the process lifetime ends. In addition, if
there exists a process group whose process group ID is equal to that process ID, the process ID
shall not be reused by the system until the process group lifetime ends. A process that is not a
system process shall not have a process ID of 1.

4.13 Scheduling Policy

A scheduling policy affects process or thread ordering:

- When a process or thread is a running thread and it becomes a blocked thread
- When a process or thread is a running thread and it becomes a preempted thread
- When a process or thread is a blocked thread and it becomes a runnable thread
- When a running thread calls a function that can change the priority or scheduling policy of a
  process or thread
- In other scheduling policy-defined circumstances

Conforming implementations shall define the manner in which each of the scheduling policies
may modify the priorities or otherwise affect the ordering of processes or threads at each of the
occurrences listed above. Additionally, conforming implementations shall define in what other
circumstances and in what manner each scheduling policy may modify the priorities or affect
the ordering of processes or threads.
4.14 Seconds Since the Epoch

A value that approximates the number of seconds that have elapsed since the Epoch. A Coordinated Universal Time name (specified in terms of seconds \(tm_{sec}\), minutes \(tm_{min}\), hours \(tm_{hour}\), days since January 1 of the year \(tm_{yday}\), and calendar year minus 1900 \(tm_{year}\)) is related to a time represented as seconds since the Epoch, according to the expression below.

If the year is <1970 or the value is negative, the relationship is undefined. If the year is ≥1970 and the value is non-negative, the value is related to a Coordinated Universal Time name according to the C-language expression, where \(tm_{sec}\), \(tm_{min}\), \(tm_{hour}\), \(tm_{yday}\), and \(tm_{year}\) are all integer types:

\[
\begin{align*}
& \quad \text{tm}_\text{sec} + \text{tm}_\text{min} \times 60 + \text{tm}_\text{hour} \times 3600 + \text{tm}_\text{yday} \times 86400 + \\
& (\text{tm}_\text{year} - 70) \times 31536000 + ((\text{tm}_\text{year} - 69)/4) \times 86400 - \\
& ((\text{tm}_\text{year} - 1)/100) \times 86400 + ((\text{tm}_\text{year} + 299)/400) \times 86400
\end{align*}
\]

The relationship between the actual time of day and the current value for seconds since the Epoch is unspecified.

How any changes to the value of seconds since the Epoch are made to align to a desired relationship with the current actual time are made is implementation-defined. As represented in seconds since the Epoch, each and every day shall be accounted for by exactly 86 400 seconds.

Note: The last three terms of the expression add in a day for each year that follows a leap year starting with the first leap year since the Epoch. The first term adds a day every 4 years starting in 1973, the second subtracts a day back out every 100 years starting in 2001, and the third adds a day back in every 400 years starting in 2001. The divisions in the formula are integer divisions; that is, the remainder is discarded leaving only the integer quotient.

4.15 Semaphore

A minimum synchronization primitive to serve as a basis for more complex synchronization mechanisms to be defined by the application program.

For the semaphores associated with the Semaphores option, a semaphore is represented as a shareable resource that has a non-negative integer value. When the value is zero, there is a (possibly empty) set of threads awaiting the availability of the semaphore.

For the semaphores associated with the X/Open System Interface Extension (XSI), a semaphore is a positive integer (0 through 32767). The `semget()` function can be called to create a set or array of semaphores. A semaphore set can contain one or more semaphores up to an implementation-defined value.

Semaphore Lock Operation

An operation that is applied to a semaphore. If, prior to the operation, the value of the semaphore is zero, the semaphore lock operation shall cause the calling thread to be blocked and added to the set of threads awaiting the semaphore; otherwise, the value shall be decremented.
Semaphore Unlock Operation

An operation that is applied to a semaphore. If, prior to the operation, there are any threads in
the set of threads awaiting the semaphore, then some thread from that set shall be removed from
the set and becomes unblocked; otherwise, the semaphore value shall be incremented.

4.16 Thread-Safety

Refer to the System Interfaces volume of IEEE Std 1003.1-2001, Section 2.9, Threads.

4.17 Tracing

The trace system allows a traced process to have a selection of events created for it. Traces
consist of streams of trace event types.

A trace event type is identified on the one hand by a trace event type name, also referenced as a
trace event name, and on the other hand by a trace event type identifier. A trace event name is a
human-readable string. A trace event type identifier is an opaque identifier used by the trace
system. There shall be a one-to-one relationship between trace event type identifiers and trace
event names for a given trace stream and also for a given traced process. The trace event type
identifier shall be generated automatically from a trace event name by the trace system either
when a trace controller process invokes posix_trace_trid_eventid_open() or when an instrumented
application process invokes posix_trace_eventid_open(). Trace event type identifiers are used to
filter trace event types, to allow interpretation of user data, and to identify the kind of trace point
that generated a trace event.

Each trace event shall be of a particular trace event type, and associated with a trace event type
identifier. The execution of a trace point shall generate a trace event if a trace stream has been
created and started for the process that executed the trace point and if the corresponding trace
event type identifier is not ignored by filtering.

A generated trace event shall be recorded in a trace stream, and optionally also in a trace log if a
trace log is associated with the trace stream, except that:

- For a trace stream, if no resources are available for the event, the event is lost.
- For a trace log, if no resources are available for the event, or a flush operation does not
  succeed, the event is lost.

A trace event recorded in an active trace stream may be retrieved by an application having the
appropriate privileges.

A trace event recorded in a trace log may be retrieved by an application having the appropriate
privileges after opening the trace log as a pre-recorded trace stream, with the function
posix_trace_open().

When a trace event is reported it is possible to retrieve the following:

- A trace event type identifier
- A timestamp
- The process ID of the traced process, if the trace event is process-dependent
- Any optional trace event data including its length
If the Threads option is supported, the thread ID, if the trace event is process-dependent

The program address at which the trace point was invoked

Trace events may be mapped from trace event types to trace event names. One such mapping shall be associated with each trace stream. An active trace stream is associated with a traced process, and also with its children if the Trace Inherit option is supported and also the inheritance policy is set to _POSIX_TRACE_INHERIT. Therefore each traced process has a mapping of the trace event names to trace event type identifiers that have been defined for that process.

Traces can be recorded into either trace streams or trace logs.

The implementation and format of a trace stream are unspecified. A trace stream need not be and generally is not persistent. A trace stream may be either active or pre-recorded:

- An active trace stream is a trace stream that has been created and has not yet been shut down. It can be of one of the two following classes:
  
  1. An active trace stream without a trace log that was created with the `posix_trace_create()` function
  
  2. If the Trace Log option is supported, an active trace stream with a trace log that was created with the `posix_trace_create_withlog()` function

- A pre-recorded trace stream is a trace stream that was opened from a trace log object using the `posix_trace_open()` function.

An active trace stream can loop. This behavior means that when the resources allocated by the trace system for the trace stream are exhausted, the trace system reuses the resources associated with the oldest recorded trace events to record new trace events.

If the Trace Log option is supported, an active trace stream with a trace log can be flushed. This operation causes the trace system to write trace events from the trace stream to the associated trace log, following the defined policies or using an explicit function call. After this operation, the trace system may reuse the resources associated with the flushed trace events.

An active trace stream with or without a trace log can be cleared. This operation shall cause all the resources associated with this trace stream to be reinitialized. The trace stream shall behave as if it was returning from its creation, except that the mapping of trace event type identifiers to trace event names shall not be cleared. If a trace log was associated with this trace stream, the trace log shall also be reinitialized.

A trace log shall be recorded when the `posix_trace_shutdown()` operation is invoked or during tracing, depending on the tracing strategy which is defined by a log policy. After the trace stream has been shut down, the trace information can be retrieved from the associated trace log using the same interface used to retrieve information from an active trace stream.

For a traced process, if the Trace Inherit option is supported and the trace stream’s inheritance attribute is _POSIX_TRACE_INHERIT, the initial targeted traced process shall be traced together with all of its future children. The `posix_pid` member of each trace event in a trace stream shall be the process ID of the traced process.

Each trace point may be an implementation-defined action such as a context switch, or an application-programmed action such as a call to a specific operating system service (for example, `fork()` or a call to `posix_trace_event()`).

Trace points may be filtered. The operation of the filter is to filter out (ignore) selected trace events. By default, no trace events are filtered.
The results of the tracing operations can be analyzed and monitored by a trace controller process or a trace analyzer process.

Only the trace controller process has control of the trace stream it has created. The control of the operation of a trace stream is done using its corresponding trace stream identifier. The trace controller process is able to:

- Initialize the attributes of a trace stream
- Create the trace stream
- Start and stop tracing
- Know the mapping of the traced process
- If the Trace Event Filter option is supported, filter the type of trace events to be recorded
- Shut the trace stream down

A traced process may also be a trace controller process. Only the trace controller process can control its trace stream(s). A trace stream created by a trace controller process shall be shut down if its controller process terminates or executes another file.

A trace controller process may also be a trace analyzer process. Trace analysis can be done concurrently with the traced process or can be done off-line, in the same or in a different platform.

4.18 Treatment of Error Conditions for Mathematical Functions

For all the functions in the `<math.h>` header, an application wishing to check for error situations should set `errno` to 0 and call `feclearexcept(FE_ALL_EXCEPT)` before calling the function. On return, if `errno` is non-zero or `fetestexcept(FE_INVALID | FE_DIVBYZERO | FE_OVERFLOW | FE_UNDERFLOW)` is non-zero, an error has occurred.

The following error conditions are defined for all functions in the `<math.h>` header.

4.18.1 Domain Error

A “domain error” shall occur if an input argument is outside the domain over which the mathematical function is defined. The description of each function lists any required domain errors; an implementation may define additional domain errors, provided that such errors are consistent with the mathematical definition of the function.

On a domain error, the function shall return an implementation-defined value; if the integer expression (math_errhandling & MATH_ERRNO) is non-zero, `errno` shall be set to [EDOM]; if the integer expression (math_errhandling & MATH_ERREXCEPT) is non-zero, the “invalid” floating-point exception shall be raised.
4.18.2 Pole Error

A “pole error” occurs if the mathematical result of the function is an exact infinity (for example, log(0.0)).

On a pole error, the function shall return the value of the macro HUGE_VAL, HUGE_VALF, or HUGE_VALL according to the return type, with the same sign as the correct value of the function; if the integer expression (math_errhandling & MATH_ERRNO) is non-zero, errno shall be set to [ERANGE]; if the integer expression (math_errhandling & MATH_ERREXCEPT) is non-zero, the “divide-by-zero” floating-point exception shall be raised.

4.18.3 Range Error

A “range error” shall occur if the finite mathematical result of the function cannot be represented in an object of the specified type, due to extreme magnitude.

4.18.3.1 Result Overflows

A floating result overflows if the magnitude of the mathematical result is finite but so large that the mathematical result cannot be represented without extraordinary roundoff error in an object of the specified type. If a floating result overflows and default rounding is in effect, then the function shall return the value of the macro HUGE_VAL, HUGE_VALF, or HUGE_VALL according to the return type, with the same sign as the correct value of the function; if the integer expression (math_errhandling & MATH_ERRNO) is non-zero, errno shall be set to [ERANGE]; if the integer expression (math_errhandling & MATH_ERREXCEPT) is non-zero, the “overflow” floating-point exception shall be raised.

4.18.3.2 Result Underflows

The result underflows if the magnitude of the mathematical result is so small that the mathematical result cannot be represented, without extraordinary roundoff error, in an object of the specified type. If the result underflows, the function shall return an implementation-defined value whose magnitude is no greater than the smallest normalized positive number in the specified type; if the integer expression (math_errhandling & MATH_ERRNO) is non-zero, whether errno is set to [ERANGE] is implementation-defined; if the integer expression (math_errhandling & MATH_ERREXCEPT) is non-zero, whether the “underflow” floating-point exception is raised is implementation-defined.

4.19 Treatment of NaN Arguments for the Mathematical Functions

For functions called with a NaN argument, no errors shall occur and a NaN shall be returned, except where stated otherwise.

If a function with one or more NaN arguments returns a NaN result, the result should be the same as one of the NaN arguments (after possible type conversion), except perhaps for the sign.

On implementations that support the IEC 60559:1989 standard floating point, functions with signaling NaN argument(s) shall be treated as if the function were called with an argument that is a required domain error and shall return a quiet NaN result, except where stated otherwise.

Note: The function might never see the signaling NaN, since it might trigger when the arguments are evaluated during the function call.

On implementations that support the IEC 60559:1989 standard floating point, for those functions that do not have a documented domain error, the following shall apply:
These functions shall fail if:

Domain Error Any argument is a signaling NaN.

Either, the integer expression (math_errno & MATH_ERRNO) is non-zero and *errno* shall be set to [EDOM], or the integer expression (math_errno & MATH_ERREXCEPT) is non-zero and the invalid floating-point exception shall be raised.

### 4.20 Utility

A utility program shall be either an executable file, such as might be produced by a compiler or linker system from computer source code, or a file of shell source code, directly interpreted by the shell. The program may have been produced by the user, provided by the system implementor, or acquired from an independent distributor.

The system may implement certain utilities as shell functions (see the Shell and Utilities volume of IEEE Std 1003.1-2001, Section 2.9.5, Function Definition Command) or built-in utilities, but only an application that is aware of the command search order described in the Shell and Utilities volume of IEEE Std 1003.1-2001, Section 2.9.1.1, Command Search and Execution or of performance characteristics can discern differences between the behavior of such a function or built-in utility and that of an executable file.

### 4.21 Variable Assignment

In the shell command language, a word consisting of the following parts:

\[ \text{varname=value} \]

When used in a context where assignment is defined to occur and at no other time, the *value* (representing a word or field) shall be assigned as the value of the variable denoted by *varname*.

**Note:** For further information, see the Shell and Utilities volume of IEEE Std 1003.1-2001, Section 2.9.1, Simple Commands.

The *varname* and *value* parts shall meet the requirements for a name and a word, respectively, except that they are delimited by the embedded unquoted equals-sign, in addition to other delimiters.

**Note:** Additional delimiters are described in the Shell and Utilities volume of IEEE Std 1003.1-2001, Section 2.3, Token Recognition.

When a variable assignment is done, the variable shall be created if it did not already exist. If *value* is not specified, the variable shall be given a null value.

**Note:** An alternative form of variable assignment:

\[ \text{symbol=value} \]

(where *symbol* is a valid word delimited by an equals-sign, but not a valid name) produces unspecified results. The form *symbol=value* is used by the KornShell name[expression]=value syntax.
File Format Notation

The STDIN, STDOUT, STDERR, INPUT FILES, and OUTPUT FILES sections of the utility descriptions use a syntax to describe the data organization within the files, when that organization is not otherwise obvious. The syntax is similar to that used by the System Interfaces volume of IEEE Std 1003.1-2001 `printf()` function, as described in this chapter. When used in STDIN or INPUT FILES sections of the utility descriptions, this syntax describes the format that could have been used to write the text to be read, not a format that could be used by the System Interfaces volume of IEEE Std 1003.1-2001 `scanf()` function to read the input file.

The description of an individual record is as follows:

\[
\text{"<format>"}, \ [\text{<arg1>}, \text{<arg2>}, \ldots, \text{<argn>}]\]

The `format` is a character string that contains three types of objects defined below:

1. **Characters** that are not "escape sequences" or "conversion specifications", as described below, shall be copied to the output.
2. **Escape Sequences** represent non-graphic characters.
3. **Conversion Specifications** specify the output format of each argument; see below.

The following characters have the following special meaning in the format string:

- `' ' (An empty character position.) Represents one or more <blank>s.
- `\text{\Delta}` Represents exactly one <space>.

Table 5-1 lists escape sequences and associated actions on display devices capable of the action.
conversion specifiers, a non-zero result has 0x or 0X prefixed to it, respectively. For specifiers, the behavior is undefined. For the flags both appear, in any order, that modify the meaning of the conversion specification.

Each conversion specification is introduced by the percent-sign character (‘%’). After the character ‘%’, the following shall appear in sequence:

flags

A conversion specifier character (see below) that indicates the type of conversion to be applied.

The flag characters and their meanings are:

− The result of the conversion shall be left-justified within the field.

+ The result of a signed conversion shall always begin with a sign (‘+’ or ‘−’).

<space> If the first character of a signed conversion is not a sign, a <space> shall be prefixed to the result. This means that if the <space> and ‘+’ flags both appear, the <space> flag shall be ignored.

# The value shall be converted to an alternative form. For c, d, i, u, and s conversion specifiers, the behavior is undefined. For the o conversion specifier, it shall increase the precision to force the first digit of the result to be a zero. For x or X conversion specifiers, a non-zero result has 0x or 0X prefixed to it, respectively.

</tbody>
</table>

Each conversion specification is introduced by the percent-sign character (‘%’). After the character ‘%’, the following shall appear in sequence:

flags

An optional string of decimal digits to specify a minimum field width. For an output field, if the converted value has fewer bytes than the field width, it shall be padded on the left (or right, if the left-adjustment flag (‘−’), described below, has been given) to the field width.

precision

Gives the minimum number of digits to appear for the d, o, i, u, x, or X conversion specifiers (the field is padded with leading zeros), the number of digits to appear after the radix character for the e and f conversion specifiers, the maximum number of significant digits for the g conversion specifier; or the maximum number of bytes to be written from a string in the s conversion specifier. The precision shall take the form of a period (‘.’) followed by a decimal digit string; a null digit string is treated as zero.
The conversion specifiers and their meanings are:

- **d**, **i**, **o**, **u**, **x**, **X**
  - The integer argument shall be written as signed decimal (\(d\) or \(i\)), unsigned octal (\(o\)), unsigned decimal (\(u\)), or unsigned hexadecimal notation (\(x\) and \(X\)). The \(d\) and \(i\) specifiers shall convert to signed decimal in the style "\([-\]dd\(dd\)\]". The \(x\) conversion specifier shall use the numbers and letters "0123456789abcdef" and the \(X\) conversion specifier shall use the numbers and letters "0123456789ABCDEF". The **precision** component of the argument shall specify the minimum number of digits to appear. If the value being converted can be represented in fewer digits than the specified minimum, it shall be expanded with leading zeros. The default precision shall be 1. The result of converting a zero value with a precision of 0 shall be no characters. If both the field width and precision are omitted, the implementation may precede, follow, or precede and follow numeric arguments of types \(d\), \(i\), and \(u\) with <blank>s; arguments of type \(o\) (octal) may be preceded with leading zeros.

- **f**
  - The floating-point number argument shall be written in decimal notation in the style [\([-\]ld\(dd..dd\)\] where the number of digits after the radix character (shown here as a decimal point) shall be equal to the **precision** specification. The **locale** category shall determine the radix character to use in this format. If the **precision** is omitted from the argument, six digits shall be written after the radix character; if the **precision** is explicitly 0, no radix character shall appear.

- **e**, **E**
  - The floating-point number argument shall be written in the style [\([-\]ld\(ddedx\dd\) (the symbol '+' indicates either a plus or minus sign), where there is one digit before the radix character (shown here as a decimal point) and the number of digits after it is equal to the precision. The **locale** category shall determine the radix character to use in this format. When the precision is missing, six digits shall be written after the radix character; if the precision is 0, no radix character shall appear. The **E** conversion specifier shall produce a number with **E** instead of **e** introducing the exponent. The exponent shall always contain at least two digits. However, if the value to be written requires an exponent greater than two digits, additional exponent digits shall be written as necessary.

- **g**, **G**
  - The floating-point number argument shall be written in style **f** or **e** (or in style **F** or **E** in the case of a **G** conversion specifier), with the precision specifying the number of significant digits. The style used depends on the value converted: style **e** (or **E**) shall be used only if the exponent resulting from the conversion is less than \(-4\) or greater than or equal to the precision. Trailing zeros are removed from the result. A radix character shall appear only if it is followed by a digit.
The integer argument shall be converted to an **unsigned char** and the resulting byte shall be written.

The argument shall be taken to be a string and bytes from the string shall be written until the end of the string or the number of bytes indicated by the *precision* specification of the argument is reached. If the precision is omitted from the argument, it shall be taken to be infinite, so all bytes up to the end of the string shall be written.

Write a ‘%’ character; no argument is converted.

In no case does a nonexistent or insufficient field width cause truncation of a field; if the result of a conversion is wider than the field width, the field is simply expanded to contain the conversion result. The term “field width” should not be confused with the term “precision” used in the description of `%s`.

**Examples**

To represent the output of a program that prints a date and time in the form Sunday, July 3, 10:02, where `weekday` and `month` are strings:

```
"%s,%s%d,%d:%.2d\n" <weekday>, <month>, <day>, <hour>, <min>
```

To show ‘π’ written to 5 decimal places:

```
"π\n",<value of π>
```

To show an input file format consisting of five colon-separated fields:

```
"%s:%s:%s:%s:%s\n", <arg1>, <arg2>, <arg3>, <arg4>, <arg5>
```
Chapter 6

Character Set

6.1 Portable Character Set

Conforming implementations shall support one or more coded character sets. Each supported locale shall include the portable character set, which is the set of symbolic names for characters in Table 6-1. This is used to describe characters within the text of IEEE Std 1003.1-2001. The first eight entries in Table 6-1 are defined in the ISO/IEC 6429:1992 standard and the rest of the characters are defined in the ISO/IEC 10646-1:2000 standard.

</table>

IEEE Std 1003.1-2001 uses character names other than the above, but only in an informative way; for example, in examples to illustrate the use of characters beyond the portable character set with the facilities of IEEE Std 1003.1-2001.

Table 6-1 (on page 115) defines the characters in the portable character set and the corresponding symbolic character names used to identify each character in a character set description file. The table contains more than one symbolic character name for characters whose traditional name differs from the chosen name. Characters defined in Table 6-2 (on page 120) may also be used in character set description files.

IEEE Std 1003.1-2001 places only the following requirements on the encoded values of the characters in the portable character set:

- If the encoded values associated with each member of the portable character set are not invariant across all locales supported by the implementation, if an application accesses any pair of locales where the character encodings differ, or accesses data from an application running in a locale which has different encodings from the application's current locale, the results are unspecified.

Base Definitions, Issue 6 — Copyright © 2001-2003, IEEE and The Open Group. All rights reserved. 117
• The encoded values associated with the digits 0 to 9 shall be such that the value of each
character after 0 shall be one greater than the value of the previous character.

• A null character, NUL, which has all bits set to zero, shall be in the set of characters.

• The encoded values associated with the members of the portable character set are each
represented in a single byte. Moreover, if the value is stored in an object of C-language type
char, it is guaranteed to be positive (except the NUL, which is always zero).

Conforming implementations shall support certain character and character set attributes, as
defined in Section 7.2 (on page 124).

6.2 Character Encoding

The POSIX locale contains the characters in Table 6-1 (on page 115), which have the properties
listed in Section 7.3.1 (on page 126). In other locales, the presence, meaning, and representation
of any additional characters are locale-specific.

In locales other than the POSIX locale, a character may have a state-dependent encoding. There
are two types of these encodings:

• A single-shift encoding (where each character not in the initial shift state is preceded by a
shift code) can be defined if each shift-code and character sequence is considered a multi-
byte character. This is done using the concatenated-constant format in a character set
description file, as described in Section 6.4 (on page 119). If the implementation supports a
character encoding of this type, all of the standard utilities in the Shell and Utilities volume of
IEEE Std 1003.1-2001 shall support it. Use of a single-shift encoding with any of the functions
in the System Interfaces volume of IEEE Std 1003.1-2001 that do not specifically mention the
effects of state-dependent encoding is implementation-defined.

• A locking-shift encoding (where the state of the character is determined by a shift code that
may affect more than the single character following it) cannot be defined with the current
character set description file format. Use of a locking-shift encoding with any of the standard
utilities in the Shell and Utilities volume of IEEE Std 1003.1-2001 or with any of the functions
in the System Interfaces volume of IEEE Std 1003.1-2001 that do not specifically mention the
effects of state-dependent encoding is implementation-defined.

While in the initial shift state, all characters in the portable character set shall retain their usual
interpretation and shall not alter the shift state. The interpretation for subsequent bytes in the
sequence shall be a function of the current shift state. A byte with all bits zero shall be
interpreted as the null character independent of shift state. Thus a byte with all bits zero shall
never occur in the second or subsequent bytes of a character.

The maximum allowable number of bytes in a character in the current locale shall be indicated
by [MB_CUR_MAX], defined in the <stdlib.h> header and by the <mb_cur_max> value in a
character set description file; see Section 6.4 (on page 119). The implementation’s maximum
number of bytes in a character shall be defined by the C-language macro [MB_LEN_MAX].
6.3 C Language Wide-Character Codes

In the shell, the standard utilities are written so that the encodings of characters are described by the locale’s LC_CTYPE definition (see Section 7.3.1 (on page 126)) and there is no differentiation between characters consisting of single octets (8-bit bytes) or multiple bytes. However, in the C language, a differentiation is made. To ease the handling of variable length characters, the C language has introduced the concept of wide-character codes.

All wide-character codes in a given process consist of an equal number of bits. This is in contrast to characters, which can consist of a variable number of bytes. The byte or byte sequence that represents a character can also be represented as a wide-character code. Wide-character codes thus provide a uniform size for manipulating text data. A wide-character code having all bits zero is the null wide-character code (see Section 3.246 (on page 69)), and terminates wide-character strings (see Section 3.432 (on page 95)). The wide-character value for each member of the portable character set shall equal its value when used as the lone character in an integer character constant. Wide-character codes for other characters are locale and implementation-defined. State shift bytes shall not have a wide-character code representation.

6.4 Character Set Description File

Implementations shall provide a character set description file for at least one coded character set supported by the implementation. These files are referred to elsewhere in IEEE Std 1003.1-2001 as charmap files. It is implementation-defined whether or not users or applications can provide additional character set description files.

IEEE Std 1003.1-2001 does not require that multiple character sets or codesets be supported. Although multiple charmap files are supported, it is the responsibility of the implementation to provide the file or files; if only one is provided, only that one is accessible using the localedef utility’s --f option.

Each character set description file, except those that use the ISO/IEC 10646-1:2000 standard position values as the encoding values, shall define characteristics for the coded character set and the encoding for the characters specified in Table 6-1 (on page 115), and may define encoding for additional characters supported by the implementation. Other information about the coded character set may also be in the file. Coded character set character values shall be defined using symbolic character names followed by character encoding values.

Each symbolic name specified in Table 6-1 (on page 115) shall be included in the file and shall be mapped to a unique coding value, except as noted below. The glyphs '{', '}', ',', '-', ',', '/', '\', '.', and '^' have more than one symbolic name; all symbolic names for each such glyph shall be included, each with identical encoding. If some or all of the control characters identified in Table 6-2 (on page 120) are supported by the implementation, the symbolic names and their corresponding encoding values shall be included in the file. Some of the encodings associated with the symbolic names in Table 6-2 (on page 120) may be the same as characters found in Table 6-1 (on page 115); both names shall be provided for each encoding.
Table 6-2 Control Character Set

<td>&lt;SO&gt;</td>
<td>&lt;VT&gt;</td>
</tr>
</tbody>
</table>

The following declarations can precede the character definitions. Each shall consist of the symbol shown in the following list, starting in column 1, including the surrounding brackets, followed by one or more <blank>s, followed by the value to be assigned to the symbol.

<code_set_name> The name of the coded character set for which the character set description file is defined. The characters of the name shall be taken from the set of characters with visible glyphs defined in Table 6-1 (on page 115).

<mb_cur_max> The maximum number of bytes in a multi-byte character. This shall default to 1.

<mb_cur_min> An unsigned positive integer value that defines the minimum number of bytes in a character for the encoded character set. On XSI-conformant systems, <mb_cur_min> shall always be 1.

<escape_char> The character used to indicate that the characters following shall be interpreted in a special way, as defined later in this section. This shall default to backslash ('\'), which is the character used in all the following text and examples, unless otherwise noted.

<comment_char> The character that, when placed in column 1 of a charmap line, is used to indicate that the line shall be ignored. The default character shall be the number sign ('#').

The character set mapping definitions shall be all the lines immediately following an identifier line containing the string "CHARMAP" starting in column 1, and preceding a trailer line containing the string "END CHARMAP" starting in column 1. Empty lines and lines containing a <comment_char> in the first column shall be ignored. Each non-comment line of the character set mapping definition (that is, between the "CHARMAP" and "END CHARMAP" lines of the file) shall be in either of two forms:

"%s %s %s\n", <symbolic-name>, <encoding>, <comments>
or:

"%s...%s %s %s\n", <symbolic-name>, <symbolic-name>,
<encoding>, <comments>

In the first format, the line in the character set mapping definition shall define a single symbolic name and a corresponding encoding. A symbolic name is one or more characters from the set shown with visible glyphs in Table 6-1 (on page 115), enclosed between angle brackets. A character following an escape character is interpreted as itself; for example, the sequence "\" represents the symbolic name "\" enclosed between angle brackets.

In the second format, the line in the character set mapping definition shall define a range of one or more symbolic names. In this form, the symbolic names shall consist of zero or more non-numeric characters from the set shown with visible glyphs in Table 6-1 (on page 115), followed by an integer formed by one or more decimal digits. Both integers shall contain the same number of digits. The characters preceding the integer shall be identical in the two symbolic names, and
the integer formed by the digits in the second symbolic name shall be equal to or greater than the integer formed by the digits in the first name. This shall be interpreted as a series of symbolic names formed from the common part and each of the integers between the first and the second integer, inclusive. As an example, <j0101>...<j0104> is interpreted as the symbolic names <j0101>, <j0102>, <j0103>, and <j0104>, in that order.

A character set mapping definition line shall exist for all symbolic names specified in Table 6-1 (on page 115), and shall define the coded character value that corresponds to the character indicated in the table, or the coded character value that corresponds to the control character symbolic name. If the control characters commonly associated with the symbolic names in Table 6-2 (on page 120) are supported by the implementation, the symbolic name and the corresponding encoding value shall be included in the file. Additional unique symbolic names may be included. A coded character value can be represented by more than one symbolic name.

The encoding part is expressed as one (for single-byte character values) or more concatenated decimal, octal, or hexadecimal constants in the following formats:

- "%cd%u", <escape_char>, <decimal byte value>
- "%cx%x", <escape_char>, <hexadecimal byte value>
- "%c%o", <escape_char>, <octal byte value>

Decimal constants shall be represented by two or three decimal digits, preceded by the escape character and the lowercase letter 'd'; for example, "\d05", "\d97", or "\d143". Hexadecimal constants shall be represented by two hexadecimal digits, preceded by the escape character and the lowercase letter 'x'; for example, "\x05", "\x61", or "\x8f". Octal constants shall be represented by two or three octal digits, preceded by the escape character; for example, "\05", "\141", or "\217". In a portable charmap file, each constant represents an 8-bit byte. When constants are concatenated for multi-byte character values, they shall be of the same type, and interpreted in byte order from first to last with the least significant byte of the multi-byte character specified by the last constant. The manner in which these constants are represented in the character stored in the system is implementation-defined. (This notation was chosen for reasons of portability. There is no requirement that the internal representation in the computer memory be in this same order.) Omitting bytes from a multi-byte character definition produces undefined results.

In lines defining ranges of symbolic names, the encoded value shall be the value for the first symbolic name in the range (the symbolic name preceding the ellipsis). Subsequent symbolic names defined by the range shall have encoding values in increasing order. Bytes shall be treated as unsigned octets, and carry shall be propagated between the bytes as necessary to represent the range. For example, the line:

<j0101>...<j0104> \d129\d254

is interpreted as:

<j0101> \d129\d254
<j0102> \d129\d255
<j0103> \d130\d0
<j0104> \d130\d1

The comment is optional.

The following declarations can follow the character set mapping definitions (after the "END CHARMAP" statement). Each shall consist of the keyword shown in the following list, starting in column 1, followed by the value(s) to be associated to the keyword, as defined below.

- WIDTH An unsigned positive integer value defining the column width (see Section 3.103 (on page 49)) for the printable characters in the coded character set specified in
Table 6-1 (on page 115) and Table 6-2 (on page 120). Coded character set character
values shall be defined using symbolic character names followed by column width
values. Defining a character with more than one WIDTH produces undefined
results. The END WIDTH keyword shall be used to terminate the WIDTH
definitions. Specifying the width of a non-printable character in a WIDTH
declaration produces undefined results.

**WIDTH_DEFAULT**

An unsigned positive integer value defining the default column width for any
printable character not listed by one of the WIDTH keywords. If no
WIDTH_DEFAULT keyword is included in the charmap, the default character
width shall be 1.

**Example**

After the "END CHARMAP" statement, a syntax for a width definition would be:

```plaintext
WIDTH
<A> 1
<B> 1
<C>...<Z> 1
...
<foo1>...<foon> 2
...
END WIDTH
```

In this example, the numerical code point values represented by the symbols <A> and <B> are
assigned a width of 1. The code point values <C> to <Z> inclusive (<C>, <D>, <E>, and so on)
are also assigned a width of 1. Using <A>...<Z> would have required fewer lines, but the
alternative was shown to demonstrate flexibility. The keyword WIDTH_DEFAULT could have
been added as appropriate.

### 6.4.1 State-Dependent Character Encodings

This section addresses the use of state-dependent character encodings (that is, those in which the
encoding of a character is dependent on one or more shift codes that may precede it).

A single-shift encoding (where each character not in the initial shift state is preceded by a shift
code) can be defined in the charmap format if each shift-code/character sequence is considered a
multi-byte character, defined using the concatenated-constant format described in Section 6.4
(on page 119). If the implementation supports a character encoding of this type, all of the
standard utilities shall support it. A locking-shift encoding (where the state of the character is
determined by a shift code that may affect more than the single character following it) could be
defined with an extension to the charmap format described in Section 6.4 (on page 119). If the
implementation supports a character encoding of this type, any of the standard utilities that
describe character (versus byte) or text-file manipulation shall have the following characteristics:

1. The utility shall process the statefully encoded data as a concatenation of state-
   independent characters. The presence of redundant locking shifts shall not affect the
   comparison of two statefully encoded strings.

2. A utility that divides, truncates, or extracts substrings from statefully encoded data shall
   produce output that contains locking shifts at the beginning or end of the resulting data, if
   appropriate, to retain correct state information.
7.1 General

A locale is the definition of the subset of a user’s environment that depends on language and cultural conventions. It is made up from one or more categories. Each category is identified by its name and controls specific aspects of the behavior of components of the system. Category names correspond to the following environment variable names:

- LC_CTYPE  Character classification and case conversion.
- LC_COLLATE Collation order.
- LC_MONETARY Monetary formatting.
- LC_NUMERIC Numeric, non-monetary formatting.
- LC_TIME Date and time formats.
- LC_MESSAGES Formats of informative and diagnostic messages and interactive responses.

The standard utilities in the Shell and Utilities volume of IEEE Std 1003.1-2001 shall base their behavior on the current locale, as defined in the ENVIRONMENT VARIABLES section for each utility. The behavior of some of the C-language functions defined in the System Interfaces volume of IEEE Std 1003.1-2001 shall also be modified based on the current locale, as defined by the last call to setlocale().

Locales other than those supplied by the implementation can be created via the localedef utility, provided that the _POSIX2_LOCALEDEF symbol is defined on the system. Even if localedef is not provided, all implementations conforming to the System Interfaces volume of IEEE Std 1003.1-2001 shall provide one or more locales that behave as described in this chapter.

The input to the utility is described in Section 7.3 (on page 124). The value that is used to specify a locale when using environment variables shall be the string specified as the name operand to the localedef utility when the locale was created. The strings "C" and "POSIX" are reserved as identifiers for the POSIX locale (see Section 7.2 (on page 124)). When the value of a locale environment variable begins with a slash ('/'), it shall be interpreted as the path name of the locale definition; the type of file (regular, directory, and so on) used to store the locale definition is implementation-defined. If the value does not begin with a slash, the mechanism used to locate the locale is implementation-defined.

If different character sets are used by the locale categories, the results achieved by an application utilizing these categories are undefined. Likewise, if different codesets are used for the data being processed by interfaces whose behavior is dependent on the current locale, or the codeset is different from the codeset assumed when the locale was created, the result is also undefined.

Applications can select the desired locale by invoking the setlocale() function (or equivalent) with the appropriate value. If the function is invoked with an empty string, such as:

```
setlocale(LC_ALL, "");
```

the value of the corresponding environment variable is used. If the environment variable is unset or is set to the empty string, the implementation shall set the appropriate environment as defined in Chapter 8 (on page 161).
7.2 POSIX Locale

Conforming systems shall provide a POSIX locale, also known as the C locale. The behavior of standard utilities and functions in the POSIX locale shall be as if the locale was defined via the `localedef` utility with input data from the POSIX locale tables in Section 7.3.

The tables in Section 7.3 describe the characteristics and behavior of the POSIX locale for data consisting entirely of characters from the portable character set and the control character set. For other characters, the behavior is unspecified. For C-language programs, the POSIX locale shall be the default locale when the `setlocale()` function is not called.

The POSIX locale can be specified by assigning to the appropriate environment variables the values "C" or "POSIX".

All implementations shall define a locale as the default locale, to be invoked when no environment variables are set, or set to the empty string. This default locale can be the POSIX locale or any other implementation-defined locale. Some implementations may provide facilities for local installation administrators to set the default locale, customizing it for each location. IEEE Std 1003.1-2001 does not require such a facility.

7.3 Locale Definition

The capability to specify additional locales to those provided by an implementation is optional, denoted by the _POSIX2 LocaleDEF symbol. If the option is not supported, only implementation-supplied locales are available. Such locales shall be documented using the format specified in this section.

Locales can be described with the file format presented in this section. The file format is that accepted by the `localedef` utility. For the purposes of this section, the file is referred to as the "locale definition file", but no locales shall be affected by this file unless it is processed by `localedef` or some similar mechanism. Any requirements in this section imposed upon the utility shall apply to `localedef` or to any other similar utility used to install locale information using the locale definition file format described here.

The locale definition file shall contain one or more locale category source definitions, and shall not contain more than one definition for the same locale category. If the file contains source definitions for more than one category, implementation-defined categories, if present, shall appear after the categories defined by Section 7.1 (on page 123). A category source definition contains either the definition of a category or a copy directive. For a description of the copy directive, see `localedef`. In the event that some of the information for a locale category, as specified in this volume of IEEE Std 1003.1-2001, is missing from the locale source definition, the behavior of that category, if it is referenced, is unspecified.

A category source definition shall consist of a category header, a category body, and a category trailer. A category header shall consist of the character string naming of the category, beginning with the characters LC_. The category trailer shall consist of the string "END", followed by one or more <blank>s and the string used in the corresponding category header.

The category body shall consist of one or more lines of text. Each line shall contain an identifier, optionally followed by one or more operands. Identifiers shall be either keywords, identifying a particular locale element, or collating elements. In addition to the keywords defined in this volume of IEEE Std 1003.1-2001, the source can contain implementation-defined keywords. Each keyword within a locale shall have a unique name (that is, two categories cannot have a commonly-named keyword); no keyword shall start with the characters LC_. Identifiers shall be separated from the operands by one or more <blank>s.
Operands shall be characters, collating elements, or strings of characters. Strings shall be enclosed in double-quotes. Literal double-quotes within strings shall be preceded by the \textless escape character\textgreater, described below. When a keyword is followed by more than one operand, the operands shall be separated by semicolons; \textless blank\textgreater s shall be allowed both before and after a semicolon.

The first category header in the file can be preceded by a line modifying the comment character. It shall have the following format, starting in column 1:

\texttt{"comment\_char \%c\n", <comment character>}

The comment character shall default to the number sign (\textquotesingle \#\textquotesingle). Blank lines and lines containing the \textless comment character\textgreater in the first position shall be ignored.

The first category header in the file can be preceded by a line modifying the escape character to be used in the file. It shall have the following format, starting in column 1:

\texttt{"escape\_char \%c\n", <escape character>}

The escape character shall default to backslash, which is the character used in all examples shown in this volume of IEEE Std 1003.1-2001.

A line can be continued by placing an escape character as the last character on the line; this continuation character shall be discarded from the input. Although the implementation need not accept any one portion of a continued line with a length exceeding \texttt{LINE\_MAX} bytes, it shall place no limits on the accumulated length of the continued line. Comment lines shall not be continued on a subsequent line using an escaped \textless newline\textgreater.

Individual characters, characters in strings, and collating elements shall be represented using symbolic names, as defined below. In addition, characters can be represented using the characters themselves or as octal, hexadecimal, or decimal constants. When non-symbolic notation is used, the resultant locale definitions are in many cases not portable between systems.

The left angle bracket (\textless \textless) is a reserved symbol, denoting the start of a symbolic name; when used to represent itself it shall be preceded by the escape character. The following rules apply to character representation:

1. A character can be represented via a symbolic name, enclosed within angle brackets \textless and \textgreater. The symbolic name, including the angle brackets, shall exactly match a symbolic name defined in the charmap file specified via the \texttt{localedef \_f} option, and it shall be replaced by a character value determined from the value associated with the symbolic name in the charmap file. The use of a symbolic name not found in the charmap file shall constitute an error, unless the category is \texttt{LC\_CTYPE} or \texttt{LC\_COLLATE}, in which case it shall constitute a warning condition (see \texttt{localedef} for a description of actions resulting from errors and warnings). The specification of a symbolic name in a \texttt{collating-element} or \texttt{collating-symbol} section that duplicates a symbolic name in the charmap file (if present) shall be an error. Use of the escape character or a right angle bracket within a symbolic name is invalid unless the character is preceded by the escape character.

For example:

\texttt{<c>;<c-cedilla} "<M><a><y>"

2. A character in the portable character set can be represented by the character itself, in which case the value of the character is implementation-defined. (Implementations may allow other characters to be represented as themselves, but such locale definitions are not portable.) Within a string, the double-quote character, the escape character, and the right angle bracket character shall be escaped (preceded by the escape character) to be interpreted as the character itself. Outside strings, the characters:
shall be escaped to be interpreted as the character itself.

For example:

```
c    "May"
```

3. A character can be represented as an octal constant. An octal constant shall be specified as
the escape character followed by two or three octal digits. Each constant shall represent a
byte value. Multi-byte values can be represented by concatenated constants specified in
byte order with the last constant specifying the least significant byte of the character.

For example:

```
\143;\347;\143\150 "\115\141\171"
```

4. A character can be represented as a hexadecimal constant. A hexadecimal constant shall be
specified as the escape character followed by an ‘x’ followed by two hexadecimal digits.
Each constant shall represent a byte value. Multi-byte values can be represented by
concatenated constants specified in byte order with the last constant specifying the least
significant byte of the character.

For example:

```
\x63;\xe7;\x63\x68 "\x4d\x61\x79"
```

5. A character can be represented as a decimal constant. A decimal constant shall be specified
as the escape character followed by a ‘d’ followed by two or three decimal digits. Each
constant represents a byte value. Multi-byte values can be represented by concatenated
constants specified in byte order with the last constant specifying the least significant byte
of the character.

For example:

```
\d99;\d231;\d99\d104 "\d77\d97\d121"
```

Implementations may accept single-digit octal, decimal, or hexadecimal constants following the
escape character. Only characters existing in the character set for which the locale definition is
created shall be specified, whether using symbolic names, the characters themselves, or octal,
decimal, or hexadecimal constants. If a charmap file is present, only characters defined in the
charmap can be specified using octal, decimal, or hexadecimal constants. Symbolic names not
present in the charmap file can be specified and shall be ignored, as specified under item 1
above.

7.3.1 LC_CTYPE

The LC_CTYPE category shall define character classification, case conversion, and other
character attributes. In addition, a series of characters can be represented by three adjacent
periods representing an ellipsis symbol ("..."). The ellipsis specification shall be interpreted as
meaning that all values between the values preceding and following it represent valid
characters. The ellipsis specification shall be valid only within a single encoded character set;
that is, within a group of characters of the same size. An ellipsis shall be interpreted as including
in the list all characters with an encoded value higher than the encoded value of the character
preceding the ellipsis and lower than the encoded value of the character following the ellipsis.

For example:

```
\x30;...;\x39;
```
includes in the character class all characters with encoded values between the endpoints.

The following keywords shall be recognized. In the descriptions, the term “automatically included” means that it shall not be an error either to include or omit any of the referenced characters; the implementation provides them if missing (even if the entire keyword is missing) and accepts them silently if present. When the implementation automatically includes a missing character, it shall have an encoded value dependent on the charmap file in effect (see the description of the *localedef* -f option); otherwise, it shall have a value derived from an implementation-defined character mapping.

The character classes *digit*, *xdigit*, *lower*, *upper*, and *space* have a set of automatically included characters. These only need to be specified if the character values (that is, encoding) differ from the implementation default values. It is not possible to define a locale without these automatically included characters unless some implementation extension is used to prevent their inclusion. Such a definition would not be a proper superset of the C or POSIX locale and, thus, it might not be possible for conforming applications to work properly.

**copy**
Specify the name of an existing locale which shall be used as the definition of this category. If this keyword is specified, no other keyword shall be specified.

**upper**
Define characters to be classified as uppercase letters.

In the POSIX locale, the 26 uppercase letters shall be included:

```
ABCDEFGHIJKLMNOPQRSTUVWXYZ
```

In a locale definition file, no character specified for the keywords *cntrl*, *digit*, *punct*, or *space* shall be specified. The uppercase letters <A> to <Z>, as defined in Section 6.4 (on page 119) (the portable character set), are automatically included in this class.

**lower**
Define characters to be classified as lowercase letters.

In the POSIX locale, the 26 lowercase letters shall be included:

```
abcdefghijklmnopqrstuvwxyz
```

In a locale definition file, no character specified for the keywords *cntrl*, *digit*, *punct*, or *space* shall be specified. The lowercase letters <a> to <z> of the portable character set are automatically included in this class.

**alpha**
Define characters to be classified as letters.

In the POSIX locale, all characters in the classes *upper* and *lower* shall be included.

In a locale definition file, no character specified for the keywords *cntrl*, *digit*, *punct*, or *space* shall be specified. Characters classified as either *upper* or *lower* are automatically included in this class.

**digit**
Define the characters to be classified as numeric digits.

In the POSIX locale, only:

```
0 1 2 3 4 5 6 7 8 9
```

shall be included.

In a locale definition file, only the digits <zero>, <one>, <two>, <three>, <four>, <five>, <six>, <seven>, <eight>, and <nine> shall be specified, and in contiguous ascending sequence by numerical value. The digits <zero> to <nine> of the portable character set are automatically included in this class.
Locale Definition

alnum Define characters to be classified as letters and numeric digits. Only the characters specified for the alpha and digit keywords shall be specified. Characters specified for the keywords alpha and digit are automatically included in this class.

space Define characters to be classified as white-space characters.

In the POSIX locale, at a minimum, the <space>, <form-feed>, <newline>, <carriage-return>, <tab>, and <vertical-tab> shall be included.

In a locale definition file, no character specified for the keywords upper, lower, alpha, digit, graph, or xdigit shall be specified. The <space>, <form-feed>, <newline>, <carriage-return>, <tab>, and <vertical-tab> of the portable character set, and any characters included in the class blank are automatically included in this class.

cntrl Define characters to be classified as control characters.

In the POSIX locale, no characters in classes alpha or print shall be included.

In a locale definition file, no character specified for the keywords upper, lower, alpha, digit, punct, graph, print, or xdigit shall be specified.

punct Define characters to be classified as punctuation characters.

In the POSIX locale, neither the <space> nor any characters in classes alpha, digit, or cntrl shall be included.

In a locale definition file, no character specified for the keywords upper, lower, alpha, digit, cntrl, xdigit, or as the <space> shall be specified.

graph Define characters to be classified as printable characters, not including the <space>.

In the POSIX locale, all characters in classes alpha, digit, and punct shall be included; no characters in class cntrl shall be included.

In a locale definition file, characters specified for the keywords upper, lower, alpha, digit, xdigit, and punct are automatically included in this class. No character specified for the keyword cntrl shall be specified.

print Define characters to be classified as printable characters, including the <space>.

In the POSIX locale, all characters in class graph shall be included; no characters in class cntrl shall be included.

In a locale definition file, characters specified for the keywords upper, lower, alpha, digit, xdigit, punct, graph, and the <space> are automatically included in this class. No character specified for the keyword cntrl shall be specified.

xdigit Define the characters to be classified as hexadecimal digits.

In the POSIX locale, only:

```
0 1 2 3 4 5 6 7 8 9 A B C D E F a b c d e f
```

shall be included.

In a locale definition file, only the characters defined for the class digit shall be specified, in contiguous ascending sequence by numerical value, followed by one or more sets of six characters representing the hexadecimal digits 10 to 15.
in inclusive, with each set in ascending order (for example, <A>, <B>, <C>, <D>, <E>, <F>, <a>, <b>, <c>, <d>, <e>, <f>). The digits <zero> to <nine>, the uppercase letters <A> to <F>, and the lowercase letters <a> to <f> of the portable character set are automatically included in this class.

blank

Define characters to be classified as <blank>s.

In the POSIX locale, only the <space> and <tab> shall be included.

In a locale definition file, the <space> and <tab> are automatically included in this class.

charclass

Define one or more locale-specific character class names as strings separated by semicolons. Each named character class can then be defined subsequently in the LC_CTYPE definition. A character class name shall consist of at least one and at most {CHARCLASS_NAME_MAX} bytes of alphanumeric characters from the portable filename character set. The first character of a character class name shall not be a digit. The name shall not match any of the LC_CTYPE keywords defined in this volume of IEEE Std 1003.1-2001. Future revisions of IEEE Std 1003.1-2001 will not specify any LC_CTYPE keywords containing uppercase letters.

charclass-name

Define characters to be classified as belonging to the named locale-specific character class. In the POSIX locale, locale-specific named character classes need not exist.

If a class name is defined by a charclass keyword, but no characters are subsequently assigned to it, this is not an error; it represents a class without any characters belonging to it.

The charclass-name can be used as the property argument to the wctype() function, in regular expression and shell pattern-matching bracket expressions, and by the tr command.

toupper

Define the mapping of lowercase letters to uppercase letters.

In the POSIX locale, at a minimum, the 26 lowercase characters:

  a b c d e f g h i j k l m n o p q r s t u v w x y z

shall be mapped to the corresponding 26 uppercase characters:

  A B C D E F G H I J K L M N O P Q R S T U V W X Y Z

In a locale definition file, the operand shall consist of character pairs, separated by semicolons. The characters in each character pair shall be separated by a comma and the pair enclosed by parentheses. The first character in each pair is the lowercase letter, the second the corresponding uppercase letter. Only characters specified for the keywords lower and upper shall be specified. The lowercase letters <a> to <z>, and their corresponding uppercase letters <A> to <Z>, of the portable character set are automatically included in this mapping, but only when the toupper keyword is omitted from the locale definition.

tolower

Define the mapping of uppercase letters to lowercase letters.

In the POSIX locale, at a minimum, the 26 uppercase characters:

  A B C D E F G H I J K L M N O P Q R S T U V W X Y Z
shall be mapped to the corresponding 26 lowercase characters:

```
abcdefghijklmnopqrstuvwxyz
```

In a locale definition file, the operand shall consist of character pairs, separated by semicolons. The characters in each character pair shall be separated by a comma and the pair enclosed by parentheses. The first character in each pair is the uppercase letter, the second the corresponding lowercase letter. Only characters specified for the keywords `lower` and `upper` shall be specified. If the `tolower` keyword is omitted from the locale definition, the mapping is the reverse mapping of the one specified for `toupper`.

The following table shows the character class combinations allowed:

<table>
<thead>
<tr>
<th>In Class</th>
<th>Can Also Belong To</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>upper</td>
</tr>
<tr>
<td>upper</td>
<td>—</td>
</tr>
<tr>
<td>lower</td>
<td>—</td>
</tr>
<tr>
<td>alpha</td>
<td>—</td>
</tr>
<tr>
<td>digit</td>
<td>x</td>
</tr>
<tr>
<td>space</td>
<td>x</td>
</tr>
<tr>
<td>ctrl</td>
<td>x</td>
</tr>
<tr>
<td>punct</td>
<td>x</td>
</tr>
<tr>
<td>graph</td>
<td>—</td>
</tr>
<tr>
<td>print</td>
<td>—</td>
</tr>
<tr>
<td>xdigit</td>
<td>—</td>
</tr>
<tr>
<td>blank</td>
<td>x</td>
</tr>
</tbody>
</table>

Notes:

1. Explanation of codes:
   - A  Automatically included; see text.
   - —  Permitted.
   - x  Mutually-exclusive.
   - *  See note 2.

2. The `<space>`, which is part of the `space` and `blank` classes, cannot belong to `punct` or `graph`, but shall automatically belong to the `print` class. Other `space` or `blank` characters can be classified as any of `punct`, `graph`, or `print`.

### 7.3.1.1 LC_CTYPE Category in the POSIX Locale

The character classifications for the POSIX locale follow; the code listing depicts the `localedef` input, and the table represents the same information, sorted by character.

```bash
# The following is the POSIX locale LC_CTYPE.
# "alpha" is by default "upper" and "lower"
# "alnum" is by definition "alpha" and "digit"
# "print" is by default "alnum", "punct", and the <space>
# "graph" is by default "alnum" and "punct"
upper <A>;<B>;<C>;<D>;<E>;<F>;<G>;<H>;<I>;<J>;<K>;<L>;<M>;
```

7.3.2 LC_COLLATE

The LC_COLLATE category provides a collation sequence definition for numerous utilities in the Shell and Utilities volume of IEEE Std 1003.1-2001 (sort, uniq, and so on), regular expression matching (see Chapter 9 (on page 169)), and the strcoll(), strxfrm(), wcscoll(), and wcsxfrm() functions in the System Interfaces volume of IEEE Std 1003.1-2001.

A collation sequence definition shall define the relative order between collating elements (characters and multi-character collating elements) in the locale. This order is expressed in terms of collation values; that is, by assigning each element one or more collation values (also known as collation weights). This does not imply that implementations shall assign such values, but that ordering of strings using the resultant collation definition in the locale behaves as if such assignment is done and used in the collation process. At least the following capabilities are provided:

1. **Multi-character collating elements.** Specification of multi-character collating elements (that is, sequences of two or more characters to be collated as an entity).
2. **User-defined ordering of collating elements.** Each collating element shall be assigned a collation value defining its order in the character (or basic) collation sequence. This ordering is used by regular expressions and pattern matching and, unless collation weights are explicitly specified, also as the collation weight to be used in sorting.

3. **Multiple weights and equivalence classes.** Collating elements can be assigned one or more (up to the limit |COLL_WEIGHTS_MAX|, as defined in `<limits.h>`) collating weights for use in sorting. The first weight is hereafter referred to as the primary weight.

4. **One-to-many mapping.** A single character is mapped into a string of collating elements.

5. **Equivalence class definition.** Two or more collating elements have the same collation value (primary weight).

6. **Ordering by weights.** When two strings are compared to determine their relative order, the two strings are first broken up into a series of collating elements; the elements in each successive pair of elements are then compared according to the relative primary weights for the elements. If equal, and more than one weight has been assigned, then the pairs of collating elements are re-compared according to the relative subsequent weights, until either a pair of collating elements compare unequal or the weights are exhausted.

The following keywords shall be recognized in a collation sequence definition. They are described in detail in the following sections.

- `copy` Specify the name of an existing locale which shall be used as the definition of this category. If this keyword is specified, no other keyword shall be specified.
- `collating-element` Define a collating-element symbol representing a multi-character collating element. This keyword is optional.
- `collating-symbol` Define a collating symbol for use in collation order statements. This keyword is optional.
- `order_start` Define collation rules. This statement shall be followed by one or more collation order statements, assigning character collation values and collation weights to collating elements.
- `order_end` Specify the end of the collation-order statements.

### 7.3.2.1 The collating-element Keyword

In addition to the collating elements in the character set, the `collating-element` keyword can be used to define multi-character collating elements. The syntax is as follows:

```
collating-element %s from "\%s\"\n", <collating-symbol>, <string>
```

The `<collating-symbol>` operand shall be a symbolic name, enclosed between angle brackets (`'<'` and `'>'`), and shall not duplicate any symbolic name in the current charmap file (if any), or any other symbolic name defined in this collation definition. The string operand is a string of two or more characters that collates as an entity. A `<collating-element>` defined via this keyword is only recognized with the `LC_COLLATE` category.

For example:

```
collating-element <ch> from "<c><h>"
collating-element <e-acute> from "<acute><e>"
collating-element <ll> from "ll"
```
7.3.2.2 The collating-symbol Keyword

This keyword shall be used to define symbols for use in collation sequence statements; that is, between the order_start and the order_end keywords. The syntax is as follows:

```
"collating-symbol %s\n", <collating-symbol>
```

The <collating-symbol> shall be a symbolic name, enclosed between angle brackets ('<' and '>', and shall not duplicate any symbolic name in the current charmap file (if any), or any other symbolic name defined in this collation definition. A <collating-symbol> defined via this keyword is only recognized within the LC_COLLATE category.

For example:

```
collating-symbol <UPPER_CASE>
collating-symbol <HIGH>
```

The collating-symbol keyword defines a symbolic name that can be associated with a relative position in the character order sequence. While such a symbolic name does not represent any collating element, it can be used as a weight.

7.3.2.3 The order_start Keyword

The order_start keyword shall precede collation order entries and also define the number of weights for this collation sequence definition and other collation rules. The syntax is as follows:

```
"order_start %s;%s;%s\n", <sort-rules>, <sort-rules> ...
```

The operands to the order_start keyword are optional. If present, the operands define rules to be applied when strings are compared. The number of operands define how many weights each element is assigned; if no operands are present, one forward operand is assumed. If present, the first operand defines rules to be applied when comparing strings using the first (primary) weight; the second when comparing strings using the second weight, and so on. Operands shall be separated by semicolons (';'). Each operand shall consist of one or more collation directives, separated by commas (','). If the number of operands exceeds the {COLL_WEIGHTS_MAX} limit, the utility shall issue a warning message. The following directives shall be supported:

- **forward** Specifies that comparison operations for the weight level shall proceed from start of string towards the end of string.
- **backward** Specifies that comparison operations for the weight level shall proceed from end of string towards the beginning of string.
- **position** Specifies that comparison operations for the weight level shall consider the relative position of elements in the strings not subject to IGNORE. The string containing an element not subject to IGNORE after the fewest collating elements subject to IGNORE from the start of the compare shall collate first. If both strings contain a character not subject to IGNORE in the same relative position, the collating values assigned to the elements shall determine the ordering. In case of equality, subsequent characters not subject to IGNORE shall be considered in the same manner.

The directives forward and backward are mutually-exclusive.

If no operands are specified, a single forward operand shall be assumed.
For example:

```
order_start forward;backward
```

### 7.3.2.4 Collation Order

The **order_start** keyword shall be followed by collating identifier entries. The syntax for the collating element entries is as follows:

```
"%s %s;%s;...;%s\n", <collating-identifier>, <weight>, <weight>, ...
```

Each **collating-identifier** shall consist of either a character (in any of the forms defined in Section 7.3 (on page 124)), a **collating-element**, a **collating-symbol**, an ellipsis, or the special symbol **UNDEFINED**. The order in which collating elements are specified determines the character order sequence, such that each collating element shall compare less than the elements following it.

A **collating-element** shall be used to specify multi-character collating elements, and indicates that the character sequence specified via the **collating-element** is to be collated as a unit and in the relative order specified by its place.

A **collating-symbol** can be used to define a position in the relative order for use in weights. No weights shall be specified with a **collating-symbol**.

The ellipsis symbol specifies that a sequence of characters shall collate according to their encoded character values. It shall be interpreted as indicating that all characters with a coded character set value higher than the value of the character in the preceding line, and lower than the coded character set value for the character in the following line, in the current coded character set, shall be placed in the character collation order between the previous and the following character in ascending order according to their coded character set values. An initial ellipsis shall be interpreted as if the preceding line specified the NUL character, and a trailing ellipsis as if the following line specified the highest coded character set value in the current coded character set. An ellipsis shall be treated as invalid if the preceding or following lines do not specify characters in the current coded character set. The use of the ellipsis symbol ties the definition to a specific coded character set and may preclude the definition from being portable between implementations.

The symbol **UNDEFINED** shall be interpreted as including all coded character set values not specified explicitly or via the ellipsis symbol. Such characters shall be inserted in the character collation order at the point indicated by the symbol, and in ascending order according to their coded character set values. If no **UNDEFINED** symbol is specified, and the current coded character set contains characters not specified in this section, the utility shall issue a warning message and place such characters at the end of the character collation order.

The optional operands for each collation-element shall be used to define the primary, secondary, or subsequent weights for the collating element. The first operand specifies the relative primary weight, the second the relative secondary weight, and so on. Two or more collation-elements can be assigned the same weight; they belong to the same “equivalence class” if they have the same primary weight. Collation shall behave as if, for each weight level, elements subject to **IGNORE** are removed, unless the **position** collation directive is specified for the corresponding level with the **order_start** keyword. Then each successive pair of elements shall be compared according to the relative weights for the elements. If the two strings compare equal, the process shall be repeated for the next weight level, up to the limit `{COLL_WEIGHTS_MAX}`.

Weights shall be expressed as characters (in any of the forms specified in Section 7.3 (on page 124)), **collating-symbol**, **collating-element**, an ellipsis, or the special symbol **IGNORE**. A single character, a **collating-symbol**, or a **collating-element** shall represent the relative position
in the character collating sequence of the character or symbol, rather than the character or symbols themselves. Thus, rather than assigning absolute values to weights, a particular weight is expressed using the relative order value assigned to a collating element based on its order in the character collation sequence.

One-to-many mapping is indicated by specifying two or more concatenated characters or symbolic names. For example, if the `<eszet>` is given the string "<s><s>" as a weight, comparisons are performed as if all occurrences of the `<eszet>` are replaced by "<s><s>" (assuming that "<s>" has the collating weight "<s>"). If it is necessary to define `<eszet>` and "<s><s>" as an equivalence class, then a collating element must be defined for the string "ss".

All characters specified via an ellipsis shall by default be assigned unique weights, equal to the relative order of characters. Characters specified via an explicit or implicit `UNDEFINED` symbol shall by default be assigned the same primary weight (that is, they belong to the same equivalence class). An ellipsis symbol as a weight shall be interpreted to mean that each character in the sequence shall have unique weights, equal to the relative order of their character in the character collation sequence. The use of the ellipsis as a weight shall be treated as an error if the collating element is neither an ellipsis nor the special symbol `UNDEFINED`.

The special keyword `IGNORE` as a weight shall indicate that when strings are compared using the weights at the level where `IGNORE` is specified, the collating element shall be ignored; that is, as if the string did not contain the collating element. In regular expressions and pattern matching, all characters that are subject to `IGNORE` in their primary weight form an equivalence class.

An empty operand shall be interpreted as the collating element itself.

For example, the order statement:

```
<a> <a>;<a>
```

is equal to:

```
<a>
```

An ellipsis can be used as an operand if the collating element was an ellipsis, and shall be interpreted as the value of each character defined by the ellipsis.

The collation order as defined in this section affects the interpretation of bracket expressions in regular expressions (see Section 9.3.5 (on page 172)).

For example:
This example is interpreted as follows:

1. The **UNDEFINED** means that all characters not specified in this definition (explicitly or via the ellipsis) shall be ignored for collation purposes.
2. All characters between `<space>` and `'a'` shall have the same primary equivalence class and individual secondary weights based on their ordinal encoded values.
3. All characters based on the uppercase or lowercase character `'a'` belong to the same primary equivalence class.
4. The multi-character collating element `<ch>` is represented by the collating symbol `<ch>` and belongs to the same primary equivalence class as the multi-character collating element `<Ch>`.

### 7.3.2.5 The order_end Keyword

The collating order entries shall be terminated with an **order_end** keyword.

### 7.3.2.6 LC_COLLATE Category in the POSIX Locale

The collation sequence definition of the POSIX locale follows; the code listing depicts the `localedef` input.

```plaintext
order_start forward;backward
UNDEFINED IGNORE;IGNORE
<LOW>
<space> <LOW>;<space>
... <LOW>;...
<a> <a>;<a>
<a-acute> <a>;<a-acute>
<a-grave> <a>;<a-grave>
<A> <a>;<A>
<A-acute> <a>;<A-acute>
<A-grave> <a>;<A-grave>

7.3.3 LC_MONETARY

The LC_MONETARY category shall define the rules and symbols that are used to format monetary numeric information.

Some of the information is also available in an alternative form via the nl_langinfo() function (see CRNCYSTR in <langinfo.h>).

The following items are defined in this category of the locale. The item names are the keywords recognized by the localedef utility when defining a locale. They are also similar to the member names of the lconv structure defined in <locale.h>; see <locale.h> for the exact symbols in the header. The localeconv() function returns {CHAR_MAX} for unspecified integer items and the empty string (""") for unspecified or size zero string items.

In a locale definition file, the operands are strings, formatted as indicated by the grammar in Section 7.4 (on page 153). For some keywords, the strings can contain only integers. Keywords that are not provided, string values set to the empty string (""), or integer keywords set to −1, are used to indicate that the value is not available in the locale. The following keywords shall be recognized:

- **copy** Specify the name of an existing locale which shall be used as the definition of this category. If this keyword is specified, no other keyword shall be specified.
  
  Note: This is a localedef utility keyword, unavailable through localeconv().

- **int_curr_symbol** The international currency symbol. The operand shall be a four-character string, with the first three characters containing the alphabetic international currency symbol. The international currency symbol should be chosen in accordance with those specified in the ISO 4217 standard. The fourth character shall be the character used to separate the international currency symbol from the monetary quantity.

- **currency_symbol** The string that shall be used as the local currency symbol.

- **mon_decimal_point** The operand is a string containing the symbol that shall be used as the decimal delimiter (radix character) in monetary formatted quantities.
The operand is a string containing the symbol that shall be used as a separator for groups of digits to the left of the decimal delimiter in formatted monetary quantities.

Define the size of each group of digits in formatted monetary quantities. The operand is a sequence of integers separated by semicolons. Each integer specifies the number of digits in each group, with the initial integer defining the size of the group immediately preceding the decimal delimiter, and the following integers defining the preceding groups. If the last integer is not −1, then the size of the previous group (if any) shall be repeatedly used for the remainder of the digits. If the last integer is −1, then no further grouping shall be performed.

A string that shall be used to indicate a non-negative-valued formatted monetary quantity.

A string that shall be used to indicate a negative-valued formatted monetary quantity.

An integer representing the number of fractional digits (those to the right of the decimal delimiter) to be written in a formatted monetary quantity using \texttt{int_curr_symbol}.

An integer representing the number of fractional digits (those to the right of the decimal delimiter) to be written in a formatted monetary quantity using \texttt{currency_symbol}.

An integer set to 1 if the \texttt{currency_symbol} precedes the value for a monetary quantity with a non-negative value, and set to 0 if the symbol succeeds the value.

An integer set to 0 if no space separates the \texttt{currency_symbol} from the value for a monetary quantity with a non-negative value, set to 1 if a space separates the symbol from the value, and set to 2 if a space separates the symbol and the sign string, if adjacent.

An integer set to 1 if the \texttt{currency_symbol} precedes the value for a monetary quantity with a negative value, and set to 0 if the symbol succeeds the value.

An integer set to 0 if no space separates the \texttt{currency_symbol} from the value for a monetary quantity with a negative value, set to 1 if a space separates the symbol from the value, and set to 2 if a space separates the symbol and the sign string, if adjacent.

An integer set to a value indicating the positioning of the \texttt{positive_sign} for a monetary quantity with a non-negative value. The following integer values shall be recognized for \texttt{int_n_sign_posn}, \texttt{int_p_sign_posn}, \texttt{n_sign_posn}, and \texttt{p_sign_posn}:

\begin{itemize}
  \item 0 Parentheses enclose the quantity and the \texttt{currency_symbol}.
  \item 1 The sign string precedes the quantity and the \texttt{currency_symbol}.
  \item 2 The sign string succeeds the quantity and the \texttt{currency_symbol}.
  \item 3 The sign string precedes the \texttt{currency_symbol}.
  \item 4 The sign string succeeds the \texttt{currency_symbol}.
\end{itemize}
Locale Definition

4856  n_sign_posn  An integer set to a value indicating the positioning of the negative_sign for a negative formatted monetary quantity.
4857
4858  int_p_cs_precedes  An integer set to 1 if the int_curr_symbol precedes the value for a monetary quantity with a non-negative value, and set to 0 if the symbol succeeds the value.
4859
4860  int_n_cs_precedes  An integer set to 1 if the int_curr_symbol precedes the value for a monetary quantity with a negative value, and set to 0 if the symbol succeeds the value.
4861
4864  int_p_sep_by_space  An integer set to 0 if no space separates the int_curr_symbol from the value for a monetary quantity with a non-negative value, set to 1 if a space separates the symbol from the value, and set to 2 if a space separates the symbol and the sign string, if adjacent.
4865
4868  int_n_sep_by_space  An integer set to 0 if no space separates the int_curr_symbol from the value for a monetary quantity with a negative value, set to 1 if a space separates the symbol from the value, and set to 2 if a space separates the symbol and the sign string, if adjacent.
4869
4872  int_p_sign_posn  An integer set to a value indicating the positioning of the positive_sign for a positive monetary quantity formatted with the international format.
4873
4874  int_n_sign_posn  An integer set to a value indicating the positioning of the negative_sign for a negative monetary quantity formatted with the international format.
4875

7.3.3.1 LC_MONETARY Category in the POSIX Locale

The monetary formatting definitions for the POSIX locale follow; the code listing depicting the localedef input, the table representing the same information with the addition of localeconv() and nl_langinfo() formats. All values are unspecified in the POSIX locale.

4880  LC_MONETARY
4881  # This is the POSIX locale definition for
4882  # the LC_MONETARY category.
4883  #
4884  int_curr_symbol  ""
4885  currency_symbol  ""
4886  mon_decimal_point  ""
4887  mon_thousands_sep  ""
4888  mon_grouping  -1
4889  positive_sign  ""
4890  negative_sign  ""
4891  int_frac_digits  -1
4892  frac_digits  -1
4893  p_cs_precedes  -1
4894  p_sep_by_space  -1
4895  n_cs_precedes  -1
4896  n_sep_by_space  -1
4897  p_sign_posn  -1
4898  n_sign_posn  -1
4899  int_p_cs_precedes -1
4900  int_p_sep_by_space -1
4901  int_n_cs_precedes -1
4902  int_n_sep_by_space -1
In the preceding table, the langinfo Constant column represents an XSI-conformant extension. The entry N/A indicates that the value is not available in the POSIX locale.

### 7.3.4 LC_NUMERIC

The LC_NUMERIC category shall define the rules and symbols that are used to format non-monetary numeric information. This information is available through the \texttt{localeconv()} function. Some of the information is also available in an alternative form via the \texttt{nl_langinfo()} function.

The following items are defined in this category of the locale. The item names are the keywords recognized by the \texttt{localedef} utility when defining a locale. They are also similar to the member names of the \texttt{iconv} structure defined in \texttt{<locale.h>}; see \texttt{<locale.h>} for the exact symbols in the header. The \texttt{localeconv()} function returns [CHAR_MAX] for unspecified integer items and the empty string (" ") for unspecified or size zero string items.

In a locale definition file, the operands are strings, formatted as indicated by the grammar in Section 7.4 (on page 153). For some keywords, the strings can only contain integers. Keywords that are not provided, string values set to the empty string (" "), or integer keywords set to -1, shall be used to indicate that the value is not available in the locale. The following keywords shall be recognized:

- **copy** Specify the name of an existing locale which shall be used as the definition of this category. If this keyword is specified, no other keyword shall be specified.

**Note:** This is a \texttt{localedef} utility keyword, unavailable through \texttt{localeconv()}.
localedef

Locale Definition

The operand is a string containing the symbol that shall be used as the
decimal delimiter (radix character) in numeric, non-monetary formatted
terminated. In contexts where standards limit the decimal_point to a single byte,

the result of specifying a multi-byte operand shall be unspecified.

The operand is a string containing the symbol that shall be used as a separator
for groups of digits to the left of the decimal delimiter in numeric, non-
monetary formatted monetary quantities. In contexts where standards limit
the thousands_sep to a single byte, the result of specifying a multi-byte
operand shall be unspecified.

Define the size of each group of digits in formatted non-monetary quantities.
The operand is a sequence of integers separated by semicolons. Each integer
specifies the number of digits in each group, with the initial integer defining
the size of the group immediately preceding the decimal delimiter, and the
following integers defining the preceding groups. If the last integer is not −1,
then the size of the previous group (if any) shall be repeatedly used for the
remainder of the digits. If the last integer is −1, then no further grouping shall
be performed.

The non-monetary numeric formatting definitions for the POSIX locale follow; the code listing
depicting the localedef input, the table representing the same information with the addition of
localeconv() values, and nl_langinfo() constants.

# This is the POSIX locale definition for
# the LC_NUMERIC category.
# decimal_point "<period>"
# thousands_sep ""
# grouping -1

END LC_NUMERIC

<table>

In the preceding table, the langinfo Constant column represents an XSI-conforming extension.
The entry N/A indicates that the value is not available in the POSIX locale.
7.3.5 LC_TIME

The LC_TIME category shall define the interpretation of the conversion specifications supported by the date utility and shall affect the behavior of the strftime(), wcsftime(), strptime(), and nl_langinfo() functions. Since the interfaces for C-language access and locale definition differ significantly, they are described separately.

7.3.5.1 LC_TIME Locale Definition

In a locale definition, the following mandatory keywords shall be recognized:

- **copy** Specify the name of an existing locale which shall be used as the definition of this category. If this keyword is specified, no other keyword shall be specified.

- **abday** Define the abbreviated weekday names, corresponding to the %a conversion specification (conversion specification in the strftime(), wcsftime(), and strptime() functions). The operand shall consist of seven semicolon-separated strings, each surrounded by double-quotes. The first string shall be the abbreviated name of the day corresponding to Sunday, the second the abbreviated name of the day corresponding to Monday, and so on.

- **day** Define the full weekday names, corresponding to the %A conversion specification. The operand shall consist of seven semicolon-separated strings, each surrounded by double-quotes. The first string is the full name of the day corresponding to Sunday, the second the full name of the day corresponding to Monday, and so on.

- **abmon** Define the abbreviated month names, corresponding to the %b conversion specification. The operand shall consist of twelve semicolon-separated strings, each surrounded by double-quotes. The first string shall be the abbreviated name of the first month of the year (January), the second the abbreviated name of the second month, and so on.

- **mon** Define the full month names, corresponding to the %B conversion specification. The operand shall consist of twelve semicolon-separated strings, each surrounded by double-quotes. The first string shall be the full name of the first month of the year (January), the second the full name of the second month, and so on.

- **d_t_fmt** Define the appropriate date and time representation, corresponding to the %c conversion specification. The operand shall consist of a string containing any combination of characters and conversion specifications. In addition, the string can contain escape sequences defined in the table in Table 5-1 (on page 112) (‘\’’, ‘\a’, ‘\b’, ‘\e’, ‘\n’, ‘\’t’, ‘\’v’).

- **d_fmt** Define the appropriate date representation, corresponding to the %x conversion specification. The operand shall consist of a string containing any combination of characters and conversion specifications. In addition, the string can contain escape sequences defined in Table 5-1 (on page 112).

- **t_fmt** Define the appropriate time representation, corresponding to the %X conversion specification. The operand shall consist of a string containing any combination of characters and conversion specifications. In addition, the string can contain escape sequences defined in Table 5-1 (on page 112).

- **am_pm** Define the appropriate representation of the ante-meridiem and post-meridiem strings, corresponding to the %p conversion specification. The operand shall consist of two strings, separated by a semicolon, each surrounded by double-quotes.
quotes. The first string shall represent the *ante-meridiem* designation, the last string the *post-meridiem* designation.

**t_fmt_ampm** Define the appropriate time representation in the 12-hour clock format with *am_pm*, corresponding to the `%r` conversion specification. The operand shall consist of a string and can contain any combination of characters and conversion specifications. If the string is empty, the 12-hour format is not supported in the locale.

**era** Define how years are counted and displayed for each era in a locale. The operand shall consist of semicolon-separated strings. Each string shall be an era description segment with the format:

```
direction:offset:start_date:end_date:era_name:era_format
```

according to the definitions below. There can be as many era description segments as are necessary to describe the different eras.

**Note:** The start of an era might not be the earliest point in the era—it may be the latest. For example, the Christian era BC starts on the day before January 1, AD 1, and increases with earlier time.

**direction** Either a '+' or a '-' character. The '+' character shall indicate that years closer to the *start_date* have lower numbers than those closer to the *end_date*. The '-' character shall indicate that years closer to the *start_date* have higher numbers than those closer to the *end_date*.

**offset** The number of the year closest to the *start_date* in the era, corresponding to the `%EY` conversion specification.

**start_date** A date in the form `yyyy/mm/dd`, where `yyyy`, `mm`, and `dd` are the year, month, and day numbers respectively of the start of the era. Years prior to AD 1 shall be represented as negative numbers.

**end_date** The ending date of the era, in the same format as the *start_date*, or one of the two special values "--" or "++". The value "--" shall indicate that the ending date is the beginning of time. The value "++" shall indicate that the ending date is the end of time.

**era_name** A string representing the name of the era, corresponding to the `%EC` conversion specification.

**era_format** A string for formatting the year in the era, corresponding to the `%EY` conversion specification.

**era_d_fmt** Define the format of the date in alternative era notation, corresponding to the `%Ex` conversion specification.

**era_t_fmt** Define the locale’s appropriate alternative time format, corresponding to the `%EX` conversion specification.

**era_d_t_fmt** Define the locale’s appropriate alternative date and time format, corresponding to the `%Ec` conversion specification.

**alt_digits** Define alternative symbols for digits, corresponding to the `%O` modified conversion specification. The operand shall consist of semicolon-separated strings, each surrounded by double-quotes. The first string shall be the alternative symbol corresponding with zero, the second string the symbol
corresponding with one, and so on. Up to 100 alternative symbol strings can be specified. The %O modifier shall indicate that the string corresponding to the value specified via the conversion specification shall be used instead of the value.

7.3.5.2 LC_TIME C-Language Access

This section describes extensions to access information in the LC_TIME category using the nl_langinfo() function. This functionality is dependent on support of the XSI extension (and the rest of this section is not further shaded for this option).

The following constants used to identify items of langinfo data can be used as arguments to the nl_langinfo() function to access information in the LC_TIME category. These constants are defined in the <langinfo.h> header.

- ABDAY_x: The abbreviated weekday names (for example, Sun), where x is a number from 1 to 7.
- DAY_x: The full weekday names (for example, Sunday), where x is a number from 1 to 7.
- ABMON_x: The abbreviated month names (for example, Jan), where x is a number from 1 to 12.
- MON_x: The full month names (for example, January), where x is a number from 1 to 12.
- D_T_FMT: The appropriate date and time representation.
- D_FMT: The appropriate date representation.
- T_FMT: The appropriate time representation.
- AM_STR: The appropriate ante-meridiem affix.
- PM_STR: The appropriate post-meridiem affix.
- T_FMT_AMPM: The appropriate time representation in the 12-hour clock format with AM_STR and PM_STR.
- ERA: The era description segments, which describe how years are counted and displayed for each era in a locale. Each era description segment shall have the format:
  
  direction:offset:start_date:end_date:era_name:era_format

  according to the definitions below. There can be as many era description segments as are necessary to describe the different eras. Era description segments are separated by semicolons.

- direction: Either a ‘+’ or a ‘−’ character. The ‘+’ character shall indicate that years closer to the start_date have lower numbers than those closer to the end_date. The ‘−’ character shall indicate that years closer to the start_date have higher numbers than those closer to the end_date.
- offset: The number of the year closest to the start_date in the era.
- start_date: A date in the form yyyy/mm/dd, where yyyy, mm, and dd are the year, month, and day numbers respectively of the start of the era. Years prior to AD 1 shall be represented as negative
end_date  The ending date of the era, in the same format as the start_date, or one of the two special values "−***" or "***+". The value "−***" shall indicate that the ending date is the beginning of time. The value "***+" shall indicate that the ending date is the end of time.

era_name  The era, corresponding to the %EC conversion specification.

era_format  The format of the year in the era, corresponding to the %EY conversion specification.

ERA_D_FMT  The era date format.

ERA_T_FMT  The locale’s appropriate alternative time format, corresponding to the %EX conversion specification.

ERA_D_T_FMT  The locale’s appropriate alternative date and time format, corresponding to the %Ec conversion specification.

ALT_DIGITS  The alternative symbols for digits, corresponding to the %O conversion specification modifier. The value consists of semicolon-separated symbols. The first is the alternative symbol corresponding to zero, the second is the symbol corresponding to one, and so on. Up to 100 alternative symbols may be specified.

7.3.5.3 LC_TIME Category in the POSIX Locale

The LC_TIME category definition of the POSIX locale follows; the code listing depicts the localedef input; the table represents the same information with the addition of localedef keywords, conversion specifiers used by the date utility and the strftime(), wcsftime(), and strptime() XSI functions, and nl_langinfo() constants.

LC_TIME

# This is the POSIX locale definition for
# the LC_TIME category.
#
# Abbreviated weekday names (%a)
abday "<S><u><n>n"; "M><o><n>n"; "T><u><e>"; "W><e><d>"; \\

The entry N/A indicates the value is not available in the POSIX locale.

### 7.3.6 LC_MESSAGES

The `LC_MESSAGES` category shall define the format and values used by various utilities for affirmative and negative responses. This information is available through the `nl_langinfo()` function.

```
    COPY  Specify the name of an existing locale which shall be used as the definition of this category. If this keyword is specified, no other keyword shall be specified.
```

**Note:** This is a `localedef` keyword, unavailable through `nl_langinfo()`.
7.3.6.1 LC_MESSAGES Category in the POSIX Locale

The format and values for affirmative and negative responses of the POSIX locale follow; the code listing depicting the `localedef` input, the table representing the same information with the addition of `nl_langinfo()` constants.

```
LC_MESSAGES
# This is the POSIX locale definition for
# the LC_MESSAGES category.
#
yesexpr "<circumflex><left-square-bracket><y><Y><right-square-bracket>"
#
noexpr "<circumflex><left-square-bracket><n><N><right-square-bracket>"
#
END LC_MESSAGES
```

<table>
<thead>
<tr>
<th>localedef Keyword</th>
<th>langinfo Constant</th>
<th>POSIX Locale Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>yesexpr</td>
<td>YESEXPR</td>
<td>&quot;^ [yY] &quot;</td>
</tr>
<tr>
<td>noexpr</td>
<td>NOEXPR</td>
<td>&quot;^ [nN] &quot;</td>
</tr>
</tbody>
</table>

In the preceding table, the `langinfo Constant` column represents an XSI-conformant extension.

7.4 Locale Definition Grammar

The grammar and lexical conventions in this section shall together describe the syntax for the locale definition source. The general conventions for this style of grammar are described in the Shell and Utilities volume of IEEE Std 1003.1-2001, Section 1.10, Grammar Conventions. The grammar shall take precedence over the text in this chapter.

7.4.1 Locale Lexical Conventions

The lexical conventions for the locale definition grammar are described in this section.

The following tokens shall be processed (in addition to those string constants shown in the grammar):

- `LOC_NAME`: A string of characters representing the name of a locale.
- `CHAR`: Any single character.
- `NUMBER`: A decimal number, represented by one or more decimal digits.
- `COLLSYMBOL`: A symbolic name, enclosed between angle brackets. The string cannot duplicate any charmap symbol defined in the current charmap (if any), or a `COLLELEMENT` symbol.
- `COLLELEMENT`: A symbolic name, enclosed between angle brackets, which cannot duplicate either any charmap symbol or a `COLLSYMBOL` symbol.
A string of alphanumeric characters from the portable character set, the first of which is not a digit, consisting of at least one and at most \{CHARCLASS\_NAME\_MAX\} bytes, and optionally surrounded by double-quotes.

A symbolic name, enclosed between angle brackets, from the current charmap (if any).

One or more octal representations of the encoding of each byte in a single character. The octal representation consists of an escape character (normally a backslash) followed by two or more octal digits.

One or more hexadecimal representations of the encoding of each byte in a single character. The hexadecimal representation consists of an escape character followed by the constant \(x\) and two or more hexadecimal digits.

One or more decimal representations of the encoding of each byte in a single character. The decimal representation consists of an escape character followed by a character ‘\(d\)’ and two or more decimal digits.

The string ". . . ".

An extended regular expression as defined in the grammar in Section 9.5 (on page 179).

The line termination character <newline>.

This section presents the grammar for the locale definition.

Environment Variables

8.1 Environment Variable Definition

Environment variables defined in this chapter affect the operation of multiple utilities, functions, and applications. There are other environment variables that are of interest only to specific utilities. Environment variables that apply to a single utility only are defined as part of the utility description. See the ENVIRONMENT VARIABLES section of the utility descriptions in the Shell and Utilities volume of IEEE Std 1003.1-2001 for information on environment variable usage.

The value of an environment variable is a string of characters. For a C-language program, an array of strings called the environment shall be made available when a process begins. The array is pointed to by the external variable `environ`, which is defined as:

```c
extern char **environ;
```

These strings have the form `name=value;` names shall not contain the character `=`. For values to be portable across systems conforming to IEEE Std 1003.1-2001, the value shall be composed of characters from the portable character set (except NUL and as indicated below). There is no meaning associated with the order of strings in the environment. If more than one string in a process’ environment has the same `name`, the consequences are undefined.

Environment variable names used by the utilities in the Shell and Utilities volume of IEEE Std 1003.1-2001 consist solely of uppercase letters, digits, and the ‘_’ (underscore) from the characters defined in Table 6-1 (on page 115) and do not begin with a digit. Other characters may be permitted by an implementation; applications shall tolerate the presence of such names. Uppercase and lowercase letters shall retain their unique identities and shall not be folded together. The name space of environment variable names containing lowercase letters is reserved for applications. Applications can define any environment variables with names from this name space without modifying the behavior of the standard utilities.

Note: Other applications may have difficulty dealing with environment variable names that start with a digit. For this reason, use of such names is not recommended anywhere.

The values that the environment variables may be assigned are not restricted except that they are considered to end with a null byte and the total space used to store the environment and the arguments to the process is limited to `[ARG_MAX]` bytes.

Other `name=value` pairs may be placed in the environment by, for example, calling any of the `setenv()`, `unsetenv()`, or `putenv()` functions, manipulating the `environ` variable, or by using `envp` arguments when creating a process; see `exec` in the System Interfaces volume of IEEE Std 1003.1-2001.

It is unwise to conflict with certain variables that are frequently exported by widely used command interpreters and applications:
8.2 Internationalization Variables

This section describes environment variables that are relevant to the operation of internationalized interfaces described in IEEE Std 1003.1-2001.

Users may use the following environment variables to announce specific localization requirements to applications. Applications can retrieve this information using the `setlocale()` function to initialize the correct behavior of the internationalized interfaces. The descriptions of the internationalization environment variables describe the resulting behavior only when the application locale is initialized in this way. The use of the internationalization variables by utilities described in the Shell and Utilities volume of IEEE Std 1003.1-2001 is described in the ENVIRONMENT VARIABLES section for those utilities in addition to the global effects described in this section.

**LANG**

This variable shall determine the locale category for native language, local customs, and coded character set in the absence of the `LC_ALL` and other `LC_*` (`LC_COLLATE`, `LC_CTYPE`, `LC_MESSAGES`, `LC_MONETARY`, `LC_NUMERIC`, `LC_TIME`) environment variables. This can be used by applications to determine the language to use for error messages and instructions, collating sequences, date formats, and so on.
Environment Variables

LC_ALL
This variable shall determine the values for all locale categories. The value of the LC_ALL environment variable has precedence over any of the other environment variables starting with LC_(LC_COLLATE, LC_CTYPE, LC_MESSAGES, LC_MONETARY, LC_NUMERIC, LC_TIME) and the LANG environment variable.

LC_COLLATE
This variable shall determine the locale category for character collation. It determines collation information for regular expressions and sorting, including equivalence classes and multi-character collating elements, in various utilities and the strcoll() and strxfrm() functions. Additional semantics of this variable, if any, are implementation-defined.

LC_CTYPE
This variable shall determine the locale category for character handling functions, such as tolower(), toupper(), and isalpha(). This environment variable determines the interpretation of sequences of bytes of text data as characters (for example, single as opposed to multi-byte characters), the classification of characters (for example, alpha, digit, graph), and the behavior of character classes. Additional semantics of this variable, if any, are implementation-defined.

LC_MESSAGES
This variable shall determine the locale category for processing affirmative and negative responses and the language and cultural conventions in which messages should be written. It also affects the behavior of the catopen() function in determining the message catalog. Additional semantics of this variable, if any, are implementation-defined. The language and cultural conventions of diagnostic and informative messages whose format is unspecified by IEEE Std 1003.1-2001 should be affected by the setting of LC_MESSAGES.

LC_MONETARY
This variable shall determine the locale category for monetary-related numeric formatting information. Additional semantics of this variable, if any, are implementation-defined.

LC_NUMERIC
This variable shall determine the locale category for numeric formatting (for example, thousands separator and radix character) information in various utilities as well as the formatted I/O operations in printf() and scanf() and the string conversion functions in strtod(). Additional semantics of this variable, if any, are implementation-defined.

LC_TIME
This variable shall determine the locale category for date and time formatting information. It affects the behavior of the time functions in strftime(). Additional semantics of this variable, if any, are implementation-defined.

XSI

NLSPATH
This variable shall contain a sequence of templates that the catopen() function uses when attempting to locate message catalogs. Each template consists of an optional prefix, one or more conversion specifications, a filename, and an optional suffix.

For example:

NLSPATH="/system/nlslib/%N.cat"

defines that catopen() should look for all message catalogs in the directory /system/nlslib, where the catalog name should be constructed from the name parameter passed to catopen() (%N), with the suffix .cat.

Conversion specifications consist of a '*' symbol, followed by a single-letter keyword. The following keywords are currently defined:
Internationalization Variables

Environment Variables

The value of the `name` parameter passed to `catopen()`.

The value of the `LC_MESSAGES` category.

The `language` element from the `LC_MESSAGES` category.

The `territory` element from the `LC_MESSAGES` category.

The `codeset` element from the `LC_MESSAGES` category.

A single `'%'` character.

An empty string is substituted if the specified value is not currently defined. The separators underscore (`'_'`) and period (`'.'`) are not included in the `%t` and `%c` conversion specifications.

Templates defined in `NLSPATH` are separated by colons (`':'`). A leading or two adjacent colons `'::'` is equivalent to specifying `%N`. For example:

```
NLSPATH="$%N.cat:/nlslib/%L/%N.cat"
```

indicates to `catopen()` that it should look for the requested message catalog in `name, name.cat`, and `/nlslib/category/name.cat`, where `category` is the value of the `LC_MESSAGES` category of the current locale.

Users should not set the `NLSPATH` variable unless they have a specific reason to override the default system path. Setting `NLSPATH` to override the default system path produces undefined results in the standard utilities and in applications with appropriate privileges.

The environment variables `LANG`, `LC_ALL`, `LC_COLLATE`, `LC_CTYPE`, `LC_MESSAGES`, `LC_MONETARY`, `LC_NUMERIC`, `LC_TIME`, and `NLSPATH` provide for the support of internationalized applications. The standard utilities shall make use of these environment variables as described in this section and the individual ENVIRONMENT VARIABLES sections for the utilities. If these variables specify locale categories that are not based upon the same underlying codeset, the results are unspecified.

The values of locale categories shall be determined by a precedence order; the first condition met below determines the value:

1. If the `LC_ALL` environment variable is defined and is not null, the value of `LC_ALL` shall be used.
2. If the `LC_*` environment variable (`LC_COLLATE`, `LC_CTYPE`, `LC_MESSAGES`, `LC_MONETARY`, `LC_NUMERIC`, `LC_TIME`) is defined and is not null, the value of the environment variable shall be used to initialize the category that corresponds to the environment variable.
3. If the `LANG` environment variable is defined and is not null, the value of the `LANG` environment variable shall be used.
4. If the `LANG` environment variable is not set or is set to the empty string, the implementation-defined default locale shall be used.

If the locale value is "C" or "POSIX", the POSIX locale shall be used and the standard utilities behave in accordance with the rules in Section 7.2 (on page 124) for the associated category.

If the locale value begins with a slash, it shall be interpreted as the pathname of a file that was created in the output format used by the `localedef` utility; see OUTPUT FILES under `localedef`. Referencing such a pathname shall result in that locale being used for the indicated category.

The environment variables `LANG`, `LC_ALL`, `LC_COLLATE`, `LC_CTYPE`, `LC_MESSAGES`, `LC_MONETARY`, `LC_NUMERIC`, `LC_TIME`, and `NLSPATH` provide for the support of internationalized applications. The standard utilities shall make use of these environment variables as described in this section and the individual ENVIRONMENT VARIABLES sections for the utilities. If these variables specify locale categories that are not based upon the same underlying codeset, the results are unspecified.

The values of locale categories shall be determined by a precedence order; the first condition met below determines the value:

1. If the `LC_ALL` environment variable is defined and is not null, the value of `LC_ALL` shall be used.
2. If the `LC_*` environment variable (`LC_COLLATE`, `LC_CTYPE`, `LC_MESSAGES`, `LC_MONETARY`, `LC_NUMERIC`, `LC_TIME`) is defined and is not null, the value of the environment variable shall be used to initialize the category that corresponds to the environment variable.
3. If the `LANG` environment variable is defined and is not null, the value of the `LANG` environment variable shall be used.
4. If the `LANG` environment variable is not set or is set to the empty string, the implementation-defined default locale shall be used.

If the locale value is "C" or "POSIX", the POSIX locale shall be used and the standard utilities behave in accordance with the rules in Section 7.2 (on page 124) for the associated category.

If the locale value begins with a slash, it shall be interpreted as the pathname of a file that was created in the output format used by the `localedef` utility; see OUTPUT FILES under `localedef`. Referencing such a pathname shall result in that locale being used for the indicated category.
If the locale value has the form:

```
language[_territory][_codeset]
```

it refers to an implementation-provided locale, where settings of language, territory, and codeset are implementation-defined.

```
LC_COLLATE, LC_CTYPE, LC_MESSAGES, LC_MONETARY, LC_NUMERIC, and LC_TIME are defined
to accept an additional field @modifier, which allows the user to select a specific instance
of localization data within a single category (for example, for selecting the dictionary as opposed
to the character ordering of data). The syntax for these environment variables is thus defined as:
```

For example, if a user wanted to interact with the system in French, but required to sort German
text files, LANG and LC_COLLATE could be defined as:

```
LANG=Fr_FR
LC_COLLATE=De_DE
```

This could be extended to select dictionary collation (say) by use of the @modifier field; for example:

```
LC_COLLATE=De_DE@dict
```

An implementation may support other formats.

If the locale value is not recognized by the implementation, the behavior is unspecified.

At runtime, these values are bound to a program’s locale by calling the `setlocale()` function.

Additional criteria for determining a valid locale name are implementation-defined.

### 8.3 Other Environment Variables

**COLLUMNS**

This variable shall represent a decimal integer >0 used to indicate the user’s preferred width in column positions for the terminal screen or window; see Section 3.103 (on page 49). If this variable is unset or null, the implementation determines the number of columns, appropriate for the terminal or window, in an unspecified manner. When COLLUMNS is set, any terminal-width information implied by TERM is overridden. Users and conforming applications should not set COLLUMNS unless they wish to override the system selection and produce output unrelated to the terminal characteristics.

Users should not need to set this variable in the environment unless there is a specific reason to override the implementation’s default behavior, such as to display data in an area arbitrarily smaller than the terminal or window.

**DATEMS**

Indicates the pathname of the template file used by `getdate()`.

**HOME**

The system shall initialize this variable at the time of login to be a pathname of the user’s home directory. See `<pwd.h>`.

**LINES**

This variable shall represent a decimal integer >0 used to indicate the user’s preferred number of lines on a page or the vertical screen or window size in lines. A line in this case is a vertical measure large enough to hold the tallest character in the character set being displayed. If this variable is unset or null, the implementation determines the number of lines, appropriate for the
terminal or window (size, terminal baud rate, and so on), in an unspecified manner. When LINES is set, any terminal-height information implied by TERM is overridden. Users and conforming applications should not set LINES unless they wish to override the system selection and produce output unrelated to the terminal characteristics.

Users should not need to set this variable in the environment unless there is a specific reason to override the implementation’s default behavior, such as to display data in an area arbitrarily smaller than the terminal or window.

**LOGNAME**

The system shall initialize this variable at the time of login to be the user’s login name. See `<pwd.h>`. For a value of LOGNAME to be portable across implementations of IEEE Std 1003.1-2001, the value should be composed of characters from the portable filename character set.

**MSGVERB**

Describes which message components shall be used in writing messages by `fmtmsg()`.

**PATH**

This variable shall represent the sequence of path prefixes that certain functions and utilities apply in searching for an executable file known only by a filename. The prefixes shall be separated by a colon (`:`). When a non-zero-length prefix is applied to this filename, a slash shall be inserted between the prefix and the filename. A zero-length prefix is a legacy feature that indicates the current working directory. It appears as two adjacent colons (`"::"`), as an initial colon preceding the rest of the list, or as a trailing colon following the rest of the list. A strictly conforming application shall use an actual pathname (such as `. ) to represent the current working directory in PATH. The list shall be searched from beginning to end, applying the filename to each prefix, until an executable file with the specified name and appropriate execution permissions is found. If the pathname being sought contains a slash, the search through the path prefixes shall not be performed. If the pathname begins with a slash, the specified path is resolved (see Section 4.11 (on page 102)). If PATH is unset or is set to null, the path search is implementation-defined.

**PWD**

This variable shall represent an absolute pathname of the current working directory. It shall not contain any filename components of dot or dot-dot. The value is set by the `cd` utility.

**SHELL**

This variable shall represent a pathname of the user’s preferred command language interpreter. If this interpreter does not conform to the Shell Command Language in the Shell and Utilities volume of IEEE Std 1003.1-2001, Chapter 2, Shell Command Language, utilities may behave differently from those described in IEEE Std 1003.1-2001.

**TMPDIR**

This variable shall represent a pathname of a directory made available for programs that need a place to create temporary files.

**TERM**

This variable shall represent the terminal type for which output is to be prepared. This information is used by utilities and application programs wishing to exploit special capabilities specific to a terminal. The format and allowable values of this environment variable are unspecified.

**TZ**

This variable shall represent timezone information. The contents of the environment variable named TZ shall be used by the `ctime()`, `localtime()`, `strftime()`, `mktime()`, `ctime_r()`, and `localtime_r()` functions, and by various utilities, to override the default timezone. The value of TZ has one of the two
forms (spaces inserted for clarity):

\[ : \text{characters} \]

or:

\[ \text{std offset dst offset, rule} \]

If TZ is of the first format (that is, if the first character is a colon), the characters following the colon are handled in an implementation-defined manner.

The expanded format (for all TZs whose value does not have a colon as the first character) is as follows:

\[ \text{stdoffset[dst[offset] [start[/time],end[/time]]]} \]

Where:

**std and dst** Indicate no less than three, nor more than \{TZNAME_MAX\}, bytes that are the designation for the standard (std) or the alternative (dst—such as Daylight Savings Time) timezone. Only std is required; if dst is missing, then the alternative time does not apply in this locale.

Each of these fields may occur in either of two formats quoted or unquoted:

— In the quoted form, the first character shall be the less-than ('<') character and the last character shall be the greater-than ('>') character. All characters between these quoting characters shall be alphanumeric characters from the portable character set in the current locale, the plus-sign ('+') character, or the minus-sign ('−') character. The std and dst fields in this case shall not include the quoting characters.

— In the unquoted form, all characters in these fields shall be alphabetic characters from the portable character set in the current locale.

The interpretation of these fields is unspecified if either field is less than three bytes (except for the case when dst is missing), more than \{TZNAME_MAX\} bytes, or if they contain characters other than those specified.

**offset** Indicates the value added to the local time to arrive at Coordinated Universal Time. The offset has the form:

\[ hh[:mm[:ss]] \]

The minutes (mm) and seconds (ss) are optional. The hour (hh) shall be required and may be a single digit. The offset following std shall be required. If no offset follows dst, the alternative time is assumed to be one hour ahead of standard time. One or more digits may be used; the value is always interpreted as a decimal number. The hour shall be between zero and 24, and the minutes (and seconds)—if present—between zero and 59. The result of using values outside of this range is unspecified. If preceded by a '−', the timezone shall be east of the Prime Meridian;
otherwise, it shall be west (which may be indicated by an
optional preceding ‘+’).

\textit{rule} Indicates when to change to and back from the alternative time.
The \textit{rule} has the form:

\textit{date[/time], date[/time]}

where the first \textit{date} describes when the change from standard to
alternative time occurs and the second \textit{date} describes when the
change back happens. Each \textit{time} field describes when, in current
local time, the change to the other time is made.

The format of \textit{date} is one of the following:

\textbf{Jn} The Julian day \(n\) \((1 \leq n \leq 365)\). Leap days shall not be
counted. That is, in all years—including leap years—
February 28 is day 59 and March 1 is day 60. It is
impossible to refer explicitly to the occasional February
29.

\textbf{n} The zero-based Julian day \((0 \leq n \leq 365)\). Leap days shall
be counted, and it is possible to refer to February 29.

\textbf{Mm.n.d} The \(d\)’th day \((0 \leq d \leq 6)\) of week \(n\) of month \(m\) of the
year \((1 \leq n \leq 5, 1 \leq m \leq 12,\) where week 5 means “the
last \(d\) day in month \(m’\)” which may occur in either the
fourth or the fifth week). Week 1 is the first week in
which the \(d\)’th day occurs. Day zero is Sunday.

The \textit{time} has the same format as \textit{offset} except that no leading sign
(‘−’ or ‘+’) is allowed. The default, if \textit{time} is not given, shall be
02:00:00.
Regular Expressions (REs) provide a mechanism to select specific strings from a set of character strings.

Regular expressions are a context-independent syntax that can represent a wide variety of character sets and character set orderings, where these character sets are interpreted according to the current locale. While many regular expressions can be interpreted differently depending on the current locale, many features, such as character class expressions, provide for contextual invariance across locales.

The Basic Regular Expression (BRE) notation and construction rules in Section 9.3 (on page 171) shall apply to most utilities supporting regular expressions. Some utilities, instead, support the Extended Regular Expressions (ERE) described in Section 9.4 (on page 175); any exceptions for both cases are noted in the descriptions of the specific utilities using regular expressions. Both BREs and EREs are supported by the Regular Expression Matching interface in the System Interfaces volume of IEEE Std 1003.1-2001 under `regcomp()`, `regexec()`, and related functions.

### 9.1 Regular Expression Definitions

For the purposes of this section, the following definitions shall apply:

**entire regular expression**

The concatenated set of one or more BREs or EREs that make up the pattern specified for string selection.

**matched**

A sequence of zero or more characters shall be said to be matched by a BRE or ERE when the characters in the sequence correspond to a sequence of characters defined by the pattern.

Matching shall be based on the bit pattern used for encoding the character, not on the graphic representation of the character. This means that if a character set contains two or more encodings for a graphic symbol, or if the strings searched contain text encoded in more than one codeset, no attempt is made to search for any other representation of the encoded symbol. If that is required, the user can specify equivalence classes containing all variations of the desired graphic symbol.

The search for a matching sequence starts at the beginning of a string and stops when the first sequence matching the expression is found, where “first” is defined to mean “begins earliest in the string”. If the pattern permits a variable number of matching characters and thus there is more than one such sequence starting at that point, the longest such sequence is matched. For example, the BRE "\bb*" matches the second to fourth characters of the string "abbabc", and the ERE "(wee|week)(knights|night)" matches all ten characters of the string "weeknights".

Consistent with the whole match being the longest of the leftmost matches, each subpattern, from left to right, shall match the longest possible string. For this purpose, a null string shall be considered to be longer than no match at all. For example, matching the BRE "\(.*\).*$" against "abcdef", the subexpression "(\1)" is "abcdef", and matching the BRE "\(a*\)\*" against "bce", the subexpression "(\1)" is the null string.
When a multi-character collating element in a bracket expression (see Section 9.3.5 (on page 172)) is involved, the longest sequence shall be measured in characters consumed from the string to be matched; that is, the collating element counts not as one element, but as the number of characters it matches.

**BRE (ERE) matching a single character**

A BRE or ERE that shall match either a single character or a single collating element. Only a BRE or ERE of this type that includes a bracket expression (see Section 9.3.5 (on page 172)) can match a collating element.

**BRE (ERE) matching multiple characters**

A BRE or ERE that shall match a concatenation of single characters or collating elements. Such a BRE or ERE is made up from a BRE (ERE) matching a single character and BRE (ERE) special characters.

**invalid**

This section uses the term “invalid” for certain constructs or conditions. Invalid REs shall cause the utility or function using the RE to generate an error condition. When invalid is not used, violations of the specified syntax or semantics for REs produce undefined results: this may entail an error, enabling an extended syntax for that RE, or using the construct in error as literal characters to be matched. For example, the BRE construct "\{1,2,3\}" does not comply with the grammar. A conforming application cannot rely on it producing an error nor matching the literal characters "\{1,2,3\}".

### 9.2 Regular Expression General Requirements

The requirements in this section shall apply to both basic and extended regular expressions.

The use of regular expressions is generally associated with text processing. REs (BREs and EREs) operate on text strings; that is, zero or more characters followed by an end-of-string delimiter (typically NUL). Some utilities employing regular expressions limit the processing to lines; that is, zero or more characters followed by a <newline>. In the regular expression processing described in IEEE Std 1003.1-2001, the <newline> is regarded as an ordinary character and both a period and a non-matching list can match one. The Shell and Utilities volume of IEEE Std 1003.1-2001 specifies within the individual descriptions of those standard utilities employing regular expressions whether they permit matching of <newline>; if not stated otherwise, the use of literal <newline>s or any escape sequence equivalent produces undefined results. Those utilities (like grep) that do not allow <newline>s to match are responsible for eliminating any <newline> from strings before matching against the RE. The regcomp() function in the System Interfaces volume of IEEE Std 1003.1-2001, however, can provide support for such processing without violating the rules of this section.

The interfaces specified in IEEE Std 1003.1-2001 do not permit the inclusion of a NUL character in an RE or in the string to be matched. If during the operation of a standard utility a NUL is included in the text designated to be matched, that NUL may designate the end of the text string for the purposes of matching.

When a standard utility or function that uses regular expressions specifies that pattern matching shall be performed without regard to the case (uppercase or lowercase) of either data or patterns, then when each character in the string is matched against the pattern, not only the character, but also its case counterpart (if any), shall be matched. This definition of case-insensitive processing is intended to allow matching of multi-character collating elements as well as characters, as each character in the string is matched using both its cases. For example, in
a locale where "Ch" is a multi-character collating element and where a matching list expression
matches such elements, the RE "[.Ch.]" when matched against the string "char" is in
reality matched against "ch", "Ch", "cH", and "CH".
The implementation shall support any regular expression that does not exceed 256 bytes in
length.

9.3 Basic Regular Expressions

9.3.1 BREs Matching a Single Character or Collating Element
A BRE ordinary character, a special character preceded by a backslash, or a period shall match a
single character. A bracket expression shall match a single character or a single collating
element.

9.3.2 BRE Ordinary Characters
An ordinary character is a BRE that matches itself: any character in the supported character set,
except for the BRE special characters listed in Section 9.3.3.
The interpretation of an ordinary character preceded by a backslash (\) is undefined, except for:
- The characters ( ), ] , and \}
- The digits 1 to 9 inclusive (see Section 9.3.6 (on page 174))
- A character inside a bracket expression

9.3.3 BRE Special Characters
A BRE special character has special properties in certain contexts. Outside those contexts, or
when preceded by a backslash, such a character is a BRE that matches the special character itself.
The BRE special characters and the contexts in which they have their special meaning are as
follows:
- [ \ . The period, left-bracket, and backslash shall be special except when used in a bracket
expression (see Section 9.3.5 (on page 172)). An expression containing a \ that is not
preceded by a backslash and is not part of a bracket expression produces undefined
results.
- * The asterisk shall be special except when used:
  - In a bracket expression
  - As the first character of an entire BRE (after an initial \, if any)
  - As the first character of a subexpression (after an initial \, if any); see Section
  9.3.6 (on page 174)
- ^ The circumflex shall be special when used as:
  - An anchor (see Section 9.3.8 (on page 175))
  - The first character of a bracket expression (see Section 9.3.5 (on page 172))
- $ The dollar sign shall be special when used as an anchor.
### 9.3.4 Periods in BREs

A period (`.`) , when used outside a bracket expression, is a BRE that shall match any character in the supported character set except NUL.

### 9.3.5 RE Bracket Expression

A bracket expression (an expression enclosed in square brackets, `"[ ]"`) is an RE that shall match a single collating element contained in the non-empty set of collating elements represented by the bracket expression.

The following rules and definitions apply to bracket expressions:

1. A bracket expression is either a matching list expression or a non-matching list expression. It consists of one or more expressions: collating elements, collating symbols, equivalence classes, character classes, or range expressions. The right-bracket (`"]`) shall lose its special meaning and represent itself in a bracket expression if it occurs first in the list (after an initial circumflex (`"^"`), if any). Otherwise, it shall terminate the bracket expression, unless it appears in a collating symbol (such as `"[.] ."]`) or is the ending right-bracket for a collating symbol, equivalence class, or character class. The special characters ``, ``, ``, and ``, (period, asterisk, left-bracket, and backslash, respectively) shall lose their special meaning within a bracket expression.

The character sequences `"[.] .", "[=] (left-bracket followed by a period, equals-sign, or colon) shall be special inside a bracket expression and are used to delimit collating symbols, equivalence class expressions, and character class expressions. These symbols shall be followed by a valid expression and the matching terminating sequence `".]", "[=]", or "[:]", as described in the following items.

2. A matching list expression specifies a list that shall match any single-character collating element in any of the expressions represented in the list. The first character in the list shall not be the circumflex; for example, `"[a|b|c]"` is an RE that matches any of the characters `a`, `b`, or `c`. It is unspecified whether a matching list expression matches a multi-character collating element that is matched by one of the expressions.

3. A non-matching list expression begins with a circumflex (`"^"`), and specifies a list that shall match any single-character collating element except for the expressions represented in the list after the leading circumflex. For example, `"[^a|b|c]"` is an RE that matches any character except the characters `a`, `b`, or `c`. It is unspecified whether a non-matching list expression matches a multi-character collating element that is not matched by any of the expressions. The circumflex shall have this special meaning only when it occurs first in the list, immediately following the left-bracket.

4. A collating symbol is a collating element enclosed within bracket-period (`"[. .]"`) delimiters. Collating elements are defined as described in Section 7.3.2.4 (on page 137). Conforming applications shall represent multi-character collating elements as collating symbols when it is necessary to distinguish them from a list of the individual characters that make up the multi-character collating element. For example, if the string `"ch"` is a collating element defined using the line:

```
collating-element <ch-digraph> from "<c><h>"
```

in the locale definition, the expression `"[.ch .]"` shall be treated as an RE containing the collating symbol `ch`, while `"[ch]"` shall be treated as an RE matching `c` or `h`.

Collating symbols are recognized only inside bracket expressions. If the string is not a collating element in the current locale, the expression is invalid.
5. An equivalence class expression shall represent the set of collating elements belonging to an equivalence class, as described in Section 7.3.2.4 (on page 137). Only primary equivalence classes shall be recognized. The class shall be expressed by enclosing any one of the collating elements in the equivalence class within bracket-equal ("[=]" and "[=]") delimiters. For example, if ‘a’, ‘â’, and ‘â’ belong to the same equivalence class, then "[=a=]b", "[=â=]b", and "[=â=]b"
are each equivalent to "[aââb]". If the collating element does not belong to an equivalence class, the equivalence class expression shall be treated as a collating symbol.

6. A character class expression shall represent the union of two sets:

   a. The set of single-character collating elements whose characters belong to the character class, as defined in the LC_CTYPE category in the current locale.

   b. An unspecified set of multi-character collating elements.

All character classes specified in the current locale shall be recognized. A character class expression is expressed as a character class name enclosed within bracket-colon ("[:" and ":]") delimiters.

The following character class expressions shall be supported in all locales:

\[\text{:alnum:} \text{:cntrl:} \text{:lower:} \text{:space:}\]
\[\text{:alpha:} \text{:digit:} \text{:print:} \text{:upper:}\]
\[\text{:blank:} \text{:graph:} \text{:punct:} \text{:xdigit:}\]

In addition, character class expressions of the form:

\[\text{:name:}\]

are recognized in those locales where the name keyword has been given a charclass definition in the LC_CTYPE category.

7. In the POSIX locale, a range expression represents the set of collating elements that fall between two elements in the collation sequence, inclusive. In other locales, a range expression has unspecified behavior: strictly conforming applications shall not rely on whether the range expression is valid, or on the set of collating elements matched. A range expression shall be expressed as the starting point and the ending point separated by a hyphen (’−’).

In the following, all examples assume the POSIX locale.

The starting range point and the ending range point shall be a collating element or collating symbol. An equivalence class expression used as a starting or ending point of a range expression produces unspecified results. An equivalence class can be used portably within a bracket expression, but only outside the range. If the represented set of collating elements is empty, it is unspecified whether the expression matches nothing, or is treated as invalid.

The interpretation of range expressions where the ending range point is also the starting range point of a subsequent range expression (for example, "[a−m−o]") is undefined.

The hyphen character shall be treated as itself if it occurs first (after an initial ’−’, if any) or last in the list, or as an ending range point in a range expression. As examples, the expressions "[−ac]
and "[ac−]" are equivalent and match any of the characters ‘a’, ‘c’, or ‘−’; "[−ac]" and "[ac−]" are equivalent and match any characters except ‘a’, ‘c’, or ‘−’; the expression "[−@]
matches any of the characters between ‘−’ and ‘@’ inclusive; the expression "[−@]" matches any of the characters between ‘−’ and ‘@’ inclusive; and the expression "[a−@]
is either invalid or equivalent to ‘@’,
because the letter ‘a’ follows the symbol ‘−’ in the POSIX locale. To use a hyphen as the starting range point, it shall either come first in the bracket expression or be specified as a collating symbol; for example, "[ ] [−. .]0 ", which matches either a right bracket or any character or collating element that collates between hyphen and 0, inclusive.

If a bracket expression specifies both ‘−’ and ‘]’, the ‘]’ shall be placed first (after the ‘^’, if any) and the ‘−’ last within the bracket expression.

9.3.6 BREs Matching Multiple Characters

The following rules can be used to construct BREs matching multiple characters from BREs matching a single character:

1. The concatenation of BREs shall match the concatenation of the strings matched by each component of the BRE.

2. A subexpression can be defined within a BRE by enclosing it between the character pairs "(" and ")". Such a subexpression shall match whatever it would have matched without the "(" and ")", except that anchoring within subexpressions is optional behavior; see Section 9.3.8 (on page 175). Subexpressions can be arbitrarily nested.

3. The back-reference expression ‘\n’ shall match the same (possibly empty) string of characters as was matched by a subexpression enclosed between "(" and ")" preceding the ‘\n’. The character ‘n’ shall be a digit from 1 through 9, specifying the nth subexpression (the one that begins with the nth "(" from the beginning of the pattern and ends with the corresponding paired ")"). The expression is invalid if less than n subexpressions precede the ‘\n’. For example, the expression "(.*\)\1$" matches a line consisting of two adjacent appearances of the same string, and the expression "(a\)\1" fails to match ‘a’. When the referenced subexpression matched more than one string, the back-referenced expression shall refer to the last matched string. If the subexpression referenced by the back-reference matches more than one string because of an asterisk (‘*’) or an interval expression (see item (5)), the back-reference shall match the last (rightmost) of these strings.

4. When a BRE matching a single character, a subexpression, or a back-reference is followed by the special character asterisk (‘*’), together with that asterisk it shall match what zero or more consecutive occurrences of the BRE would match. For example, "[ab]*" and " [ab] [ab] " are equivalent when matching the string "ab".

5. When a BRE matching a single character, a subexpression, or a back-reference is followed by an interval expression of the format "\{m\}" or "\{m,n\}" and "\{m,.\}" or "\{m,\}" together with that interval expression it shall match what repeated consecutive occurrences of the BRE would match. The values of m and n are decimal integers in the range 0 \leq m \leq [RE_DUP_MAX], where m specifies the exact or minimum number of occurrences and n specifies the maximum number of occurrences. The expression "\{m\}" shall match exactly m occurrences of the preceding BRE, "\{m,\}" shall match at least m occurrences, and "\{m,n\}" shall match any number of occurrences between m and n, inclusive.

   For example, in the string "abababccccdd" the BRE "c\{3\}" is matched by characters seven to nine, the BRE "\(ab\)\{4,\}" is not matched at all, and the BRE "c\{1,3\}d" is matched by characters ten to thirteen.

   The behavior of multiple adjacent duplication symbols (‘*’ and intervals) produces undefined results.

   A subexpression repeated by an asterisk (‘*’) or an interval expression shall not match a null expression unless this is the only match for the repetition or it is necessary to satisfy the exact or
9.3.7 BRE Precedence

The order of precedence shall be as shown in the following table:

<table>
<thead>
<tr>
<th>BRE Precedence (from high to low)</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Collation-related bracket symbols</td>
<td>[==] [::] [..]</td>

<td></td>
</tr>
<tr>
<td>Anchoring</td>
<td>^ $</td>
</tr>
</tbody>
</table>

9.3.8 BRE Expression Anchoring

A BRE can be limited to matching strings that begin or end a line; this is called “anchoring”. The circumflex and dollar sign special characters shall be considered BRE anchors in the following contexts:

1. A circumflex (’ˆ’) shall be an anchor when used as the first character of an entire BRE. The implementation may treat the circumflex as an anchor when used as the first character of a subexpression. The circumflex shall anchor the expression (or optionally subexpression) to the beginning of a string; only sequences starting at the first character of a string shall be matched by the BRE. For example, the BRE "ˆab" matches "ab" in the string "abcdef", but fails to match in the string "cdefab". The BRE "$\(\^ab\)" may match the former string. A portable BRE shall escape a leading circumflex in a subexpression to match a literal circumflex.

2. A dollar sign (’$’) shall be an anchor when used as the last character of an entire BRE. The implementation may treat a dollar sign as an anchor when used as the last character of a subexpression. The dollar sign shall anchor the expression (or optionally subexpression) to the end of the string being matched; the dollar sign can be said to match the end-of-string following the last character.

3. A BRE anchored by both ’ˆ’ and ’$’ shall match only an entire string. For example, the BRE "ˆabcdef$" matches strings consisting only of "abcdef".

9.4 Extended Regular Expressions

The extended regular expression (ERE) notation and construction rules shall apply to utilities defined as using extended regular expressions; any exceptions to the following rules are noted in the descriptions of the specific utilities using EREs.
ERE Matching a Single Character or Collating Element

An ERE ordinary character, a special character preceded by a backslash, or a period shall match a single character. A bracket expression shall match a single character or a single collating element. An ERE matching a single character enclosed in parentheses shall match the same as the ERE without parentheses would have matched.

ERE Ordinary Characters

An ordinary character is an ERE that matches itself. An ordinary character is any character in the supported character set, except for the ERE special characters listed in Section 9.4.3. The interpretation of an ordinary character preceded by a backslash (\) is undefined.

ERE Special Characters

An ERE special character has special properties in certain contexts. Outside those contexts, or when preceded by a backslash, such a character shall be an ERE that matches the special character itself. The extended regular expression special characters and the contexts in which they shall have their special meaning are as follows:

- . [ \ ( The period, left-bracket, backslash, and left-parenthesis shall be special except when used in a bracket expression (see Section 9.3.5). Outside a bracket expression, a left-parenthesis immediately followed by a right-parenthesis produces undefined results.

- ) The right-parenthesis shall be special when matched with a preceding left-parenthesis, both outside a bracket expression.

- * + ? { The asterisk, plus-sign, question-mark, and left-brace shall be special except when used in a bracket expression (see Section 9.3.5). Any of the following uses produce undefined results:

  - If these characters appear first in an ERE, or immediately following a vertical-line, circumflex, or left-parenthesis

  - If a left-brace is not part of a valid interval expression (see Section 9.4.6)

- | The vertical-line is special except when used in a bracket expression (see Section 9.3.5). A vertical-line appearing first or last in an ERE, or immediately following a vertical-line or a left-parenthesis, or immediately preceding a right-parenthesis, produces undefined results.

- ^ The circumflex shall be special when used as:

  - An anchor (see Section 9.4.9)

  - The first character of a bracket expression (see Section 9.3.5)

- $ The dollar sign shall be special when used as an anchor.
### 9.4.4 Periods in EREs

A period (\'.\'), when used outside a bracket expression, is an ERE that shall match any character in the supported character set except NUL.

### 9.4.5 ERE Bracket Expression

The rules for ERE Bracket Expressions are the same as for Basic Regular Expressions; see Section 9.3.5 (on page 172).

### 9.4.6 EREs Matching Multiple Characters

The following rules shall be used to construct EREs matching multiple characters from EREs matching a single character:

1. A concatenation of EREs shall match the concatenation of the character sequences matched by each component of the ERE. A concatenation of EREs enclosed in parentheses shall match whatever the concatenation without the parentheses matches. For example, both the ERE "cd" and the ERE "(cd)" are matched by the third and fourth character of the string "abcdefabcdef".

2. When an ERE matching a single character or an ERE enclosed in parentheses is followed by the special character plus-sign (\'+\'), together with that plus-sign it shall match what one or more consecutive occurrences of the ERE would match. For example, the ERE "b+(bc)" matches the fourth to seventh characters in the string "acabbbcde". And, "[ab]+" and "[ab] [ab] *" are equivalent.

3. When an ERE matching a single character or an ERE enclosed in parentheses is followed by the special character asterisk (\'*\'), together with that asterisk it shall match what zero or more consecutive occurrences of the ERE would match. For example, the ERE "b*c" matches the first character in the string "cabbbcde", and the ERE "b*cd" matches the third to seventh characters in the string "cabbcbdbbbbbcdebc". And, "[ab] *" and "[ab] [ab] *" are equivalent when matching the string "ab".

4. When an ERE matching a single character or an ERE enclosed in parentheses is followed by the special character question-mark (\'?\'), together with that question-mark it shall match what zero or one consecutive occurrences of the ERE would match. For example, the ERE "b?c" matches the second character in the string "cabbbcde".

5. When an ERE matching a single character or an ERE enclosed in parentheses is followed by an interval expression of the format "\{m\}"", or "\{m, \}" or "\{m, n\}"", together with that interval expression it shall match what repeated consecutive occurrences of the ERE would match. The values of m and n are decimal integers in the range 0 ≤ m ≤ [RE_DUP_MAX], where m specifies the exact or minimum number of occurrences and n specifies the maximum number of occurrences. The expression "\{m\}" matches exactly m occurrences of the preceding ERE, "\{m, \}" matches at least m occurrences, and "\{m, n\}" matches any number of occurrences between m and n, inclusive.

For example, in the string "abababcccccd" the ERE "c\{3\}" is matched by characters seven to nine and the ERE "(ab) \{2, \}" is matched by characters one to six.

The behavior of multiple adjacent duplication symbols ('+', '*', '?', and intervals) produces undefined results.

An ERE matching a single character repeated by an '*', '?', or an interval expression shall not match a null expression unless this is the only match for the repetition or it is necessary to satisfy the exact or minimum number of occurrences for the interval expression.
9.4.7 ERE Alternation

Two EREs separated by the special character vertical-line (‘|’) shall match a string that is matched by either. For example, the ERE "a((bc)\|d)" matches the string "abc" and the string "ad". Single characters, or expressions matching single characters, separated by the vertical bar and enclosed in parentheses, shall be treated as an ERE matching a single character.

9.4.8 ERE Precedence

The order of precedence shall be as shown in the following table:

<table>
<thead>
<tr>
<th>ERE Precedence (from high to low)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Collation-related bracket symbols</td>
</tr>
<tr>
<td>Escaped characters</td>
</tr>
<tr>
<td>Bracket expression</td>
</tr>
<tr>
<td>Grouping</td>
</tr>
<tr>
<td>Single-character-ERE duplication</td>
</tr>
<tr>
<td>Concatenation</td>
</tr>
<tr>
<td>Anchoring</td>
</tr>
<tr>
<td>Alternation</td>
</tr>
</tbody>
</table>

For example, the ERE "abba|cde" matches either the string "abba" or the string "cde" (rather than the string "abbade" or "abcde", because concatenation has a higher order of precedence than alternation).

9.4.9 ERE Expression Anchoring

An ERE can be limited to matching strings that begin or end a line; this is called “anchoring”. The circumflex and dollar sign special characters shall be considered ERE anchors when used anywhere outside a bracket expression. This shall have the following effects:

1. A circumflex (‘^’) outside a bracket expression shall anchor the expression or subexpression it begins to the beginning of a string; such an expression or subexpression can match only a sequence starting at the first character of a string. For example, the EREs "^ab" and "(^ab)" match "ab" in the string "abcdef", but fail to match in the string "cdedef", and the ERE "a^b" is valid, but can never match because the ‘a’ prevents the expression "^b" from matching starting at the first character.

2. A dollar sign ('$') outside a bracket expression shall anchor the expression or subexpression it ends to the end of a string; such an expression or subexpression can match only a sequence ending at the last character of a string. For example, the EREs "ef$" and "(ef$)" match "ef" in the string "abcdef", but fail to match in the string "cdedef", and the ERE "e$f" is valid, but can never match because the ‘f’ prevents the expression "e$" from matching ending at the last character.
Regular Expression Grammar

Grammars describing the syntax of both basic and extended regular expressions are presented in this section. The grammar takes precedence over the text. See the Shell and Utilities volume of IEEE Std 1003.1-2001, Section 1.10, Grammar Conventions.

9.5.1 BRE/ERE Grammar Lexical Conventions

The lexical conventions for regular expressions are as described in this section.

Except as noted, the longest possible token or delimiter beginning at a given point is recognized. The following tokens are processed (in addition to those string constants shown in the grammar):

COLL_ELEM_SINGLE

Any single-character collating element, unless it is a META_CHAR.

COLL_ELEM_MULTI

Any multi-character collating element.

BACKREF

Applicable only to basic regular expressions. The character string consisting of \ followed by a single-digit numeral, 1 to 9.

DUP_COUNT

Represents a numeric constant. It shall be an integer in the range 0 ≤DUP_COUNT ≤RE_DUP_MAX. This token is only recognized when the context of the grammar requires it. At all other times, digits not preceded by \ are treated as ORD_CHAR.

META_CHAR

One of the characters:

^ When found first in a bracket expression
– When found anywhere but first (after an initial ^, if any) or last in a bracket expression, or as the ending range point in a range expression
[
] When found anywhere but first (after an initial ^, if any) in a bracket expression

L_ANCHOR

Applicable only to basic regular expressions. The character ^ when it appears as the first character of a basic regular expression and when not QUOTED_CHAR. The ^ may be recognized as an anchor elsewhere; see Section 9.3.8 (on page 175).

ORD_CHAR

A character, other than one of the special characters in SPEC_CHAR.

QUOTED_CHAR

In a BRE, one of the character sequences:

\^ \. \* \[ \$ \]

In an ERE, one of the character sequences:

\^ \. \[ \$ \{ \}

R_ANCHOR

(Applicable only to basic regular expressions.) The character $ when it appears as the last character of a basic regular expression and when not QUOTED_CHAR. The $ may be recognized as an anchor elsewhere; see Section 9.3.8 (on page 175).
For basic regular expressions, one of the following special characters:

- . Anywhere outside bracket expressions
- \ Anywhere outside bracket expressions
- [ Anywhere outside bracket expressions
- ^ When used as an anchor (see Section 9.3.8 (on page 175)) or when first in a bracket expression
- $ When used as an anchor
- * Anywhere except first in an entire RE, anywhere in a bracket expression, directly following ")", directly following an anchoring ‘^’

For extended regular expressions, shall be one of the following special characters found anywhere outside bracket expressions:

- ^ . [ $ ( ) ]
- * + ? { \}

(The close-parenthesis shall be considered special in this context only if matched with a preceding open-parenthesis.)

### 9.5.2 RE and Bracket Expression Grammar

This section presents the grammar for basic regular expressions, including the bracket expression grammar that is common to both BREs and EREs.

The BRE grammar does not permit \texttt{L\_ANCHOR} or \texttt{R\_ANCHOR} inside \texttt{"\("} and \texttt{"\")} (which implies that \texttt{\^} and \texttt{\$} are ordinary characters). This reflects the semantic limits on the application, as noted in Section 9.3.8 (on page 175). Implementations are permitted to extend the language to interpret \texttt{\^} and \texttt{\$} as anchors in these locations, and as such, conforming applications cannot use unescaped \texttt{\^} and \texttt{\$} in positions inside \texttt{"\("} and \texttt{"\")} that might be interpreted as anchors.

### 9.5.3 ERE Grammar

This section presents the grammar for extended regular expressions, excluding the bracket expression grammar.

\textbf{Note:} The bracket expression grammar and the associated \%token lines are identical between BREs and EREs. It has been omitted from the ERE section to avoid unnecessary editorial duplication.
The ERE grammar does not permit several constructs that previous sections specify as having undefined results:

- **ORD_CHAR** preceded by `\`
- One or more `ERE_dupl_symbol` appearing first in an ERE, or immediately following `|`, `^`, or `{`
- `{` not part of a valid `ERE_dupl_symbol`
- `|` appearing first or last in an ERE, or immediately following `|` or `{`, or immediately preceding `}`

Implementations are permitted to extend the language to allow these. Conforming applications cannot use such constructs.
10.1 Directory Structure and Files

The following directories shall exist on conforming systems and conforming applications shall make use of them only as described. Strictly conforming applications shall not assume the ability to create files in any of these directories, unless specified below.

/ The root directory.
/dev Contains /dev/console, /dev/null, and /dev/tty, described below.

The following directory shall exist on conforming systems and shall be used as described:
/tmp A directory made available for applications that need a place to create temporary files. Applications shall be allowed to create files in this directory, but shall not assume that such files are preserved between invocations of the application.

The following files shall exist on conforming systems and shall be both readable and writable:
/dev/null An infinite data source and data sink. Data written to /dev/null shall be discarded. Reads from /dev/null shall always return end-of-file (EOF).
/dev/tty In each process, a synonym for the controlling terminal associated with the process group of that process, if any. It is useful for programs or shell procedures that wish to be sure of writing messages to or reading data from the terminal no matter how output has been redirected. It can also be used for applications that demand the name of a file for output, when typed output is desired and it is tiresome to find out what terminal is currently in use.

The following file shall exist on conforming systems and need not be readable or writable:
/dev/console The /dev/console file is a generic name given to the system console (see Section 3.382 (on page 88)). It is usually linked to an implementation-defined special file. It shall provide an interface to the system console conforming to the requirements of the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 11, General Terminal Interface.

10.2 Output Devices and Terminal Types

The utilities in the Shell and Utilities volume of IEEE Std 1003.1-2001 historically have been implemented on a wide range of terminal types, but a conforming implementation need not support all features of all utilities on every conceivable terminal. IEEE Std 1003.1-2001 states which features are optional for certain classes of terminals in the individual utility description sections. The implementation shall document which terminal types it supports and which of these features and utilities are not supported by each terminal.

When a feature or utility is not supported on a specific terminal type, as allowed by IEEE Std 1003.1-2001, and the implementation considers such a condition to be an error preventing use of the feature or utility, the implementation shall indicate such conditions through diagnostic messages or exit status values or both (as appropriate to the specific utility description) that inform the user that the terminal type lacks the appropriate capability.
IEEE Std 1003.1-2001 uses a notational convention based on historical practice that identifies some of the control characters defined in Section 7.3.1 (on page 126) in a manner easily remembered by users on many terminals. The correspondence between this “\(<\text{control}>\text{-char}\)” notation and the actual control characters is shown in the following table. When IEEE Std 1003.1-2001 refers to a character by its “\(<\text{control}>\text{-name}\)”, it is referring to the actual control key sequence on all terminals. Some terminals have keyboards that do not allow the direct transmission of all the non-alphanumeric characters shown. In such cases, the system documentation shall describe which data sequences transmitted by the terminal are interpreted by the system as representing the special characters.

**Note:** The notation uses uppercase letters for arbitrary editorial reasons. There is no implication that the keystrokes represent control-shift-letter sequences.
Chapter 11

General Terminal Interface

This chapter describes a general terminal interface that shall be provided. It shall be supported on any asynchronous communications ports if the implementation provides them. It is implementation-defined whether it supports network connections or synchronous ports, or both.

11.1 Interface Characteristics

11.1.1 Opening a Terminal Device File

When a terminal device file is opened, it normally causes the thread to wait until a connection is established. In practice, application programs seldom open these files; they are opened by special programs and become an application’s standard input, output, and error files.

As described in open(), opening a terminal device file with the O_NONBLOCK flag clear shall cause the thread to block until the terminal device is ready and available. If CLOCAL mode is not set, this means blocking until a connection is established. If CLOCAL mode is set in the terminal, or the O_NONBLOCK flag is specified in the open(), the open() function shall return a file descriptor without waiting for a connection to be established.

11.1.2 Process Groups

A terminal may have a foreground process group associated with it. This foreground process group plays a special role in handling signal-generating input characters, as discussed in Section 11.1.9 (on page 191).

A command interpreter process supporting job control can allocate the terminal to different jobs, or process groups, by placing related processes in a single process group and associating this process group with the terminal. A terminal’s foreground process group may be set or examined by a process, assuming the permission requirements are met; see tcgetpgrp() and tcsetpgrp(). The terminal interface aids in this allocation by restricting access to the terminal by processes that are not in the current process group; see Section 11.1.4 (on page 188).

When there is no longer any process whose process ID or process group ID matches the foreground process group ID, the terminal shall have no foreground process group. It is unspecified whether the terminal has a foreground process group when there is a process whose process ID matches the foreground process group ID, but whose process group ID does not. No actions defined in IEEE Std 1003.1-2001, other than allocation of a controlling terminal or a successful call to tcsetpgrp(), shall cause a process group to become the foreground process group of the terminal.
11.1.3 The Controlling Terminal

A terminal may belong to a process as its controlling terminal. Each process of a session that has a controlling terminal has the same controlling terminal. A terminal may be the controlling terminal for at most one session. The controlling terminal for a session is allocated by the session leader in an implementation-defined manner. If a session leader has no controlling terminal, and opens a terminal device file that is not already associated with a session without using the O_NOCTTY option (see open()), it is implementation-defined whether the terminal becomes the controlling terminal of the session leader. If a process which is not a session leader opens a terminal file, or the O_NOCTTY option is used on open(), then that terminal shall not become the controlling terminal of the calling process. When a controlling terminal becomes associated with a session, its foreground process group shall be set to the process group of the session leader.

The controlling terminal is inherited by a child process during a fork() function call. A process relinquishes its controlling terminal when it creates a new session with the setsid() function; other processes remaining in the old session that had this terminal as their controlling terminal continue to have it. Upon the close of the last file descriptor in the system (whether or not it is in the current session) associated with the controlling terminal, it is unspecified whether all processes that had that terminal as their controlling terminal cease to have any controlling terminal. Whether and how a session leader can reacquire a controlling terminal after the controlling terminal has been relinquished in this fashion is unspecified. A process does not relinquish its controlling terminal simply by closing all of its file descriptors associated with the controlling terminal if other processes continue to have it open.

When a controlling process terminates, the controlling terminal is dissociated from the current session, allowing it to be acquired by a new session leader. Subsequent access to the terminal by other processes in the earlier session may be denied, with attempts to access the terminal treated as if a modem disconnect had been sensed.

11.1.4 Terminal Access Control

If a process is in the foreground process group of its controlling terminal, read operations shall be allowed, as described in Section 11.1.5 (on page 189). Any attempts by a process in a background process group to read from its controlling terminal cause its process group to be sent a SIGTTIN signal unless one of the following special cases applies: if the reading process is ignoring or blocking the SIGTTIN signal, or if the process group of the reading process is orphaned, the read() shall return -1, with errno set to [EIO] and no signal shall be sent. The default action of the SIGTTIN signal shall be to stop the process to which it is sent. See <signal.h>.

If a process is in the foreground process group of its controlling terminal, write operations shall be allowed as described in Section 11.1.8 (on page 191). Attempts by a process in a background process group to write to its controlling terminal shall cause the process group to be sent a SIGTTOU signal unless one of the following special cases applies: if TOSTOP is not set, or if TOSTOP is set and the process is ignoring or blocking the SIGTTOU signal, the process is allowed to write to the terminal and the SIGTTOU signal is not sent. If TOSTOP is set, and the process group of the writing process is orphaned, and the writing process is not ignoring or blocking the SIGTTOU signal, the write() shall return -1, with errno set to [EIO] and no signal shall be sent.

Certain calls that set terminal parameters are treated in the same fashion as write(), except that TOSTOP is ignored; that is, the effect is identical to that of terminal writes when TOSTOP is set (see Section 11.2.5 (on page 197), tcdrain(), tcflow(), tcflush(), tcsendbreak(), tcsetattr(), and tcsetpgrp()).
11.1.5 Input Processing and Reading Data

A terminal device associated with a terminal device file may operate in full-duplex mode, so that data may arrive even while output is occurring. Each terminal device file has an input queue associated with it, into which incoming data is stored by the system before being read by a process. The system may impose a limit, [MAX_INPUT], on the number of bytes that may be stored in the input queue. The behavior of the system when this limit is exceeded is implementation-defined.

Two general kinds of input processing are available, determined by whether the terminal device file is in canonical mode or non-canonical mode. These modes are described in Section 11.1.6 and Section 11.1.7 (on page 190). Additionally, input characters are processed according to the c_iflag (see Section 11.2.2 (on page 193)) and c_lflag (see Section 11.2.5 (on page 197)) fields. Such processing can include "echoing", which in general means transmitting input characters immediately back to the terminal when they are received from the terminal. This is useful for terminals that can operate in full-duplex mode.

The manner in which data is provided to a process reading from a terminal device file is dependent on whether the terminal file is in canonical or non-canonical mode, and on whether or not the O_NONBLOCK flag is set by open() or fcntl().

If the O_NONBLOCK flag is clear, then the read request shall be blocked until data is available or a signal has been received. If the O_NONBLOCK flag is set, then the read request shall be completed, without blocking, in one of three ways:

1. If there is enough data available to satisfy the entire request, the read() shall complete successfully and shall return the number of bytes read.

2. If there is not enough data available to satisfy the entire request, the read() shall complete successfully, having read as much data as possible, and shall return the number of bytes it was able to read.

3. If there is no data available, the read() shall return −1, with errno set to [EAGAIN].

When data is available depends on whether the input processing mode is canonical or non-canonical. Section 11.1.6 and Section 11.1.7 (on page 190) describe each of these input processing modes.

11.1.6 Canonical Mode Input Processing

In canonical mode input processing, terminal input is processed in units of lines. A line is delimited by a newline character (NL), an end-of-file character (EOF), or an end-of-line (EOL) character. See Section 11.1.9 (on page 191) for more information on EOF and EOL. This means that a read request shall not return until an entire line has been typed or a signal has been received. Also, no matter how many bytes are requested in the read() call, at most one line shall be returned. It is not, however, necessary to read a whole line at once; any number of bytes, even one, may be requested in a read() without losing information.

If [MAX_CANON] is defined for this terminal device, it shall be a limit on the number of bytes in a line. The behavior of the system when this limit is exceeded is implementation-defined. If [MAX_CANON] is not defined, there shall be no such limit; see pathconf().

Erase and kill processing occur when either of two special characters, the ERASE and KILL characters (see Section 11.1.9 (on page 191)), is received. This processing shall affect data in the input queue that has not yet been delimited by an NL, EOF, or EOL character. This un-delimited data makes up the current line. The ERASE character shall delete the last character in the current line, if there is one. The KILL character shall delete all data in the current line, if there is any. The ERASE and KILL characters shall have no effect if there is no data in the current line. The ERASE
and KILL characters themselves shall not be placed in the input queue.

11.1.7 Non-Canonical Mode Input Processing

In non-canonical mode input processing, input bytes are not assembled into lines, and erase and kill processing shall not occur. The values of the MIN and TIME members of the c_cc array are used to determine how to process the bytes received. IEEE Std 1003.1-2001 does not specify whether the setting of O_NONBLOCK takes precedence over MIN or TIME settings. Therefore, if O_NONBLOCK is set, read() may return immediately, regardless of the setting of MIN or TIME. Also, if no data is available, read() may either return 0, or return −1 with errno set to [EAGAIN].

MIN represents the minimum number of bytes that should be received when the read() function returns successfully. TIME is a timer of 0.1 second granularity that is used to time out bursty and short-term data transmissions. If MIN is greater than [MAX_INPUT], the response to the request is undefined. The four possible values for MIN and TIME and their interactions are described below.

Case A: MIN>0, TIME>0

In case A, TIME serves as an inter-byte timer which shall be activated after the first byte is received. Since it is an inter-byte timer, it shall be reset after a byte is received. The interaction between MIN and TIME is as follows. As soon as one byte is received, the inter-byte timer shall be started. If MIN bytes are received before the inter-byte timer expires (remember that the timer is reset upon receipt of each byte), the read shall be satisfied. If the timer expires before MIN bytes are received, the characters received to that point shall be returned to the user. Note that if TIME expires at least one byte shall be returned because the timer would not have been enabled unless a byte was received. In this case (MIN>0, TIME>0) the read shall block until the MIN and TIME mechanisms are activated by the receipt of the first byte, or a signal is received. If data is in the buffer at the time of the read(), the result shall be as if data has been received immediately after the read().

Case B: MIN>0, TIME=0

In case B, since the value of TIME is zero, the timer plays no role and only MIN is significant. A pending read shall not be satisfied until MIN bytes are received (that is, the pending read shall block until MIN bytes are received), or a signal is received. A program that uses case B to read record-based terminal I/O may block indefinitely in the read operation.

Case C: MIN=0, TIME>0

In case C, since MIN=0, TIME no longer represents an inter-byte timer. It now serves as a read timer that shall be activated as soon as the read() function is processed. A read shall be satisfied as soon as a single byte is received or the read timer expires. Note that in case C if the timer expires, no bytes shall be returned. If the timer does not expire, the only way the read can be satisfied is if a byte is received. If bytes are not received, the read shall not block indefinitely waiting for a byte; if no byte is received within TIME*0.1 seconds after the read is initiated, the read() shall return a value of zero, having read no data. If data is in the buffer at the time of the read(), the timer shall be started as if data has been received immediately after the read().
Case D: MIN=0, TIME=0

The minimum of either the number of bytes requested or the number of bytes currently available shall be returned without waiting for more bytes to be input. If no characters are available, \texttt{read()} shall return a value of zero, having read no data.

11.1.8 Writing Data and Output Processing

When a process writes one or more bytes to a terminal device file, they are processed according to the \texttt{c_oflag} field (see Section 11.2.3 (on page 194)). The implementation may provide a buffering mechanism; as such, when a call to \texttt{write()} completes, all of the bytes written have been scheduled for transmission to the device, but the transmission has not necessarily completed. See \texttt{write()} for the effects of O_NONBLOCK on \texttt{write()}.

11.1.9 Special Characters

Certain characters have special functions on input or output or both. These functions are summarized as follows:

- **INTR** Special character on input, which is recognized if the ISIG flag is set. Generates a SIGINT signal which is sent to all processes in the foreground process group for which the terminal is the controlling terminal. If ISIG is set, the INTR character shall be discarded when processed.

- **QUIT** Special character on input, which is recognized if the ISIG flag is set. Generates a SIGQUIT signal which is sent to all processes in the foreground process group for which the terminal is the controlling terminal. If ISIG is set, the QUIT character shall be discarded when processed.

- **ERASE** Special character on input, which is recognized if the ICANON flag is set. Erases the last character in the current line; see Section 11.1.6 (on page 189). It shall not erase beyond the start of a line, as delimited by an NL, EOF, or EOL character. If ICANON is set, the ERASE character shall be discarded when processed.

- **KILL** Special character on input, which is recognized if the ICANON flag is set. Deletes the entire line, as delimited by an NL, EOF, or EOL character. If ICANON is set, the KILL character shall be discarded when processed.

- **EOF** Special character on input, which is recognized if the ICANON flag is set. When received, all the bytes waiting to be read are immediately passed to the process without waiting for a newline, and the EOF is discarded. Thus, if there are no bytes waiting (that is, the EOF occurred at the beginning of a line), a byte count of zero shall be returned from the \texttt{read()}, representing an end-of-file indication. If ICANON is set, the EOF character shall be discarded when processed.

- **NL** Special character on input, which is recognized if the ICANON flag is set. It is the line delimiter newline. It cannot be changed.

- **EOL** Special character on input, which is recognized if the ICANON flag is set. It is an additional line delimiter, like NL.

- **SUSP** If the ISIG flag is set, receipt of the SUSP character shall cause a SIGTSTP signal to be sent to all processes in the foreground process group for which the terminal is the controlling terminal, and the SUSP character shall be discarded when processed.

- **STOP** Special character on both input and output, which is recognized if the IXON (output control) or IXOFF (input control) flag is set. Can be used to suspend output temporarily. It is useful with CRT terminals to prevent output from disappearing
before it can be read. If IXON is set, the STOP character shall be discarded when processed.

START Special character on both input and output, which is recognized if the IXON (output control) or IXOFF (input control) flag is set. Can be used to resume output that has been suspended by a STOP character. If IXON is set, the START character shall be discarded when processed.

CR Special character on input, which is recognized if the ICANON flag is set; it is the carriage-return character. When ICANON and ICRNL are set and IGNCR is not set, this character shall be translated into an NL, and shall have the same effect as an NL character.

The NL and CR characters cannot be changed. It is implementation-defined whether the START and STOP characters can be changed. The values for INTR, QUIT, ERASE, KILL, EOF, EOL, and SUSP shall be changeable to suit individual tastes. Special character functions associated with changeable special control characters can be disabled individually.

If two or more special characters have the same value, the function performed when that character is received is undefined.

A special character is recognized not only by its value, but also by its context; for example, an implementation may support multi-byte sequences that have a meaning different from the meaning of the bytes when considered individually. Implementations may also support additional single-byte functions. These implementation-defined multi-byte or single-byte functions shall be recognized only if the IEXTEN flag is set; otherwise, data is received without interpretation, except as required to recognize the special characters defined in this section.

If IEXTEN is set, the ERASE, KILL, and EOF characters can be escaped by a preceding \ character, in which case no special function shall occur.

11.1.10 Modem Disconnect

If a modem disconnect is detected by the terminal interface for a controlling terminal, and if CLOCAL is not set in the c_cflag field for the terminal (see Section 11.2.4 (on page 196)), the SIGHUP signal shall be sent to the controlling process for which the terminal is the controlling terminal. Unless other arrangements have been made, this shall cause the controlling process to terminate (see exit()). Any subsequent read from the terminal device shall return the value of zero, indicating end-of-file; see read(). Thus, processes that read a terminal file and test for end-of-file can terminate appropriately after a disconnect. If the EIO condition as specified in read() also exists, it is unspecified whether on EOF condition or [EIO] is returned. Any subsequent write() to the terminal device shall return −1, with errno set to [EIO], until the device is closed.

11.1.11 Closing a Terminal Device File

The last process to close a terminal device file shall cause any output to be sent to the device and any input to be discarded. If HUPCL is set in the control modes and the communications port supports a disconnect function, the terminal device shall perform a disconnect.
11.2 Parameters that Can be Set

11.2.1 The termios Structure

Routines that need to control certain terminal I/O characteristics shall do so by using the termios structure as defined in the `<termios.h>` header. The members of this structure include (but are not limited to):

<table>
<thead>
<tr>
<th>Member Type</th>
<th>Array Size</th>
<th>Member Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tcflag_t</td>
<td></td>
<td>c_iflag</td>
<td>Input modes.</td>
</tr>
<tr>
<td>tcflag_t</td>
<td></td>
<td>c_oflag</td>
<td>Output modes.</td>
</tr>
<tr>
<td>tcflag_t</td>
<td></td>
<td>c_cflag</td>
<td>Control modes.</td>
</tr>
<tr>
<td>tcflag_t</td>
<td></td>
<td>c_lflag</td>
<td>Local modes.</td>
</tr>
<tr>
<td>cc_t</td>
<td>NCCS</td>
<td>c_cc[</td>
<td>Control characters.</td>
</tr>
</tbody>
</table>

The types tcflag_t and cc_t are defined in the `<termios.h>` header. They shall be unsigned integer types.

11.2.2 Input Modes

Values of the c_iflag field describe the basic terminal input control, and are composed of the bitwise-inclusive OR of the masks shown, which shall be bitwise-distinct. The mask name symbols in this table are defined in `<termios.h>`:

<table>
<thead>
<tr>
<th>Mask Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BRKINT</td>
<td>Signal interrupt on break.</td>
</tr>
<tr>
<td>ICRNL</td>
<td>Map CR to NL on input.</td>
</tr>
<tr>
<td>IGNBRK</td>
<td>Ignore break condition.</td>
</tr>
<tr>
<td>IGNCR</td>
<td>Ignore CR.</td>
</tr>
<tr>
<td>IGNPAR</td>
<td>Ignore characters with parity errors.</td>
</tr>
<tr>
<td>INLCR</td>
<td>Map NL to CR on input.</td>
</tr>
<tr>
<td>INPCK</td>
<td>Enable input parity check.</td>
</tr>
<tr>
<td>ISTRIP</td>
<td>Strip character.</td>
</tr>
<tr>
<td>IXANY</td>
<td>Enable any character to restart output.</td>
</tr>
<tr>
<td>IXOFF</td>
<td>Enable start/stop input control.</td>
</tr>
<tr>
<td>IXON</td>
<td>Enable start/stop output control.</td>
</tr>
<tr>
<td>PARMRK</td>
<td>Mark parity errors.</td>
</tr>
</tbody>
</table>

In the context of asynchronous serial data transmission, a break condition shall be defined as a sequence of zero-valued bits that continues for more than the time to send one byte. The entire sequence of zero-valued bits is interpreted as a single break condition, even if it continues for a time equivalent to more than one byte. In contexts other than asynchronous serial data transmission, the definition of a break condition is implementation-defined.

If IGNBRK is set, a break condition detected on input shall be ignored; that is, not put on the input queue and therefore not read by any process. If IGNBRK is not set and BRKINT is set, the break condition shall flush the input and output queues, and if the terminal is the controlling terminal of a foreground process group, the break condition shall generate a single SIGINT signal to that foreground process group. If neither IGNBRK nor BRKINT is set, a break condition shall be read as a single 0x00, or if PARMRK is set, as 0xff 0x00 0x00.

If IGNPAR is set, a byte with a framing or parity error (other than break) shall be ignored.
If PARMRK is set, and IGNPAR is not set, a byte with a framing or parity error (other than break) shall be given to the application as the three-byte sequence 0xff 0x00 X, where 0xff 0x00 is a two-byte flag preceding each sequence and X is the data of the byte received in error. To avoid ambiguity in this case, if ISTRIP is not set, a valid byte of 0xff is given to the application as 0xff. If neither PARMRK nor IGNPAR is set, a framing or parity error (other than break) shall be given to the application as a single byte 0x00.

If INPCK is set, input parity checking shall be enabled. If INPCK is not set, input parity checking shall be disabled, allowing output parity generation without input parity errors. Note that whether input parity checking is enabled or disabled is independent of whether parity detection is enabled or disabled (see Section 11.2.4 (on page 196)). If parity detection is enabled but input parity checking is disabled, the hardware to which the terminal is connected shall recognize the parity bit, but the terminal special file shall not check whether or not this bit is correctly set.

If ISTRIP is set, valid input bytes shall first be stripped to seven bits; otherwise, all eight bits shall be processed.

If INLCR is set, a received NL character shall be translated into a CR character. If IGNCR is set, a received CR character shall be ignored (not read). If IGNCR is not set and ICRNL is set, a received CR character shall be translated into an NL character.

If IXANY is set, any input character shall restart output that has been suspended.

If IXON is set, start/stop output control shall be enabled. A received STOP character shall suspend output and a received START character shall restart output. When IXON is set, START and STOP characters are not read, but merely perform flow control functions. When IXON is not set, the START and STOP characters shall be read.

If IXOFF is set, start/stop input control shall be enabled. The system shall transmit STOP characters, which are intended to cause the terminal device to stop transmitting data, as needed to prevent the input queue from overflowing and causing implementation-defined behavior, and shall transmit START characters, which are intended to cause the terminal device to resume transmitting data, as soon as the device can continue transmitting data without risk of overflowing the input queue. The precise conditions under which STOP and START characters are transmitted are implementation-defined.

The initial input control value after open() is implementation-defined.

### 11.2.3 Output Modes

The c_oflag field specifies the terminal interface’s treatment of output, and is composed of the bitwise-inclusive OR of the masks shown, which shall be bitwise-distinct. The mask name symbols in the following table are defined in <termios.h>:
<table>
<thead>
<tr>
<th>Mask Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>OPOST</td>
<td>Perform output processing.</td>
</tr>
<tr>
<td>ONLCR</td>
<td>Map NL to CR-NL on output.</td>
</tr>
<tr>
<td>OCRNL</td>
<td>Map CR to NL on output.</td>
</tr>
<tr>
<td>ONOCR</td>
<td>No CR output at column 0.</td>
</tr>
<tr>
<td>ONLRET</td>
<td>NL performs CR function.</td>
</tr>
<tr>
<td>OFILL</td>
<td>Use fill characters for delay.</td>
</tr>
<tr>
<td>OFDEL</td>
<td>Fill is DEL, else NUL.</td>
</tr>
<tr>
<td>NLDLY</td>
<td>Select newline delays:</td>
</tr>
<tr>
<td>NL0</td>
<td>Newline character type 0.</td>
</tr>
<tr>
<td>NL1</td>
<td>Newline character type 1.</td>
</tr>
<tr>
<td>CRDLY</td>
<td>Select carriage-return delays:</td>
</tr>
<tr>
<td>CR0</td>
<td>Carriage-return delay type 0.</td>
</tr>
<tr>
<td>CR1</td>
<td>Carriage-return delay type 1.</td>
</tr>
<tr>
<td>CR2</td>
<td>Carriage-return delay type 2.</td>
</tr>
<tr>
<td>CR3</td>
<td>Carriage-return delay type 3.</td>
</tr>
<tr>
<td>TABDLY</td>
<td>Select horizontal-tab delays:</td>
</tr>
<tr>
<td>TAB0</td>
<td>Horizontal-tab delay type 0.</td>
</tr>
<tr>
<td>TAB1</td>
<td>Horizontal-tab delay type 1.</td>
</tr>
<tr>
<td>TAB2</td>
<td>Horizontal-tab delay type 2.</td>
</tr>
<tr>
<td>TAB3</td>
<td>Expand tabs to spaces.</td>
</tr>
<tr>
<td>BSDLY</td>
<td>Select backspace delays:</td>
</tr>
<tr>
<td>BS0</td>
<td>Backspace-delay type 0.</td>
</tr>
<tr>
<td>BS1</td>
<td>Backspace-delay type 1.</td>
</tr>
<tr>
<td>VTDLY</td>
<td>Select vertical-tab delays:</td>
</tr>
<tr>
<td>VT0</td>
<td>Vertical-tab delay type 0.</td>
</tr>
<tr>
<td>VT1</td>
<td>Vertical-tab delay type 1.</td>
</tr>
<tr>
<td>FFDLY</td>
<td>Select form-feed delays:</td>
</tr>
<tr>
<td>FF0</td>
<td>Form-feed delay type 0.</td>
</tr>
<tr>
<td>FF1</td>
<td>Form-feed delay type 1.</td>
</tr>
</tbody>
</table>

If OPOST is set, output data shall be post-processed as described below, so that lines of text are modified to appear appropriately on the terminal device; otherwise, characters shall be transmitted without change.

If ONLCR is set, the NL character shall be transmitted as the CR-NL character pair. If OCRNL is set, the CR character shall be transmitted as the NL character. If ONOCR is set, no CR character shall be transmitted when at column 0 (first position). If ONLRET is set, the NL character is assumed to do the carriage-return function; the column pointer shall be set to 0 and the delays specified for CR shall be used. Otherwise, the NL character is assumed to do just the line-feed function; the column pointer remains unchanged. The column pointer shall also be set to 0 if the CR character is actually transmitted.

The delay bits specify how long transmission stops to allow for mechanical or other movement when certain characters are sent to the terminal. In all cases a value of 0 shall indicate no delay. If OFILL is set, fill characters shall be transmitted for delay instead of a timed delay. This is useful for high baud rate terminals which need only a minimal delay. If OFDEL is set, the fill character shall be DEL; otherwise, NUL.

If a form-feed or vertical-tab delay is specified, it shall last for about 2 seconds.

Newline delay shall last about 0.10 seconds. If ONLRET is set, the carriage-return delays shall be used instead of the newline delays. If OFILL is set, two fill characters shall be transmitted.
Carriage-return delay type 1 shall be dependent on the current column position, type 2 shall be about 0.10 seconds, and type 3 shall be about 0.15 seconds. If OFILL is set, delay type 1 shall transmit two fill characters, and type 2 four fill characters.

Horizontal-tab delay type 1 shall be dependent on the current column position. Type 2 shall be about 0.10 seconds. Type 3 specifies that tabs shall be expanded into spaces. If OFILL is set, two fill characters shall be transmitted for any delay.

Backspace delay shall last about 0.05 seconds. If OFILL is set, one fill character shall be transmitted.

The actual delays depend on line speed and system load.

The initial output control value after open() is implementation-defined.

11.2.4 Control Modes

The c_cflag field describes the hardware control of the terminal, and is composed of the bitwise-inclusive OR of the masks shown, which shall be bitwise-distinct. The mask name symbols in this table are defined in `<termios.h>`; not all values specified are required to be supported by the underlying hardware:

<table>
<thead>
<tr>
<th>Mask Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLOCAL</td>
<td>Ignore modem status lines.</td>
</tr>
<tr>
<td>CREAD</td>
<td>Enable receiver.</td>
</tr>
<tr>
<td>CSIZE</td>
<td>Number of bits transmitted or received per byte:</td>
</tr>
<tr>
<td>CS5</td>
<td>5 bits</td>
</tr>
<tr>
<td>CS6</td>
<td>6 bits</td>
</tr>
<tr>
<td>CS7</td>
<td>7 bits</td>
</tr>
<tr>
<td>CS8</td>
<td>8 bits.</td>
</tr>
<tr>
<td>CSTOPB</td>
<td>Send two stop bits, else one.</td>
</tr>
<tr>
<td>HUPCL</td>
<td>Hang up on last close.</td>
</tr>
<tr>
<td>PARENB</td>
<td>Parity enable.</td>
</tr>
<tr>
<td>PARODD</td>
<td>Odd parity, else even.</td>
</tr>
</tbody>
</table>

In addition, the input and output baud rates are stored in the `termios` structure. The symbols in the following table are defined in `<termios.h>`. Not all values specified are required to be supported by the underlying hardware.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>B0</td>
<td>Hang up</td>
<td>B600</td>
<td>600 baud</td>
</tr>
<tr>
<td>B50</td>
<td>50 baud</td>
<td>B1200</td>
<td>1200 baud</td>
</tr>
<tr>
<td>B75</td>
<td>75 baud</td>
<td>B1800</td>
<td>1800 baud</td>
</tr>
<tr>
<td>B110</td>
<td>110 baud</td>
<td>B2400</td>
<td>2400 baud</td>
</tr>
<tr>
<td>B134</td>
<td>134.5 baud</td>
<td>B4800</td>
<td>4800 baud</td>
</tr>
<tr>
<td>B150</td>
<td>150 baud</td>
<td>B9600</td>
<td>9600 baud</td>
</tr>
<tr>
<td>B200</td>
<td>200 baud</td>
<td>B19200</td>
<td>19200 baud</td>
</tr>
<tr>
<td>B300</td>
<td>300 baud</td>
<td>B38400</td>
<td>38400 baud</td>
</tr>
</tbody>
</table>

The following functions are provided for getting and setting the values of the input and output baud rates in the `termios` structure: `cgetispeed()`, `cgetospeed()`, `cfsetispeed()`, and `cfsetospeed()`. The effects on the terminal device shall not become effective and not all errors need be detected until the `tcsetattr()` function is successfully called.

The CSIZE bits shall specify the number of transmitted or received bits per byte. If ISTRIP is not set, the value of all the other bits is unspecified. If ISTRIP is set, the value of all but the 7 low-
order bits shall be zero, but the value of any other bits beyond CSIZE is unspecified when read. CSIZE shall not include the parity bit, if any. If CSTOPB is set, two stop bits shall be used; otherwise, one stop bit. For example, at 110 baud, two stop bits are normally used.

If CREAD is set, the receiver shall be enabled; otherwise, no characters shall be received.

If PARENB is set, parity generation and detection shall be enabled and a parity bit is added to each byte. If parity is enabled, PARODD shall specify odd parity if set; otherwise, even parity shall be used.

If HUPCL is set, the modem control lines for the port shall be lowered when the last process with the port open closes the port or the process terminates. The modem connection shall be broken.

If CLOCAL is set, a connection shall not depend on the state of the modem status lines. If CLOCAL is clear, the modem status lines shall be monitored.

Under normal circumstances, a call to the open() function shall wait for the modem connection to complete. However, if the O_NONBLOCK flag is set (see open()) or if CLOCAL has been set, the open() function shall return immediately without waiting for the connection.

If the object for which the control modes are set is not an asynchronous serial connection, some of the modes may be ignored; for example, if an attempt is made to set the baud rate on a network connection to a terminal on another host, the baud rate need not be set on the connection between that terminal and the machine to which it is directly connected.

The initial hardware control value after open() is implementation-defined.

### 11.2.5 Local Modes

The c_lflag field of the argument structure is used to control various functions. It is composed of the bitwise-inclusive OR of the masks shown, which shall be bitwise-distinct. The mask name symbols in this table are defined in `<termios.h>`; not all values specified are required to be supported by the underlying hardware:

<table>
<thead>
<tr>
<th>Mask Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ECHO</td>
<td>Enable echo.</td>
</tr>
<tr>
<td>ECHOE</td>
<td>Echo ERASE as an error correcting backspace.</td>
</tr>
<tr>
<td>ECHOK</td>
<td>Echo KILL.</td>
</tr>
<tr>
<td>ECHONL</td>
<td>Echo &lt;newline&gt;.</td>
</tr>
<tr>
<td>ICANON</td>
<td>Canonical input (erase and kill processing).</td>
</tr>
<tr>
<td>IEXTEN</td>
<td>Enable extended (implementation-defined) functions.</td>
</tr>
<tr>
<td>ISIG</td>
<td>Enable signals.</td>
</tr>
<tr>
<td>NOFLSH</td>
<td>Disable flush after interrupt, quit, or suspend.</td>
</tr>
<tr>
<td>TOSTOP</td>
<td>Send SIGTTOU for background output.</td>
</tr>
</tbody>
</table>

If ECHO is set, input characters shall be echoed back to the terminal. If ECHO is clear, input characters shall not be echoed.

If ECHOE and ICANON are set, the ERASE character shall cause the terminal to erase, if possible, the last character in the current line from the display. If there is no character to erase, an implementation may echo an indication that this was the case, or do nothing.

If ECHOK and ICANON are set, the KILL character shall either cause the terminal to erase the line from the display or shall echo the newline character after the KILL character.
If ECHONL and ICANON are set, the newline character shall be echoed even if ECHO is not set.

If ICANON is set, canonical processing shall be enabled. This enables the erase and kill edit functions, and the assembly of input characters into lines delimited by NL, EOF, and EOL, as described in Section 11.1.6 (on page 189).

If ICANON is not set, read requests shall be satisfied directly from the input queue. A read shall not be satisfied until at least MIN bytes have been received or the timeout value TIME expired between bytes. The time value represents tenths of a second. See Section 11.1.7 (on page 190) for more details.

If IEXTEN is set, implementation-defined functions shall be recognized from the input data. It is implementation-defined how IEXTEN being set interacts with ICANON, ISIG, IXON, or IXOFF.

If IEXTEN is not set, implementation-defined functions shall not be recognized and the corresponding input characters are processed as described for ICANON, ISIG, IXON, and IXOFF.

If ISIG is set, each input character shall be checked against the special control characters INTR, QUIT, and SUSP. If an input character matches one of these control characters, the function associated with that character shall be performed. If ISIG is not set, no checking shall be done. Thus these special input functions are possible only if ISIG is set.

If NOFLSH is set, the normal flush of the input and output queues associated with the INTR, QUIT, and SUSP characters shall not be done.

If TOSTOP is set, the signal SIGTTOU shall be sent to the process group of a process that tries to write to its controlling terminal if it is not in the foreground process group for that terminal. This signal, by default, stops the members of the process group. Otherwise, the output generated by that process shall be output to the current output stream. Processes that are blocking or ignoring SIGTTOU signals are excepted and allowed to produce output, and the SIGTTOU signal shall not be sent.

The initial local control value after open() is implementation-defined.

11.2.6 Special Control Characters

The special control character values shall be defined by the array c_cc. The subscript name and description for each element in both canonical and non-canonical modes are as follows:
### Subscript Usage

<table>
<thead>
<tr>
<th>Canonical Mode</th>
<th>Non-Canonical Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VEOF</td>
<td></td>
<td>EOF character</td>
</tr>
<tr>
<td>VEOL</td>
<td></td>
<td>EOL character</td>
</tr>
<tr>
<td>VERASE</td>
<td></td>
<td>ERASE character</td>
</tr>
<tr>
<td>VINTR</td>
<td>VINTR</td>
<td>INTR character</td>
</tr>
<tr>
<td>VKILL</td>
<td>VMIN</td>
<td>KILL character</td>
</tr>
<tr>
<td>VQUIT</td>
<td>VQUIT</td>
<td>MIN value</td>
</tr>
<tr>
<td>VSUSP</td>
<td>VSUSP</td>
<td>SUSP character</td>
</tr>
<tr>
<td>VTIME</td>
<td>VTIME</td>
<td>TIME value</td>
</tr>
<tr>
<td>VSTART</td>
<td>VSTART</td>
<td>START character</td>
</tr>
<tr>
<td>VSTOP</td>
<td>VSTOP</td>
<td>STOP character</td>
</tr>
</tbody>
</table>

The subscript values are unique, except that the VMIN and VTIME subscripts may have the same values as the VEOF and VEOL subscripts, respectively.

Implementations that do not support changing the START and STOP characters may ignore the character values in the `c_cc` array indexed by the VSTART and VSTOP subscripts when `tcsetattr()` is called, but shall return the value in use when `tcgetattr()` is called.

The initial values of all control characters are implementation-defined.

If the value of one of the changeable special control characters (see Section 11.1.9 (on page 191)) is `_POSIX_VDISABLE`, that function shall be disabled; that is, no input data is recognized as the disabled special character. If ICANON is not set, the value of `_POSIX_VDISABLE` has no special meaning for the VMIN and VTIME entries of the `c_cc` array.
12.1 Utility Argument Syntax

This section describes the argument syntax of the standard utilities and introduces terminology used throughout IEEE Std 1003.1-2001 for describing the arguments processed by the utilities. Within IEEE Std 1003.1-2001, a special notation is used for describing the syntax of a utility’s arguments. Unless otherwise noted, all utility descriptions use this notation, which is illustrated by this example (see the Shell and Utilities volume of IEEE Std 1003.1-2001, Section 2.9.1, Simple Commands):

```plaintext
utility_name[-a][-b][-c option_argument]
[-d][e][-f option_argument][operand...]
```

The notation used for the SYNOPSIS sections imposes requirements on the implementors of the standard utilities and provides a simple reference for the application developer or system user.

1. The utility in the example is named `utility_name`. It is followed by options, option-arguments, and operands. The arguments that consist of hyphens and single letters or digits, such as `a`, are known as “options” (or, historically, “flags”). Certain options are followed by an “option-argument”, as shown with `[-c option_argument]`. The arguments following the last options and option-arguments are named “operands”.

2. Option-arguments are sometimes shown separated from their options by spaces, sometimes directly adjacent. This reflects the situation that in some cases an option-argument is included within the same argument string as the option; in most cases it is the next argument. The Utility Syntax Guidelines in Section 12.2 (on page 203) require that the option be a separate argument from its option-argument, but there are some exceptions in IEEE Std 1003.1-2001 to ensure continued operation of historical applications:

   a. If the SYNOPSIS of a standard utility shows a space between an option and option-argument (as with `[-c option_argument]` in the example), a conforming application shall use separate arguments for that option and its option-argument.

   b. If a space is not shown (as with `[-f option_argument]` in the example), a conforming application shall place an option and its option-argument directly adjacent in the same argument string, without intervening spaces.

   c. Notwithstanding the preceding requirements on conforming applications, a conforming implementation shall permit an application to specify options and option-arguments as a single argument or as separate arguments whether or not a space is shown on the synopsis line, except in those cases (marked with the XSI portability warning) where an option-argument is optional and no separation can be used.

   d. A standard utility may also be implemented to operate correctly when the required separation into multiple arguments is violated by a non-conforming application.

3. Options are usually listed in alphabetical order unless this would make the utility description more confusing. There are no implied relationships between the options based upon the order in which they appear, unless otherwise stated in the OPTIONS section, or unless the exception in Guideline 11 of Section 12.2 (on page 203) applies. If an option that
does not have option-arguments is repeated, the results are undefined, unless otherwise stated.

4. Frequently, names of parameters that require substitution by actual values are shown with embedded underscores. Alternatively, parameters are shown as follows:

   `<parameter name>`

   The angle brackets are used for the symbolic grouping of a phrase representing a single parameter and conforming applications shall not include them in data submitted to the utility.

5. When a utility has only a few permissible options, they are sometimes shown individually, as in the example. Utilities with many flags generally show all of the individual flags (that do not take option-arguments) grouped, as in:

   `utility_name [−abcDxyz] [−p arg] [operand]`

   Utilities with very complex arguments may be shown as follows:

   `utility_name [options] [operands]`

6. Unless otherwise specified, whenever an operand or option-argument is, or contains, a numeric value:

   • The number is interpreted as a decimal integer.

   • Numerals in the range 0 to 2 147 483 647 are syntactically recognized as numeric values.

   • When the utility description states that it accepts negative numbers as operands or option-arguments, numerals in the range −2 147 483 647 to 2 147 483 647 are syntactically recognized as numeric values.

   • Ranges greater than those listed here are allowed.

   This does not mean that all numbers within the allowable range are necessarily semantically correct. A standard utility that accepts an option-argument or operand that is to be interpreted as a number, and for which a range of values smaller than that shown above is permitted by the IEEE Std 1003.1-2001, describes that smaller range along with the description of the option-argument or operand. If an error is generated, the utility’s diagnostic message shall indicate that the value is out of the supported range, not that it is syntactically incorrect.

7. Arguments or option-arguments enclosed in the ‘ [ ’ and ‘ ] ’ notation are optional and can be omitted. Conforming applications shall not include the ‘ [ ’ and ‘ ] ’ symbols in data submitted to the utility.

8. Arguments separated by the ‘ | ’ vertical bar notation are mutually-exclusive. Conforming applications shall not include the ‘ | ’ symbol in data submitted to the utility. Alternatively, mutually-exclusive options and operands may be listed with multiple synopsis lines. For example:

   `utility_name −d[−a] [−c option_argument] [operand...]`

   `utility_name [−a] [−b] [operand...]`

   When multiple synopsis lines are given for a utility, it is an indication that the utility has mutually-exclusive arguments. These mutually-exclusive arguments alter the functionality of the utility so that only certain other arguments are valid in combination with one of the mutually-exclusive arguments. Only one of the mutually-exclusive arguments is allowed for invocation of the utility. Unless otherwise stated in an accompanying OPTIONS section, the relationships between arguments depicted in the SYNOPSIS sections are
mandatory requirements placed on conforming applications. The use of conflicting
mutually-exclusive arguments produces undefined results, unless a utility description
specifies otherwise. When an option is shown without the ‘[‘ and ‘]’ brackets, it means
that option is required for that version of the SYNOPSIS. However, it is not required to be
the first argument, as shown in the example above, unless otherwise stated.

9. Ellipses (“...”) are used to denote that one or more occurrences of an option or operand
are allowed. When an option or an operand followed by ellipses is enclosed in brackets,
zero or more options or operands can be specified. The forms:

utility_name −f option_argument...[operand...]
utility_name −g option_argument...[operand...]

indicate that multiple occurrences of the option and its option-argument preceding the
ellipses are valid, with semantics as indicated in the OPTIONS section of the utility. (See
also Guideline 11 in Section 12.2.) In the first example, each option-argument requires a
preceding −f and at least one −f option_argument must be given.

10. When the synopsis line is too long to be printed on a single line in the Shell and Utilities
volume of IEEE Std 1003.1-2001, the indented lines following the initial line are
continuation lines. An actual use of the command would appear on a single logical line.

12.2 Utility Syntax Guidelines

The following guidelines are established for the naming of utilities and for the specification of
options, option-arguments, and operands. The getopt() function in the System Interfaces volume
of IEEE Std 1003.1-2001 assists utilities in handling options and operands that conform to these
guidelines.

Operands and option-arguments can contain characters not specified in the portable character
set.

The guidelines are intended to provide guidance to the authors of future utilities, such as those
written specific to a local system or that are components of a larger application. Some of the
standard utilities do not conform to all of these guidelines; in those cases, the OPTIONS sections
describe the deviations.

Guideline 1: Utility names should be between two and nine characters, inclusive.

Guideline 2: Utility names should include lowercase letters (the lower character
classification) and digits only from the portable character set.

Guideline 3: Each option name should be a single alphanumeric character (the alnum
classification) from the portable character set. The −W (capital-W) option shall be reserved for vendor options.

Guideline 4: Multi-digit options should not be allowed.

Guideline 5: All options should be preceded by the ‘−’ delimiter character.

Guideline 6: Options without option-arguments should be accepted when grouped behind
one ‘−’ delimiter.

Guideline 7: Each option and option-argument should be a separate argument, except as
noted in Section 12.1 (on page 201), item (2).

Guideline 8: Option-arguments should not be optional.
Guideline 8: When multiple option-arguments are specified to follow a single option, they should be presented as a single argument, using commas within that argument or <blank>s within that argument to separate them.

Guideline 9: All options should precede operands on the command line.

Guideline 10: The argument -- should be accepted as a delimiter indicating the end of options. Any following arguments should be treated as operands, even if they begin with the ‘−’ character. The -- argument should not be used as an option or as an operand.

Guideline 11: The order of different options relative to one another should not matter, unless the options are documented as mutually-exclusive and such an option is documented to override any incompatible options preceding it. If an option that has option-arguments is repeated, the option and option-argument combinations should be interpreted in the order specified on the command line.

Guideline 12: The order of operands may matter and position-related interpretations should be determined on a utility-specific basis.

Guideline 13: For utilities that use operands to represent files to be opened for either reading or writing, the ‘−’ operand should be used only to mean standard input (or standard output when it is clear from context that an output file is being specified).

The utilities in the Shell and Utilities volume of IEEE Std 1003.1-2001 that claim conformance to these guidelines shall conform completely to these guidelines as if these guidelines contained the term “shall” instead of “should”. On some implementations, the utilities accept usage in violation of these guidelines for backwards-compatibility as well as accepting the required form.

It is recommended that all future utilities and applications use these guidelines to enhance user portability. The fact that some historical utilities could not be changed (to avoid breaking existing applications) should not deter this future goal.
Chapter 13

Headers

This chapter describes the contents of headers.

Headers contain function prototypes, the definition of symbolic constants, common structures, preprocessor macros, and defined types. Each function in the System Interfaces volume of IEEE Std 1003.1-2001 specifies the headers that an application shall include in order to use that function. In most cases, only one header is required. These headers are present on an application development system; they need not be present on the target execution system.

13.1 Format of Entries

The entries in this chapter are based on a common format as follows. The only sections relating to conformance are the SYNOPSIS and DESCRIPTION.

NAME
This section gives the name or names of the entry and briefly states its purpose.

SYNOPSIS
This section summarizes the use of the entry being described.

DESCRIPTION
This section describes the functionality of the header.

APPLICATION USAGE
This section is informative.

This section gives warnings and advice to application writers about the entry. In the event of conflict between warnings and advice and a normative part of this volume of IEEE Std 1003.1-2001, the normative material is to be taken as correct.

RATIONALE
This section is informative.

This section contains historical information concerning the contents of this volume of IEEE Std 1003.1-2001 and why features were included or discarded by the standard developers.

FUTURE DIRECTIONS
This section is informative.

This section provides comments which should be used as a guide to current thinking; there is not necessarily a commitment to adopt these future directions.

SEE ALSO
This section is informative.

This section gives references to related information.

CHANGE HISTORY
This section is informative.

This section shows the derivation of the entry and any significant changes that have been made to it.
NAME  
aio.h — asynchronous input and output (REALTIME)

SYNOPSIS
AIO  
#include <aio.h>

DESCRIPTION  
The <aio.h> header shall define the aiocb structure which shall include at least the following members:

- int aio_fildes  File descriptor.
- off_t aio_offset  File offset.
- volatile void *aio_buf  Location of buffer.
- size_t aio_nbytes  Length of transfer.
- int aio_reqprio  Request priority offset.
- struct sigevent aio_sigevent  Signal number and value.
- int aio_lio_opcode  Operation to be performed.

This header shall also include the following constants:

- AIO_ALLDONE  A return value indicating that none of the requested operations could be canceled since they are already complete.
- AIO_CANCELED  A return value indicating that all requested operations have been canceled.
- AIO_NOTCANCELED  A return value indicating that some of the requested operations could not be canceled since they are in progress.
- LIO_NOP  A lio_listio() element operation option indicating that no transfer is requested.
- LIO_NOWAIT  A lio_listio() synchronization operation indicating that the calling thread is to continue execution while the lio_listio() operation is being performed, and no notification is given when the operation is complete.
- LIO_READ  A lio_listio() element operation option requesting a read.
- LIO_WAIT  A lio_listio() synchronization operation indicating that the calling thread is to suspend until the lio_listio() operation is complete.
- LIO_WRITE  A lio_listio() element operation option requesting a write.

The following shall be declared as functions and may also be defined as macros. Function prototypes shall be provided:

- int aio_cancel(int, struct aiocb *);
- int aio_error(const struct aiocb *);
- int aio_fsync(int, struct aiocb *);
- int aio_read(struct aiocb *);
- ssize_t aio_return(struct aiocb *);
- int aio_suspend(const struct aiocb *const[], int,  
  const struct timespec *);
- int aio_write(struct aiocb *);
- int lio_listio(int, struct aiocb *restrict const[restrict], int,  
  struct sigevent *restrict);
Inclusion of the `<aio.h>` header may make visible symbols defined in the headers `<fcntl.h>`, `<signal.h>`, `<sys/types.h>`, and `<time.h>`.

**APPLICATION USAGE**
None.

**RATIONALE**
None.

**FUTURE DIRECTIONS**
None.

**SEE ALSO**
`<fcntl.h>`, `<signal.h>`, `<sys/types.h>`, `<time.h>`, the System Interfaces volume of IEEE Std 1003.1-2001, `fsync()`, `lseek()`, `read()`, `write()`

**CHANGE HISTORY**
First released in Issue 5. Included for alignment with the POSIX Realtime Extension.

**Issue 6**
The `<aio.h>` header is marked as part of the Asynchronous Input and Output option.

The description of the constants is expanded.

The `restrict` keyword is added to the prototype for `lio_listio()`.
NAME
arpa/inet.h — definitions for internet operations

SYNOPSIS
#include <arpa/inet.h>

DESCRIPTION
The in_port_t and in_addr_t types shall be defined as described in <netinet/in.h>.
The in_addr structure shall be defined as described in <netinet/in.h>.
IPv6 The INET_ADDRSTRLEN and INET6_ADDRSTRLEN macros shall be defined as described in <netinet/in.h>.
The following shall either be declared as functions, defined as macros, or both. If functions are declared, function prototypes shall be provided.

uint32_t htonl(uint32_t);
uint16_t htons(uint16_t);
uint32_t ntohl(uint32_t);
uint16_t ntohs(uint16_t);
The uint32_t and uint16_t types shall be defined as described in <inttypes.h>.
The following shall be declared as functions and may also be defined as macros. Function prototypes shall be provided.
in_addr_t inet_addr(const char *);
char *inet_ntoa(struct in_addr);
const char *inet_ntop(int, const void *restrict, char *restrict,
socklen_t);
int inet_pton(int, const char *restrict, void *restrict);
Inclusion of the <arpa/inet.h> header may also make visible all symbols from <netinet/in.h> and <inttypes.h>.

APPLICATION USAGE
None.

RATIONALE
None.

FUTURE DIRECTIONS
None.

SEE ALSO
<netinet/in.h>, <inttypes.h>, the System Interfaces volume of IEEE Std 1003.1-2001, htonl(), inet_addr()

CHANGE HISTORY
First released in Issue 6. Derived from the XNS, Issue 5.2 specification.
The restrict keyword is added to the prototypes for inet_ntop() and inet_pton().
NAME
assert.h — verify program assertion

SYNOPSIS
#include <assert.h>

DESCRIPTION
The functionality described on this reference page is aligned with the ISO C standard. Any
conflict between the requirements described here and the ISO C standard is unintentional. This

The <assert.h> header shall define the assert() macro. It refers to the macro NDEBUG which is
not defined in the header. If NDEBUG is defined as a macro name before the inclusion of this
header, the assert() macro shall be defined simply as:

#define assert(ignore)((void) 0)

Otherwise, the macro behaves as described in assert().

The assert() macro shall be redefined according to the current state of NDEBUG each time
<assert.h> is included.

The assert() macro shall be implemented as a macro, not as a function. If the macro definition is
suppressed in order to access an actual function, the behavior is undefined.

APPLICATION USAGE
None.

RATIONALE
None.

FUTURE DIRECTIONS
None.

SEE ALSO
The System Interfaces volume of IEEE Std 1003.1-2001, assert()

CHANGE HISTORY
First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 6
The definition of the assert() macro is changed for alignment with the ISO/IEC 9899:1999
standard.
NAME
complex.h — complex arithmetic

SYNOPSIS
#include <complex.h>

DESCRIPTION
The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-2001 defers to the ISO C standard.

The <complex.h> header shall define the following macros:

complex Expands to _Complex.

_Complex_I Expands to a constant expression of type const float _Complex, with the value of the imaginary unit (that is, a number i such that i^2 = -1).

imaginary Expands to _Imaginary.

__Imaginary_I Expands to a constant expression of type const float _Imaginary, with the value of the imaginary unit.

I Expands to either _Imaginary_I or _Complex_I. If _Imaginary_I is not defined, I expands to _Complex_I.

The macros imaginary and __Imaginary_I shall be defined if and only if the implementation supports imaginary types.

An application may undefine and then, perhaps, redefine the complex, imaginary, and I macros.

The following shall be declared as functions and may also be defined as macros. Function prototypes shall be provided.

double cabs(double complex);
float cabsf(float complex);
long double cabsl(long double complex);
double complex cacos(double complex);
float complex cacosf(float complex);
double complex cacosh(double complex);
float complex cacoshf(float complex);
long double complex cacoshl(long double complex);
long double complex casin(double complex);
float complex casinf(float complex);
double complex casinh(double complex);
float complex casinhf(float complex);
long double complex casinhl(long double complex);
long double complex catan(double complex);
float complex catanf(float complex);
double complex catanh(double complex);
float complex catanhf(float complex);
long double complex catanhl(long double complex);
long double complex cacosl(long double complex);
long double complex carg(double complex);
float complex cargf(float complex);
long double complex cargl(long double complex);
double complex casinl(long double complex);
float complex casinfl(float complex);
long double complex casinhl(long double complex);
double complex catanl(long double complex);
### APPLICATION USAGE

Values are interpreted as radians, not degrees.

### RATIONALE

The choice of \( I \) instead of \( i \) for the imaginary unit concedes to the widespread use of the identifier \( i \) for other purposes. The application can use a different identifier, say \( j \), for the imaginary unit by following the inclusion of the `<complex.h>` header with:

```c
#undef I
#define j _Imaginary_I
```
An \textit{I} suffix to designate imaginary constants is not required, as multiplication by \textit{I} provides a sufficiently convenient and more generally useful notation for imaginary terms. The corresponding real type for the imaginary unit is \texttt{float}, so that use of \textit{I} for algorithmic or notational convenience will not result in widening types.

On systems with imaginary types, the application has the ability to control whether use of the macro \texttt{I} introduces an imaginary type, by explicitly defining \texttt{I} to be \_Imaginary\_I or \_Complex\_I. Disallowing imaginary types is useful for some applications intended to run on implementations without support for such types.

The macro \_Imaginary\_I provides a test for whether imaginary types are supported.

The \textit{cis}() function \((\cos(x) + \textit{I}\sin(x))\) was considered but rejected because its implementation is easy and straightforward, even though some implementations could compute sine and cosine more efficiently in tandem.

\textbf{FUTURE DIRECTIONS}

The following function names and the same names suffixed with \texttt{f} or \texttt{l} are reserved for future use, and may be added to the declarations in the \texttt{<complex.h>} header.

- \texttt{cerf()}
- \texttt{cexpm1()}
- \texttt{clog2()}
- \texttt{cerfc()}
- \texttt{clog10()}
- \texttt{cigamma()}
- \texttt{cexp2()}
- \texttt{clog1p()}
- \texttt{ctgamma()}

\textbf{SEE ALSO}

\textbf{CHANGE HISTORY}

NAME
cpio.h — cpio archive values

SYNOPSIS
_xsi
#include <cpio.h>

DESCRIPTION
Values needed by the c_mode field of the cpio archive format are described as follows:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Value (Octal)</th>
</tr>
</thead>
<tbody>
<tr>
<td>C_IRUSR</td>
<td>Read by owner.</td>
<td>0000400</td>
</tr>
<tr>
<td>C_IWUSR</td>
<td>Write by owner.</td>
<td>0000200</td>
</tr>
<tr>
<td>C_IXUSR</td>
<td>Execute by owner.</td>
<td>0000100</td>
</tr>
<tr>
<td>C_IRGRP</td>
<td>Read by group.</td>
<td>0000040</td>
</tr>
<tr>
<td>C_IWGRP</td>
<td>Write by group.</td>
<td>0000020</td>
</tr>
<tr>
<td>C_IXGRP</td>
<td>Execute by group.</td>
<td>0000010</td>
</tr>
<tr>
<td>C_IROTH</td>
<td>Read by others.</td>
<td>0000004</td>
</tr>
<tr>
<td>C_IWOTH</td>
<td>Write by others.</td>
<td>0000002</td>
</tr>
<tr>
<td>C_IXOTH</td>
<td>Execute by others.</td>
<td>0000001</td>
</tr>
<tr>
<td>C_ISUID</td>
<td>Set user ID.</td>
<td>0004000</td>
</tr>
<tr>
<td>C_ISGID</td>
<td>Set group ID.</td>
<td>0002000</td>
</tr>
<tr>
<td>C_ISVTX</td>
<td>On directories, restricted deletion flag.</td>
<td>0001000</td>
</tr>
<tr>
<td>C_ISDIR</td>
<td>Directory.</td>
<td>0040000</td>
</tr>
<tr>
<td>C_ISFIFO</td>
<td>FIFO.</td>
<td>0010000</td>
</tr>
<tr>
<td>C_ISREG</td>
<td>Regular file.</td>
<td>0100000</td>
</tr>
<tr>
<td>C_ISBLK</td>
<td>Block special.</td>
<td>0060000</td>
</tr>
<tr>
<td>C_ISCHR</td>
<td>Character special.</td>
<td>0020000</td>
</tr>
<tr>
<td>C_ISCTG</td>
<td>Reserved.</td>
<td>0110000</td>
</tr>
<tr>
<td>C_ISLNK</td>
<td>Symbolic link.</td>
<td>0120000</td>
</tr>
<tr>
<td>C_ISSOCK</td>
<td>Socket.</td>
<td>0140000</td>
</tr>
</tbody>
</table>

The header shall define the symbolic constant:

```
MAGIC  "070707"
```

APPLICATION USAGE
None.

RATIONALE
None.

FUTURE DIRECTIONS
None.

SEE ALSO
The Shell and Utilities volume of IEEE Std 1003.1-2001, pax

CHANGE HISTORY

Issue 6
The SEE ALSO is updated to refer to pax, since the cpio utility is not included in the Shell and Utilities volume of IEEE Std 1003.1-2001.
NAME
c-type.h — character types

SYNOPSIS
#include <ctype.h>

DESCRIPTION
Some of the functionality described on this reference page extends the ISO C standard. Applications shall define the appropriate feature test macro (see the System Interfaces volume of IEEE Std 1003.1-2001, Section 2.2, The Compilation Environment) to enable the visibility of these symbols in this header.

The following shall be declared as functions and may also be defined as macros. Function prototypes shall be provided.

```c
int isalnum(int);
int isalpha(int);
int isascii(int);
int isblank(int);
int iscntrl(int);
int isdigit(int);
int isgraph(int);
int islower(int);
int isprint(int);
int ispunct(int);
int isspace(int);
int isupper(int);
int isxdigit(int);
int toascii(int);
int tolower(int);
int toupper(int);
```

The following are defined as macros:

```c
int _toupper(int);
int _tolower(int);
```

CHANGE HISTORY
First released in Issue 1. Derived from Issue 1 of the SVID.
Extensions beyond the ISO C standard are marked.
NAME
    dirent.h — format of directory entries

SYNOPSIS
    #include <dirent.h>

DESCRIPTION
    The internal format of directories is unspecified.

    The <dirent.h> header shall define the following type:
    DIR        A type representing a directory stream.

    It shall also define the structure dirent which shall include the following members:

    xsi  ino_t d_ino   File serial number.
    char  d_name[]   Name of entry.

    xsi  The type ino_t shall be defined as described in <sys/types.h>.

    The character array d_name is of unspecified size, but the number of bytes preceding the
    terminating null byte shall not exceed [NAME_MAX].

    The following shall be declared as functions and may also be defined as macros. Function
    prototypes shall be provided.

    int         closedir(DIR *);
    DIR *       opendir(const char *);
    struct dirent * readdir(DIR *);
    int         readdir_r(DIR *restrict, struct dirent *restrict,
                           struct dirent **restrict);
    void        rewinddir(DIR *);
    xsi  void    seekdir(DIR *, long);
    long        telldir(DIR *);

APPLICATION USAGE
    None.

RATIONALE
    Information similar to that in the <dirent.h> header is contained in a file <sys/dir.h> in 4.2 BSD
    and 4.3 BSD. The equivalent in these implementations of struct dirent from this volume of
    IEEE Std 1003.1-2001 is struct direct. The filename was changed because the name <sys/dir.h>
    was also used in earlier implementations to refer to definitions related to the older access
    method; this produced name conflicts. The name of the structure was changed because this
    volume of IEEE Std 1003.1-2001 does not completely define what is in the structure, so it could
    be different on some implementations from struct direct.

    The name of an array of char of an unspecified size should not be used as an lvalue. Use of:
    size_of(d_name)

    is incorrect; use:
    strlen(d_name)

    instead.

    The array of char d_name is not a fixed size. Implementations may need to declare struct dirent
    with an array size for d_name of 1, but the actual number of characters provided matches (or
    only slightly exceeds) the length of the filename.
FUTURE DIRECTIONS
None.

SEE ALSO
<sys/types.h>, the System Interfaces volume of IEEE Std 1003.1-2001, closedir(), opendir(), readdir(), readdir_r(), rewinddir(), seekdir(), telldir()

CHANGE HISTORY
First released in Issue 2.

Issue 5
The DESCRIPTION is updated for alignment with the POSIX Threads Extension.

Issue 6
The Open Group Corrigendum U026/7 is applied, correcting the prototype for readdir_r().

The restrict keyword is added to the prototype for readdir_r().
NAME

dlfcn.h — dynamic linking

SYNOPSIS

```
xsi #include <dlfcn.h>
```

DESCRIPTION

The `<dlfcn.h>` header shall define at least the following macros for use in the construction of a `dlopen()` mode argument:

- `RTLD_LAZY` Relocations are performed at an implementation-defined time.
- `RTLD_NOW` Relocations are performed when the object is loaded.
- `RTLD_GLOBAL` All symbols are available for relocation processing of other modules.
- `RTLD_LOCAL` All symbols are not made available for relocation processing by other modules.

The following shall be declared as functions and may also be defined as macros. Function prototypes shall be provided.

```
int dlclose(void *);
char *dlerror(void);
void *dlopen(const char *, int);
void *dlsym(void *restrict, const char *restrict);
```

APPLICATION USAGE

None.

RATIONALE

None.

FUTURE DIRECTIONS

Issue 6

The `restrict` keyword is added to the prototype for `dlsym()`.
NAME
errno.h — system error numbers

SYNOPSIS
#include <errno.h>

DESCRIPTION
Some of the functionality described on this reference page extends the ISO C standard. Any
conflict between the requirements described here and the ISO C standard is unintentional. This

The ISO C standard only requires the symbols [EDOM], [EILSEQ], and [ERANGE] to be defined.
The <errno.h> header shall provide a declaration for errno and give positive values for the
following symbolic constants. Their values shall be unique except as noted below.

[E2BIG] Argument list too long.
[EACCES] Permission denied.
[EADDRINUSE] Address in use.
[EADDRNOTAVAIL] Address not available.
[EAFNOSUPPORT] Address family not supported.
[EAGAIN] Resource unavailable, try again (may be the same value as
[EWOULDBLOCK]).
[EALREADY] Connection already in progress.
[EBADF] Bad file descriptor.
[EBADMSG] Bad message.
[EBUSY] Device or resource busy.
[ECANCELED] Operation canceled.
[ECHILD] No child processes.
[CONNABORTED] Connection aborted.
[CONNREFUSED] Connection refused.
[CONNECTION_RESET] Connection reset.
[DEADLK] Resource deadlock would occur.
[DESTADDRREQ] Destination address required.
[EDQUOT] Reserved.
[EEXIST] File exists.
[EFAULT] Bad address.
[EBACK] File too large.
[EHOSTUNREACH] Host is unreachable.
[EIDRM] Identifier removed.
[EILSEQ] Illegal byte sequence.
7748 [EINTR] Interrupted function.
7749 [EINVAL] Invalid argument.
7750 [EIO] I/O error.
7751 [EISCONN] Socket is connected.
7752 [EISDIR] Is a directory.
7753 [ELOOP] Too many levels of symbolic links.
7754 [EMFILE] Too many open files.
7755 [EMFILE] Too many links.
7756 [EMSGSIZE] Message too large.
7757 [EMULTIHOP] Reserved.
7758 [ENAMEETOOLONG] Filename too long.
7759 [ENETDOWN] Network is down.
7760 [ENETRESET] Connection aborted by network.
7761 [ENETUNREACH] Network unreachable.
7762 [ENFILE] Too many files open in system.
7763 [ENOBUFS] No buffer space available.
7764 [ENODATA] No message is available on the STREAM head read queue.
7765 [ENODEV] No such device.
7766 [ENOENT] No such file or directory.
7767 [ENOEXEC] Executable file format error.
7768 [ENOLCK] No locks available.
7769 [ENOLINK] Reserved.
7770 [ENOMEM] Not enough space.
7771 [ENOMEM] No message of the desired type.
7772 [ENOPROTOOPT] Protocol not available.
7773 [ENOSPC] No space left on device.
7774 [ENOSR] No STREAM resources.
7775 [ENOSR] Not a STREAM.
7776 [ENOSYS] Function not supported.
7777 [ENOTCONN] The socket is not connected.
7778 [ENOTDIR] Not a directory.
7780 [ENOTSOCK] Not a socket.
7781  [ENOTSUP]  Not supported.
7782  [ENOTTY]  Inappropriate I/O control operation.
7783  [ENXIO]  No such device or address.
7784  [EOPNOTSUPP]  Operation not supported on socket.
7785  [EOVERFLOW]  Value too large to be stored in data type.
7786  [EPERM]  Operation not permitted.
7787  [EPIPE]  Broken pipe.
7788  [EPROTO]  Protocol error.
7789  [EPROTONOSUPPORT]  Protocol not supported.
7790  [EPROTOTYPE]  Protocol wrong type for socket.
7791  [ERANGE]  Result too large.
7792  [EROFS]  Read-only file system.
7793  [ESPIPE]  Invalid seek.
7794  [ESRCH]  No such process.
7795  [ESTALE]  Reserved.
7796  [ETIME]  Stream ioctl() timeout.
7797  [ETIMEDOUT]  Connection timed out.
7799  [EWOULDBLOCK]  Operation would block (may be the same value as [EAGAIN]).
7800  [EXDEV]  Cross-device link.

APPLICATION USAGE
Additional error numbers may be defined on conforming systems; see the System Interfaces volume of IEEE Std 1003.1-2001.

RATIONALE
None.

FUTURE DIRECTIONS
None.

SEE ALSO
The System Interfaces volume of IEEE Std 1003.1-2001, Section 2.3, Error Numbers

CHANGE HISTORY
First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 5
Updated for alignment with the POSIX Realtime Extension.

Issue 6
The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

• The majority of the error conditions previously marked as extensions are now mandatory, except for the STREAMS-related error conditions.
Values for *errno* are now required to be distinct positive values rather than non-zero values. This change is for alignment with the ISO/IEC 9899:1999 standard.
NAME
fcntl.h — file control options

SYNOPSIS
#include <fcntl.h>

DESCRIPTION
The <fcntl.h> header shall define the following requests and arguments for use by the functions
fcntl() and open().
Values for cmd used by fcntl() (the following values are unique) are as follows:
F_DUPFD  Duplicate file descriptor.
F_GETFD  Get file descriptor flags.
F_SETFD  Set file descriptor flags.
F_GETFL  Get file status flags and file access modes.
F_SETFL  Set file status flags.
F_GETLK  Get record locking information.
F_SETLK  Set record locking information.
F_SETLKW Set record locking information; wait if blocked.
F_GETOWN Get process or process group ID to receive SIGURG signals.
F_SETOWN Set process or process group ID to receive SIGURG signals.

File descriptor flags used for fcntl() are as follows:
FD_CLOEXEC Close the file descriptor upon execution of an exec family function.
Values for l_type used for record locking with fcntl() (the following values are unique) are as
follows:
F_RDLCK  Shared or read lock.
F_UNLCK  Unlock.
F_WRLCK  Exclusive or write lock.

XSI The values used for l_whence, SEEK_SET, SEEK_CUR, and SEEK_END shall be defined as
described in <unistd.h>.
The following values are file creation flags and are used in the oflag value to open(). They shall
be bitwise-distinct.
O_CREAT Create file if it does not exist.
O_EXCL  Exclusive use flag.
O_NOCTTY Do not assign controlling terminal.
O_TRUNC Truncate flag.
File status flags used for open() and fcntl() are as follows:
O_APPEND Set append mode.
O_DSYNC Write according to synchronized I/O data integrity completion.
O_NONBLOCK Non-blocking mode.
**O_RSYNC** Synchronized read I/O operations.

**O_SYNC** Write according to synchronized I/O file integrity completion.

Mask for use with file access modes is as follows:

**O_ACCMODE** Mask for file access modes.

File access modes used for `open()` and `fcntl()` are as follows:

**O_RDONLY** Open for reading only.

**O_RDWR** Open for reading and writing.

**O_WRONLY** Open for writing only.

The symbolic names for file modes for use as values of `mode_t` shall be defined as described in `<sys/stat.h>`.

Values for `advice` used by `posix_fadvise()` are as follows:

- **POSIX_FADV_NORMAL**
  The application has no advice to give on its behavior with respect to the specified data. It is the default characteristic if no advice is given for an open file.

- **POSIX_FADV_SEQUENTIAL**
  The application expects to access the specified data sequentially from lower offsets to higher offsets.

- **POSIX_FADV_RANDOM**
  The application expects to access the specified data in a random order.

- **POSIX_FADV_WILLNEED**
  The application expects to access the specified data in the near future.

- **POSIX_FADV_DONTNEED**
  The application expects that it will not access the specified data in the near future.

- **POSIX_FADV_NOREUSE**
  The application expects to access the specified data once and then not reuse it thereafter.

The structure `flock` describes a file lock. It shall include the following members:

- **short l_type** Type of lock; F_RDLCK, F_WRLCK, F_UNLCK.
- **short l_whence** Flag for starting offset.
- **off_t l_start** Relative offset in bytes.
- **off_t l_len** Size; if 0 then until EOF.
- **pid_t l_pid** Process ID of the process holding the lock; returned with F_GETLK.

The `mode_t`, `off_t`, and `pid_t` types shall be defined as described in `<sys/types.h>`.

The following shall be declared as functions and may also be defined as macros. Function prototypes shall be provided.

- **int creat(const char *, mode_t);**
- **int fcntl(int, int, ...);**
- **int open(const char *, int, ...);**
- **int POSIX_FADVISE(int, off_t, size_t, int);**
- **int POSIX_FALLOCATE(int, off_t, size_t);**
Inclusion of the `<fcntl.h>` header may also make visible all symbols from `<sys/stat.h>` and `<unistd.h>.

APPLICATION USAGE
None.

RATIONALE
None.

FUTURE DIRECTIONS
None.

CHANGE HISTORY
First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 5
The DESCRIPTION is updated for alignment with the POSIX Realtime Extension.

Issue 6
The following changes are made for alignment with the ISO POSIX-1:1996 standard:

- O_DSYNC and O_RSYNC are marked as part of the Synchronized Input and Output option.
- The following new requirements on POSIX implementations derive from alignment with the
  Single UNIX Specification:
    - The definition of the mode_t, off_t, and pid_t types is mandated.
- The F_GETOWN and F_SETOWN values are added for sockets.

The posix_fadvise(), posix_fallocate(), and posix_madvise() functions are added for alignment with

IEEE PASC Interpretation 1003.1 #102 is applied, moving the prototype for posix_madvise() to
<sys/mman.h>.
NAME
fenv.h — floating-point environment

SYNOPSIS
#include <fenv.h>

DESCRIPTION
CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-2001 defers to the ISO C standard.
The <fenv.h> header shall define the following data types through typedef:

fenv_t Represents the entire floating-point environment. The floating-point environment refers collectively to any floating-point status flags and control modes supported by the implementation.

fexcept_t Represents the floating-point status flags collectively, including any status the implementation associates with the flags. A floating-point status flag is a system variable whose value is set (but never cleared) when a floating-point exception is raised, which occurs as a side effect of exceptional floating-point arithmetic to provide auxiliary information. A floating-point control mode is a system variable whose value may be set by the user to affect the subsequent behavior of floating-point arithmetic.

The <fenv.h> header shall define the following constants if and only if the implementation supports the floating-point exception by means of the floating-point functions `feclearexcept()`, `fegetexceptflag()`, `feraiseexcept()`, `fesetexceptflag()`, and `fetestexcept()`. Each expands to an integer constant expression with values such that bitwise-inclusive ORs of all combinations of the constants result in distinct values.

FE_DIVBYZERO
FE_INEXACT
FE_INVALID
FE_OVERFLOW
FE_UNDERFLOW

The <fenv.h> header shall define the following constant, which is simply the bitwise-inclusive OR of all floating-point exception constants defined above:

FE_ALL_EXCEPT

The <fenv.h> header shall define the following constants if and only if the implementation supports getting and setting the represented rounding direction by means of the `fegetround()` and `fesetround()` functions. Each expands to an integer constant expression whose values are distinct non-negative values.

FE_DOWNWARD
FE_TONEAREST
FE_TOWARDZERO
FE_UPWARD

The <fenv.h> header shall define the following constant, which represents the default floating-point environment (that is, the one installed at program startup) and has type pointer to const-qualified fenv_t. It can be used as an argument to the functions within the <fenv.h> header that manage the floating-point environment.

FE_DFL_ENV
The following shall be declared as functions and may also be defined as macros. Function
prototypes shall be provided.

```c
int fecl except (int);
int fegetexceptflag(fexcept_t *, int);
int feraiseexcept(int);
int fe setexceptflag(const fexcept_t *, int);
int fetestexcept(int);
int fegetround(void);
int fesetround(int);
int feget env(fenv_t *);
int fe holdexcept(fenv_t *);
int fesetenv(const fenv_t *);
int feupdateenv(const fenv_t *);
```

The FENV_ACCESS pragma provides a means to inform the implementation when an
application might access the floating-point environment to test floating-point status flags or run
under non-default floating-point control modes. The pragma shall occur either outside external
declarations or preceding all explicit declarations and statements inside a compound statement.

When outside external declarations, the pragma takes effect from its occurrence until another
FENV_ACCESS pragma is encountered, or until the end of the translation unit. When inside a
compound statement, the pragma takes effect from its occurrence until another FENV_ACCESS
pragma is encountered (including within a nested compound statement), or until the end of the
compound statement; at the end of a compound statement the state for the pragma is restored to
its condition just before the compound statement. If this pragma is used in any other context, the
behavior is undefined. If part of an application tests floating-point status flags, sets floating-
point control modes, or runs under non-default mode settings, but was translated with the state
for the FENV_ACCESS pragma off, the behavior is undefined. The default state (on or off) for
the pragma is implementation-defined. (When execution passes from a part of the application
translated with FENV_ACCESS off to a part translated with FENV_ACCESS on, the state of the
floating-point status flags is unspecified and the floating-point control modes have their default
settings.)

**APPLICATION USAGE**

This header is designed to support the floating-point exception status flags and directed-
rounding control modes required by the IEC 60559:1989 standard, and other similar floating-
point state information. Also it is designed to facilitate code portability among all systems.

Certain application programming conventions support the intended model of use for the
floating-point environment:

- A function call does not alter its caller’s floating-point control modes, clear its caller’s
  floating-point status flags, nor depend on the state of its caller’s floating-point status flags
  unless the function is so documented.
- A function call is assumed to require default floating-point control modes, unless its
documentation promises otherwise.
- A function call is assumed to have the potential for raising floating-point exceptions, unless
  its documentation promises otherwise.

With these conventions, an application can safely assume default floating-point control modes
(or be unaware of them). The responsibilities associated with accessing the floating-point
environment fall on the application that does so explicitly.

Even though the rounding direction macros may expand to constants corresponding to the
values of FLT_ROUNDS, they are not required to do so.
For example:

```c
#include <fenv.h>
void f(double x)
{
    #pragma STDC FENV_ACCESS ON
    void g(double);
    void h(double);
    /* ... */
    g(x + 1);
    h(x + 1);
    /* ... */
}
```

If the function `g()` might depend on status flags set as a side effect of the first `x+1`, or if the second `x+1` might depend on control modes set as a side effect of the call to function `g()`, then the application shall contain an appropriately placed invocation as follows:

```c
#pragma STDC FENV_ACCESS ON
```

### Rationale

#### The `fexcept_t` Type

`fexcept_t` does not have to be an integer type. Its values must be obtained by a call to `fegetexceptflag()`, and cannot be created by logical operations from the exception macros. An implementation might simply implement `fexcept_t` as an `int` and use the representations reflected by the exception macros, but is not required to; other representations might contain extra information about the exceptions. `fexcept_t` might be a `struct` with a member for each exception (that might hold the address of the first or last floating-point instruction that caused that exception). The ISO/IEC 9899:1999 standard makes no claims about the internals of an `fexcept_t`, and so the user cannot inspect it.

#### Exception and Rounding Macros

Macros corresponding to unsupported modes and rounding directions are not defined by the implementation and must not be defined by the application. An application might use `#ifdef` to test for this.

### Future Directions

None.

### See Also

The System Interfaces volume of IEEE Std 1003.1-2001, `feclearexcept()`, `fegetenv()`, `fegetexceptflag()`, `fegetround()`, `feholdexcept()`, `fraiseexcept()`, `fesetenv()`, `fesetexceptflag()`, `fesetround()`, `fetestexcept()`, `feupdateenv()`.

### Change History

The return types for `feclearexcept()`, `fegetexceptflag()`, `fraiseexcept()`, `fesetexceptflag()`, `fegetenv()`, `fesetenv()`, and `feupdateenv()` are changed from `void` to `int` for alignment with the ISO/IEC 9899:1999 standard, Defect Report 202.
NAME
float.h — floating types

SYNOPSIS
#include <float.h>

DESCRIPTION

The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-2001 defers to the ISO C standard.

The characteristics of floating types are defined in terms of a model that describes a representation of floating-point numbers and values that provide information about an implementation's floating-point arithmetic.

The following parameters are used to define the model for each floating-point type:

s  Sign (±1).

b  Base or radix of exponent representation (an integer >1).

e  Exponent (an integer between a minimum $e_{\min}$ and a maximum $e_{\max}$).

p  Precision (the number of base–$b$ digits in the significand).

$\mathbf{f}_k$  Non-negative integers less than $b$ (the significand digits).

A floating-point number $x$ is defined by the following model:

$$x = sb^e \sum_{k=1}^{p} f_k b^{-k}, \quad e_{\min} \leq e \leq e_{\max}$$

In addition to normalized floating-point numbers ($f_1>0$ if $x\neq0$), floating types may be able to contain other kinds of floating-point numbers, such as subnormal floating-point numbers ($x\neq0$, $e = e_{\min}, f_1=0$) and unnormalized floating-point numbers ($x\neq0, e>e_{\min}, f_1=0$), and values that are not floating-point numbers, such as infinities and NaNs. A NaN is an encoding signifying Not-a-Number. A quiet NaN propagates through almost every arithmetic operation without raising a floating-point exception; a signaling NaN generally raises a floating-point exception when occurring as an arithmetic operand.

The accuracy of the floating-point operations (‘+’, ‘-’, ‘*’, ‘/’) and of the library functions in <math.h> and <complex.h> that return floating-point results is implementation-defined. The implementation may state that the accuracy is unknown.

All integer values in the <float.h> header, except FLT_ROUNDS, shall be constant expressions suitable for use in #if preprocessing directives; all floating values shall be constant expressions. All except DECIMAL_DIG, FLT_EVAL_METHOD, FLT_RADIX, and FLT_ROUNDS have separate names for all three floating-point types. The floating-point model representation is provided for all values except FLT_EVAL_METHOD and FLT_ROUNDS.

The rounding mode for floating-point addition is characterized by the implementation-defined value of FLT_ROUNDS:

-1  Indeterminable.

0  Toward zero.

1  To nearest.

2  Toward positive infinity.
3 Toward negative infinity.
All other values for FLT_ROUNDS characterize implementation-defined rounding behavior.

The values of operations with floating operands and values subject to the usual arithmetic
conversions and of floating constants are evaluated to a format whose range and precision may
be greater than required by the type. The use of evaluation formats is characterized by the
implementation-defined value of FLT_EVAL_METHOD:

−1 Indeterminable.
0 Evaluate all operations and constants just to the range and precision of the type.
1 Evaluate operations and constants of type float and double to the range and precision of the
double type; evaluate long double operations and constants to the range and precision of
the long double type.
2 Evaluate all operations and constants to the range and precision of the long double type.
All other negative values for FLT_EVAL_METHOD characterize implementation-defined
behavior.

The values given in the following list shall be defined as constant expressions with
implementation-defined values that are greater or equal in magnitude (absolute value) to those
shown, with the same sign.

- Radix of exponent representation, \( b \).

\[
\text{FLT_RADIX} = 2
\]

- Number of base-FLT_RADIX digits in the floating-point significand, \( p \).

\[
\text{FLT_MANT_DIG} \\
\text{DBL_MANT_DIG} \\
\text{LDBL_MANT_DIG}
\]

- Number of decimal digits, \( n \), such that any floating-point number in the widest supported
floating type with \( p_{\text{max}} \) radix \( b \) digits can be rounded to a floating-point number with \( n \)
decimal digits and back again without change to the value.

\[
\begin{cases} 
  p_{\text{max}} \log_{10} b & \text{if } b \text{ is a power of } 10 \\
  1 + p_{\text{max}} \log_{10} b & \text{otherwise}
\end{cases}
\]

\[
\text{DECIMAL_DIG} = 10
\]

- Number of decimal digits, \( q \), such that any floating-point number with \( q \) decimal digits can
be rounded into a floating-point number with \( p \) radix \( b \) digits and back again without change
to the \( q \) decimal digits.

\[
\begin{cases} 
  p \log_{10} b & \text{if } b \text{ is a power of } 10 \\
  (p - 1) \log_{10} b & \text{otherwise}
\end{cases}
\]

\[
\text{FLT_DIG} = 6 \\
\text{DBL_DIG} = 10
\]
- Minimum negative integer such that FLT_RADIX raised to that power minus 1 is a normalized floating-point number, $e_{\min}$.

- Minimum negative integer such that 10 raised to that power is in the range of normalized floating-point numbers.
  \[ \log_{10} b^{e_{\min} - 1} \]

- Maximum integer such that FLT_RADIX raised to that power minus 1 is a representable finite floating-point number, $e_{\max}$.

- Maximum integer such that 10 raised to that power is in the range of representable finite floating-point numbers.
  \[ \log_{10}(1 - b^{-p}) b^{e_{\max}} \]

The values given in the following list shall be defined as constant expressions with implementation-defined values that are greater than or equal to those shown:

- Maximum representable finite floating-point number.
  \[ (1 - b^{-p}) b^{e_{\max}} \]

The values given in the following list shall be defined as constant expressions with implementation-defined (positive) values that are less than or equal to those shown:

- The difference between 1 and the least value greater than 1 that is representable in the given floating-point type, $b^{1-p}$.

- The difference between 1 and the least value greater than 1 that is representable in the given floating-point type, $b^{1-p}$.
8170 LDBL_EPSILON 1E−9
8171 • Minimum normalized positive floating-point number, $b^{\text{min}}$.
8172 FLT_MIN 1E−37
8173 DBL_MIN 1E−37
8174 LDBL_MIN 1E−37

APPLICATION USAGE

First released in Issue 4. Derived from the ISO C standard.

Issue 6
The description of the operations with floating-point values is updated for alignment with the ISO/IEC 9899: 1999 standard.
NAME
fmtmsg.h — message display structures

SYNOPSIS

XSI
#include <fmtmsg.h>

DESCRIPTION
The <fmtmsg.h> header shall define the following macros, which expand to constant integer expressions:

- **MM_HARD**: Source of the condition is hardware.
- **MM_SOFT**: Source of the condition is software.
- **MM_FIRM**: Source of the condition is firmware.
- **MM_APPL**: Condition detected by application.
- **MM_UTIL**: Condition detected by utility.
- **MM_OPSYS**: Condition detected by operating system.
- **MM_RECOVER**: Recoverable error.
- **MM_NRECOV**: Non-recoverable error.
- **MM_HALT**: Error causing application to halt.
- **MM_ERROR**: Application has encountered a non-fatal fault.
- **MM_WARNING**: Application has detected unusual non-error condition.
- **MM_INFO**: Informative message.
- **MM_NOSEV**: No severity level provided for the message.
- **MM_PRINT**: Display message on standard error.
- **MM_CONSOLE**: Display message on system console.

The table below indicates the null values and identifiers for fmtmsg() arguments. The <fmtmsg.h> header shall define the macros in the **Identifier** column, which expand to constant expressions that expand to expressions of the type indicated in the **Type** column:

<table>
<thead>
<tr>
<th>Argument</th>
<th>Type</th>
<th>Null-Value</th>
<th>Identifier</th>
</tr>
</thead>
<tbody>
<tr>
<td>label</td>
<td>char*</td>
<td>(char*)0</td>
<td>MM_NULLLBL</td>
</tr>
<tr>
<td>severity</td>
<td>int</td>
<td>0</td>
<td>MM_NULLSEV</td>
</tr>
<tr>
<td>class</td>
<td>long</td>
<td>0L</td>
<td>MM_NULLMC</td>
</tr>
<tr>
<td>text</td>
<td>char*</td>
<td>(char*)0</td>
<td>MM_NULLTXT</td>
</tr>
<tr>
<td>action</td>
<td>char*</td>
<td>(char*)0</td>
<td>MM_NULLACT</td>
</tr>
<tr>
<td>tag</td>
<td>char*</td>
<td>(char*)0</td>
<td>MM_NULLTAG</td>
</tr>
</tbody>
</table>

The <fmtmsg.h> header shall also define the following macros for use as return values for fmtmsg():

- **MM_OK**: The function succeeded.
- **MM_NOTOK**: The function failed completely.
- **MM_NOMSG**: The function was unable to generate a message on standard error, but otherwise succeeded.
MM_NOCON  The function was unable to generate a console message, but otherwise
succeeded.

The following shall be declared as a function and may also be defined as a macro. A function
prototype shall be provided.

int fmtmsg(long, const char *, int,
const char *, const char *, const char *);

APPLICATION USAGE
None.

RATIONALE
None.

FUTURE DIRECTIONS
None.

CHANGE HISTORY
First released in Issue 4, Version 2.
NAME
fnmatch.h — filename-matching types

SYNOPSIS
#include <fnmatch.h>

DESCRIPTION
The <fnmatch.h> header shall define the following constants:

- FNM_NOMATCH: The string does not match the specified pattern.
- FNM_PATHNAME: Slash in string only matches slash in pattern.
- FNM_PERIOD: Leading period in string must be exactly matched by period in pattern.
- FNM_NOESCAPE: Disable backslash escaping.

The following shall be declared as a function and may also be defined as a macro. A function prototype shall be provided.

```c
int fnmatch(const char *, const char *, int);
```

APPLICATION USAGE
None.

RATIONALE
None.

FUTURE DIRECTIONS
None.

SEE ALSO

CHANGE HISTORY

Issue 6
The constant FNM_NOSYS is marked obsolescent.
NAME
ftw.h — file tree traversal

SYNOPSIS
#include <ftw.h>

DESCRIPTION
The `<ftw.h>` header shall define the `FTW` structure that includes at least the following members:

- `int base`
- `int level`

The `<ftw.h>` header shall define macros for use as values of the third argument to the application-supplied function that is passed as the second argument to `ftw()` and `nftw()`:

- `FTW_F` File
- `FTW_D` Directory
- `FTW_DNR` Directory without read permission
- `FTW_DP` Directory with subdirectories visited
- `FTW_NS` Unknown type; `stat()` failed
- `FTW_SL` Symbolic link
- `FTW_SLN` Symbolic link that names a nonexistent file

The `<ftw.h>` header shall define macros for use as values of the fourth argument to `nftw()`:

- `FTW_PHYS` Physical walk, does not follow symbolic links. Otherwise, `nftw()` follows links but does not walk down any path that crosses itself.
- `FTW_MOUNT` The walk does not cross a mount point.
- `FTW_DEPTH` All subdirectories are visited before the directory itself.
- `FTW_CHDIR` The walk changes to each directory before reading it.

The following shall be declared as functions and may also be defined as macros. Function prototypes shall be provided.

- `int ftw(const char *, int (*)(const char *, const struct stat *, int), int);`
- `int nftw(const char *, int (*)(const char *, const struct stat *, int, struct FTW*), int, int);`

The `<ftw.h>` header shall define the `stat` structure and the symbolic names for `st_mode` and the file type test macros as described in `<sys/stat.h>`.

Inclusion of the `<ftw.h>` header may also make visible all symbols from `<sys/stat.h>`. 
APPLICATION USAGE
None.

RATIONALE
None.

FUTURE DIRECTIONS
None.

SEE ALSO
<sys/stat.h>, the System Interfaces volume of IEEE Std 1003.1-2001, ftw(), nftw()

CHANGE HISTORY
First released in Issue 1. Derived from Issue 1 of the SVID.
Issue 5
A description of FTW_DP is added.
NAME
glob.h — pathname pattern-matching types

SYNOPSIS
#include <glob.h>

DESCRIPTION
The <glob.h> header shall define the structures and symbolic constants used by the glob() function.

The structure type glob_t shall contain at least the following members:
size_t gl_pathc Count of paths matched by pattern.
char **gl_pathv Pointer to a list of matched pathnames.
size_t gl_offs Slots to reserve at the beginning of gl_pathv.

The following constants shall be provided as values for the flags argument:
GLOB_APPEND Append generated pathnames to those previously obtained.
GLOB_DOOFFS Specify how many null pointers to add to the beginning of gl_pathv.
GLOB_ERR Cause glob() to return on error.
GLOB_MARK Each pathname that is a directory that matches pattern has a slash appended.
GLOB_NOCHECK If pattern does not match any pathname, then return a list consisting of only pattern.
GLOB_NOESCAPE Disable backslash escaping.
GLOB_NOSORT Do not sort the pathnames returned.

The following constants shall be defined as error return values:
GLOB_ABORTED The scan was stopped because GLOB_ERR was set or (*errfunc()) returned non-zero.
GLOB_NOMATCH The pattern does not match any existing pathname, and GLOB_NOCHECK was not set in flags.
GLOB_NOSPACE An attempt to allocate memory failed.

The following shall be declared as functions and may also be defined as macros. Function prototypes shall be provided.

int glob(const char *restrict, int, int (*)(const char *, int),
         glob_t *restrict);
void globfree (glob_t *);

The implementation may define additional macros or constants using names beginning with GLOB_.

CHANGE HISTORY

Issue 6
The restrict keyword is added to the prototype for glob().

The constant GLOB_NOSYS is marked obsolescent.

IEEE Std 1003.1-2001/Cor 1-2002, item XBD/TC1/D6/8 is applied, correcting the glob() prototype definition by removing the restrict qualifier from the function pointer argument.
NAME

grp.h — group structure

SYNOPSIS

#include <grp.h>

DESCRIPTION

The <grp.h> header shall declare the structure group which shall include the following members:

- char *gr_name The name of the group.
- gid_t gr_gid Numerical group ID.
- char **gr_mem Pointer to a null-terminated array of character pointers to member names.

The gid_t type shall be defined as described in <sys/types.h>.

The following shall be declared as functions and may also be defined as macros. Function prototypes shall be provided.

- struct group *getgrgid(gid_t);
- struct group *getgrnam(const char *);
- int getgrgid_r(gid_t, struct group *, char *, size_t, struct group **);
- int getgrnam_r(const char *, struct group *, char *, size_t, struct group **);
- struct group *getgrent(void);
- void endgrent(void);
- void setgrent(void);

APPLICATION USAGE

None.

RATIONALE

None.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 1.

Issue 5

The DESCRIPTION is updated for alignment with the POSIX Threads Extension.

Issue 6

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The definition of gid_t is mandated.
- The getgrgid_r() and getgrnam_r() functions are marked as part of the Thread-Safe Functions option.
NAME
iconv.h — codeset conversion facility

SYNOPSIS
#include <iconv.h>

DESCRIPTION
The <iconv.h> header shall define the following type:

iconv_t
Identifies the conversion from one codeset to another.

The following shall be declared as functions and may also be defined as macros. Function prototypes shall be provided.

iconv_t iconv_open(const char *, const char *);
size_t iconv(iconv_t, char **restrict, size_t *restrict,
char **restrict, size_t *restrict);
int iconv_close(iconv_t);

APPLICATION USAGE
None.

Issue 6
The restrict keyword is added to the prototype for iconv().
NAME
inttypes.h — fixed size integer types

SYNOPSIS
#include <inttypes.h>

DESCRIPTION
Some of the functionality described on this reference page extends the ISO C standard. Applications shall define the appropriate feature test macro (see the System Interfaces volume of IEEE Std 1003.1-2001, Section 2.2, The Compilation Environment) to enable the visibility of these symbols in this header.

The <inttypes.h> header shall include the <stdint.h> header.

The <inttypes.h> header shall include a definition of at least the following type:

imaxdiv_t Structure type that is the type of the value returned by the imaxdiv() function.

The following macros shall be defined. Each expands to a character string literal containing a conversion specifier, possibly modified by a length modifier, suitable for use within the format argument of a formatted input/output function when converting the corresponding integer type. These macros have the general form of PRI (character string literals for the fprintf() and fwprintf() family of functions) or SCN (character string literals for the fscanf() and fwsnprintf() family of functions), followed by the conversion specifier, followed by a name corresponding to a similar type name in <stdint.h>. In these names, N represents the width of the type as described in <stdint.h>. For example, PRIdFAST32 can be used in a format string to print the value of an integer of type int_fast32_t.

The fprintf() macros for signed integers are:

PRIdN PRIdLEASTN PRIdFASTN PRIdMAX PRIdPTR
PRIiN PRIiLEASTN PRIiFASTN PRIiMAX PRIiPTR

The fprintf() macros for unsigned integers are:

PRIoN PRIoLEASTN PRIoFASTN PRIoMAX PRIoPTR
PRIuN PRIuLEASTN PRIuFASTN PRIuMAX PRIuPTR
PRIxN PRIxLEASTN PRIxFASTN PRIxMAX PRIxPTR
PRIxN PRIxLEASTN PRIxFASTN PRIxMAX PRIxPTR

The fscanf() macros for signed integers are:

SCNdN SCNdLEASTN SCNdFASTN SCNdMAX SCNdPTR
SCNiN SCNiLEASTN SCNiFASTN SCNiMAX SCNiPTR

The fscanf() macros for unsigned integers are:

SCNoN SCNoLEASTN SCNoFASTN SCNoMAX SCNoPTR
SCNuN SCNuLEASTN SCNuFASTN SCNuMAX SCNuPTR
SCNxN SCNzLEASTN SCNzFASTN SCNzMAX SCNzPTR

For each type that the implementation provides in <stdint.h>, the corresponding fprintf() and fwprintf() macros shall be defined and the corresponding fscanf() and fwsnprintf() macros shall be defined unless the implementation does not have a suitable modifier for the type.

The following shall be declared as functions and may also be defined as macros. Function prototypes shall be provided.

intmax_t imaxabs(intmax_t);
imaxdiv_t imaxdiv(intmax_t, intmax_t);
intmax_t strtoimax(const char *restrict, char **restrict, int);
uintmax_t strtoumax(const char *restrict, char **restrict, int);
intmax_t wcstolmax(const wchar_t *restrict, wchar_t **restrict, int);
uintmax_t wcstoumax(const wchar_t *restrict, wchar_t **restrict, int);

EXAMPLES
#include <inttypes.h>
#include <wchar.h>
int main(void)
{
    uintmax_t i = UINTMAX_MAX; // This type always exists.
    wprintf(L"The largest integer value is %020" PRIxMAX "\n", i);
    return 0;
}

APPLICATION USAGE
The purpose of <inttypes.h> is to provide a set of integer types whose definitions are consistent across machines and independent of operating systems and other implementation idiosyncrasies. It defines, via typedef, integer types of various sizes. Implementations are free to typedef them as ISO C standard integer types or extensions that they support. Consistent use of this header will greatly increase the portability of applications across platforms.

RATIONALE
The ISO/IEC 9899:1990 standard specified that the language should support four signed and unsigned integer data types—char, short, int, and long—but placed very little requirement on their size other than that int and short be at least 16 bits and long be at least as long as int and not smaller than 32 bits. For 16-bit systems, most implementations assigned 8, 16, 16, and 32 bits to char, short, int, and long, respectively. For 32-bit systems, the common practice has been to assign 8, 16, 32, and 32 bits to these types. This difference in int size can create some problems for users who migrate from one system to another which assigns different sizes to integer types, because the ISO C standard integer promotion rule can produce silent changes unexpectedly. The need for defining an extended integer type increased with the introduction of 64-bit systems.

FUTURE DIRECTIONS
Macro names beginning with PRI or SCN followed by any lowercase letter or ‘X’ may be added to the macros defined in the <inttypes.h> header.

CHANGE HISTORY
First released in Issue 5.

Issue 6
The Open Group Base Resolution bwg97-006 is applied.
This reference page is updated to align with the ISO/IEC 9899:1999 standard.
NAME
iso646.h — alternative spellings

SYNOPSIS
#include <iso646.h>

DESCRIPTION
The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-2001 defers to the ISO C standard.

The `<iso646.h>` header shall define the following eleven macros (on the left) that expand to the corresponding tokens (on the right):

```
and         &&
and_eq      &=
bitand      &
bitor       |
compl       ~
not         !
not_eq      !=
or          ||
or_eq       |=
xor         ^
xor_eq      ^=
```

<td>Negative response expression.</td>
</tr>
<tr>
<td>CRNCYSTR</td>
<td>LC_MONETARY</td>
<td>Local currency symbol, preceded by ‘-‘ if the symbol should appear before the value, ‘+‘ if the symbol should appear after the value, or ‘.‘ if the symbol should replace the radix character. If the local currency symbol is the empty string, implementations may return the empty string (&quot;&quot;).</td>
</tr>
</tbody>
</table>

If the locale’s values for p_cs_precedes and n_cs_precedes do not match, the value of nl_langinfo(CRNCYSTR) is unspecified.

The following shall be declared as a function and may also be defined as a macro. A function prototype shall be provided.

```c
char *nl_langinfo(nl_item);
```

Inclusion of the `<langinfo.h>` header may also make visible all symbols from `<nl_types.h>`.

**APPLICATION USAGE**

Wherever possible, users are advised to use functions compatible with those in the ISO C standard to access items of langinfo data. In particular, the strftime() function should be used to access date and time information defined in category LC_TIME. The localeconv() function should be used to access information corresponding to RADIXCHAR, THOUSSEP, and CRNCYSTR.

**RATIONALE**

None.

**FUTURE DIRECTIONS**

None.

CHANGE HISTORY

First released in Issue 2.

Issue 5

The constants YESSTR and NOSTR are marked LEGACY.

Issue 6

The constants YESSTR and NOSTR are removed.

IEEE Std 1003.1-2001/Cor 1-2002, item XBD/TC1/D6/9 is applied, adding a sentence to the "Meaning" column entry for the CRNCYSTR constant. This change is to accommodate historic practice.
NAME
libgen.h — definitions for pattern matching functions

SYNOPSIS
XSI
#include <libgen.h>

DESCRIPTION
The following shall be declared as functions and may also be defined as macros. Function
types shall be provided.

char *basename(char *);
char *dirname(char *);

APPLICATION USAGE
None.

RATIONALE
None.

FUTURE DIRECTIONS
None.

SEE ALSO
The System Interfaces volume of IEEE Std 1003.1-2001, basename(), dirname()

CHANGE HISTORY
First released in Issue 4, Version 2.
Issue 5
The function prototypes for basename() and dirname() are changed to indicate that the first
argument is of type char * rather than const char *.

Issue 6
The __loc1 symbol and the regcmp() and regex() functions are removed.
NAME
limits.h — implementation-defined constants

SYNOPSIS
#include <limits.h>

DESCRIPTION

Some of the functionality described on this reference page extends the ISO C standard. Applications shall define the appropriate feature test macro (see the System Interfaces volume of IEEE Std 1003.1-2001, Section 2.2, The Compilation Environment) to enable the visibility of these symbols in this header.

Many of the symbols listed here are not defined by the ISO/IEC 9899: 1999 standard. Such symbols are not shown as CX shaded.

The <limits.h> header shall define various symbolic names. Different categories of names are described below.

The names represent various limits on resources that the implementation imposes on applications.

Implementations may choose any appropriate value for each limit, provided it is not more restrictive than the Minimum Acceptable Values listed below. Symbolic constant names beginning with _POSIX may be found in <unistd.h>.

Applications should not assume any particular value for a limit. To achieve maximum portability, an application should not require more resource than the Minimum Acceptable Value quantity. However, an application wishing to avail itself of the full amount of a resource available on an implementation may make use of the value given in <limits.h> on that particular implementation, by using the symbolic names listed below. It should be noted, however, that many of the listed limits are not invariant, and at runtime, the value of the limit may differ from those given in this header, for the following reasons:

- The limit is pathname-dependent.
- The limit differs between the compile and runtime machines.

For these reasons, an application may use the fpathconf(), pathconf(), and sysconf() functions to determine the actual value of a limit at runtime.

The items in the list ending in _MIN give the most negative values that the mathematical types are guaranteed to be capable of representing. Numbers of a more negative value may be supported on some implementations, as indicated by the <limits.h> header on the implementation, but applications requiring such numbers are not guaranteed to be portable to all implementations. For positive constants ending in _MIN, this indicates the minimum acceptable value.

Runtime Invariant Values (Possibly Indeterminate)

A definition of one of the symbolic names in the following list shall be omitted from <limits.h> on specific implementations where the corresponding value is equal to or greater than the stated minimum, but is unspecified.

This indetermination might depend on the amount of available memory space on a specific instance of a specific implementation. The actual value supported by a specific instance shall be provided by the sysconf() function.

<table>
<thead>
<tr>
<th>AIO</th>
<th>(AIO_LISTIO_MAX)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maximum number of I/O operations in a single list I/O call supported by the</td>
<td></td>
</tr>
</tbody>
</table>
AIO_MAX
Minimum Acceptable Value: \{_POSIX_AIO_MAX\}

AIO_PRIO_DELTA_MAX
The maximum amount by which a process can decrease its asynchronous I/O priority level from its own scheduling priority.
Minimum Acceptable Value: 0

ARG_MAX
Maximum length of argument to the exec functions including environment data.
Minimum Acceptable Value: \{_POSIX_ARG_MAX\}

ATEXIT_MAX
Maximum number of functions that may be registered with atexit().
Minimum Acceptable Value: 32

CHILD_MAX
Maximum number of simultaneous processes per real user ID.
Minimum Acceptable Value: \{_POSIX_CHILD_MAX\}

DELAYTIMER_MAX
Maximum number of timer expiration overruns.
Minimum Acceptable Value: \{_POSIX_DELAYTIMER_MAX\}

HOST_NAME_MAX
Maximum length of a host name (not including the terminating null) as returned from the gethostname() function.
Minimum Acceptable Value: \{_POSIX_HOST_NAME_MAX\}

IOV_MAX
Maximum number of iovec structures that one process has available for use with readv() or writev().
Minimum Acceptable Value: \{_XOPEN_IOV_MAX\}

LOGIN_NAME_MAX
Maximum length of a login name.
Minimum Acceptable Value: \{_POSIX_LOGIN_NAME_MAX\}

MQ_OPEN_MAX
The maximum number of open message queue descriptors a process may hold.
Minimum Acceptable Value: \{_POSIX_MQ_OPEN_MAX\}

MQ_PRIO_MAX
The maximum number of message priorities supported by the implementation.
Minimum Acceptable Value: \{_POSIX_MQ_PRIO_MAX\}

OPEN_MAX
Maximum number of files that one process can have open at any one time.
Minimum Acceptable Value: \{_POSIX_OPEN_MAX\}

pagesize
Size in bytes of a page.
Minimum Acceptable Value: 1
[PAGE_SIZE]
Equivalent to {PAGESIZE}. If either {PAGESIZE} or {PAGE_SIZE} is defined, the other is defined with the same value.

[PTHREAD_DESTRUCTOR_ITERATIONS]
Maximum number of attempts made to destroy a thread's thread-specific data values on thread exit.
Minimum Acceptable Value: {_POSIX_THREAD_DESTRUCTOR_ITERATIONS}

[PTHREAD_KEYS_MAX]
Maximum number of data keys that can be created by a process.
Minimum Acceptable Value: {_POSIX_THREAD_KEYS_MAX}

[PTHREAD_STACK_MIN]
Minimum size in bytes of thread stack storage.
Minimum Acceptable Value: 0

[PTHREAD_THREADS_MAX]
Maximum number of threads that can be created per process.
Minimum Acceptable Value: {_POSIX_THREAD_THREADS_MAX}

[RE_DUP_MAX]
The number of repeated occurrences of a BRE permitted by the regexec() and regcomp() functions when using the interval notation \( \{m,n\} \); see Section 9.3.6 (on page 174).
Minimum Acceptable Value: {_POSIX2_RE_DUP_MAX}

[RTSIG_MAX]
Maximum number of realtime signals reserved for application use in this implementation.
Minimum Acceptable Value: {_POSIX_RTSIG_MAX}

[SEM_NSEMS_MAX]
Maximum number of semaphores that a process may have.
Minimum Acceptable Value: {_POSIXSEM_NSEMS_MAX}

[SEM_VALUE_MAX]
The maximum value a semaphore may have.
Minimum Acceptable Value: {_POSIXSEM_VALUE_MAX}

[SIGQUEUE_MAX]
Maximum number of queued signals that a process may send and have pending at the receiver(s) at any time.
Minimum Acceptable Value: {_POSIX_SIGQUEUE_MAX}

[SS_REPL_MAX]
The maximum number of replenishment operations that may be simultaneously pending for a particular sporadic server scheduler.
Minimum Acceptable Value: {_POSIX_SS_REPL_MAX}

[STREAM_MAX]
The number of streams that one process can have open at one time. If defined, it has the same value as {FOPEN_MAX} (see <stdio.h>).
Minimum Acceptable Value: {_POSIX_STREAM_MAX}

[SYMLOOP_MAX]
Maximum number of symbolic links that can be reliably traversed in the resolution of a pathname in the absence of a loop.
Minimum Acceptable Value: {_POSIX_SYMLOOP_MAX}
<table>

<td>[_POSIX_TZNAME_MAX]</td>
</tr>
</tbody>
</table>

**Note:** The length given by [TZNAME_MAX] does not include the quoting characters mentioned in Section 8.3 (on page 165).

### Pathname Variable Values

The values in the following list may be constants within an implementation or may vary from one pathname to another. For example, file systems or directories may have different characteristics.

A definition of one of the values shall be omitted from the `<limits.h>` header on specific implementations where the corresponding value is equal to or greater than the stated minimum, but where the value can vary depending on the file to which it is applied. The actual value supported for a specific pathname shall be provided by the `pathconf()` function.

- **[FILESIZEBITS]**
  Minimum number of bits needed to represent, as a signed integer value, the maximum size of a regular file allowed in the specified directory.
  Minimum Acceptable Value: 32

- **[LINK_MAX]**
  Maximum number of links to a single file.
  Minimum Acceptable Value: [_POSIX_LINK_MAX]

- **[MAX_CANON]**
  Maximum number of bytes in a terminal canonical input line.
  Minimum Acceptable Value: [_POSIX_MAX_CANON]

- **[MAX_INPUT]**
  Minimum number of bytes for which space is available in a terminal input queue; therefore,
the maximum number of bytes a conforming application may require to be typed as input
before reading them.
Minimum Acceptable Value: \[\text{\_POSIX\_MAX\_INPUT}\]

\[\text{NAME\_MAX}\]
Maximum number of bytes in a filename (not including terminating null).
Minimum Acceptable Value: \[\text{\_POSIX\_NAME\_MAX}\]
XSI Minimum Acceptable Value: \[\text{\_XOPEN\_NAME\_MAX}\]

\[\text{PATH\_MAX}\]
Maximum number of bytes in a pathname, including the terminating null character.
Minimum Acceptable Value: \[\text{\_POSIX\_PATH\_MAX}\]
XSI Minimum Acceptable Value: \[\text{\_XOPEN\_PATH\_MAX}\]

\[\text{PIPE\_BUF}\]
Maximum number of bytes that is guaranteed to be atomic when writing to a pipe.
Minimum Acceptable Value: \[\text{\_POSIX\_PIPE\_BUF}\]

ADV \[\text{POSIX\_ALLOC\_SIZE\_MIN}\]
Minimum number of bytes of storage actually allocated for any portion of a file.
Minimum Acceptable Value: Not specified.

ADV \[\text{POSIX\_REC\_INCR\_XFER\_SIZE}\]
Recommended increment for file transfer sizes between the \[\text{POSIX\_REC\_MIN\_XFER\_SIZE}\] and \[\text{POSIX\_REC\_MAX\_XFER\_SIZE}\] values.
Minimum Acceptable Value: Not specified.

ADV \[\text{POSIX\_REC\_MAX\_XFER\_SIZE}\]
Maximum recommended file transfer size.
Minimum Acceptable Value: Not specified.

ADV \[\text{POSIX\_REC\_MIN\_XFER\_SIZE}\]
Minimum recommended file transfer size.
Minimum Acceptable Value: Not specified.

ADV \[\text{POSIX\_REC\_XFER\_ALIGN}\]
Recommended file transfer buffer alignment.
Minimum Acceptable Value: Not specified.

\[\text{SYMLINK\_MAX}\]
Maximum number of bytes in a symbolic link.
Minimum Acceptable Value: \[\text{\_POSIX\_SYMLINK\_MAX}\]

Runtime Increasable Values
The magnitude limitations in the following list shall be fixed by specific implementations. An
application should assume that the value supplied by \text{\_limits\_h} in a specific implementation is
the minimum that pertains whenever the application is run under that implementation. A
specific instance of a specific implementation may increase the value relative to that supplied by
\text{\_limits\_h} for that implementation. The actual value supported by a specific instance shall be
provided by the \text{sysconf()} function.

\[\text{BC\_BASE\_MAX}\]
Maximum \text{obase} values allowed by the \text{bc} utility.
Minimum Acceptable Value: \[\text{\_POSIX2\_BC\_BASE\_MAX}\]

\[\text{BC\_DIM\_MAX}\]
Maximum number of elements permitted in an array by the \text{bc} utility.
Minimum Acceptable Value: \_POSIX2\_BC\_DIM\_MAX

{BC\_SCALE\_MAX}
  Maximum scale value allowed by the bc utility.
  Minimum Acceptable Value: \_POSIX2\_BC\_SCALE\_MAX

{BC\_STRING\_MAX}
  Maximum length of a string constant accepted by the bc utility.
  Minimum Acceptable Value: \_POSIX2\_BC\_STRING\_MAX

{CHARCLASS\_NAME\_MAX}
  Maximum number of bytes in a character class name.
  Minimum Acceptable Value: \_POSIX2\_CHARCLASS\_NAME\_MAX

{COLL\_WEIGHTS\_MAX}
  Maximum number of weights that can be assigned to an entry of the LC\_COLLATE order keyword in the locale definition file; see Chapter 7 (on page 123).
  Minimum Acceptable Value: \_POSIX2\_COLL\_WEIGHTS\_MAX

{EXPR\_NEST\_MAX}
  Maximum number of expressions that can be nested within parentheses by the expr utility.
  Minimum Acceptable Value: \_POSIX2\_EXPR\_NEST\_MAX

{LINE\_MAX}
  Unless otherwise noted, the maximum length, in bytes, of a utility’s input line (either standard input or another file), when the utility is described as processing text files. The length includes room for the trailing <newline>.
  Minimum Acceptable Value: \_POSIX2\_LINE\_MAX

{NGROUPS\_MAX}
  Maximum number of simultaneous supplementary group IDs per process.
  Minimum Acceptable Value: \_POSIX\_NGROUPS\_MAX

{RE\_DUP\_MAX}
  Maximum number of repeated occurrences of a regular expression permitted when using the interval notation \{m,n\}; see Chapter 9 (on page 169).
  Minimum Acceptable Value: \_POSIX2\_RE\_DUP\_MAX

Maximum Values

TMR{\_POSIX\_CLOCKRES\_MIN}
The resolution of the CLOCK\_REALTIME clock, in nanoseconds.
Value: 20 000 000

MON If the Monotonic Clock option is supported, the resolution of the CLOCK\_MONOTONIC clock, in nanoseconds, is represented by \_POSIX\_CLOCKRES\_MIN.
**Minimum Values**

The symbolic constants in the following list shall be defined in `<limits.h>` with the values shown. These are symbolic names for the most restrictive value for certain features on an implementation conforming to this volume of IEEE Std 1003.1-2001. Related symbolic constants are defined elsewhere in this volume of IEEE Std 1003.1-2001 which reflect the actual implementation and which need not be as restrictive. A conforming implementation shall provide values at least this large. A strictly conforming application must not require a larger value for correct operation.

<limits.h>

Numerical Limits

The values in the following lists shall be defined in <limits.h> and are constant expressions suitable for use in #if preprocessing directives. Moreover, except for {CHAR_BIT}, {DBL_DIG}, {DBL_MAX}, {FLT_DIG}, {FLT_MAX}, {LONG_BIT}, {WORD_BIT}, and {MB_LEN_MAX}, the symbolic names are defined as expressions of the correct type.

If the value of an object of type char is treated as a signed integer when used in an expression, the value of {CHAR_MIN} is the same as that of {SCHAR_MIN} and the value of {CHAR_MAX} is the same as that of {SCHAR_MAX}. Otherwise, the value of {CHAR_MIN} is 0 and the value of {CHAR_MAX} is the same as that of {UCHAR_MAX}.
[CHAR_BIT]
Number of bits in a type char.
Value: 8

[CHAR_MAX]
Maximum value of type char.
Value: {UCHAR_MAX} or {SCHAR_MAX}

[CHAR_MIN]
Minimum value of type char.
Value: {SCHAR_MIN} or 0

[INT_MAX]
Maximum value of an int.
Minimum Acceptable Value: 2 147 483 647

[XSI]
{LONG_BIT}
Number of bits in a long.
Minimum Acceptable Value: 32

{LONG_MAX}
Maximum value of a long.
Minimum Acceptable Value: +2 147 483 647

[MB_LEN_MAX]
Maximum number of bytes in a character, for any supported locale.
Minimum Acceptable Value: 1

[SCHAR_MAX]
Maximum value of type signed char.
Value: +127

[SHRT_MAX]
Maximum value of type short.
Minimum Acceptable Value: +32 767

[SSIZE_MAX]
Maximum value of an object of type ssize_t.
Minimum Acceptable Value: {_POSIX_SSIZE_MAX}

[UCHAR_MAX]
Maximum value of type unsigned char.
Value: 255

[UINT_MAX]
Maximum value of type unsigned.
Minimum Acceptable Value: 4 294 967 295

[ULONG_MAX]
Maximum value of type unsigned long.
Minimum Acceptable Value: 4 294 967 295

[USHRT_MAX]
Maximum value for a type unsigned short.
Minimum Acceptable Value: 65 535

[XSI]
{WORD_BIT}
Number of bits in a word or type int.
Minimum Acceptable Value: 16
9168  {INT_MIN}
9169   Minimum value of type int.
9170   Maximum Acceptable Value: \(-2 \, 147 \, 483 \, 647\)
9171  {LONG_MIN}
9172   Minimum value of type long.
9173   Maximum Acceptable Value: \(-2 \, 147 \, 483 \, 647\)
9174  {SCHAR_MIN}
9175   Minimum value of type signed char.
9176   Value: \(-128\)
9177  {SHRT_MIN}
9178   Minimum value of type short.
9179   Maximum Acceptable Value: \(-32 \, 767\)
9180  {LONGLONG_MIN}
9181   Minimum value of type long long.
9182   Maximum Acceptable Value: \(-9 \, 223 \, 372 \, 036 \, 854 \, 775 \, 807\)
9183  {LONGLONG_MAX}
9184   Maximum value of type long long.
9185   Minimum Acceptable Value: +9 \, 223 \, 372 \, 036 \, 854 \, 775 \, 807
9186  {ULLONG_MAX}
9187   Maximum value of type unsigned long long.
9188   Minimum Acceptable Value: 18 \, 446 \, 744 \, 073 \, 709 \, 551 \, 615

APPLICATION USAGE

None.

RATIONALE

A request was made to reduce the value of \_POSIX\_LINK\_MAX from the value of 8 specified for it in the POSIX.1-1990 standard to 2. The standard developers decided to deny this request for several reasons:

- They wanted to avoid making any changes to the standard that could break conforming applications, and the requested change could have that effect.
- The use of multiple hard links to a file cannot always be replaced with use of symbolic links. Symbolic links are semantically different from hard links in that they associate a pathname with another pathname rather than a pathname with a file. This has implications for access control, file permanence, and transparency.
- The original standard developers had considered the issue of allowing for implementations that did not in general support hard links, and decided that this would reduce consensus on the standard.

Systems that support historical versions of the development option of the ISO POSIX-2 standard retain the name \_POSIX2\_RE\_DUP\_MAX as an alias for \_POSIX\_RE\_DUP\_MAX.

\[\text{PATH}\_\text{MAX}\]

IEEE PASC Interpretation 1003.1 #15 addressed the inconsistency in the standard with the definition of pathname and the description of [\text{PATH}\_\text{MAX}]. allowing application writers to allocate either [\text{PATH}\_\text{MAX}] or [\text{PATH}\_\text{MAX}]+1 bytes. The inconsistency has been removed by correction to the [\text{PATH}\_\text{MAX}] definition to include the null character. With this change, applications that previously allocated [\text{PATH}\_\text{MAX}] bytes will continue to succeed.

\[\text{SYMLINK}\_\text{MAX}\]

This symbol refers to space for data that is stored in the file system, as opposed to [\text{PATH}\_\text{MAX}] which is the length of a name that can be passed to a function. In some existing implementations, the filenames pointed to by symbolic links are stored in the inodes of the links, so it is important that [\text{SYMLINK}\_\text{MAX}] not be constrained to be as large as [\text{PATH}\_\text{MAX}].

FUTURE DIRECTIONS

None.

SEE ALSO

The System Interfaces volume of IEEE Std 1003.1-2001, \text{fpathconf()}, \text{pathconf()}, \text{sysconf()}

CHANGE HISTORY

First released in Issue 1.

Issue 5

The DESCRIPTION is updated for alignment with the POSIX Realtime Extension and the POSIX Threads Extension.

[\text{FILESIZEBITS}] is added for the Large File Summit extensions.

The minimum acceptable values for [\text{INT}\_\text{MAX}], [\text{INT}\_\text{MIN}], and [\text{UINT}\_\text{MAX}] are changed to make 32-bit values the minimum requirement.
The entry is restructured to improve readability.

Issue 6

The Open Group Corrigendum U033/4 is applied. The wording is made clear for \texttt{CHAR_MIN}, \texttt{INT_MIN}, \texttt{LONG_MIN}, \texttt{SCHAR_MIN}, and \texttt{SHRT_MIN} that these are maximum acceptable values.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The minimum value for \texttt{CHILD_MAX} is 25. This is a FIPS requirement.
- The minimum value for \texttt{OPEN_MAX} is 20. This is a FIPS requirement.
- The minimum value for \texttt{NGROUPS_MAX} is 8. This is also a FIPS requirement.

Symbolic constants are added for \texttt{POSIX_SYMLINK_MAX}, \texttt{POSIX_SYMLOOP_MAX}, \texttt{POSIX_RE_DUP_MAX}, \texttt{RE_DUP_MAX}, \texttt{SYMLOOP_MAX}, and \texttt{SYMLINK_MAX}.

The following values are added for alignment with IEEE Std 1003.1d-1999:

\texttt{POSIX_SS_REPL_MAX}

\texttt{SS_REPL_MAX}

\texttt{POSIX_ALLOC_SIZE_MIN}

\texttt{POSIX_REC_INCR_XFER_SIZE}

\texttt{POSIX_REC_MAX_XFER_SIZE}

\texttt{POSIX_REC_MIN_XFER_SIZE}

\texttt{POSIX_REC_XFER_ALIGN}

Reference to \texttt{CLOCK_MONOTONIC} is added in the description of \texttt{POSIX_CLOCKRES_MIN} for alignment with IEEE Std 1003.1j-2000.

The constants \texttt{LLONG_MIN}, \texttt{LLONG_MAX}, and \texttt{ULLONG_MAX} are added for alignment with the ISO/IEC 9899:1999 standard.

The following values are added for alignment with IEEE Std 1003.1q-2000:

\texttt{POSIX_TRACE_EVENT_NAME_MAX}

\texttt{POSIX_TRACE_NAME_MAX}

\texttt{POSIX_TRACE_SYS_MAX}

\texttt{POSIX_TRACE_USER_EVENT_MAX}

\texttt{TRACE_EVENT_NAME_MAX}

\texttt{TRACE_NAME_MAX}

\texttt{TRACE_SYS_MAX}

\texttt{TRACE_USER_EVENT_MAX}

The new limits \texttt{XOPEN_NAME_MAX} and \texttt{XOPEN_PATH_MAX} are added as minimum values for \texttt{PATH_MAX} and \texttt{NAME_MAX} limits on XSI-conformant systems.

The legacy symbols \texttt{PASS_MAX} and \texttt{TMP_MAX} are removed.

The values for the limits \texttt{CHAR_BIT}, \texttt{SCHAR_MAX}, and \texttt{UCHAR_MAX} are now required to be 8, +127, and 255, respectively.

The value for the limit \texttt{CHAR_MAX} is now \texttt{UCHAR_MAX} or \texttt{SCHAR_MAX}.

The value for the limit \texttt{CHAR_MIN} is now \texttt{SCHAR_MIN} or zero.

IEEE Std 1003.1-2001/Cor 1-2002, item XBD/TC1/D6/10 is applied, correcting the value of \texttt{POSIX_CHILD_MAX} from 6 to 25. This is for FIPS 151-2 alignment.
NAME
locale.h — category macros

SYNOPSIS
#include <locale.h>

DESCRIPTION
Some of the functionality described on this reference page extends the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-2001 defers to the ISO C standard.
The <locale.h> header shall provide a definition for lconv structure, which shall include at least the following members. (See the definitions of LC_MONETARY in Section 7.3.3 (on page 142) and Section 7.3.4 (on page 145).)

- char *currency_symbol
- char *decimal_point
- char frac_digits
- char *grouping
- char *int_curr_symbol
- char int_frac_digits
- char int_n_cs_precedes
- char int_n_sep_by_space
- char int_n_sign_posn
- char int_p_cs_precedes
- char int_p_sep_by_space
- char int_p_sign_posn
- char *mon_decimal_point
- char *mon_grouping
- char *mon_thousands_sep
- char *negative_sign
- char n_cs_precedes
- char n_sep_by_space
- char n_sign_posn
- char *positive_sign
- char p_cs_precedes
- char p_sep_by_space
- char p_sign_posn
- char *thousands_sep

The <locale.h> header shall define NULL (as defined in <stddef.h>) and at least the following as macros:

- LC_ALL
- LC_COLLATE
- LC_CTYPE
- LC_MESSAGES
- LC_MONETARY
- LC_NUMERIC
- LC_TIME

which shall expand to distinct integer constant expressions, for use as the first argument to the setlocale() function.

Additional macro definitions, beginning with the characters LC_ and an uppercase letter, may also be given here.
The following shall be declared as functions and may also be defined as macros. Function
prototypes shall be provided.

```
struct lconv *localeconv (void);
char   *setlocale(int, const char *);
```

The System Interfaces volume of IEEE Std 1003.1-2001, `localeconv()`, `setlocale()`, Chapter 8 (on
page 161)

**CHANGE HISTORY**
First released in Issue 3.

Included for alignment with the ISO C standard.

**Issue 6**
The `lconv` structure is expanded with new members (`int_n_cs_precedes`, `int_n_sep_by_space`,
`int_n_sign_posn`, `int_p_cs_precedes`, `int_p_sep_by_space`, and `int_p_sign_posn`) for alignment

Extensions beyond the ISO C standard are marked.
NAME
math.h — mathematical declarations

SYNOPSIS
#include <math.h>

DESCRIPTION
Some of the functionality described on this reference page extends the ISO C standard:
Applications shall define the appropriate feature test macro (see the System Interfaces volume of
IEEE Std 1003.1-2001, Section 2.2, The Compilation Environment) to enable the visibility of these
symbols in this header.

The <math.h> header shall include definitions for at least the following types:

float_t A real-floating type at least as wide as float.
double_t A real-floating type at least as wide as double, and at least as wide as float_t.

If FLT_EVAL_METHOD equals 0, float_t and double_t shall be float and double, respectively; if
FLT_EVAL_METHOD equals 1, they shall both be double; if FLT_EVAL_METHOD equals 2,
they shall both be long double; for other values of FLT_EVAL_METHOD, they are otherwise
implementation-defined.

The <math.h> header shall define the following macros, where real-floating indicates that the
argument shall be an expression of real-floating type:

int fpclassify(real-floating x);
int isfinite(real-floating x);
int isinf(real-floating x);
int isnan(real-floating x);
int isnormal(real-floating x);
int signbit(real-floating x);
int isgreater(real-floating x, real-floating y);
int isgreaterequal(real-floating x, real-floating y);
int isless(real-floating x, real-floating y);
int islessequal(real-floating x, real-floating y);
int islessgreater(real-floating x, real-floating y);
int isunordered(real-floating x, real-floating y);

The <math.h> header shall provide for the following constants. The values are of type double
and are accurate within the precision of the double type.

M_E Value of e
M_LOG2E Value of log_2 e
M_LOG10E Value of log_10 e
M_LN2 Value of log_2 10
M_LN10 Value of log_10 2
M_PI Value of π
M_PI_2 Value of π/2
M_PI_4 Value of π/4
M_1_PI Value of 1/π
M_2_PI Value of 2/π
The following symbolic constants:

- **M_2_SQRTPI**: Value of $2\sqrt{\pi}$
- **M_SQRT2**: Value of $\sqrt{2}$
- **M_SQRT1_2**: Value of $1/\sqrt{2}$

The header shall define the following symbolic constants:

- **XSI_MAXFLOAT**: Value of maximum non-infinite single-precision floating-point number.
- **HUGE_VAL**: A positive `double` expression, not necessarily representable as a `float`. Used as an error value returned by the mathematics library. HUGE_VAL evaluates to +infinity on systems supporting IEEE Std 754-1985.
- **HUGE_VALF**: A positive `float` constant expression. Used as an error value returned by the mathematics library. HUGE_VALF evaluates to +infinity on systems supporting IEEE Std 754-1985.
- **HUGE_VALL**: A positive `long double` constant expression. Used as an error value returned by the mathematics library. HUGE_VALL evaluates to +infinity on systems supporting IEEE Std 754-1985.
- **INFINITY**: A constant expression of type `float` representing positive or unsigned infinity, if available; else a positive constant of type `float` that overflows at translation time.
- **NAN**: A constant expression of type `float` representing a quiet NaN. This symbolic constant is only defined if the implementation supports quiet NaNs for the `float` type.

The following macros shall be defined for number classification. They represent the mutually-exclusive kinds of floating-point values. They expand to integer constant expressions with distinct values. Additional implementation-defined floating-point classifications, with macro definitions beginning with FP_ and an uppercase letter, may also be specified by the implementation.

- **FP_INFINITE**
- **FP_NAN**
- **FP_NORMAL**
- **FP_SUBNORMAL**
- **FP_ZERO**

The following optional macros indicate whether the `fma()` family of functions are fast compared with direct code:

- **FP_FAST_FMA**
- **FP_FAST_FMAF**
- **FP_FAST_FMAL**

The FP_FAST_FMA macro shall be defined to indicate that the `fma()` function generally executes about as fast as, or faster than, a multiply and an add of `double` operands. The other macros have the equivalent meaning for the `float` and `long double` versions.

The following macros shall expand to integer constant expressions whose values are returned by `ilogb(x)` if `x` is zero or NaN, respectively. The value of FP_ILOGB0 shall be either INT_MIN or −[INT_MAX]. The value of FP_ILOGBNAN shall be either INT_MAX or INT_MIN.

- **FP_ILOGB0**
- **FP_ILOGBNAN**
The following macros shall expand to the integer constants 1 and 2, respectively:

- `MATH_ERRNO`
- `MATH_ERREXCEPT`

The following macro shall expand to an expression that has type `int` and the value `MATH_ERRNO`, `MATH_ERREXCEPT`, or the bitwise-inclusive OR of both:

- `math_errhandling`

The value of `math_errhandling` is constant for the duration of the program. It is unspecified whether `math_errhandling` is a macro or an identifier with external linkage. If a macro definition is suppressed or a program defines an identifier with the name `math_errhandling`, the behavior is undefined. If the expression `(math_errhandling & MATH_ERREXCEPT)` can be non-zero, the implementation shall define the macros `FE_DIVBYZERO`, `FE_INVALID`, and `FE_OVERFLOW` in `<fenv.h>`.

The following shall be declared as functions and may also be defined as macros. Function prototypes shall be provided:

- `double acos(double);`
- `float acosf(float);`
- `double acosh(double);`
- `float acoshf(float);`
- `long double acoshl(long double);`
- `long double acosl(long double);`
- `double asin(double);`
- `float asinf(float);`
- `double asinh(double);`
- `float asinhf(float);`
- `long double asinhl(long double);`
- `long double asinl(long double);`
- `double atan(double);`
- `double atan2(double, double);`
- `float atan2f(float, float);`
- `long double atan2l(long double, long double);`
- `float atanf(float);`
- `double atanh(double);`
- `double atanhf(float);`
- `long double atanhl(long double);`
- `long double atanhll(long double);`
- `double cbrt(double);`
- `float cbrtf(float);`
- `long double cbrtl(long double);`
- `long double cbrtl1(long double);`
- `double ceil(double);`
- `float ceilf(float);`
- `long double ceill(long double);`
- `long double ceilll(long double);`
- `double copysign(double, double);`
- `float copysignf(float, float);`
- `long double copysignl(long double, long double);`
- `double cos(double);`
- `float cosf(float);`
- `double cosh(double);`
- `float coshf(float);`
- `long double coshl(long double);`
long double cosl(long double);
double erf(double);
double erfc(double);
float erfcf(float);
long double erfc1(long double);
float erff(float);

double trunc(double);
float  trunctf(float);
long double truncl(long double);

double y0(double);
double y1(double);
double yn(int, double);

extern int signgam;

The behavior of each of the functions defined in `<math.h>` is specified in the System Interfaces volume of IEEE Std 1003.1-2001 for all representable values of its input arguments, except where stated otherwise. Each function shall execute as if it were a single operation without generating any externally visible exceptional conditions.
The FP_CONTRACT pragma can be used to allow (if the state is on) or disallow (if the state is off) the implementation to contract expressions. Each pragma can occur either outside external declarations or preceding all explicit declarations and statements inside a compound statement. When outside external declarations, the pragma takes effect from its occurrence until another FP_CONTRACT pragma is encountered, or until the end of the translation unit. When inside a compound statement, the pragma takes effect from its occurrence until another FP_CONTRACT pragma is encountered (including within a nested compound statement), or until the end of the compound statement; at the end of a compound statement the state for the pragma is restored to its condition just before the compound statement. If this pragma is used in any other context, the behavior is undefined. The default state (on or off) for the pragma is implementation-defined.

Before the ISO/IEC 9899:1999 standard, the math library was defined only for the floating type double. All the names formed by appending ‘f’ or ‘l’ to a name in <math.h> were reserved to allow for the definition of float and long double libraries; and the ISO/IEC 9899:1999 standard provides for all three versions of math functions.

The functions ecvt(), fcvt(), and gcvt() have been dropped from the ISO C standard since their capability is available through sprintf(). These are provided on XSI-conformant systems supporting the Legacy Option Group.

None.

NAME
monetary.h — monetary types

SYNOPSIS
XSI
#include <monetary.h>

DESCRIPTION
The <monetary.h> header shall define the following types:
size_t As described in <stddef.h>.
ssize_t As described in <sys/types.h>.
The following shall be declared as a function and may also be defined as a macro. A function prototype shall be provided.
ssize_t strfmon(char *restrict, size_t, const char *restrict, ...);

APPLICATION USAGE
None.

RATIONALE
None.

FUTURE DIRECTIONS
None.

SEE ALSO
The System Interfaces volume of IEEE Std 1003.1-2001, strfmon() 

CHANGE HISTORY
First released in Issue 4.

Issue 6
The restrict keyword is added to the prototype for strfmon().
NAME
mqueue.h — message queues (REALTIME)

SYNOPSIS
MSG #include <mqueue.h>

DESCRIPTION
The <mqueue.h> header shall define the mqd_t type, which is used for message queue
descriptors. This is not an array type.

The <mqueue.h> header shall define the sigevent structure (as described in <signal.h>) and the
mq_attr structure, which is used in getting and setting the attributes of a message queue.
Attributes are initially set when the message queue is created. An mq_attr structure shall have at
least the following fields:

long mq_flags Message queue flags.
long mq_maxmsg Maximum number of messages.
long mq_msgsize Maximum message size.
long mq_curmsgs Number of messages currently queued.

The following shall be declared as functions and may also be defined as macros. Function
prototypes shall be provided.

int mq_close(mqd_t);
int mq_getattr(mqd_t, struct mq_attr *);
int mq_notify(mqd_t, const struct sigevent *);
mqd_t mq_open(const char *, int, ...);
ssize_t mq_receive(mqd_t, char *, size_t, unsigned *);
int mq_send(mqd_t, const char *, size_t, unsigned );
int mq_setattr(mqd_t, const struct mq_attr *restrict,
            struct mq_attr *restrict);
ssize_t mq_timedreceive(mqd_t, char *restrict, size_t,
                unsigned *restrict, const struct timespec *restrict);
int mq_timedsend(mqd_t, const char *, size_t, unsigned ,
            const struct timespec *);
int mq_unlink(const char *

Inclusion of the <mqueue.h> header may make visible symbols defined in the headers <fcntl.h>,
<signal.h>, <sys/types.h>, and <time.h>.

APPLICATION USAGE
None.

RATIONALE
None.

FUTURE DIRECTIONS
None.

SEE ALSO
<fcntl.h>, <signal.h>, <sys/types.h>, <time.h>, the System Interfaces volume of

mq_setattr(), mq_timedreceive(), mq_timedsend(), mq_unlink()
<mqueue.h>

CHANGE HISTORY

First released in Issue 5. Included for alignment with the POSIX Realtime Extension.

Issue 6

The <mqueue.h> header is marked as part of the Message Passing option.

The `mq_timedreceive()` and `mq_timedsend()` functions are added for alignment with IEEE Std 1003.1d-1999.

The `restrict` keyword is added to the prototypes for `mq_setattr()` and `mq_timedreceive()`.
SYNOPSIS

#include <ndbm.h>

DESCRIPTION

The `<ndbm.h>` header shall define the `datum` type as a structure that includes at least the following members:

- `void *dptr` - A pointer to the application's data.
- `size_t dsize` - The size of the object pointed to by `dptr`.

The `size_t` type shall be defined as described in `<stddef.h>`.

The `<ndbm.h>` header shall define the `DBM` type.

The following constants shall be defined as possible values for the `store_mode` argument to `dbm_store()`:

- `DBM_INSERT` - Insertion of new entries only.
- `DBM_REPLACE` - Allow replacing existing entries.

The following shall be declared as functions and may also be defined as macros. Function prototypes shall be provided.

- `int dbm_clearerr(DBM *)`;
- `void dbm_close(DBM *)`;
- `int dbm_delete(DBM *, datum)`;
- `int dbm_error(DBM *)`;
- `datum dbm_fetch(DBM *, datum)`;
- `datum dbm_firstkey(DBM *)`;
- `datum dbm_nextkey(DBM *)`;
- `DBM *dbm_open(const char *, int, mode_t)`;
- `int dbm_store(DBM *, datum, datum, int)`;

The `mode_t` type shall be defined through `typedef` as described in `<sys/types.h>`.

APPLICATION USAGE

None.

RATIONALE

None.

FUTURE DIRECTIONS

None.

SEE ALSO

- `<stddef.h>`, `<sys/types.h>`, the System Interfaces volume of IEEE Std 1003.1-2001, `dbm_clearerr()`

CHANGE HISTORY

First released in Issue 4, Version 2.

Issue 5

References to the definitions of `size_t` and `mode_t` are added to the DESCRIPTION.
SYNOPSIS
#include <net/if.h>

DESCRIPTION
The <net/if.h> header shall define the if_nameindex structure that includes at least the following members:

- unsigned if_index: Numeric index of the interface.
- char *if_name: Null-terminated name of the interface.

The <net/if.h> header shall define the following macro for the length of a buffer containing an interface name (including the terminating NULL character):

IF_NAMESIZE: Interface name length.

The following shall be declared as functions and may also be defined as macros. Function prototypes shall be provided:

- unsigned if_nametoindex(const char *):
- char *if_indextoname(unsigned, char *):
- struct if_nameindex *if_nameindex(void):
- void if_frenameindex(struct if_nameindex *):

APPLICATION USAGE
None.

RATIONALE
None.

FUTURE DIRECTIONS
None.

SEE ALSO
The System Interfaces volume of IEEE Std 1003.1-2001, if_frenameindex(), if_indextoname(), if_nameindex(), if_nametoindex()

CHANGE HISTORY
First released in Issue 6. Derived from the XNS, Issue 5.2 specification.
NAME
netdb.h — definitions for network database operations

SYNOPSIS
#include <netdb.h>

DESCRIPTION
The <netdb.h> header may define the in_port_t type and the in_addr_t type as described in
<netinet/in.h>.

The <netdb.h> header shall define the hostent structure that includes at least the following
members:

char *h_name Official name of the host.
char **h_aliases A pointer to an array of pointers to
alternative host names, terminated by a
null pointer.
int h_addrtype Address type.
int h_length The length, in bytes, of the address.
char **h_addr_list A pointer to an array of pointers to network
addresses (in network byte order) for the host,
terminated by a null pointer.

The <netdb.h> header shall define the netent structure that includes at least the following
members:

char *n_name Official, fully-qualified (including the
domain) name of the host.
char **n_aliases A pointer to an array of pointers to
alternative network names, terminated by a
null pointer.
int n_addrtype The address type of the network.
uint32_t n_net The network number, in host byte order.

The uint32_t type shall be defined as described in <inttypes.h>.

The <netdb.h> header shall define the protoent structure that includes at least the following
members:

char *p_name Official name of the protocol.
char **p_aliases A pointer to an array of pointers to
alternative protocol names, terminated by
a null pointer.
int p_proto The protocol number.

The <netdb.h> header shall define the servent structure that includes at least the following
members:

char *s_name Official name of the service.
char **s_aliases A pointer to an array of pointers to
alternative service names, terminated by
a null pointer.
int s_port The port number at which the service
resides, in network byte order.
char *s_proto The name of the protocol to use when
contacting the service.
The \texttt{<netdb.h>} header shall define the \texttt{IPPORT_RESERVED} macro with the value of the highest reserved Internet port number.

When the \texttt{<netdb.h>} header is included, \texttt{h_errno} shall be available as a modifiable lvalue of type \texttt{int}. It is unspecified whether \texttt{h_errno} is a macro or an identifier declared with external linkage.

The \texttt{<netdb.h>} header shall define the following macros for use as error values for \texttt{gethostbyaddr()} and \texttt{gethostbyname()}:

- \texttt{HOST_NOT_FOUND}
- \texttt{NO_DATA}
- \texttt{NO_RECOVERY}
- \texttt{TRYAGAIN}

\textbf{Address Information Structure}

The \texttt{<netdb.h>} header shall define the \texttt{addrinfo} structure that includes at least the following members:

- \texttt{int ai_flags} Input flags.
- \texttt{int ai_family} Address family of socket.
- \texttt{int ai_socktype} Socket type.
- \texttt{int ai_protocol} Protocol of socket.
- \texttt{socklen_t ai_addrlen} Length of socket address.
- \texttt{struct sockaddr *ai_addr} Socket address of socket.
- \texttt{char *ai_canonname} Canonical name of service location.
- \texttt{struct addrinfo *ai_next} Pointer to next in list.

The \texttt{<netdb.h>} header shall define the following macros that evaluate to bitwise-distinct integer constants for use in the \texttt{flags} field of the \texttt{addrinfo} structure:

- \texttt{AI_PASSIVE} Socket address is intended for \texttt{bind()}.
- \texttt{AI_CANONNAME} Request for canonical name.
- \texttt{AI_NUMERICHOST} Return numeric host address as name.
- \texttt{AI_NUMERICSERV} Inhibit service name resolution.
- \texttt{AI_V4MAPPED} If no IPv6 addresses are found, query for IPv4 addresses and return them to the caller as IPv4-mapped IPv6 addresses.
- \texttt{AI_ALL} Query for both IPv4 and IPv6 addresses.
- \texttt{AI_ADDRCONFIG} Query for IPv4 addresses only when an IPv4 address is configured; query for IPv6 addresses only when an IPv6 address is configured.

The \texttt{<netdb.h>} header shall define the following macros that evaluate to bitwise-distinct integer constants for use in the \texttt{flags} argument to \texttt{getnameinfo()}:

- \texttt{NI_NOFQDN} Only the nodename portion of the FQDN is returned for local hosts.
- \texttt{NI_NUMERICHOST} The numeric form of the node's address is returned instead of its name.
NI_NAMEREQD Return an error if the node’s name cannot be located in the database.

NI_NUMERICSERV
The numeric form of the service address is returned instead of its name.

NI_NUMERICSCOPED
For IPv6 addresses, the numeric form of the scope identifier is returned instead of its name.

NI_DGRAM Indicates that the service is a datagram service (SOCK_DGRAM).

Address Information Errors
The <netdb.h> header shall define the following macros for use as error values for getaddrinfo() and getnameinfo():

EAI_AGAIN The name could not be resolved at this time. Future attempts may succeed.

EAI_BADFLAGS The flags had an invalid value.

EAI_FAIL A non-recoverable error occurred.

EAI_FAMILY The address family was not recognized or the address length was invalid for the specified family.

EAI_MEMORY There was a memory allocation failure.

EAI_NONAME The name does not resolve for the supplied parameters.

NI_NAMEREQD is set and the host’s name cannot be located, or both nodename and servname were null.

EAI_SERVICE The service passed was not recognized for the specified socket type.

EAI_SOCKTYPE The intended socket type was not recognized.

EAI_SYSTEM A system error occurred. The error code can be found in errno.

EAI_OVERFLOW An argument buffer overflowed.

The following shall be declared as functions and may also be defined as macros. Function prototypes shall be provided.

void endhostent(void);

void endnetent(void);

void endprotoent(void);

void endservent(void);

void freeaddrinfo(struct addrinfo *);

const char *gai_strerror(int);

int getaddrinfo(const char *restrict, const char *restrict,
const struct addrinfo *restrict,
struct addrinfo **restrict);

struct hostent *gethostbyaddr(const void *, socklen_t, int);

struct hostent *gethostbyname(const char *);

struct hostent *gethostent(void);

int getnameinfo(const struct sockaddr *restrict, socklen_t, char *restrict, socklen_t, char *restrict, int);

struct netent *getnetbyaddr(uint32_t, int);

struct netent *getnetbyname(const char *);
The type `socklen_t` shall be defined through `typedef` as described in `<sys/socket.h>`.

Inclusion of the `<netdb.h>` header may also make visible all symbols from `<netinet/in.h>`, `<sys/socket.h>`, and `<inttypes.h>`.

APPLICATION USAGE
None.

RATIONALE
None.

FUTURE DIRECTIONS
None.

SEE ALSO
`<netinet/in.h>`, `<inttypes.h>`, `<sys/socket.h>`, the System Interfaces volume of IEEE Std 1003.1-2001, `bind()` , `endhostent()` , `endnetent()` , `endprotoent()` , `endservent()` , `getaddrinfo()` , `getnameinfo()`.

CHANGE HISTORY
First released in Issue 6. Derived from the XNS, Issue 5.2 specification.

The Open Group Base Resolution bwg2001-009 is applied, which changes the return type for `gai_strerror()` from `char *` to `const char *`. This is for coordination with the IPnG Working Group.

IEEE Std 1003.1-2001/Cor 1-2002, item XBD/TC1/D6/11 is applied, adding a description of the NI_NUMERICSCOPE macro and correcting the `getnameinfo()` function prototype. These changes are for alignment with IPv6.
NAME
netinet/in.h — Internet address family

SYNOPSIS
#include <netinet/in.h>

DESCRIPTION
The <netinet/in.h> header shall define the following types:

- `in_port_t` Equivalent to the type `uint16_t` as defined in `<inttypes.h>`.
- `in_addr_t` Equivalent to the type `uint32_t` as defined in `<inttypes.h>`.

The `sa_family_t` type shall be defined as described in `<sys/socket.h>`.

The `uint8_t` and `uint32_t` type shall be defined as described in `<inttypes.h>`. Inclusion of the `<netinet/in.h>` header may also make visible all symbols from `<inttypes.h>` and `<sys/socket.h>`.

The <netinet/in.h> header shall define the `in_addr` structure that includes at least the following member:

- `in_addr_t s_addr`

The <netinet/in.h> header shall define the `socket_in` structure that includes at least the following members (all in network byte order):

- `sa_family_t sin_family` AF_INET.
- `in_port_t sin_port` Port number.
- `struct in_addr sin_addr` IP address.

The `socket_in` structure is used to store addresses for the Internet address family. Values of this type shall be cast by applications to `struct sockaddr` for use with socket functions.

The <netinet/in.h> header shall define the `in6_addr` structure that contains at least the following member:

- `uint8_t s6_addr[16]`

This array is used to contain a 128-bit IPv6 address, stored in network byte order.

The <netinet/in.h> header shall define the `socket_in6` structure that includes at least the following members (all in network byte order):

- `sa_family_t sin6_family` AF_INET6.
- `in_port_t sin6_port` Port number.
- `uint32_t sin6_flowinfo` IPv6 traffic class and flow information.
- `struct in6_addr sin6_addr` IPv6 address.
- `uint32_t sin6_scope_id` Set of interfaces for a scope.

The `socket_in6` structure shall be set to zero by an application prior to using it, since implementations are free to have additional, implementation-defined fields in `socket_in6`.

The `sin6_scope_id` field is a 32-bit integer that identifies a set of interfaces as appropriate for the scope of the address carried in the `sin6_addr` field. For a link scope `sin6_addr`, the application shall ensure that `sin6_scope_id` is a link index. For a site scope `sin6_addr`, the application shall ensure that `sin6_scope_id` is a site index. The mapping of `sin6_scope_id` to an interface or set of interfaces is implementation-defined.

The <netinet/in.h> header shall declare the following external variable:

- `const struct in6_addr in6addr_any`
This variable is initialized by the system to contain the wildcard IPv6 address. The
<netinet/in.h> header also defines the IN6ADDR_ANY_INIT macro. This macro must be
constant at compile time and can be used to initialize a variable of type struct in6_addr to the
IPv6 wildcard address.

The <netinet/in.h> header shall declare the following external variable:

const struct in6_addr in6addr_loopback

This variable is initialized by the system to contain the loopback IPv6 address. The
<netinet/in.h> header also defines the IN6ADDR_LOOPBACK_INIT macro. This macro must be
constant at compile time and can be used to initialize a variable of type struct in6_addr to the
IPv6 loopback address.

The <netinet/in.h> header shall define the ipv6_mreq structure that includes at least the
following members:

struct in6_addr ipv6mr_multiaddr IPv6 multicast address.
unsigned ipv6mr_interface Interface index.

The <netinet/in.h> header shall define the following macros for use as values of the level
argument of getsockopt() and setsockopt():

IPPROTO_IP Internet protocol.
IPPROTO_ICMP Control message protocol.
IPPROTO_RAW Raw IP Packets Protocol.
IPPROTO_TCP Transmission control protocol.
IPPROTO_UDP User datagram protocol.

The <netinet/in.h> header shall define the following macros for use as destination addresses for
connect(), sendmsg(), and sendto():

INADDR_ANY IPv4 local host address.
INADDR_BROADCAST IPv4 broadcast address.

The <netinet/in.h> header shall define the following macro to help applications declare buffers
of the proper size to store IPv4 addresses in string form:

INET_ADDRSTRLEN 16. Length of the string form for IP.

The htonl(), htons(), ntohs(), and ntohl() functions shall be available as defined in <arpa/inet.h>.
Inclusion of the <netinet/in.h> header may also make visible all symbols from <arpa/inet.h>.

The <netinet/in.h> header shall define the following macro to help applications declare buffers
of the proper size to store IPv6 addresses in string form:

The <netinet/in.h> header shall define the following macros, with distinct integer values, for use
in the option_name argument in the getsockopt() or setsockopt() functions at protocol level
IPPROTO_IPV6:

IPV6_JOIN_GROUP Join a multicast group.
The `<netinet/in.h>` header shall define the following macros that test for special IPv6 addresses. Each macro is of type `int` and takes a single argument of type `const struct in6_addr *`:

<table>
<thead>
<tr>
<th>Macro</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IN6_IS_ADDR_UNSPECIFIED</td>
<td>Unspecified address</td>
</tr>
<tr>
<td>IN6_IS_ADDR_LOOPBACK</td>
<td>Loopback address</td>
</tr>
<tr>
<td>IN6_IS_ADDR_MULTICAST</td>
<td>Multicast address</td>
</tr>
<tr>
<td>IN6_IS_ADDR_LINKLOCAL</td>
<td>Unicast link-local address</td>
</tr>
<tr>
<td>IN6_IS_ADDR_SITELOCAL</td>
<td>Unicast site-local address</td>
</tr>
<tr>
<td>IN6_IS_ADDR_V4MAPPED</td>
<td>IPv4 mapped address</td>
</tr>
<tr>
<td>IN6_IS_ADDR_V4COMPAT</td>
<td>IPv4-compatible address</td>
</tr>
<tr>
<td>IN6_IS_ADDR_MC_NODELOCAL</td>
<td>Multicast node-local address</td>
</tr>
<tr>
<td>IN6_IS_ADDR_MC_LINKLOCAL</td>
<td>Multicast link-local address</td>
</tr>
<tr>
<td>IN6_IS_ADDR_MC_SITELOCAL</td>
<td>Multicast site-local address</td>
</tr>
<tr>
<td>IN6_IS_ADDR_MC_ORGLOCAL</td>
<td>Multicast organization-local address</td>
</tr>
<tr>
<td>IN6_IS_ADDR_MC_GLOBAL</td>
<td>Multicast global address</td>
</tr>
</tbody>
</table>
<netinet/in.h>

APPLICATION USAGE
None.

RATIONALE
None.

FUTURE DIRECTIONS
None.

Section 4.8 (on page 101), <arpa/inet.h>, <inttypes.h>, <sys/socket.h>, the System Interfaces volume of IEEE Std 1003.1-2001, connect(), getsockopt(), htonl(), htons(), ntohl(), ntohs(), sendmsg(), sendto(), setsockopt()

CHANGE HISTORY
First released in Issue 6. Derived from the XNS, Issue 5.2 specification.

The sin_zero member was removed from the sockaddr_in structure as per The Open Group Base Resolution bwg2001-004.

IEEE Std 1003.1-2001/Cor 1-2002, item XBD/TC1/D6/12 is applied, adding const qualifiers to the in6addr_any and in6addr_loopback external variables.
NAME
netinet/tcp.h — definitions for the Internet Transmission Control Protocol (TCP)

SYNOPSIS
#include <netinet/tcp.h>

DESCRIPTION
The <netinet/tcp.h> header shall define the following macro for use as a socket option at the
IPPROTO_TCP level:

TCP_NODELAY  Avoid coalescing of small segments.

The macro shall be defined in the header. The implementation need not allow the value of the
option to be set via setsockopt() or retrieved via getsockopt().

APPLICATION USAGE
None.

RATIONALE
None.

FUTURE DIRECTIONS
None.

SEE ALSO
<sys/socket.h>, the System Interfaces volume of IEEE Std 1003.1-2001, getsockopt(), setsockopt()

CHANGE HISTORY
First released in Issue 6. Derived from the XNS, Issue 5.2 specification.
The `<nl_types.h>` header shall contain definitions of at least the following types:

- `nl_catd`: Used by the message catalog functions `catopen()`, `catgets()`, and `catclose()` to identify a catalog descriptor.
- `nl_item`: Used by `nl_langinfo()` to identify items of `langinfo` data. Values of objects of type `nl_item` are defined in `<langinfo.h>`.

The `<nl_types.h>` header shall contain definitions of at least the following constants:

- `NL_SETD`: Used by `gencat` when no `$set` directive is specified in a message text source file; see the Internationalization Guide. This constant can be passed as the value of `set_id` on subsequent calls to `catgets()` (that is, to retrieve messages from the default message set). The value of `NL_SETD` is implementation-defined.
- `NL_CAT_LOCALE`: Value that must be passed as the `oflag` argument to `catopen()` to ensure that message catalog selection depends on the `LC_MESSAGES` locale category, rather than directly on the `LANG` environment variable.

The following shall be declared as functions and may also be defined as macros. Function prototypes shall be provided.

```c
int catclose(nl_catd);
char *catgets(nl_catd, int, int, const char *);
nl_catd catopen(const char *, int);
```

### APPLICATION USAGE

- None.

### RATIONALE

- None.

### FUTURE DIRECTIONS

- None.

### SEE ALSO

### CHANGE HISTORY

- First released in Issue 2.
NAME
poll.h — definitions for the poll() function

SYNOPSIS
#include <poll.h>

DESCRIPTION
The <poll.h> header shall define the pollfd structure that includes at least the following members:

int fd  The following descriptor being polled.
short events  The input event flags (see below).
short revents  The output event flags (see below).

The <poll.h> header shall define the following type through typedef:

nfds_t  An unsigned integer type used for the number of file descriptors.

The implementation shall support one or more programming environments in which the width of nfds_t is no greater than the width of type long. The names of these programming environments can be obtained using the confstr() function or the getconf utility.

The following symbolic constants shall be defined, zero or more of which may be OR’ed together to form the events or revents members in the pollfd structure:

POLLIN  Data other than high-priority data may be read without blocking.
POLLRDNORM  Normal data may be read without blocking.
POLLRDBAND  Priority data may be read without blocking.
POLLPRI  High priority data may be read without blocking.
POLLPOLLRT  Normal data may be written without blocking.
POLLWNRNORM  Equivalent to POLLPOLLRT.
POLLWRBAND  Priority data may be written.
POLLERR  An error has occurred (revents only).
POLLHUP  Device has been disconnected (revents only).
POLLNVAL  Invalid fd member (revents only).

The significance and semantics of normal, priority, and high-priority data are file and device-specific.

The following shall be declared as a function and may also be defined as a macro. A function prototype shall be provided.

int poll(struct pollfd[], nfds_t, int);
APPLICATION USAGE
None.

RATIONALE
None.

FUTURE DIRECTIONS
None.

SEE ALSO

CHANGE HISTORY
First released in Issue 4, Version 2.

Issue 6
The description of the symbolic constants is updated to match the poll() function.
Text related to STREAMS has been moved to the poll() reference page.
A note is added to the DESCRIPTION regarding the significance and semantics of normal, priority, and high-priority data.
NAME

pthread.h — threads

SYNOPSIS

```c
#include <pthread.h>
```

DESCRIPTION

The `<pthread.h>` header shall define the following symbols:

- `PTHREAD_BARRIER_SERIAL_THREAD`
- `PTHREAD_CANCEL_ASYNCHRONOUS`
- `PTHREAD_CANCEL_ENABLE`
- `PTHREAD_CANCEL_DEFERRED`
- `PTHREAD_CANCEL_DISABLE`
- `PTHREAD_CANCELED`
- `PTHREAD_COND_INITIALIZER`
- `PTHREAD_CREATE_DETACHED`
- `PTHREAD_CREATE_JOINABLE`
- `PTHREAD_EXPLICIT_SCHED`
- `PTHREAD_INHERIT_SCHED`
- `PTHREAD_MUTEX_DEFAULT`
- `PTHREAD_MUTEX_ERRORCHECK`
- `PTHREAD_MUTEX_INITIALIZER`
- `PTHREAD_MUTEX_NORMAL`
- `PTHREAD_MUTEX_RECURSIVE`
- `PTHREAD_ONCE_INIT`
- `PTHREAD_PRIO_INHERIT`
- `PTHREAD_PRIO_NONE`
- `PTHREAD_PRIO_PROTECT`
- `PTHREAD_PROCESS_SHARED`
- `PTHREAD_PROCESS_PRIVATE`
- `PTHREAD_SCOPE_PROCESS`
- `PTHREAD_SCOPE_SYSTEM`

The following types shall be defined as described in `<sys/types.h>`:

- `pthread_attr_t`
- `pthread_barrier_t`
- `pthread_barrierattr_t`
- `pthread_cond_t`
- `pthread_condattr_t`
- `pthread_key_t`
- `pthread_mutex_t`
- `pthread_mutexattr_t`
- `pthread_once_t`
- `pthread_rwlock_t`
- `pthread_rwlockattr_t`
- `pthread_spinlock_t`
- `pthread_t`

The following shall be declared as functions and may also be defined as macros. Function prototypes shall be provided.
int pthread_atfork(void (*)(void), void (*)(void),
   void (*)(void));

NAME
pwd.h — password structure

SYNOPSIS
#include <pwd.h>

DESCRIPTION
The <pwd.h> header shall provide a definition for struct passwd, which shall include at least the following members:

- char *pw_name User’s login name.
- uid_t pw_uid Numerical user ID.
- gid_t pw_gid Numerical group ID.
- char *pw_dir Initial working directory.
- char *pw_shell Program to use as shell.

The gid_t and uid_t types shall be defined as described in <sys/types.h>.

The following shall be declared as functions and may also be defined as macros. Function prototypes shall be provided.

struct passwd *getpwnam(const char *);
struct passwd *getpwuid(uid_t);

TSF
int getpwnam_r(const char *, struct passwd *, char *, size_t, struct passwd **);
int getpwuid_r(uid_t, struct passwd *, char *, size_t, struct passwd **);

XSI
void endpwent(void);
struct passwd *getpwent(void);

RATIONALE
None.

FUTURE DIRECTIONS
None.

SEE ALSO
<sys/types.h>, the System Interfaces volume of IEEE Std 1003.1-2001, endpwent(), getpwnam(), getpwuid()

CHANGE HISTORY
First released in Issue 1.

Issue 5
The DESCRIPTION is updated for alignment with the POSIX Threads Extension.

Issue 6
The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The gid_t and uid_t types are mandated.
- The getpwnam_r() and getpwuid_r() functions are marked as part of the Thread-Safe Functions option.
NAME
regex.h — regular expression matching types

SYNOPSIS
#include <regex.h>

DESCRIPTION
The <regex.h> header shall define the structures and symbolic constants used by the regcomp(),
regexec(), regerror(), and regfree() functions.

The structure type regex_t shall contain at least the following member:

size_t re_nsub Number of parenthesized subexpressions.

The type size_t shall be defined as described in <sys/types.h>.

The type regoff_t shall be defined as a signed integer type that can hold the largest value that
can be stored in either a type off_t or type ssize_t. The structure type regmatch_t shall contain
at least the following members:

regoff_t rm_so Byte offset from start of string
to start of substring.
regoff_t rm_eo Byte offset from start of string of the
first character after the end of substring.

Values for the cflags parameter to the regcomp() function are as follows:

REG_EXTENDED Use Extended Regular Expressions.
REG_ICASE Ignore case in match.
REG_NOSUB Report only success or fail in regexec().
REG_NEWLINE Change the handling of <newline>.

Values for the eflags parameter to the regexec() function are as follows:

REG_NOTBOL The circumflex character (‘^’), when taken as a special character, does
not match the beginning of string.
REG_NOTEOL The dollar sign (‘$’), when taken as a special character, does not match
the end of string.

The following constants shall be defined as error return values:

REG_NOMATCH regexec() failed to match.
REG_BADPAT Invalid regular expression.
REG_ECOLLATE Invalid collating element referenced.
REG_ECTYPE Invalid character class type referenced.
REG_EBRACK "[" or "]" imbalance.
REG_EPAREN "\(\)" or "\()" imbalance.
REG_EBRACE "\{\}" imbalance.
REG_BADBR Content of "\{\}" invalid: not a number, number too large, more than
two numbers, first larger than second.
REG_ERANGE: Invalid endpoint in range expression.
REG_ESPACE: Out of memory.
REG_BADRPT: ‘?’, ‘*’, or ‘+’ not preceded by valid regular expression.
REG_ENOSYS: Reserved.

The following shall be declared as functions and may also be defined as macros. Function prototypes shall be provided.

```c
int regcomp(regex_t *restrict, const char *restrict, int);
size_t regerror(int, const regex_t *restrict, char *restrict, size_t);
int regexec(const regex_t *restrict, const char *restrict, size_t,
  regmatch_t[restrict], int);
void regfree(regex_t *);
```

The implementation may define additional macros or constants using names beginning with REG_.

**APPLICATION USAGE**
None.

**RATIONALE**
None.

**FUTURE DIRECTIONS**
None.

**SEE ALSO**
<sys/types.h>, the System Interfaces volume of IEEE Std 1003.1-2001, regcomp(), the Shell and Utilities volume of IEEE Std 1003.1-2001

**CHANGE HISTORY**
First released in Issue 4.

Originally derived from the ISO POSIX-2 standard.

**Issue 6**
The REG_ENOSYS constant is marked obsolescent.
The `restrict` keyword is added to the prototypes for regcomp(), regerror(), and regexec().
A statement is added that the size_t type is defined as described in <sys/types.h>.

NAME

sched.h — execution scheduling (REALTIME)

SYNOPSIS

PS

#include <sched.h>

DESCRIPTION

The <sched.h> header shall define the sched_param structure, which contains the scheduling parameters required for implementation of each supported scheduling policy. This structure shall contain at least the following member:

int sched_priority Process execution scheduling priority.

In addition, if _POSIX_SPORADIC_SERVER or _POSIX_THREAD_SPORADIC_SERVER is defined, the sched_param structure defined in <sched.h> shall contain the following members in addition to those specified above:

int sched_ss_low_priority Low scheduling priority for sporadic server.

struct timespec sched_ss_repl_period Replenishment period for sporadic server.

struct timespec sched_ss_init_budget Initial budget for sporadic server.

int sched_ss_max_repl Maximum pending replenishments for sporadic server.

Each process is controlled by an associated scheduling policy and priority. Associated with each policy is a priority range. Each policy definition specifies the minimum priority range for that policy. The priority ranges for each policy may overlap the priority ranges of other policies.

Four standard policies are defined; others may be defined by the implementation. The four standard policies are indicated by the values of the following symbolic constants:

SCHED_FIFO First in-first out (FIFO) scheduling policy.

SCHED_RR Round robin scheduling policy.

SCHED_SPORADIC Sporadic server scheduling policy.

SCHED_OTHER Another scheduling policy.

The values of these constants are distinct.

The following shall be declared as functions and may also be defined as macros. Function prototypes shall be provided.

int sched_get_priority_max(int);

int sched_get_priority_min(int);

int sched_getparam(pid_t, struct sched_param *);

int sched_setscheduler(pid_t);

int sched_rr_get_interval(pid_t, struct timespec *);

int sched_setparam(pid_t, const struct sched_param *);

int sched_setscheduler(pid_t, int, const struct sched_param *);

int sched_yield(void);

Inclusion of the <sched.h> header may make visible all symbols from the <time.h> header.
APPLICATION USAGE

None.

RATIONALE

None.

FUTURE DIRECTIONS

None.

SEE ALSO

<time.h>

CHANGE HISTORY

First released in Issue 5. Included for alignment with the POSIX Realtime Extension.

Issue 6

The <sched.h> header is marked as part of the Process Scheduling option.

Sporadic server members are added to the sched_param structure, and the SCHED_SPORADIC scheduling policy is added for alignment with IEEE Std 1003.1d-1999.

IEEE PASC Interpretation 1003.1 #108 is applied, correcting the sched_param structure whose members sched_ss_repl_period and sched_ss_init_budget should be type struct timespec and not timespec.

Symbols from <time.h> may be made visible when <sched.h> is included.

NAME
search.h — search tables

SYNOPSIS
XSI
#include <search.h>

DESCRIPTION
The <search.h> header shall define the ENTRY type for structure entry which shall include the following members:

char *key
void *data

and shall define ACTION and VISIT as enumeration data types through type definitions as follows:

enum { FIND, ENTER } ACTION;
enum { preorder, postorder, endorder, leaf } VISIT;

The size_t type shall be defined as described in <sys/types.h>.

The following shall be declared as functions and may also be defined as macros. Function prototypes shall be provided.

int hcreate(size_t);
void hdestroy(void);
ENTRY *hsearch(ENTRY, ACTION);
void insque(void *, void *);
void *lfind(const void *, const void *, size_t *,
           size_t, int (*)(const void *, const void *));
void *lsearch(const void *, void *, size_t *,
              size_t, int (*)(const void *, const void *));
void remque(void *);
void *tdelete(const void *restrict, void **restrict,
              int(*)(const void *, const void *));
void *tfind(const void *, void *const *,
            int(*)(const void *, const void *));
void *tsearch(const void *, void **,
              int(*)(const void *, const void *));
void twalk(const void *,
           void (*)(const void *, VISIT, int ));

APPLICATION USAGE
None.

RATIONALE
None.

FUTURE DIRECTIONS
None.

SEE ALSO
<sys/types.h>, the System Interfaces volume of IEEE Std 1003.1-2001, hcreate(), insque(), lsearch(), remque(), tsearch()
**CHANGE HISTORY**

**First released in Issue 1. Derived from Issue 1 of the SVID.**

**Issue 6**

10689 The Open Group Corrigendum U021/6 is applied, updating the prototypes for `tdelete()` and `tsearch()`.

10690 The **restrict** keyword is added to the prototype for `tdelete()`.
NAME

semaphore.h — semaphores (REALTIME)

SYNOPSIS

#include <semaphore.h>

DESCRIPTION

The <semaphore.h> header shall define the sem_t type, used in performing semaphore operations. The semaphore may be implemented using a file descriptor, in which case applications are able to open up at least a total of {OPEN_MAX} files and semaphores. The symbol SEM_FAILED shall be defined (see sem_open()).

The following shall be declared as functions and may also be defined as macros. Function prototypes shall be provided.

```c
int sem_close(sem_t *);
int sem_destroy(sem_t *);
int sem_getvalue(sem_t *restrict, int *restrict);
int sem_init(sem_t *, int, unsigned);
sem_t *sem_open(const char *, int, ...);
int sem_post(sem_t *);
TMO int sem_timedwait(sem_t *restrict, const struct timespec *restrict);
int sem_trywait(sem_t *);
int sem_unlink(const char *);
int sem_wait(sem_t *);
```

Inclusion of the <semaphore.h> header may make visible symbols defined in the headers <fcntl.h> and <sys/types.h>.

APPLICATION USAGE

None.

RATIONALE

None.

FUTURE DIRECTIONS

None.

SEE ALSO

<fcntl.h>, <sys/types.h>, the System Interfaces volume of IEEE Std 1003.1-2001, sem_destroy(), sem_getvalue(), sem_init(), sem_open(), sem_post(), sem_timedwait(), sem_trywait(), sem_unlink(), sem_wait().

CHANGE HISTORY

First released in Issue 5. Included for alignment with the POSIX Realtime Extension.

Issue 6

The <semaphore.h> header is marked as part of the Semaphores option.

The Open Group Corrigendum U021/3 is applied, adding a description of SEM_FAILED.

The sem_timedwait() function is added for alignment with IEEE Std 1003.1d-1999.

The restrict keyword is added to the prototypes for sem_getvalue() and sem_timedwait().
NAME
setjmp.h — stack environment declarations

SYNOPSIS
#include <setjmp.h>

DESCRIPTION
Some of the functionality described on this reference page extends the ISO C standard.
Applications shall define the appropriate feature test macro (see the System Interfaces volume of
IEEE Std 1003.1-2001, Section 2.2, The Compilation Environment) to enable the visibility of these
symbols in this header.

The <setjmp.h> header shall define the array types jmp_buf and sigjmp_buf.
The following shall be declared as functions and may also be defined as macros. Function
prototypes shall be provided.

void longjmp(jmp_buf, int);
void siglongjmp(sigjmp_buf, int);
XSI _longjmp(jmp_buf, int);

The following may be declared as a function, or defined as a macro, or both. Function prototypes
shall be provided.

int setjmp(jmp_buf);
int sigsetjmp(sigjmp_buf, int);
XSI _setjmp(jmp_buf);

APPLICATION USAGE
None.

RATIONALE
None.

FUTURE DIRECTIONS
None.

SEE ALSO
The System Interfaces volume of IEEE Std 1003.1-2001, longjmp(), _longjmp(), setjmp(),
siglongjmp(), sigsetjmp()

CHANGE HISTORY
First released in Issue 1.

Issue 6
Extensions beyond the ISO C standard are marked.
NAME
signal.h — signals

SYNOPSIS
#include <signal.h>

DESCRIPTION
Some of the functionality described on this reference page extends the ISO C standard. Applications shall define the appropriate feature test macro (see the System Interfaces volume of IEEE Std 1003.1-2001, Section 2.2, The Compilation Environment) to enable the visibility of these symbols in this header.

The <signal.h> header shall define the following symbolic constants, each of which expands to a distinct constant expression of the type:

void (*)(int)
whose value matches no declarable function.

SIG_DFL Request for default signal handling.
SIG_ERR Return value from signal() in case of error.
SIG_HOLD Request that signal be held.
SIG_IGN Request that signal be ignored.

The following data types shall be defined through typedef:

sig_atomic_t Possibly volatile-qualified integer type of an object that can be accessed as an atomic entity, even in the presence of asynchronous interrupts.
sigset_t Integer or structure type of an object used to represent sets of signals.
pid_t As described in <sys/types.h>.

The <signal.h> header shall define the sigevent structure, which has at least the following members:

int sigev_notify Notification type.
int sigev_signo Signal number.
union sigval sigev_value Signal value.
void(*)(union sigval) sigev_notify_function Notification function.
(pthread_attr_t *) sigev_notify_attributes Notification attributes.

The following values of sigev_notify shall be defined:

SIGEV_NONE No asynchronous notification is delivered when the event of interest occurs.
SIGEV_SIGNAL A queued signal, with an application-defined value, is generated when the event of interest occurs.
SIGEV_THREAD A notification function is called to perform notification.

The signal union shall be defined as:

int sival_int Integer signal value.
void *sival_ptr Pointer signal value.

This header shall also declare the macros SIGRTMIN and SIGRTMAX, which evaluate to integer expressions, and specify a range of signal numbers that are reserved for application use and for which the realtime signal behavior specified in this volume of IEEE Std 1003.1-2001 is supported.
The signal numbers in this range do not overlap any of the signals specified in the following table.

The range SIGRTMIN through SIGRTMAX inclusive shall include at least \([\text{RTSIG\_MAX}]\) signal numbers.

It is implementation-defined whether realtime signal behavior is supported for other signals.

This header also declares the constants that are used to refer to the signals that occur in the system. Signals defined here begin with the letters SIG. Each of the signals have distinct positive integer values. The value 0 is reserved for use as the null signal (see \texttt{kill( )}). Additional implementation-defined signals may occur in the system.

The ISO C standard only requires the signal names SIGABRT, SIGFPE, SIGILL, SIGINT, SIGSEGV, and SIGTERM to be defined.

The following signals shall be supported on all implementations (default actions are explained below the table):

<table>
<thead>
<tr>
<th>Signal</th>
<th>Default Action</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SIGABRT</td>
<td>A</td>
<td>Process abort signal.</td>

<tr>
<td>SIGUSR2</td>
<td>T</td>
<td>User-defined signal 2.</td>
</tr>
<tr>
<td>SIGPOLL</td>
<td>T</td>
<td>Pollable event.</td>
</tr>
<tr>
<td>SIGPROF</td>
<td>T</td>
<td>Profiling timer expired.</td>
</tr>
<tr>
<td>SIGSYS</td>
<td>A</td>
<td>Bad system call.</td>
</tr>
<tr>
<td>SIGTRAP</td>
<td>A</td>
<td>Trace/breakpoint trap.</td>
</tr>
<tr>
<td>SIGURG</td>
<td>I</td>
<td>High bandwidth data is available at a socket.</td>
</tr>
<tr>
<td>SIGVTALRM</td>
<td>T</td>
<td>Virtual timer expired.</td>
</tr>
<tr>
<td>SIGCPU</td>
<td>A</td>
<td>CPU time limit exceeded.</td>
</tr>
<tr>
<td>SIGXFSZ</td>
<td>A</td>
<td>File size limit exceeded.</td>
</tr>
</tbody>
</table>

The default actions are as follows:

\(T\) Abnormal termination of the process. The process is terminated with all the consequences of \texttt{exit( )} except that the status made available to \texttt{wait( )} and \texttt{waitpid( )} indicates abnormal termination by the specified signal.
Abnormal termination of the process. Additionally, implementation-defined abnormal termination actions, such as creation of a core file, may occur. Ignore the signal. Stop the process. Continue the process, if it is stopped; otherwise, ignore the signal.

The header shall provide a declaration of `struct sigaction`, including at least the following members:

- `void (*sa_handler)(int)` Pointer to a signal-catching function or one of the macros `SIG_IGN` or `SIG_DFL`.
- `sigset_t sa_mask` Set of signals to be blocked during execution of the signal handling function.
- `int sa_flags` Special flags.
- `void (*sa_sigaction)(int, siginfo_t *, void *)` Pointer to a signal-catching function.

The storage occupied by `sa_handler` and `sa_sigaction` may overlap, and a conforming application shall not use both simultaneously.

The following shall be declared as constants:

- `SA_NOCLDSTOP` Do not generate SIGCHLD when children stop or stopped children continue.
- `SIG_BLOCK` The resulting set is the union of the current set and the signal set pointed to by the argument `set`.
- `SIG_UNBLOCK` The resulting set is the intersection of the current set and the complement of the signal set pointed to by the argument `set`.
- `SIG_SETMASK` The resulting set is the signal set pointed to by the argument `set`.
- `SA_ONSTACK` Causes signal delivery to occur on an alternate stack.
- `SA_RESETHAND` Causes signal dispositions to be set to SIG_DFL on entry to signal handlers.
- `SA_RESTART` Causes certain functions to become restartable.
- `SA_SIGINFO` Causes extra information to be passed to signal handlers at the time of receipt of a signal.
- `SA_NOCLDWAIT` Causes implementations not to create zombie processes on child death.
- `SA_NODEFER` Causes signal not to be automatically blocked on entry to signal handler.
- `SS_ONSTACK` Process is executing on an alternate signal stack.
- `SS_DISABLE` Alternate signal stack is disabled.
- `MINSIGSTKSZ` Minimum stack size for a signal handler.
- `SIGSTKSZ` Default size in bytes for the alternate signal stack.

The `ucontext_t` structure shall be defined through `typedef` as described in `<ucontext.h>`.

The `mcontext_t` type shall be defined through `typedef` as described in `<ucontext.h>`.
The `<signal.h>` header shall define the `stack_t` type as a structure that includes at least the following members:

- `void *ss_sp` Stack base or pointer.
- `size_t ss_size` Stack size.
- `int ss_flags` Flags.

The `<signal.h>` header shall define the `sigstack` structure that includes at least the following members:

- `int ss_onstack` Non-zero when signal stack is in use.
- `void *ss_sp` Signal stack pointer.

The `<signal.h>` header shall define the `siginfo_t` type as a structure that includes at least the following members:

- `int si_signo` Signal number.
- `int si_errno` If non-zero, an `errno` value associated with this signal, as defined in `<errno.h>`.
- `int si_code` Signal code.
- `pid_t si_pid` Sending process ID.
- `uid_t si_uid` Real user ID of sending process.
- `void *si_addr` Address of faulting instruction.
- `int si_status` Exit value or signal.
- `long si_band` Band event for SIGPOLL.
- `union sigval si_value` Signal value.

The macros specified in the `Code` column of the following table are defined for use as values of `si_code` that are signal-specific or non-signal-specific reasons why the signal was generated.
<table>

<td>Signal generated by arrival of a message on an empty message queue.</td>
</tr>
</tbody>
</table>

Implementations may support additional si_code values not included in this list, which may generate values included in this list under circumstances other than those described in this list, and may contain extensions or limitations that prevent some values from being generated. Implementations do not generate a different value from the ones described in this list for circumstances described in this list.
In addition, the following signal-specific information shall be available:

<table>
<thead>
<tr>
<th>Signal</th>
<th>Member</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>SIGILL</td>
<td>void * si_addr</td>
<td>Address of faulting instruction.</td>
</tr>
<tr>
<td>SIGFPE</td>
<td></td>
<td></td>
</tr>
<tr>
<td>SIGSEGV</td>
<td>void * si_addr</td>
<td>Address of faulting memory reference.</td>
</tr>
<tr>
<td>SIGBUS</td>
<td></td>
<td></td>
</tr>
<tr>
<td>SIGCHLD</td>
<td>pid_t si_pid</td>
<td>Child process ID.</td>
</tr>
<tr>
<td></td>
<td>int si_status</td>
<td>Exit value or signal.</td>
</tr>
<tr>
<td></td>
<td>uid_t si_uid</td>
<td>Real user ID of the process that sent the signal.</td>
</tr>
<tr>
<td>SIGPOLL</td>
<td>long si_band</td>
<td>Band event for POLL_IN, POLL_OUT, or POLL_MSG.</td>
</tr>
</tbody>
</table>

For some implementations, the value of si_addr may be inaccurate.

The following shall be declared as functions and may also be defined as macros:

```c
void (*bsd_signal(int, void (*)(int)))(int);
int kill(pid_t, int);
int killpg(pid_t, int);
int pthread_kill(pthread_t, int);
int pthread_sigmask(int, const sigset_t *, sigset_t *);
int raise(int);
int sigaction(int, const struct sigaction *restrict,
              struct sigaction *restrict);
int sigaddset(sigset_t *, int);
int sigaltstack(const stack_t *restrict, stack_t *restrict);
int sigdelset(sigset_t *, int);
int sigemptyset(sigset_t *);
int sigfillset(sigset_t *);
int sighold(int);
int sigignore(int);
int siginterrupt(int, int);
void (*sigset(int, void (*)(int)))(int);
int sigpause(int);
int sigpending(sigset_t *);
int sigprocmask(int, const sigset_t *restrict, sigset_t *restrict);
int sigqueue(pid_t, int, const union sigval);
int sigrelse(int);
int sigset(int, void (*)(int)));
int sigsuspend(const sigset_t *);
int sigtimedwait(const sigset_t *restrict, siginfo_t *restrict,
                 const struct timespec *restrict);
int sigwait(const sigset_t * restrict, int * restrict);
int sigwaitinfo(const sigset_t * restrict, siginfo_t * restrict);
```

Inclusion of the `<signal.h>` header may make visible all symbols from the `<time.h>` header.

Inclusion of the `<signal.h>` header may make visible all symbols from the `<time.h>` header.
APPLICATION USAGE
None.

RATIONALE
None.

FUTURE DIRECTIONS
None.

SEE ALSO

CHANGE HISTORY
First released in Issue 1.

Issue 5
The DESCRIPTION is updated for alignment with the POSIX Realtime Extension and the POSIX Threads Extension.

The default action for SIGURG is changed from i to iii. The function prototype for sigmask() is removed.

Issue 6
The Open Group Corrigendum U035/2 is applied. In the DESCRIPTION, the wording for abnormal termination is clarified.

The Open Group Corrigendum U028/8 is applied, correcting the prototype for the sigset() function.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

• The SIGCHLD, SIGCONT, SIGSTOP, SIGTSTP, SIGTTIN, and SIGTTOU signals are now mandated. This is also a FIPS requirement.

• The pid_t definition is mandated.

The RT markings are changed to RTS to denote that the semantics are part of the Realtime Signals Extension option.

The restrict keyword is added to the prototypes for sigaction(), sigaltstack(), sigprocmask(), sigtimedwait(), sigwait(), and sigwaitinfo().

IEEE PASC Interpretation 1003.1 #85 is applied, adding the statement that symbols from <time.h> may be made visible when <signal.h> is included.

Extensions beyond the ISO C standard are marked.

IEEE Std 1003.1-2001/Cor 1-2002, item XBD/TC1/D6/14 is applied, changing the descriptive text for members of struct sigaction.

IEEE Std 1003.1-2001/Cor 1-2002, item XBD/TC1/D6/15 is applied, correcting the definition of the sa_sigaction member of struct sigaction.
Name: spawn — spawn (ADVANCED REALTIME)

Synopsis

```c
#include <spawn.h>
```

Description

The `spawn.h` header shall define the `posix_spawnattr_t` and `posix_spawn_file_actions_t` types used in performing spawn operations.

The `spawn.h` header shall define the flags that may be set in a `posix_spawnattr_t` object using the `posix_spawnattr_setflags()` function:

```c
POSIX_SPAWN_RESETIDS
POSIX_SPAWN_SETGGROUP
POSIX_SPAWN_SETSCHEDPARAM
POSIX_SPAWN_SETSCHEDULER
POSIX_SPAWN_SETSIGDEF
POSIX_SPAWN_SETSIGMASK
```

The following shall be declared as functions and may also be defined as macros. Function prototypes shall be provided.

```c
int posix_spawn(pid_t *restrict, const char *restrict,
    const posix_spawn_file_actions_t *,
    const posix_spawnattr_t *restrict, char *const [restrict],
    char *const [restrict]);
int posix_spawn_file_actions_addclose(posix_spawn_file_actions_t *,
    int);
int posix_spawn_file_actions_adddup2(posix_spawn_file_actions_t *,
    int, int);
int posix_spawn_file_actions_addopen(posix_spawn_file_actions_t *restrict,
    int, int, int);
int posix_spawn_file_actions_destroy(posix_spawn_file_actions_t *);
int posix_spawn_file_actions_init(posix_spawn_file_actions_t *);
int posix_spawnattr_destroy(posix_spawnattr_t *);
int posix_spawnattr_getsigdefault(const posix_spawnattr_t *restrict,
    sigset_t *restrict);
int posix_spawnattr_getflags(const posix_spawnattr_t *restrict,
    short *restrict);
int posix_spawnattr_getpgroup(const posix_spawnattr_t *restrict,
    pid_t *restrict);
int posix_spawnattr_getschedparam(const posix_spawnattr_t *restrict,
    struct sched_param *restrict);
int posix_spawnattr_getschedpolicy(const posix_spawnattr_t *restrict,
    int *restrict);
int posix_spawnattr_getsigmask(const posix_spawnattr_t *restrict,
    sigset_t *restrict);
int posix_spawnattr_init(const posix_spawnattr_t *);
int posix_spawnattr_setsigdefault(posix_spawnattr_t *restrict,
    const sigset_t *restrict);
int posix_spawnattr_setflags(posix_spawnattr_t *, short);
int posix_spawnattr_setpgroup(posix_spawnattr_t *, pid_t);
```
int posix_spawnattr_setschedparam(posix_spawnattr_t *restrict, const struct sched_param *restrict);

int posix_spawnattr_setschedpolicy(posix_spawnattr_t *, int);

int posix_spawnp(pid_t *restrict, const char *restrict, const posix_spawn_file_actions_t *, const posix_spawnattr_t *restrict, char *const [restrict], char *const [restrict]);

Inclusion of the <spawn.h> header may make visible symbols defined in the <sched.h>, <signal.h>, and <sys/types.h> headers.

APPLICATION USAGE
None.

RATIONALE
None.

FUTURE DIRECTIONS
None.

posix_spawnattr_setsigmask(), and posix_spawnp().
NAME

`stdarg.h` — handle variable argument list

SYNOPSIS

```c
#include <stdarg.h>

void va_start(va_list ap, argN);
void va_copy(va_list dest, va_list src);
type va_arg(va_list ap, type);
void va_end(va_list ap);
```

DESCRIPTION

The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-2001 defers to the ISO C standard.

The `<stdarg.h>` header shall contain a set of macros which allows portable functions that accept variable argument lists to be written. Functions that have variable argument lists (such as `printf()`) but do not use these macros are inherently non-portable, as different systems use different argument-passing conventions.

The type `va_list` shall be defined for variables used to traverse the list.

The `va_start()` macro is invoked to initialize `ap` to the beginning of the list before any calls to `va_arg()`.

The `va_copy()` macro initializes `dest` as a copy of `src`, as if the `va_start()` macro had been applied to `dest` followed by the same sequence of uses of the `va_arg()` macro as had previously been used to reach the present state of `src`. Neither the `va_copy()` nor `va_start()` macro shall be invoked to reinitialize `dest` without an intervening invocation of the `va_end()` macro for the same `dest`.

The object `ap` may be passed as an argument to another function; if that function invokes the `va_arg()` macro with parameter `ap`, the value of `ap` in the calling function is unspecified and shall be passed to the `va_end()` macro prior to any further reference to `ap`. The parameter `argN` is the identifier of the rightmost parameter in the variable parameter list in the function definition (the one just before the `...`). If the parameter `argN` is declared with the `register` storage class, with a function type or array type, or with a type that is not compatible with the type that results after application of the default argument promotions, the behavior is undefined.

The `va_arg()` macro shall return the next argument in the list pointed to by `ap`. Each invocation of `va_arg()` modifies `ap` so that the values of successive arguments are returned in turn. The `type` parameter shall be a type name specified such that the type of a pointer to an object that has the specified type can be obtained simply by postfixing a `*` to type. If there is no actual next argument, or if `type` is not compatible with the type of the actual next argument (as promoted according to the default argument promotions), the behavior is undefined, except for the following cases:

- One type is a signed integer type, the other type is the corresponding unsigned integer type, and the value is representable in both types.
- One type is a pointer to `void` and the other is a pointer to a character type.
- Both types are pointers.

Different types can be mixed, but it is up to the routine to know what type of argument is expected.

The `va_end()` macro is used to clean up; it invalidates `ap` for use (unless `va_start()` or `va_copy()` is invoked again).
Each invocation of the `va_start()` and `va_copy()` macros shall be matched by a corresponding invocation of the `va_end()` macro in the same function.

Multiple traversals, each bracketed by `va_start()` ... `va_end()`, are possible.

**EXAMPLES**

This example is a possible implementation of `execl()`:

```c
#include <stdarg.h>
#define MAXARGS 31

/*
 * execl is called by
 * execl(file, arg1, arg2, ..., (char *)0);
 */

int execl(const char *file, const char *args, ...)
{
    va_list ap;
    char *array[MAXARGS + 1];
    int argno = 0;

    va_start(ap, args);
    while (args != 0 && argno < MAXARGS)
    {
        array[argno++] = args;
        args = va_arg(ap, const char *);
    }
    array[argno] = (char *)0;
    va_end(ap);
    return execv(file, array);
}
```

**APPLICATION USAGE**

It is up to the calling routine to communicate to the called routine how many arguments there are, since it is not always possible for the called routine to determine this in any other way. For example, `execl()` is passed a null pointer to signal the end of the list. The `printf()` function can tell how many arguments are there by the `format` argument.

**RATIONALE**

None.

**FUTURE DIRECTIONS**

**CHANGE HISTORY**

First released in Issue 4. Derived from the ANSI C standard.

**Issue 6**

This reference page is updated to align with the ISO/IEC 9899: 1999 standard.
NAME
stdbool.h — boolean type and values

SYNOPSIS
#include <stdbool.h>

DESCRIPTION
The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-2001 defers to the ISO C standard.

The <stdbool.h> header shall define the following macros:

- bool Expands to _Bool.
- true Expands to the integer constant 1.
- false Expands to the integer constant 0.
- __bool_true_false_are_defined Expands to the integer constant 1.

An application may undefine and then possibly redefine the macros bool, true, and false.

APPLICATION USAGE
None.

RATIONALE
None.

FUTURE DIRECTIONS
The ability to undefine and redefine the macros bool, true, and false is an obsolescent feature and may be withdrawn in a future version.

SEE ALSO
None.

CHANGE HISTORY
NAME
stddef.h — standard type definitions

SYNOPSIS
#include <stddef.h>

DESCRIPTION
The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-2001 defers to the ISO C standard.

The <stddef.h> header shall define the following macros:

NULL Null pointer constant.
offsetof(type, member-designator) Integer constant expression of type size_t, the value of which is the offset in bytes to the structure member (member-designator), from the beginning of its structure (type).

The <stddef.h> header shall define the following types:

ptrdiff_t Signed integer type of the result of subtracting two pointers.
wchar_t Integer type whose range of values can represent distinct wide-character codes for all members of the largest character set specified among the locales supported by the compilation environment: the null character has the code value 0 and each member of the portable character set has a code value equal to its value when used as the lone character in an integer character constant.
size_t Unsigned integer type of the result of the sizeof operator.

The implementation shall support one or more programming environments in which the widths of ptrdiff_t, size_t, and wchar_t are no greater than the width of type long. The names of these programming environments can be obtained using the confstr() function or the getconf utility.

APPLICATION USAGE
None.

RATIONALE
None.

FUTURE DIRECTIONS
None.

CHANGE HISTORY
First released in Issue 4. Derived from the ANSI C standard.
NAME
stdlib.h — integer types

SYNOPSIS
#include <stdint.h>

DESCRIPTION

Some of the functionality described on this reference page extends the ISO C standard.
Applications shall define the appropriate feature test macro (see the System Interfaces volume of
IEEE Std 1003.1-2001, Section 2.2, The Compilation Environment) to enable the visibility of these
symbols in this header.

The <stdint.h> header shall declare sets of integer types having specified widths, and shall
define corresponding sets of macros. It shall also define macros that specify limits of integer
types corresponding to types defined in other standard headers.

Note: The “width” of an integer type is the number of bits used to store its value in a pure binary
system; the actual type may use more bits than that (for example, a 28-bit type could be stored
in 32 bits of actual storage). An N-bit signed type has values in the range \(-2^{N-1}\) or \(1-2^{N-1}\) to
\(2^{N-1}-1\), while an N-bit unsigned type has values in the range 0 to \(2^N-1\).

Types are defined in the following categories:

- Integer types having certain exact widths
- Integer types having at least certain specified widths
- Fastest integer types having at least certain specified widths
- Integer types wide enough to hold pointers to objects
- Integer types having greatest width

(Some of these types may denote the same type.)

Corresponding macros specify limits of the declared types and construct suitable constants.

For each type described herein that the implementation provides, the <stdint.h> header shall
declare that typedef name and define the associated macros. Conversely, for each type described
herein that the implementation does not provide, the <stdint.h> header shall not declare that
typedef name, nor shall it define the associated macros. An implementation shall provide those
types described as required, but need not provide any of the others (described as optional).

Integer Types

When typedef names differing only in the absence or presence of the initial \(u\) are defined, they
shall denote corresponding signed and unsigned types as described in the ISO/IEC 9899: 1999
standard, Section 6.2.5; an implementation providing one of these corresponding types shall also
provide the other.

In the following descriptions, the symbol \(N\) represents an unsigned decimal integer with no
leading zeros (for example, 8 or 24, but not 04 or 048).

- Exact-width integer types

  The typedef name int\(N\)_t designates a signed integer type with width \(N\), no padding bits,
  and a two's-complement representation. Thus, int8_t denotes a signed integer type with a
  width of exactly 8 bits.

  The typedef name uint\(N\)_t designates an unsigned integer type with width \(N\). Thus,
  uint24_t denotes an unsigned integer type with a width of exactly 24 bits.
The following types are required:

```c
int8_t
int16_t
int32_t
uint8_t
uint16_t
uint32_t
```

If an implementation provides integer types with width 64 that meet these requirements, then the following types are required:

```c
int64_t
uint64_t
```

In particular, this will be the case if any of the following are true:

- The implementation supports the `_POSIX_V6_ILP32_OFFBIG` programming environment and the application is being built in the `_POSIX_V6_ILP32_OFFBIG` programming environment (see the Shell and Utilities volume of IEEE Std 1003.1-2001, c99, Programming Environments).
- The implementation supports the `_POSIX_V6_LP64_OFF64` programming environment and the application is being built in the `_POSIX_V6_LP64_OFF64` programming environment.
- The implementation supports the `_POSIX_V6_LPBIG_OFFBIG` programming environment and the application is being built in the `_POSIX_V6_LPBIG_OFFBIG` programming environment.

All other types of this form are optional.

- Minimum-width integer types

  The `typedef` name `int_leastN_t` designates a signed integer type with a width of at least \( N \), such that no signed integer type with lesser size has at least the specified width. Thus, `int_least32_t` denotes a signed integer type with a width of at least 32 bits.

  The `typedef` name `uint_leastN_t` designates an unsigned integer type with a width of at least \( N \), such that no unsigned integer type with lesser size has at least the specified width. Thus, `uint_least16_t` denotes an unsigned integer type with a width of at least 16 bits.

  The following types are required:

  ```c
  int_least8_t
  int_least16_t
  int_least32_t
  int_least64_t
  uint_least8_t
  uint_least16_t
  uint_least32_t
  uint_least64_t
  ```

  All other types of this form are optional.

- Fastest minimum-width integer types

  Each of the following types designates an integer type that is usually fastest to operate with among all integer types that have at least the specified width.
The designated type is not guaranteed to be fastest for all purposes; if the implementation has no clear grounds for choosing one type over another, it will simply pick some integer type satisfying the signedness and width requirements.

The \texttt{typedef} name \texttt{int\_fastN\_t} designates the fastest signed integer type with a width of at least \( N \). The \texttt{typedef} name \texttt{uint\_fastN\_t} designates the fastest unsigned integer type with a width of at least \( N \).

The following types are required:

\begin{verbatim}
int\_fast8\_t
int\_fast16\_t
int\_fast32\_t
int\_fast64\_t
uint\_fast8\_t
uint\_fast16\_t
uint\_fast32\_t
uint\_fast64\_t
\end{verbatim}

All other types of this form are optional.

- Integer types capable of holding object pointers

  The following type designates a signed integer type with the property that any valid pointer to \texttt{void} can be converted to this type, then converted back to a pointer to \texttt{void}, and the result will compare equal to the original pointer:

  \begin{verbatim}
  intptr\_t
  \end{verbatim}

  The following type designates an unsigned integer type with the property that any valid pointer to \texttt{void} can be converted to this type, then converted back to a pointer to \texttt{void}, and the result will compare equal to the original pointer:

  \begin{verbatim}
  uintptr\_t
  \end{verbatim}

  On XSI-conformant systems, the \texttt{intptr\_t} and \texttt{uintptr\_t} types are required; otherwise, they are optional.

- Greatest-width integer types

  The following type designates a signed integer type capable of representing any value of any signed integer type:

  \begin{verbatim}
  intmax\_t
  \end{verbatim}

  The following type designates an unsigned integer type capable of representing any value of any unsigned integer type:

  \begin{verbatim}
  uintmax\_t
  \end{verbatim}

  These types are required.

\textbf{Note:} Applications can test for optional types by using the corresponding limit macro from \texttt{Limits of Specified-Width Integer Types} (on page 319).
Limits of Specified-Width Integer Types

The following macros specify the minimum and maximum limits of the types declared in the `<stdint.h>` header. Each macro name corresponds to a similar type name in *Integer Types* (on page 316).

Each instance of any defined macro shall be replaced by a constant expression suitable for use in `#if` preprocessing directives, and this expression shall have the same type as would an expression that is an object of the corresponding type converted according to the integer promotions. Its implementation-defined value shall be equal to or greater in magnitude (absolute value) than the corresponding value given below, with the same sign, except where stated to be exactly the given value.

- Limits of exact-width integer types
  - Minimum values of exact-width signed integer types:
    ```c
    {INT_MIN} Exactly -(2^{N-1})
    ```
  - Maximum values of exact-width signed integer types:
    ```c
    {INT_MAX} Exactly 2^{N-1} - 1
    ```
  - Maximum values of exact-width unsigned integer types:
    ```c
    {UINT_MAX} Exactly 2^N - 1
    ```

- Limits of minimum-width integer types
  - Minimum values of minimum-width signed integer types:
    ```c
    {INT_LEASTN_MIN} -(2^{N-1} - 1)
    ```
  - Maximum values of minimum-width signed integer types:
    ```c
    {INT_LEASTN_MAX} 2^{N-1} - 1
    ```
  - Maximum values of minimum-width unsigned integer types:
    ```c
    {UINT_LEASTN_MAX} 2^N - 1
    ```

- Limits of fastest minimum-width integer types
  - Minimum values of fastest minimum-width signed integer types:
    ```c
    {INT_FASTN_MIN} -(2^{N-1} - 1)
    ```
  - Maximum values of fastest minimum-width signed integer types:
    ```c
    {INT_FASTN_MAX} 2^{N-1} - 1
    ```
  - Maximum values of fastest minimum-width unsigned integer types:
    ```c
    {UINT_FASTN_MAX} 2^N - 1
    ```

- Limits of integer types capable of holding object pointers
  - Minimum value of pointer-holding signed integer type:
    ```c
    {INTPTR_MIN} -(2^{15} - 1)
    ```
  - Maximum value of pointer-holding signed integer type:
    ```c
    {INTPTR_MAX} 2^{15} - 1
    ```
  - Maximum value of pointer-holding unsigned integer type:
11445 \{UINTPTR_MAX\} \qquad 2^{16} -1
11446
11447 • Limits of greatest-width integer types
11448
11449 — Minimum value of greatest-width signed integer type:
11450 \{INTMAX_MIN\} -(2^{63} -1)
11451
11452 — Maximum value of greatest-width signed integer type:
11453 \{INTMAX_MAX\} \quad 2^{63} -1
11454
11455 — Maximum value of greatest-width unsigned integer type:
11456 \{UINTMAX_MAX\} \quad 2^{64} -1
11457
11458 Limits of Other Integer Types
11459 The following macros specify the minimum and maximum limits of integer types corresponding
11460 to types defined in other standard headers.
11461 Each instance of these macros shall be replaced by a constant expression suitable for use in \#if
11462 preprocessing directives, and this expression shall have the same type as would an expression
11463 that is an object of the corresponding type converted according to the integer promotions. Its
11464 implementation-defined value shall be equal to or greater in magnitude (absolute value) than
11465 the corresponding value given below, with the same sign.
11466
11467 • Limits of ptrdiff_t:
11468 \{PTRDIFF_MIN\} \quad -65 535
11469 \{PTRDIFF_MAX\} \quad +65 535
11470
11471 • Limits of sig_atomic_t:
11472 \{SIG_ATOMIC_MIN\} \quad See below.
11473 \{SIG_ATOMIC_MAX\} \quad See below.
11474
11475 • Limit of size_t:
11476 \{SIZE_MAX\} \quad 65 535
11477
11478 • Limits of wchar_t:
11479 \{WCHAR_MIN\} \quad See below.
11480 \{WCHAR_MAX\} \quad See below.
11481
11482 • Limits of wint_t:
11483 \{WINT_MIN\} \quad See below.
11484 \{WINT_MAX\} \quad See below.
11485
11486 If sig_atomic_t (see the \texttt{<signal.h>} header) is defined as a signed integer type, the value of
11487 \{SIG_ATOMIC_MIN\} shall be no greater than \(-127\) and the value of \{SIG_ATOMIC_MAX\} shall
11488 be no less than 127; otherwise, sig_atomic_t shall be defined as an unsigned integer type, and the
11489 value of \{SIG_ATOMIC_MIN\} shall be 0 and the value of \{SIG_ATOMIC_MAX\} shall be no less
11490 than 255.
11491
11492 If wchar_t (see the \texttt{<stddef.h>} header) is defined as a signed integer type, the value of
11493 \{WCHAR_MIN\} shall be no greater than \(-127\) and the value of \{WCHAR_MAX\} shall be no less
11494 than 127; otherwise, wchar_t shall be defined as an unsigned integer type, and the value of
11495 \{WCHAR_MIN\} shall be 0 and the value of \{WCHAR_MAX\} shall be no less than 255.
If \texttt{wint_t} (see the \texttt{<wchar.h>} header) is defined as a signed integer type, the value of \{WINT_MIN\} shall be no greater than \(-32767\) and the value of \{WINT_MAX\} shall be no less than 32767; otherwise, \texttt{wint_t} shall be defined as an unsigned integer type, and the value of \{WINT_MIN\} shall be 0 and the value of \{WINT_MAX\} shall be no less than 65535.

**Macros for Integer Constant Expressions**

The following macros expand to integer constant expressions suitable for initializing objects that have integer types corresponding to types defined in the \texttt{<stdint.h>} header. Each macro name corresponds to a similar type name listed under Minimum-width integer types and Greatest-width integer types.

Each invocation of one of these macros shall expand to an integer constant expression suitable for use in \#if preprocessing directives. The type of the expression shall have the same type as would an expression that is an object of the corresponding type converted according to the integer promotions. The value of the expression shall be that of the argument.

The argument in any instance of these macros shall be a decimal, octal, or hexadecimal constant with a value that does not exceed the limits for the corresponding type.

- Macros for minimum-width integer constant expressions

  The macro \texttt{INTN_C(value)} shall expand to an integer constant expression corresponding to the type \texttt{int_leastN_t}. The macro \texttt{UINTN_C(value)} shall expand to an integer constant expression corresponding to the type \texttt{uint_leastN_t}. For example, if \texttt{uint_least64_t} is a name for the type \texttt{unsigned long long}, then \texttt{UINT64_C(0x123)} might expand to the integer constant \(0x123ULL\).

- Macros for greatest-width integer constant expressions

  The following macro expands to an integer constant expression having the value specified by its argument and the type \texttt{intmax_t}:

  \[
  \texttt{INTMAX_C(value)}
  \]

  The following macro expands to an integer constant expression having the value specified by its argument and the type \texttt{uintmax_t}:

  \[
  \texttt{UINTMAX_C(value)}
  \]

**APPLICATION USAGE**

None.

**RATIONALE**

The \texttt{<stdint.h>} header is a subset of the \texttt{<inttypes.h>} header more suitable for use in freestanding environments, which might not support the formatted I/O functions. In some environments, if the formatted conversion support is not wanted, using this header instead of the \texttt{<inttypes.h>} header avoids defining such a large number of macros.

As a consequence of adding \texttt{int8_t}, the following are true:

- A byte is exactly 8 bits.
- \{CHAR_BIT\} has the value 8, \{SCHAR_MAX\} has the value 127, \{SCHAR_MIN\} has the value \(-127\) or \(-128\), and \{UCHAR_MAX\} has the value 255.

**FUTURE DIRECTIONS**

\texttt{typedef} names beginning with \texttt{int} or \texttt{uint} and ending with \_t may be added to the types defined in the \texttt{<stdint.h>} header. Macro names beginning with \texttt{INT} or \texttt{UINT} and ending with \_MAX, \_MIN, or \_C may be added to the macros defined in the \texttt{<stdint.h>} header.
SEE ALSO

#include <inttypes.h>, <signal.h>, <stddef.h>, <wchar.h>

CHANGE HISTORY

NAME
stdio.h — standard buffered input/output

SYNOPSIS
#include <stdio.h>

DESCRIPTION
Some of the functionality described on this reference page extends the ISO C standard. Applications shall define the appropriate feature test macro (see the System Interfaces volume of IEEE Std 1003.1-2001, Section 2.2, The Compilation Environment) to enable the visibility of these symbols in this header.

The <stdio.h> header shall define the following macros as positive integer constant expressions:

BUFSIZ Size of <stdio.h> buffers.
_IOFBF Input/output fully buffered.
_IOLBF Input/output line buffered.
_IONBF Input/output unbuffered.

The following macros shall be defined as positive integer constant expressions which denote implementation limits:

FILENAME_MAX Maximum size in bytes of the longest filename string that the implementation guarantees can be opened.
FOPEN_MAX Number of streams which the implementation guarantees can be open simultaneously. The value is at least eight.
TMP_MAX Minimum number of unique filenames generated by tmpnam().

On XSI-conformant systems, the value of {TMP_MAX} is at least 10 000.

The following macro name shall be defined as a negative integer constant expression:
EOF End-of-file return value.

The following macro name shall be defined as a null pointer constant:
NULL Null pointer.

The following macro name shall be defined as a string constant:
P_tmpdir Default directory prefix for tmpnam().

The following shall be defined as expressions of type “pointer to FILE” that point to the FILE objects associated, respectively, with the standard error, input, and output streams:
stderr Standard error output stream.
stdin Standard input stream.
`stdout` Standard output stream.

The following data types shall be defined through `typedef`:

- **FILE** A structure containing information about a file.
- **fpos_t** A non-array type containing all information needed to specify uniquely every position within a file.
- **va_list** As described in `<stdarg.h>`.
- **size_t** As described in `<stddef.h>`.

The following shall be declared as functions and may also be defined as macros. Function prototypes shall be provided.

```c
void clearerr(FILE *);
char *ctermid(char *);
int fclose(FILE *);
FILE *fdopen(int, const char *);
int feof(FILE *);
int ferror(FILE *);
int fflush(FILE *);
int fgetc(FILE *);
int fgetpos(FILE *restrict, fpos_t *restrict);
char *fgets(char *restrict, int, FILE *restrict);
FILE *fileno(FILE *);
int flockfile(FILE *);
FILE *fopen(const char *restrict, const char *restrict);
int fprintf(FILE *restrict, const char *restrict, ...);
int fputc(int, FILE *);
int fputs(const char *restrict, FILE *restrict);
size_t fread(void *restrict, size_t, size_t, FILE *restrict);
FILE *freopen(const char *restrict, const char *restrict, FILE *restrict);
int fscanf(FILE *restrict, const char *restrict, ...);
int fseek(FILE *, long, int);
int fseeko(FILE *, off_t, int);
int fsetpos(FILE *, const fpos_t *);
long ftell(FILE *);
off_t ftello(FILE *);
FILE *ftrylockfile(FILE *);
void funlockfile(FILE *);
size_t fwrite(const void *restrict, size_t, size_t, FILE *restrict);
int getc(FILE *);
int getc_unlocked(FILE *);
int getchar(void);
int getc_unlocked(void);
char *gets(char *);
pclose(FILE *);
void perror(const char *);
FILE *popen(const char *, const char *);
int printf(const char *restrict, ...);
int putc(int, FILE *);
int putchar(int);
FILE *popen(const char *, const char *);
```
Inclusion of the `<stdio.h>` header may also make visible all symbols from `<stdlib.h>`.

**APPLICATION USAGE**

None.

**RATIONALE**

None.

**FUTURE DIRECTIONS**

None.

**CHANGE HISTORY**

First released in Issue 1. Derived from Issue 1 of the SVID.

**Issue 5**

The DESCRIPTION is updated for alignment with the POSIX Threads Extension.

Large File System extensions are added.

The constant L_cuserid and the external variables `optarg`, `opterr`, `optind`, and `optopt` are marked as extensions and LEGACY.

The `cuserid()` and `getopt()` functions are marked LEGACY.
The constant _L_cuserid and the external variables optarg, opterr, optind, and optopt are removed as they were previously marked LEGACY.

The cuserid(), getopt(), and getw() functions are removed as they were previously marked LEGACY.

Several functions are marked as part of the Thread-Safe Functions option.

This reference page is updated to align with the ISO/IEC 9899:1999 standard. Note that the description of the fpos_t type is now explicitly updated to exclude array types.

Extensions beyond the ISO C standard are marked.
NAME
stdlib.h — standard library definitions

SYNOPSIS
#include <stdlib.h>

DESCRIPTION
Some of the functionality described on this reference page extends the ISO C standard. Applications shall define the appropriate feature test macro (see the System Interfaces volume of IEEE Std 1003.1-2001, Section 2.2, The Compilation Environment) to enable the visibility of these symbols in this header.

The <stdlib.h> header shall define the following macros:

- **EXIT_FAILURE** Unsuccessful termination for exit(); evaluates to a non-zero value.
- **EXIT_SUCCESS** Successful termination for exit(); evaluates to 0.
- **NULL** Null pointer.
- **{RAND_MAX}** Maximum value returned by rand(); at least 32 767.
- **{MB_CUR_MAX}** Integer expression whose value is the maximum number of bytes in a character specified by the current locale.

The following data types shall be defined through typedef:

- **div_t** Structure type returned by the div() function.
- **ldiv_t** Structure type returned by the ldiv() function.
- **lldiv_t** Structure type returned by the lldiv() function.
- **size_t** As described in <stddef.h>.
- **wchar_t** As described in <stddef.h>.

In addition, the following symbolic names and macros shall be defined as in <sys/wait.h>, for use in decoding the return value from system():

- **WNOHANG**
- **WUNTRACED**
- **WEXITSTATUS**
- **WFEXITED**
- **WIFSIGNALED**
- **WIFSTOPPED**
- **WSTOPSIG**
- **WTERMSIG**

The following shall be declared as functions and may also be defined as macros. Function prototypes shall be provided.

- **void _Exit(int);**
- **long a64l(const char *);**
- **void abort(void);**
- **int abs(int);**
- **int atexit(void (*)(void));**
- **double atof(const char *);**
- **int atoi(const char *);**
- **long atol(const char *);**

11796 CHANGE HISTORY
11797 First released in Issue 3.
11798 Issue 5
11799 The DESCRIPTION is updated for alignment with the POSIX Threads Extension.
11800 The ttyslot() and valloc() functions are marked LEGACY.
11801 The type of the third argument to initstate() is changed from int to size_t. The type of the return
11802 value from setstate() is changed from char to char *, and the type of the first argument is
11803 changed from char * to const char *.
11804 Issue 6
11805 The Open Group Corrigendum U021/1 is applied, correcting the prototype for realpath() to be
11806 consistent with the reference page.
11807 The Open Group Corrigendum U028/13 is applied, correcting the prototype for putenv() to be
11808 consistent with the reference page.
11809 The rand_r() function is marked as part of the Thread-Safe Functions option.
11810 Function prototypes for setenv() and unsetenv() are added.
11811 The posix_memalign() function is added for alignment with IEEE Std 1003.1d-1999.
11812 This reference page is updated to align with the ISO/IEC 9899:1999 standard.
The `ecvt()`, `fcvt()`, `gcvt()`, and `mktemp()` functions are marked LEGACY.

The `ttyslot()` and `valloc()` functions are removed as they were previously marked LEGACY.

Extensions beyond the ISO C standard are marked.
NAME

string.h — string operations

SYNOPSIS

#include <string.h>

DESCRIPTION

Some of the functionality described on this reference page extends the ISO C standard. Applications shall define the appropriate feature test macro (see the System Interfaces volume of IEEE Std 1003.1-2001, Section 2.2, The Compilation Environment) to enable the visibility of these symbols in this header.

The <string.h> header shall define the following:

NULL Null pointer constant.

size_t As described in <stddef.h>.

The following shall be declared as functions and may also be defined as macros. Function prototypes shall be provided.

void *memccpy(void *restrict, const void *restrict, int, size_t);
void *memchr(const void *, int, size_t);
int memcmp(const void *, const void *, size_t);
void *memcpy(void *restrict, const void *restrict, size_t);
void *memmove(void *, const void *, size_t);
void *memset(void *, int, size_t);
char *strcat(char *restrict, const char *restrict);
char *strchr(const char *, int);
int strcmp(const char *, const char *);
int strcoll(const char *, const char *);
char *strcpy(char *restrict, const char *restrict);
size_t strcspn(const char *, const char *);
char *strdup(const char *);
char *strerror(int);
size_t strlen(const char *);
char *strncat(char *restrict, const char *restrict, size_t);
int strncmp(const char *, const char *, size_t);
char *strncpy(char *restrict, const char *restrict, size_t);
char *strpbrk(const char *, const char *);
char *strrchr(const char *, int);
size_t strspn(const char *, const char *);
char *strstr(const char *, const char *);
char *strtok(char *restrict, const char *restrict);
char *strtok_r(char *, const char *, char **);
size_t strxfrm(char *restrict, const char *restrict, size_t);

Inclusion of the <string.h> header may also make visible all symbols from <stddef.h>.
APPLICATION USAGE
None.

RATIONALE
None.

FUTURE DIRECTIONS
None.

strcpy(), strcspn(), strdup(), strstr(), strerror(), strlen(), strltrim(), strncat(), strncmp(), strncpy(), strpbrk(), strrev(),
strspn(), strstr(), strstr(), strxfrm()

CHANGE HISTORY
First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 5
The DESCRIPTION is updated for alignment with the POSIX Threads Extension.

Issue 6
The strtok_r() function is marked as part of the Thread-Safe Functions option.
This reference page is updated to align with the ISO/IEC 9899:1999 standard.
The strerror_r() function is added in response to IEEE PASC Interpretation 1003.1c #39.
NAME
strings.h — string operations

SYNOPSIS
XSI
#include <strings.h>

DESCRIPTION
The following shall be declared as functions and may also be defined as macros. Function prototypes shall be provided.

int bcmp(const void *, const void *, size_t); (LEGACY)
void bcopy(const void *, void *, size_t); (LEGACY)
void bzero(void *, size_t); (LEGACY)
int ffs(int);
char *index(const char *, int); (LEGACY)
char *rindex(const char *, int); (LEGACY)
int strcasecmp(const char *, const char *);
int strncasecmp(const char *, const char *, size_t);

The size_t type shall be defined through typedef as described in <stddef.h>.

APPLICATION USAGE
None.

CHANGE HISTORY
First released in Issue 4, Version 2.

Issue 6
The Open Group Corrigendum U021/2 is applied, correcting the prototype for index() to be consistent with the reference page.
The bcmp(), bcopy(), bzero(), index(), and rindex() functions are marked LEGACY.
NAME
stropts.h — STREAMS interface (STREAMS)

SYNOPSIS
XSR
#include <stropts.h>

DESCRIPTION
The <stropts.h> header shall define the bandinfo structure that includes at least the following members:

unsigned char bi_pri    Priority band.
int      bi_flag     Flushing type.

The <stropts.h> header shall define the strpeek structure that includes at least the following members:

struct strbuf ctlbuf    The control portion of the message.
struct strbuf databuf    The data portion of the message.
t_uscalar_t flags        RS_HIPRI or 0.

The <stropts.h> header shall define the strbuf structure that includes at least the following members:

int maxlen    Maximum buffer length.
int len       Length of data.
char *buf     Pointer to buffer.

The <stropts.h> header shall define the strfdinsert structure that includes at least the following members:

struct strbuf ctlbuf    The control portion of the message.
struct strbuf databuf    The data portion of the message.
t_uscalar_t flags        RS_HIPRI or 0.
int fildes    File descriptor of the other STREAM.
int offset    Relative location of the stored value.

The <stropts.h> header shall define the strioctl structure that includes at least the following members:

int ic_cmd    ioctl() command.
int ic_timout Timeout for response.
int ic_len    Length of data.
char *ic_dp   Pointer to buffer.

The <stropts.h> header shall define the strrecvfd structure that includes at least the following members:

int fda        Received file descriptor.
uid_t uid      UID of sender.
gid_t gid      GID of sender.

The uid_t and gid_t types shall be defined through typedef as described in <sys/types.h>.

The <stropts.h> header shall define the t_scalar_t and t_uscalar_t types, respectively, as signed and unsigned opaque types of equal length of at least 32 bits.

The <stropts.h> header shall define the str_list structure that includes at least the following members:
The `<stropts.h>` header shall define the `str_mlist` structure that includes at least the following member:

```c
char  l_name[FMNAMESZ+1]  A STREAMS module name.
```

At least the following macros shall be defined for use as the `request` argument to `ioctl()`:

- `I_PUSH` Push a STREAMS module.
- `I_POP` Pop a STREAMS module.
- `I_LOOK` Get the top module name.
- `I_FLUSH` Flush a STREAM.
- `I_FLUSHBAND` Flush one band of a STREAM.
- `I_SETSIG` Ask for notification signals.
- `I_GETSIG` Retrieve current notification signals.
- `I_FIND` Look for a STREAMS module.
- `I_PEEK` Peek at the top message on a STREAM.
- `I_SRDOPT` Set the read mode.
- `I_GRDOPT` Get the read mode.
- `I_NREAD` Size the top message.
- `I_FDINSERT` Send implementation-defined information about another STREAM.
- `I_STR` Send a STREAMS `ioctl()`.
- `I_SWROPT` Set the write mode.
- `I_GWROPT` Get the write mode.
- `I_SENDFD` Pass a file descriptor through a STREAMS pipe.
- `I_RECVFD` Get a file descriptor sent via `I_SENDFD`.
- `I_LIST` Get all the module names on a STREAM.
- `I_ATMARK` Is the top message “marked”?
- `I_CKBAND` See if any messages exist in a band.
- `I_GETBAND` Get the band of the top message on a STREAM.
- `I_CANPUT` Is a band writable?
- `I_SETCLTIME` Set close time delay.
- `I_GETCLTIME` Get close time delay.
- `I_LINK` Connect two STREAMs.
- `I_UNLINK` Disconnect two STREAMs.
- `I_PLINK` Persistently connect two STREAMs.
- `I_PUNLINK` Dismantle a persistent STREAMS link.
At least the following macros shall be defined for use with I_LOOK:

FMNAMESZ The minimum size in bytes of the buffer referred to by the arg argument.

At least the following macros shall be defined for use with I_FLUSH:

FLUSHR Flush read queues.
FLUSHW Flush write queues.
FLUSHRW Flush read and write queues.

At least the following macros shall be defined for use with I_SETSIG:

S_RDNORM A normal (priority band set to 0) message has arrived at the head of a STREAM head read queue.
S_RDBAND A message with a non-zero priority band has arrived at the head of a STREAM head read queue.
S_INPUT A message, other than a high-priority message, has arrived at the head of a STREAM head read queue.
S_HIPRI A high-priority message is present on a STREAM head read queue.
S_OUTPUT The write queue for normal data (priority band 0) just below the STREAM head is no longer full. This notifies the process that there is room on the queue for sending (or writing) normal data downstream.
S_WRNORM Equivalent to S_OUTPUT.
S_WRBAND The write queue for a non-zero priority band just below the STREAM head is no longer full.
S_MSG A STREAMS signal message that contains the SIGPOLL signal reaches the front of the STREAM head read queue.
S_ERROR Notification of an error condition reaches the STREAM head.
S_HANGUP Notification of a hangup reaches the STREAM head.
S_BANDURG When used in conjunction with S_RDBAND, SIGURG is generated instead of SIGPOLL when a priority message reaches the front of the STREAM head read queue.

At least the following macros shall be defined for use with I_PEEK:

RS_HIPRI Only look for high-priority messages.

At least the following macros shall be defined for use with I_SRDOPT:

RNORM Byte-STREAM mode, the default.
RMSGD Message-discard mode.
RMSGN Message-non-discard mode.
RPROTNORM Fail read() with [EBADMSG] if a message containing a control part is at the front of the STREAM head read queue.
RPROTDAT Deliver the control part of a message as data when a process issues a read().
RPROTDIS Discard the control part of a message, delivering any data part, when a process issues a read().
At least the following macros shall be defined for use with I_SWOPT:

- **SNDZERO**: Send a zero-length message downstream when a `write()` of 0 bytes occurs.

At least the following macros shall be defined for use with I_ATMARK:

- **ANYMARK**: Check if the message is marked.
- **LASTMARK**: Check if the message is the last one marked on the queue.

At least the following macros shall be defined for use with I_UNLINK:

- **MUXID_ALL**: Unlink all STREAMs linked to the STREAM associated with `fildes`.

The following macros shall be defined for `getmsg()`, `getpmsg()`, `putmsg()`, and `putpmsg()`:

- **MSG_ANY**: Receive any message.
- **MSG_BAND**: Receive message from specified band.
- **MSG_HIPRI**: Send/receive high-priority message.
- **MORECTL**: More control information is left in message.
- **MOREDATA**: More data is left in message.

The `<stropts.h>` header may make visible all of the symbols from `<unistd.h>`.

The following shall be declared as functions and may also be defined as macros. Function prototypes shall be provided.

```c
int isastream(int);
int getmsg(int, struct strbuf *restrict, struct strbuf *restrict, int *restrict);
int getpmsg(int, struct strbuf *restrict, struct strbuf *restrict, int *restrict);
int ioctl(int, int, ...);
int putmsg(int, const struct strbuf *, const struct strbuf *, int);
int putpmsg(int, const struct strbuf *, const struct strbuf *, int, int);
int fattach(int, const char *);
int fdetach(const char *
```

**APPLICATION USAGE**

None.

**RATIONALE**

None.

**FUTURE DIRECTIONS**

None.

**SEE ALSO**

- `<sys/types.h>`, `<unistd.h>`, the System Interfaces volume of IEEE Std 1003.1-2001, `close()`, `fcntl()`, `getmsg()`, `ioctl()`, `open()`, `pipe()`, `read()`, `poll()`, `putmsg()`, `signal()`, `write()`

**CHANGE HISTORY**

First released in Issue 4, Version 2.
The `flags` members of the `strpeek` and `strfdinsert` structures are changed from type `long` to `t_uscalar_t`.

This header is marked as part of the XSI STREAMS Option Group.

The `restrict` keyword is added to the prototypes for `getmsg()` and `getpmsg()`.
NAME
sys/ipc.h — XSI interprocess communication access structure

SYNOPSIS
XSI #include <sys/ipc.h>

DESCRIPTION
The <sys/ipc.h> header is used by three mechanisms for XSI interprocess communication (IPC): messages, semaphores, and shared memory. All use a common structure type, ipc_perm, to pass information used in determining permission to perform an IPC operation.

The ipc_perm structure shall contain the following members:

uid_t uid   Owner’s user ID.
gid_t gid   Owner’s group ID.
uid_t cuid  Creator’s user ID.
gid_t cgid  Creator’s group ID.
mode_t mode  Read/write permission.

The uid_t, gid_t, mode_t, and key_t types shall be defined as described in <sys/types.h>.
Definitions shall be provided for the following constants:

Mode bits:
IPC_CREAT Create entry if key does not exist.
IPC_EXCL Fail if key exists.
IPC_NOWAIT Error if request must wait.

Keys:
IPC_PRIVATE Private key.
Control commands:
IPC_RMID Remove identifier.
IPC_SET Set options.
IPC_STAT Get options.
The following shall be declared as a function and may also be defined as a macro. A function prototype shall be provided.
key_t ftok(const char *, int);

APPLICATION USAGE
None.

RATIONALE
None.

FUTURE DIRECTIONS
None.

SEE ALSO
<sys/types.h>, the System Interfaces volume of IEEE Std 1003.1-2001, ftok()
<sys/ipc.h>

CHANGE HISTORY
First released in Issue 2. Derived from System V Release 2.0.
NAME
sys/mman.h — memory management declarations

SYNOPSIS
#include <sys/mman.h>

DESCRIPTION
The <sys/mman.h> header shall be supported if the implementation supports at least one of the following options:

- The Memory Mapped Files option
- The Shared Memory Objects option
- The Process Memory Locking option
- The Memory Protection option
- The Typed Memory Objects option
- The Synchronized Input and Output option
- The Advisory Information option

If one or more of the Advisory Information, Memory Mapped Files, or Shared Memory Objects options are supported, the following protection options shall be defined:

- PROT_READ Page can be read.
- PROT_WRITE Page can be written.
- PROT_EXEC Page can be executed.
- PROT_NONE Page cannot be accessed.

The following flag options shall be defined:

- MAP_SHARED Share changes.
- MAP_PRIVATE Changes are private.
- MAP_FIXED Interpret addr exactly.

The following flags shall be defined for msync():

- MS_ASYNC Perform asynchronous writes.
- MS_SYNC Perform synchronous writes.
- MS_INVALIDATE Invalidate mappings.

The following symbolic constants shall be defined for the mlockall() function:

- MCL_CURRENT Lock currently mapped pages.
- MCL_FUTURE Lock pages that become mapped.

The symbolic constant MAP_FAILED shall be defined to indicate a failure from the mmap() function.

If the Advisory Information and either the Memory Mapped Files or Shared Memory Objects options are supported, values for advice used by posix_madvise() shall be defined as follows:

- POSIX_MADV_NORMAL
  The application has no advice to give on its behavior with respect to the specified range. It
is the default characteristic if no advice is given for a range of memory.

POSIX_MADV_SEQUENTIAL
The application expects to access the specified range sequentially from lower addresses to higher addresses.

POSIX_MADV_RANDOM
The application expects to access the specified range in a random order.

POSIX_MADV_WILLNEED
The application expects to access the specified range in the near future.

POSIX_MADV_DONTNEED
The application expects that it will not access the specified range in the near future.

The following flags shall be defined for `posix_TYPED_mem_open()`:

POSIX_TYPED_MEM_ALLOCATE
Allocate on `mmap()`.

POSIX_TYPED_MEM_ALLOCATE_CONTIG
Allocate contiguously on `mmap()`.

POSIX_TYPED_MEM_MAP_ALLOCATABLE
Map on `mmap()`, without affecting allocatability.

The `mode_t`, `off_t`, and `size_t` types shall be defined as described in `<sys/types.h>`.

The `<sys/mman.h>` header shall define the structure `posix_TYPED_mem_info`, which includes at least the following member:

```
size_t posix_tmi_length
```
Maximum length which may be allocated from a typed memory object.

The following shall be declared as functions and may also be defined as macros. Function prototypes shall be provided.

```
int mlock(const void *, size_t);
int mlockall(int);
void * mmap(void *, size_t, int, int, int, off_t);
int mprotect(void *, size_t, int);
int msync(void *, size_t, int);
int munlock(const void *, size_t);
int munlockall(void);
int munmap(void *, size_t);
int posix_madvise(void *, size_t, int);
int posix_mem_offset(const void * restrict, size_t, off_t * restrict, size_t * restrict, int * restrict);
int posix_TYPED_mem_get_info(int, struct posix_TYPED_mem_info *);
int posix_TYPED_mem_open(const char *, int, int);
int shm_open(const char *, int, mode_t);
int shm_unlink(const char *);
```
APPLICATION USAGE
None.

RATIONALE
None.

FUTURE DIRECTIONS
None.

SEE ALSO
<sys/types.h>, the System Interfaces volume of IEEE Std 1003.1-2001, mlock(), mlockall(), mmap(), mprotect(), msync(), munlock(), munlockall(), munmap(), posix_mem_offset(), posixTyped_mem_get_info(), posixTyped_mem_open(), shm_open(), shm_unlink()

CHANGE HISTORY
First released in Issue 4, Version 2.

Issue 5
Updated for alignment with the POSIX Realtime Extension.

Issue 6
The <sys/mman.h> header is marked as dependent on support for either the Memory Mapped Files, Process Memory Locking, or Shared Memory Objects options.

The following changes are made for alignment with IEEE Std 1003.1j-2000:

• The TYM margin code is added to the list of margin codes for the <sys/mman.h> header line, as well as for other lines.

• The POSIX_TYPED_MEM_ALLOCATE, POSIX_TYPED_MEM_ALLOCATE_CONTIG, and POSIX_TYPED_MEM_MAP_ALLOCATABLE flags are added.

• The posix_tmi_length structure is added.

• The posix_mem_offset(), posixTyped_mem_get_info(), and posixTyped_mem_open() functions are added.

The restrict keyword is added to the prototype for posix_mem_offset().

IEEE PASC Interpretation 1003.1 #102 is applied, adding the prototype for posix_madvise().

IEEE Std 1003.1-2001/Cor 1-2002, item XBD/TC1/D6/16 is applied, correcting margin code and shading errors for the mlock() and munlock() functions.

IEEE Std 1003.1-2001/Cor 1-2002, item XSH/TC1/D6/34 is applied, changing the margin code for the mmap() function from MF|SHM to MC3 (notation for MF|SHM|TYM).

IEEE Std 1003.1-2001/Cor 1-2002, item XSH/TC1/D6/36 is applied, changing the margin code for the munmap() function from MF|SHM to MC3 (notation for MF|SHM|TYM).
<sys/msg.h>

NAME
sys/msg.h — XSI message queue structures

SYNOPSIS
XSI
#include <sys/msg.h>

DESCRIPTION
The <sys/msg.h> header shall define the following data types through typedef:

msgqnum_t Used for the number of messages in the message queue.
msglen_t Used for the number of bytes allowed in a message queue.

These types shall be unsigned integer types that are able to store values at least as large as a type unsigned short.

The <sys/msg.h> header shall define the following constant as a message operation flag:

MSG_NOERROR No error if big message.

The msqid_ds structure shall contain the following members:

struct ipc_perm msg_perm Operation permission structure.
msgqnum_t msg_qnum Number of messages currently on queue.
msglen_t msg_qbytes Maximum number of bytes allowed on queue.
pid_t msg_lspid Process ID of last msgsnd().
pid_t msg_lrapid Process ID of last msgrcv().
time_t msg_stime Time of last msgsnd().
time_t msg_rtime Time of last msgrcv().
time_t msg_ctime Time of last change.

The pid_t, time_t, key_t, size_t, and ssize_t types shall be defined as described in <sys/types.h>.

The following shall be declared as functions and may also be defined as macros. Function prototypes shall be provided.

int msgctl(int, int, struct msqid_ds *);
int msgget(key_t, int);
ssize_t msgrcv(int, void *, size_t, long, int);
int msgsnd(int, const void *, size_t, int);

In addition, all of the symbols from <sys/ipc.h> shall be defined when this header is included.

APPLICATION USAGE
None.

RATIONALE
None.

FUTURE DIRECTIONS
None.

SEE ALSO
<sys/ipc.h>, <sys/types.h>, msgctl(), msgget(), msgrcv(), msgsnd()

CHANGE HISTORY
First released in Issue 2. Derived from System V Release 2.0.
NAME
sys/resource.h — definitions for XSI resource operations

SYNOPSIS
XSI
#include <sys/resource.h>

DESCRIPTION
The <sys/resource.h> header shall define the following symbolic constants as possible values of the which argument of getpriority() and setpriority():

PRIO_PROCESS Identifies the who argument as a process ID.
PRIO_PGRP Identifies the who argument as a process group ID.
PRIO_USER Identifies the who argument as a user ID.

The following type shall be defined through typedef:

typedef unsigned int rlim_t; /* Unsigned integer type used for limit values. */

The following symbolic constants shall be defined:

RLIM_INFINITY A value of rlim_t indicating no limit.
RLIM_SAVED_MAX A value of type rlim_t indicating an unrepresentable saved hard limit.
RLIM_SAVED_CUR A value of type rlim_t indicating an unrepresentable saved soft limit.

On implementations where all resource limits are representable in an object of type rlim_t, RLIM_SAVED_MAX and RLIM_SAVED_CUR need not be distinct from RLIM_INFINITY.

The following symbolic constants shall be defined as possible values of the who parameter of getrusage():

RUSAGE_SELF Returns information about the current process.
RUSAGE_CHILDREN Returns information about children of the current process.

The <sys/resource.h> header shall define the rlimit structure that includes at least the following members:

rlim_t rlim_cur The current (soft) limit.
rlim_t rlim_max The hard limit.

The <sys/resource.h> header shall define the rusage structure that includes at least the following members:

struct timeval ru_utime User time used.
struct timeval ru_stime System time used.

The timeval structure shall be defined as described in <sys/time.h>.

The following symbolic constants shall be defined as possible values for the resource argument of getrlimit() and setrlimit():

RLIMIT_CORE Limit on size of core file.
RLIMIT_CPU Limit on CPU time per process.
RLIMIT_DATA Limit on data segment size.
RLIMITFSIZE Limit on file size.
Headers

12301   RLIMIT_NOFILE   Limit on number of open files.
12302   RLIMIT_STACK   Limit on stack size.
12303   RLIMIT_AS      Limit on address space size.
12304   The following shall be declared as functions and may also be defined as macros. Function
12305         prototypes shall be provided.
12306   int    getpriority(int, id_t);
12307   int    getrlimit(int, struct rlimit *);
12308   int    getrusage(int, struct rusage *);
12309   int    setpriority(int, id_t, int);
12310   int    setrlimit(int, const struct rlimit *);
12311   The id_t type shall be defined through typedef as described in <sys/types.h>.
12312   Inclusion of the <sys/resource.h> header may also make visible all symbols from <sys/time.h>.

12313  APPLICATION USAGE
12314  None.
12315  RATIONALE
12316  None.
12317  FUTURE DIRECTIONS
12318  None.
12319  SEE ALSO
12320  <sys/time.h>, <sys/types.h>, the System Interfaces volume of IEEE Std 1003.1-2001, getpriority(),

12322  CHANGE HISTORY
12323  First released in Issue 4, Version 2.
12324  Issue 5
12325  Large File System extensions are added.
NAME
sys/select.h — select types

SYNOPSIS
#include <sys/select.h>

DESCRIPTION
The <sys/select.h> header shall define the timeval structure that includes at least the following members:

```
  time_t  tv_sec        Seconds.
suseconds_t  tv_usec     Microseconds.
```

The time_t and suseconds_t types shall be defined as described in <sys/types.h>.

The sigset_t type shall be defined as described in <signal.h>.

The timespec structure shall be defined as described in <time.h>.

The <sys/select.h> header shall define the fd_set type as a structure.

Each of the following may be declared as a function, or defined as a macro, or both:

```
void FD_CLR(int fd, fd_set *fdset)  
  Clears the bit for the file descriptor fd in the file descriptor set fdset.

int FD_ISSET(int fd, fd_set *fdset)  
  Returns a non-zero value if the bit for the file descriptor fd is set in the file descriptor set by fdset, and 0 otherwise.

void FD_SET(int fd, fd_set *fdset)  
  Sets the bit for the file descriptor fd in the file descriptor set fdset.

void FD_ZERO(fd_set *fdset)  
  Initializes the file descriptor set fdset to have zero bits for all file descriptors.
```

If implemented as macros, these may evaluate their arguments more than once, so applications should ensure that the arguments they supply are never expressions with side effects.

The following shall be defined as a macro:

```
FD_SETSIZE
  Maximum number of file descriptors in an fd_set structure.
```

The following shall be declared as functions and may also be defined as macros. Function prototypes shall be provided:

```
int pselect(int, fd_set *restrict, fd_set *restrict, fd_set *restrict, const struct timespec *restrict, const sigset_t *restrict);
int select(int, fd_set *restrict, fd_set *restrict, fd_set *restrict, struct timeval *restrict);
```

Inclusion of the <sys/select.h> header may make visible all symbols from the headers <signal.h>, <sys/time.h>, and <time.h>.
APPLICATION USAGE
None.

RATIONALE
None.

FUTURE DIRECTIONS
None.

CHANGE HISTORY
The requirement for the fd_set structure to have a member fds_bits has been removed as per The Open Group Base Resolution bwg2001-005.
NAME
sys/sem.h — XSI semaphore facility

SYNOPSIS
#include <sys/sem.h>

DESCRIPTION
The <sys/sem.h> header shall define the following constants and structures.

Semaphore operation flags:
- SEM_UNDO Set up adjust on exit entry.

Command definitions for the semctl() function shall be provided as follows:
- GETNCNT Get semncnt.
- GETPID Get sempid.
- GETVAL Get semval.
- GETALL Get all cases of semval.
- GETZCNT Get semzcnt.
- SETVAL Set semval.
- SETALL Set all cases of semval.

The semid_ds structure shall contain the following members:
- struct ipc_perm sem_perm Operation permission structure.
- unsigned short sem_nsems Number of semaphores in set.
- time_t sem_otime Last semop() time.
- time_t sem_ctime Last time changed by semctl().

The pid_t, time_t, key_t, and size_t types shall be defined as described in <sys/types.h>.

A semaphore shall be represented by an anonymous structure containing the following members:
- unsigned short semval Semaphore value.
- pid_t sempid Process ID of last operation.
- unsigned short semncnt Number of processes waiting for semval to become greater than current value.
- unsigned short semzcnt Number of processes waiting for semval to become 0.

The sembuf structure shall contain the following members:
- unsigned short sem_num Semaphore number.
- short sem_op Semaphore operation.
- short sem_flg Operation flags.

The following shall be declared as functions and may also be defined as macros. Function prototypes shall be provided.
- int semctl(int, int, int, ...);
- int semget(key_t, int, int);
- int semop(int, struct sembuf *, size_t);
In addition, all of the symbols from `<sys/ipc.h>` shall be defined when this header is included.

**APPLICATION USAGE**
None.

**RATIONALE**
None.

**FUTURE DIRECTIONS**
None.

NAME
sys/shm.h — XSI shared memory facility

SYNOPSIS
XSI
#include <sys/shm.h>

DESCRIPTION
The <sys/shm.h> header shall define the following symbolic constants:
SHM_RDONLY Attach read-only (else read-write).
SHM_RND Round attach address to SHMLBA.
The <sys/shm.h> header shall define the following symbolic value:
SHMLBA Segment low boundary address multiple.
The following data types shall be defined through typedef:
shmatt_t Unsigned integer used for the number of current attaches that must be able to
store values at least as large as a type unsigned short.
The shmid_ds structure shall contain the following members:
struct ipc_perm shm_perm Operation permission structure.
size_t shm_segsz Size of segment in bytes.
pid_t shm_lpid Process ID of last shared memory operation.
pid_t shm_cpid Process ID of creator.
shmatt_t shm_nattch Number of current attaches.
time_t shm_atime Time of last shmat().
time_t shm_dtime Time of last shmdt().
time_t shm_ctime Time of last change by shmctl().
The pid_t, time_t, key_t, and size_t types shall be defined as described in <sys/types.h>.
The following shall be declared as functions and may also be defined as macros. Function
prototypes shall be provided.
void *shmat(int, const void *, int);
int shmctl(int, int, struct shmid_ds *);
int shmdt(const void *);
int shmget(key_t, size_t, int);
In addition, all of the symbols from <sys/ipc.h> shall be defined when this header is included.

APPLICATION USAGE
None.

RATIONALE
None.

FUTURE DIRECTIONS
None.

CHANGE HISTORY

First released in Issue 2. Derived from System V Release 2.0.

Issue 5

The type of `shm_segsz` is changed from `int` to `size_t`. 
NAME

sys/socket.h — main sockets header

SYNOPSIS

#include <sys/socket.h>

DESCRIPTION

The <sys/socket.h> header shall define the type socklen_t, which is an integer type of width of at least 32 bits; see APPLICATION USAGE.

The <sys/socket.h> header shall define the unsigned integer type sa_family_t.

The <sys/socket.h> header shall define the sockaddr structure that includes at least the following members:

socklen_t sa_family
char sa_data[] Socket address (variable-length data).

The sockaddr structure is used to define a socket address which is used in the bind(), connect(), getpeername(), getsockname(), recvfrom(), and sendto() functions.

The <sys/socket.h> header shall define the sockaddr_storage structure. This structure shall be:

- Large enough to accommodate all supported protocol-specific address structures
- Aligned at an appropriate boundary so that pointers to it can be cast as pointers to protocol-specific address structures and used to access the fields of those structures without alignment problems

The sockaddr_storage structure shall contain at least the following members:

sa_family_t ss_family

When a sockaddr_storage structure is cast as a sockaddr structure, the ss_family field of the sockaddr_storage structure shall map onto the sa_family field of the sockaddr structure. When a sockaddr_storage structure is cast as a protocol-specific address structure, the ss_family field shall map onto a field of that structure that is of type sa_family_t and that identifies the protocol’s address family.

The <sys/socket.h> header shall define the msghdr structure that includes at least the following members:

void *msg_name Optional address.
socklen_t msg_namelen Size of address.
struct iovec *msg_iov Scatter/gather array.
int msg_iovlen Members in msg_iov.
void *msg_control Ancillary data; see below.
socklen_t msg_controllen Ancillary data buffer len.
int msg_flags Flags on received message.

The msghdr structure is used to minimize the number of directly supplied parameters to the recvmsg() and sendmsg() functions. This structure is used as a value-result parameter in the recvmsg() function and value only for the sendmsg() function.

The iovec structure shall be defined as described in <sys/uio.h>.

The <sys/socket.h> header shall define the cmsghdr structure that includes at least the following members:

socklen_t cmsg_len Data byte count, including the cmsghdr.
int cmsg_level Originating protocol.
The `cmsghdr` structure is used for storage of ancillary data object information.

Ancillary data consists of a sequence of pairs, each consisting of a `cmsghdr` structure followed by a data array. The data array contains the ancillary data message, and the `cmsghdr` structure contains descriptive information that allows an application to correctly parse the data.

The values for `cmsg_level` shall be legal values for the `level` argument to the `getsockopt()` and `setsockopt()` functions. The system documentation shall specify the `cmsg_type` definitions for the supported protocols.

Ancillary data is also possible at the socket level. The `<sys/socket.h>` header defines the following macro for use as the `cmsg_type` value when `cmsg_level` is SOL_SOCKET:

```
SCM_RIGHTS Indicates that the data array contains the access rights to be sent or received.
```

The `<sys/socket.h>` header defines the following macros to gain access to the data arrays in the ancillary data associated with a message header:

```
CMSC_DATA(cmsg)
If the argument is a pointer to a `cmsghdr` structure, this macro shall return an unsigned character pointer to the data array associated with the `cmsghdr` structure.
```

```
CMSG_NXTHDR(mhdr,cmsg)
If the first argument is a pointer to a `msghdr` structure and the second argument is a pointer to a `cmsghdr` structure in the ancillary data pointed to by the `msg_control` field of that `msghdr` structure, this macro shall return a pointer to the next `cmsghdr` structure, or a null pointer if this structure is the last `cmsghdr` in the ancillary data.
```

```
CMSG_FIRSTHDR(mhdr)
If the argument is a pointer to a `msghdr` structure, this macro shall return a pointer to the first `cmsghdr` structure in the ancillary data associated with this `msghdr` structure, or a null pointer if there is no ancillary data associated with the `msghdr` structure.
```

The `<sys/socket.h>` header shall define the `linger` structure that includes at least the following members:

```
int l_onoff Indicates whether linger option is enabled.
int l_linger Linger time, in seconds.
```

The `<sys/socket.h>` header shall define the following macros, with distinct integer values:

```
SOCKET_DGRAM Datagram socket.
```

```
SOCKET_RAW Raw Protocol Interface.
```

```
SOCKET_SEQPACKET Sequenced-packet socket.
```

```
SOCKET_STREAM Byte-stream socket.
```

The `<sys/socket.h>` header shall define the following macro for use as the `level` argument of `setsockopt()` and `getsockopt()`:

```
SOL_SOCKET Options to be accessed at socket level, not protocol level.
```

The `<sys/socket.h>` header shall define the following macros, with distinct integer values, for use as the `option_name` argument in `getsockopt()` or `setsockopt()` calls:

```
SO_ACCEPTCONN Socket is accepting connections.
```
SO_BROADCAST  Transmission of broadcast messages is supported.
SO_DEBUG  Debugging information is being recorded.
SO_DONTROUTE  Bypass normal routing.
SO_ERROR  Socket error status.
SO_KEEPALIVE  Connections are kept alive with periodic messages.
SO_LINGER  Socket lingers on close.
SO_OOBINLINE  Out-of-band data is transmitted in line.
SO_RCVBUF  Receive buffer size.
SO_RCVLOWAT  Receive “low water mark”.
SO_RCVTIMEO  Receive timeout.
SO_REUSEADDR  Reuse of local addresses is supported.
SO_SNDBUF  Send buffer size.
SO_SNDLOWAT  Send “low water mark”.
SO_SNDTIMEO  Send timeout.
SO_TYPE  Socket type.

The `<sys/socket.h>` header shall define the following macro as the maximum `backlog` queue length which may be specified by the `backlog` field of the `listen()` function:

SOMAXCONN  The maximum `backlog` queue length.

The `<sys/socket.h>` header shall define the following macros, with distinct integer values, for use as the valid values for the `msg_flags` field in the `msghdr` structure, or the `flags` parameter in `recvfrom()`, `recvmsg()`, `sendmsg()`, or `sendto()` calls:

MSG_CTRUNC  Control data truncated.
MSG_DONTROUTE  Send without using routing tables.
MSG_EOR  Terminates a record (if supported by the protocol).
MSG_OOB  Out-of-band data.
MSG_PEEK  Leave received data in queue.
MSG_TRUNC  Normal data truncated.
MSG_WAITALL  Attempt to fill the read buffer.

The `<sys/socket.h>` header shall define the following macros, with distinct integer values:

AF_INET  Internet domain sockets for use with IPv4 addresses.
AF_INET6  Internet domain sockets for use with IPv6 addresses.
AF_UNIX  UNIX domain sockets.
AF_UNSPEC  Unspecified.
SHUT_RD  Disables further receive operations.
The following shall be declared as functions and may also be defined as macros. Function prototypes shall be provided.

```c
int accept(int, struct sockaddr *restrict, socklen_t *restrict);
int bind(int, const struct sockaddr *, socklen_t);
int connect(int, const struct sockaddr *, socklen_t);
int getpeername(int, struct sockaddr *restrict, socklen_t *restrict);
int getsockname(int, struct sockaddr *restrict, socklen_t *restrict);
int getsockopt(int, int, int, void *restrict, socklen_t *restrict);
int listen(int, int);
ssize_t recv(int, void *, size_t, int);
ssize_t recvfrom(int, void *restrict, size_t, int, 
                 struct sockaddr *restrict, socklen_t *restrict);
ssize_t recvmsg(int, struct msghdr *, int);
ssize_t send(int, const void *, size_t, int);
ssize_t sendmsg(int, const struct msghdr *, int);
ssize_t sendto(int, const void *, size_t, int, const struct sockaddr *,
               socklen_t);
int setsockopt(int, int, int, const void *, socklen_t);
int shutdown(int, int);
int socket(int, int, int);
int sockatmark(int);
int socketpair(int, int, int, int[2]);
```

Inclusion of `<sys/socket.h>` may also make visible all symbols from `<sys/uio.h>`.

**APPLICATION USAGE**

To forestall portability problems, it is recommended that applications not use values larger than $2^{31} - 1$ for the `socklen_t` type.

The `sockaddr_storage` structure solves the problem of declaring storage for automatic variables which is both large enough and aligned enough for storing the socket address data structure of any family. For example, code with a file descriptor and without the context of the address family can pass a pointer to a variable of this type, where a pointer to a socket address structure is expected in calls such as `getpeername()`, and determine the address family by accessing the received content after the call.

The example below illustrates a data structure which aligns on a 64-bit boundary. An implementation-defined field `_ss_align` following `_ss_pad1` is used to force a 64-bit alignment which covers proper alignment good enough for needs of at least `sockaddr_in6` (IPv6) and `sockaddr_in` (IPv4) address data structures. The size of padding field `_ss_pad1` depends on the chosen alignment boundary. The size of padding field `_ss_pad2` depends on the value of overall size chosen for the total size of the structure. This size and alignment are represented in the above example by implementation-defined (not required) constants `_SS_MAXSIZE` (chosen value 128) and `_SS_ALIGNMENT` (with chosen value 8). Constants `_SS_PAD1SIZE` (derived value 6) and `_SS_PAD2SIZE` (derived value 112) are also for illustration and not required. The implementation-defined definitions and structure field names above start with an underscore to denote implementation private name space. Portable code is not expected to access or reference those fields or constants.

```c
/*
 * Desired design of maximum size and alignment.
 */
```
12637       /*
12638       * Definitions used for sockaddr_storage structure paddings design.
12639       */
12640       #define _SS_PAD1SIZE (_SS_ALIGNSIZE - sizeof(sa_family_t))
12641       #define _SS_PAD2SIZE (_SS_MAXSIZE - (sizeof(sa_family_t) + 
12642                          _SS_PAD1SIZE + _SS_ALIGNSIZE))
12643       struct sockaddr_storage {
12644              sa_family_t ss_family; /* Address family. */
12645              char _ss_pad1[_SS_PAD1SIZE];
12646              int64_t _ss_align; /* Field to force desired structure
12647                          storage alignment. */
12648              char _ss_pad2[_SS_PAD2SIZE];
12649       };

12650       RATIONALE
12651       None.

12652       FUTURE DIRECTIONS
12653       None.

12654       SEE ALSO
12655       <sys/uio.h>, the System Interfaces volume of IEEE Std 1003.1-2001, accept(), bind(), connect(),

12657       sendmsg(), sendto(), setsockopt(), shutdown(), socket(), socketpair()

12658       CHANGE HISTORY
12659       First released in Issue 6. Derived from the XNS, Issue 5.2 specification.
12660       The restrict keyword is added to the prototypes for accept(), getpeername(), getsockname(),
12661       getsockopt(), and recvfrom().
NAME
sys/stat.h — data returned by the stat() function

SYNOPSIS
#include <sys/stat.h>

DESCRIPTION
The <sys/stat.h> header shall define the structure of the data returned by the functions fstat(),
lstat(), and stat().

The stat structure shall contain at least the following members:

```
device_t st_dev  Device ID of device containing file.
ino_t st_ino    File serial number.
mode_t st_mode  Mode of file (see below).
nlink_t st_nlink Number of hard links to the file.
uid_t st_uid    User ID of file.
gid_t st_gid    Group ID of file.
```

The st_dev and st_ino fields taken together uniquely identify the file within the system. The
```
blksize_t st_blksize A file system-specific preferred I/O block size for
this object. In some file system types, this may
```
```
```
```
```
```
```
```
```
```
```

```
```
File mode bits:

- **S_IRWXU** Read, write, execute/search by owner.
- **S_IRUSR** Read permission, owner.
- **S_IWUSR** Write permission, owner.
- **S_IXUSR** Execute/search permission, owner.

- **S_IRWXG** Read, write, execute/search by group.
- **S_IRGRP** Read permission, group.
- **S_IWGRP** Write permission, group.
- **S_IXGRP** Execute/search permission, group.

- **S_IRWXO** Read, write, execute/search by others.
- **S_IROTH** Read permission, others.
- **S_IWOTH** Write permission, others.
- **S_IXOTH** Execute/search permission, others.

- **S_ISUID** Set-user-ID on execution.
- **S_ISGID** Set-group-ID on execution.

**XSI**

- **S_ISVTX** On directories, restricted deletion flag.

The bits defined by **S_IRUSR**, **S_IWUSR**, **S_IXUSR**, **S_IRGRP**, **S_IWGRP**, **S_IXGRP**, **S_IROTH**, **S_IWOTH**, **S_IXOTH**, **S_ISUID**, **S_ISGID**, and **S_ISVTX** shall be unique.

S_IRWXU is the bitwise-inclusive OR of **S_IRUSR**, **S_IWUSR**, and **S_IXUSR**.

S_IRWXG is the bitwise-inclusive OR of **S_IRGRP**, **S_IWGRP**, and **S_IXGRP**.

S_IRWXO is the bitwise-inclusive OR of **S_IROTH**, **S_IWOTH**, and **S_IXOTH**.

Implementations may OR other implementation-defined bits into **S_IRWXU**, **S_IRWXG**, and **S_IRWXO**, but they shall not overlap any of the other bits defined in this volume of IEEE Std 1003.1-2001. The *file permission bits* are defined to be those corresponding to the bitwise-inclusive OR of **S_IRWXU**, **S_IRWXG**, and **S_IRWXO**.

The following macros shall be provided to test whether a file is of the specified type. The value *m* supplied to the macros is the value of **st_mode** from a **stat** structure. The macro shall evaluate to a non-zero value if the test is true; 0 if the test is false.

- **S_ISBLK**(*m*) Test for a block special file.
- **S_ISCHR**(*m*) Test for a character special file.
The implementation may implement message queues, semaphores, or shared memory objects as distinct file types. The following macros shall be provided to test whether a file is of the specified type. The value of the buf argument supplied to the macros is a pointer to a stat structure. The macro shall evaluate to a non-zero value if the specified object is implemented as a distinct file type and the specified file type is contained in the stat structure referenced by buf. Otherwise, the macro shall evaluate to zero.

- S_TYPEISMQ(buf) Test for a message queue.
- S_TYPEISSEM(buf) Test for a semaphore.
- S_TYPEISSHM(buf) Test for a shared memory object.

The following shall be declared as functions and may also be defined as macros. Function prototypes shall be provided.

```c
int chmod(const char *, mode_t);
int fchmod(int, mode_t);
int fstat(int, struct stat *);
int lstat(const char *restrict, struct stat *restrict);
int mkdir(const char *, mode_t);
int mkfifo(const char *, mode_t);
int mknod(const char *, mode_t, dev_t);
int stat(const char *restrict, struct stat *restrict);
mode_t umask(mode_t);
```

**APPLICATION USAGE**

Use of the macros is recommended for determining the type of a file.

**RATIONALE**

A conforming C-language application must include `<sys/stat.h>` for functions that have arguments or return values of type `mode_t`, so that symbolic values for that type can be used. An alternative would be to require that these constants are also defined by including `<sys/types.h>`.

The S_ISUID and S_ISGID bits may be cleared on any write, not just on `open()`, as some historical implementations do.

System calls that update the time entry fields in the stat structure must be documented by the implementors. POSIX-conforming systems should not update the time entry fields for functions listed in the System Interfaces volume of IEEE Std 1003.1-2001 unless the standard requires that...
they do, except in the case of documented extensions to the standard.

Note that st_dev must be unique within a Local Area Network (LAN) in a “system” made up of multiple computers’ file systems connected by a LAN.

Networked implementations of a POSIX-conforming system must guarantee that all files visible within the file tree (including parts of the tree that may be remotely mounted from other machines on the network) on each individual processor are uniquely identified by the combination of the st_ino and st_dev fields.

The unit for the st_blocks member of the stat structure is not defined within IEEE Std 1003.1-2001. In some implementations it is 512 bytes. It may differ on a file system basis. There is no correlation between values of the st_blocks and st_blksize, and the f_bsize (from <sys/statvfs.h>) structure members.

Traditionally, some implementations defined the multiplier for st_blocks in <sys/param.h> as the symbol DEV_BSIZE.

**FUTURE DIRECTIONS**

No new S_IFMT symbolic names for the file type values of mode_t will be defined by IEEE Std 1003.1-2001; if new file types are required, they will only be testable through S_ISxx() or S_TYPEISxxx() macros instead.

**SEE ALSO**

<sys/statvfs.h>, <sys/types.h>, chmod(), fchdir(), fstat(), lstat(), mkdir(), mkfifo(), mknod(), stat(), umask()

**CHANGE HISTORY**

First released in Issue 1. Derived from Issue 1 of the SVID.

**Issue 5**

The DESCRIPTION is updated for alignment with the POSIX Realtime Extension.

The type of st_blksize is changed from long to blksize_t; the type of st_blocks is changed from long to blkcnt_t.

**Issue 6**

The S_TYPEISMQ(), S_TYPEISSEM(), and S_TYPEISSHM() macros are unconditionally mandated.

The Open Group Corrigendum U035/4 is applied. In the DESCRIPTION, the types blksize_t and blkcnt_t have been described.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The dev_t, ino_t, mode_t, nlink_t, uid_t, gid_t, off_t, and time_t types are mandated.

S_IFSOCK and S_ISSOCK are added for sockets.

The description of stat structure members is changed to reflect contents when file type is a symbolic link.

The test macro S_TYPEISTMO is added for alignment with IEEE Std 1003.1j-2000.

The restrict keyword is added to the prototypes for lstat() and stat().

The lstat() function is made mandatory.

IEEE Std 1003.1-2001/Cor 1-2002, item XBD/TC1/D6/17 is applied, adding text regarding the st_blocks member of the stat structure to the RATIONALE.
NAME
sys/statvfs.h — VFS File System information structure

SYNOPSIS
XSI
#include <sys/statvfs.h>

DESCRIPTION
The <sys/statvfs.h> header shall define the statvfs structure that includes at least the following members:

- unsigned long f_bsize: File system block size.
- unsigned long f_frsz: Fundamental file system block size.
- fsblkcnt_t f_blocks: Total number of blocks on file system in units of f_frsz.
- fsblkcnt_t f_bfree: Total number of free blocks.
- fsblkcnt_t f_bavail: Number of free blocks available to non-privileged process.
- fsfilcnt_t f_files: Total number of file serial numbers.
- fsfilcnt_t f_ffree: Total number of free file serial numbers.
- fsfilcnt_t f_favail: Number of file serial numbers available to non-privileged process.
- unsigned long f_fsid: File system ID.
- unsigned long f_flag: Bit mask of f_flag values.
- unsigned long f_namemax: Maximum filename length.

The fsblkcnt_t and fsfilcnt_t types shall be defined as described in <sys/types.h>.

The following flags for the f_flag member shall be defined:

- ST_RDONLY: Read-only file system.
- ST_NOSUID: Does not support the semantics of the ST_ISUID and ST_ISGID file mode bits.

The following shall be declared as functions and may also be defined as macros. Function prototypes shall be provided:

int statvfs(const char *restrict, struct statvfs *restrict);
int fstatvfs(int, struct statvfs *);

APPLICATION USAGE
None.

RATIONALE
None.

FUTURE DIRECTIONS
None.

SEE ALSO
<sys/types.h>, the System Interfaces volume of IEEE Std 1003.1-2001, fstatvfs(), statvfs()

CHANGE HISTORY
First released in Issue 4, Version 2.

Issue 5
The type of f_blocks, f_bfree, and f_bavail is changed from unsigned long to fsblkcnt_t; the type of f_files, f_ffree, and f_favail is changed from unsigned long to fsfilcnt_t.
The Open Group Corrigendum U035/5 is applied. In the DESCRIPTION, the types `fsblkcnt_t` and `fsfilcnt_t` have been described.

The `restrict` keyword is added to the prototype for `statvfs()`.

IEEE Std 1003.1-2001/Cor 1-2002, item XBD/TC1/D6/18 is applied, changing the description of `ST_NOSUID` from “Does not support `setuid()`/`setgid()` semantics” to “Does not support the semantics of the ST_ISUID and ST_ISGID file mode bits”.

NAME
sys/time.h — time types

SYNOPSIS
XSI
#include <sys/time.h>

DESCRIPTION
The <sys/time.h> header shall define the timeval structure that includes at least the following members:

  time_t  tv_sec  Seconds.
  suseconds_t  tv_usec  Microseconds.

The <sys/time.h> header shall define the itimerval structure that includes at least the following members:

  struct timeval  it_interval  Timer interval.
  struct timeval  it_value  Current value.

The time_t and suseconds_t types shall be defined as described in <sys/types.h>.
The fd_set type shall be defined as described in <sys/select.h>.
The <sys/time.h> header shall define the following values for the which argument of getitimer() and setitimer():
APPLICATION USAGE
None.

RATIONALE
None.

FUTURE DIRECTIONS
None.

SEE ALSO
<sys/select.h>, <sys/types.h>, the System Interfaces volume of IEEE Std 1003.1-2001, getitimer(),
gettimeofday(), select(), setitimer()

CHANGE HISTORY
First released in Issue 4, Version 2.

Issue 5
The type of tv_usec is changed from long to suseconds_t.

Issue 6
The restrict keyword is added to the prototypes for gettimeofday(), select(), and setitimer().

Issue 7
The note is added that inclusion of this header may also make symbols visible from
<sys/select.h>.

The utimes() function is marked LEGACY.
NAME
sys/timeb.h — additional definitions for date and time

SYNOPSIS
XSI
#include <sys/timeb.h>

DESCRIPTION
The <sys/timeb.h> header shall define the timeb structure that includes at least the following members:

time_t time The seconds portion of the current time.
unsigned short millitm The milliseconds portion of the current time.
short timezone The local timezone in minutes west of Greenwich.
short dstflag TRUE if Daylight Savings Time is in effect.

The time_t type shall be defined as described in <sys/types.h>.

The following shall be declared as a function and may also be defined as a macro. A function prototype shall be provided.

int ftime(struct timeb *); (LEGACY)

APPLICATION USAGE
None.

RATIONALE
None.

FUTURE DIRECTIONS
None.

SEE ALSO
/sys/types.h>, <time.h>

CHANGE HISTORY
First released in Issue 4, Version 2.

Issue 6
The ftime() function is marked LEGACY.
NAME
sys/times.h — file access and modification times structure

SYNOPSIS
#include <sys/times.h>

DESCRIPTION
The <sys/times.h> header shall define the structure tms, which is returned by times() and includes at least the following members:

- clock_t tms_utime  User CPU time.
- clock_t tms_stime  System CPU time.
- clock_t tms_cutime User CPU time of terminated child processes.
- clock_t tms_cstime System CPU time of terminated child processes.

The clock_t type shall be defined as described in <sys/types.h>.

The following shall be declared as a function and may also be defined as a macro. A function prototype shall be provided.

- clock_t times(struct tms *);

APPLICATION USAGE
None.

RATIONALE
None.

FUTURE DIRECTIONS
None.

SEE ALSO
- <sys/types.h>, the System Interfaces volume of IEEE Std 1003.1-2001, times()

CHANGE HISTORY
First released in Issue 1. Derived from Issue 1 of the SVID.
<sys/types.h>

NAME
sys/types.h — data types

SYNOPSIS
#include <sys/types.h>

DESCRIPTION
The <sys/types.h> header shall include definitions for at least the following types:

- blkcnt_t Used for file block counts.
- blksize_t Used for block sizes.
- clock_t Used for system times in clock ticks or CLOCKS_PER_SEC; see <time.h>.
- clockid_t Used for clock ID type in the clock and timer functions.
- dev_t Used for device IDs.
- fbsblkcnt_t Used for file system block counts.
- fsfilcnt_t Used for file system file counts.
- gid_t Used for group IDs.
- id_t Used as a general identifier; can be used to contain at least a pid_t, uid_t, or gid_t.
- ino_t Used for file serial numbers.
- key_t Used for XSI interprocess communication.
- mode_t Used for some file attributes.
- nlink_t Used for link counts.
- off_t Used for file sizes.
- pid_t Used for process IDs and process group IDs.
- pthread_attr_t Used to identify a thread attribute object.
- pthread_barrier_t Used to identify a barrier.
- pthread_barrierattr_t Used to define a barrier attributes object.
- pthread_cond_t Used for condition variables.
- pthread_condattr_t Used to identify a condition attribute object.
- pthread_key_t Used for thread-specific data keys.
- pthread_mutex_t Used for mutexes.
- pthread_mutexattr_t Used to identify a mutex attribute object.
- pthread_once_t Used for dynamic package initialization.
- pthread_rwlock_t Used for read-write locks.
- pthread_rwlockattr_t Used for read-write lock attributes.
- pthread_spinlock_t Used to identify a spin lock.
- pthread_t Used to identify a thread.
size_t  Used for sizes of objects.

ssize_t  Used for a count of bytes or an error indication.

suseconds_t  Used for time in microseconds.

time_t  Used for time in seconds.

timer_t  Used for timer ID returned by timer_create().

trace_attr_t  Used to identify a trace stream attributes object.

trace_event_id_t  Used to identify a trace event type.

trace_event_set_t  Used to identify a trace event type set.

trace_id_t  Used to identify a trace stream.

uid_t  Used for user IDs.

useconds_t  Used for time in microseconds.

All of the types shall be defined as arithmetic types of an appropriate length, with the following exceptions:

key_t

pthread_attr_t

pthread_barrier_t

pthread_barrierattr_t

pthread_cond_t

pthread_condattr_t

pthread_key_t

pthread_mutex_t

pthread_mutexattr_t

pthread_once_t

pthread_rwlock_t

pthread_rwlockattr_t

pthread_spinlock_t

trace_attr_t

trace_event_id_t

trace_event_set_t

trace_id_t

Additionally:

• mode_t shall be an integer type.

• nlink_t, uid_t, gid_t, and id_t shall be integer types.

• blkcnt_t and off_t shall be signed integer types.

• fsblkcnt_t, fsfilcnt_t, and ino_t shall be defined as unsigned integer types.

• size_t shall be an unsigned integer type.

• blksize_t, pid_t, and ssize_t shall be signed integer types.

• time_t and clock_t shall be integer or real-floating types.

The type ssize_t shall be capable of storing values at least in the range \([-1, \text{SSIZE_MAX}]\). The type useconds_t shall be an unsigned integer type capable of storing values at least in the range \([0, 1\,000\,000]\). The type useconds_t shall be a signed integer type capable of storing values at
least in the range \([-1, 1\,000,000]\).

The implementation shall support one or more programming environments in which the widths
of \texttt{blksize\_t}, \texttt{pid\_t}, \texttt{size\_t}, \texttt{suseconds\_t}, and \texttt{useconds\_t} are no greater than the width of
type \texttt{long}. The names of these programming environments can be obtained using the \texttt{confstr()} function or the \texttt{getconf} utility.

There are no defined comparison or assignment operators for the following types:

- \texttt{THR pthread\_attr\_t}
- \texttt{BAR pthread\_barrier\_t}
- \texttt{THR pthread\_barrierattr\_t}
- \texttt{THR pthread\_cond\_t}
- \texttt{THR pthread\_condattr\_t}
- \texttt{THR pthread\_mutex\_t}
- \texttt{THR pthread\_mutexpattr\_t}
- \texttt{THR pthread\_rwlock\_t}
- \texttt{THR pthread\_rwlockattr\_t}
- \texttt{SPI pthread\_spinlock\_t}
- \texttt{TRC trace\_attr\_t}

APPLICATION USAGE

None.

RATIONALE

None.

FUTURE DIRECTIONS

None.

SEE ALSO

\(<\texttt{time.h}>\), the System Interfaces volume of IEEE Std 1003.1-2001, \texttt{confstr()}, the Shell and Utilities
volume of IEEE Std 1003.1-2001, \texttt{getconf}

CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 5

The \texttt{clockid\_t} and \texttt{timer\_t} types are defined for alignment with the POSIX Realtime Extension.

The types \texttt{blkcnt\_t}, \texttt{blksize\_t}, \texttt{fsblkcnt\_t}, \texttt{fsfilcnt\_t}, and \texttt{suseconds\_t} are added.

Large File System extensions are added.

Updated for alignment with the POSIX Threads Extension.

Issue 6

The \texttt{pthread\_barrier\_t}, \texttt{pthread\_barrierattr\_t}, and \texttt{pthread\_spinlock\_t} types are added for
alignment with IEEE Std 1003.1j-2000.

The margin code is changed from XSI to THR for the \texttt{pthread\_rwlock\_t} and
\texttt{pthread\_rwlockattr\_t} types as Read-Write Locks have been absorbed into the POSIX Threads
option. The threads types are marked THR.
NAME
sys/uio.h — definitions for vector I/O operations

SYNOPSIS
XSI
#include <sys/uio.h>

DESCRIPTION
The <sys/uio.h> header shall define the iovec structure that includes at least the following members:

void  *iov_base Base address of a memory region for input or output.
size_t  iov_len  The size of the memory pointed to by iov_base.

The <sys/uio.h> header uses the iovec structure for scatter/gather I/O.

The ssize_t and size_t types shall be defined as described in <sys/types.h>.

The following shall be declared as functions and may also be defined as macros. Function prototypes shall be provided.

ssize_t readv(int, const struct iovec *, int);
ssize_t writev(int, const struct iovec *, int);

APPLICATION USAGE
The implementation can put a limit on the number of scatter/gather elements which can be processed in one call. The symbol {IOV_MAX} defined in <limits.h> should always be used to learn about the limits instead of assuming a fixed value.

RATIONALE
Traditionally, the maximum number of scatter/gather elements the system can process in one call were described by the symbolic value {UIO_MAXIOV}. In IEEE Std 1003.1-2001 this value is replaced by the constant {IOV_MAX} which can be found in <limits.h>.

FUTURE DIRECTIONS
None.

SEE ALSO
<limits.h>, <sys/types.h>, the System Interfaces volume of IEEE Std 1003.1-2001, read(), write()

CHANGE HISTORY
First released in Issue 4, Version 2.

Issue 6
Text referring to scatter/gather I/O is added to the DESCRIPTION.
The `<sys/un.h>` header shall define the `sockaddr_un` structure that includes at least the following members:

- `sa_family_t sun_family` Address family.
- `char sun_path[]` Socket pathname.

The `sockaddr_un` structure is used to store addresses for UNIX domain sockets. Values of this type shall be cast by applications to `struct sockaddr` for use with socket functions.

The `sa_family_t` type shall be defined as described in `<sys/socket.h>`.

### Application Usage

The size of `sun_path` has intentionally been left undefined. This is because different implementations use different sizes. For example, 4.3 BSD uses a size of 108, and 4.4 BSD uses a size of 104. Since most implementations originate from BSD versions, the size is typically in the range 92 to 108.

Applications should not assume a particular length for `sun_path` or assume that it can hold `_POSIX_PATH_MAX` characters (255).

### Rationale

None.

### Future Directions

None.

### See Also

- `<sys/socket.h>`, the System Interfaces volume of IEEE Std 1003.1-2001, `bind()`, `socket()`, `socketpair()`

### Change History

First released in Issue 6. Derived from the XNS, Issue 5.2 specification.
NAME
sys/utsname.h — system name structure

SYNOPSIS
#include <sys/utsname.h>

DESCRIPTION
The <sys/utsname.h> header shall define the structure utsname which shall include at least the following members:

char sysname[] Name of this implementation of the operating system.
char nodename[] Name of this node within an implementation-defined communications network.
char release[] Current release level of this implementation.
char version[] Current version level of this release.
char machine[] Name of the hardware type on which the system is running.

The character arrays are of unspecified size, but the data stored in them shall be terminated by a null byte.

The following shall be declared as a function and may also be defined as a macro:

int uname(struct utsname *);

APPLICATION USAGE
None.

RATIONALE
None.

FUTURE DIRECTIONS
None.

SEE ALSO
The System Interfaces volume of IEEE Std 1003.1-2001, uname()

CHANGE HISTORY
First released in Issue 1. Derived from Issue 1 of the SVID.
NAME
sys/wait.h — declarations for waiting

SYNOPSIS
#include <sys/wait.h>

DESCRIPTION
The <sys/wait.h> header shall define the following symbolic constants for use with waitpid():
- WNOHANG: Do not hang if no status is available; return immediately.

The <sys/wait.h> header shall define the following macros for analysis of process status values:
- WEXITSTATUS: Return exit status.
- WIFCONTINUED: True if child has been continued.
- WIFEXITED: True if child exited normally.
- WIFSIGNALED: True if child exited due to uncaught signal.
- WIFSTOPPED: True if child is currently stopped.
- WSTOPSIG: Return signal number that caused process to stop.
- WTERMSIG: Return signal number that caused process to terminate.

The following symbolic constants shall be defined as possible values for the options argument to waitid():
- WEXITED: Wait for processes that have exited.
- WSTOPPED: Status is returned for any child that has stopped upon receipt of a signal.
- WCONTINUED: Status is returned for any child that was stopped and has been continued.
- WNOHANG: Return immediately if there are no children to wait for.
- WNOWAIT: Keep the process whose status is returned in infop in a waitable state.

The type idtype_t shall be defined as an enumeration type whose possible values shall include at least the following:
- P_ALL
- P_PID
- P_PGID

The id_t and pid_t types shall be defined as described in <sys/types.h>.

The siginfo_t type shall be defined as described in <signal.h>.

The rusage structure shall be defined as described in <sys/resource.h>.

Inclusion of the <sys/wait.h> header may also make visible all symbols from <signal.h> and <sys/resource.h>.

The following shall be declared as functions and may also be defined as macros. Function prototypes shall be provided.

pid_t wait(int *);
int waitid(idtype_t, id_t, siginfo_t *, int);
pid_t waitpid(pid_t, int *, int);
APPLICATION USAGE
None.

RATIONALE
None.

FUTURE DIRECTIONS
None.

SEE ALSO
<signal.h>, <sys/resource.h>, <sys/types.h>, the System Interfaces volume of IEEE Std 1003.1-2001, wait(), waitid()

CHANGE HISTORY
First released in Issue 3.
Included for alignment with the POSIX.1-1988 standard.

Issue 6
The wait3() function is removed.
NAME
syslog.h — definitions for system error logging

SYNOPSIS
#include <syslog.h>

DESCRIPTION
The <syslog.h> header shall define the following symbolic constants, zero or more of which may be OR'ed together to form the logopt option of openlog():

- LOG_PID Log the process ID with each message.
- LOG_CONS Log to the system console on error.
- LOG_NDELAY Connect to syslog daemon immediately.
- LOG_ODELAY Delay open until syslog() is called.
- LOG_NOWAIT Do not wait for child processes.

The following symbolic constants shall be defined as possible values of the facility argument to openlog():

- LOG_KERN Reserved for message generated by the system.
- LOG_USER Message generated by a process.
- LOG_MAIL Reserved for message generated by mail system.
- LOG_NEWS Reserved for message generated by news system.
- LOG_UUCP Reserved for message generated by UUCP system.
- LOG_DAEMON Reserved for message generated by system daemon.
- LOG_AUTH Reserved for message generated by authorization daemon.
- LOG_CRON Reserved for message generated by clock daemon.
- LOG_LPR Reserved for message generated by printer system.
- LOG_LOCAL0 Reserved for local use.
- LOG_LOCAL1 Reserved for local use.
- LOG_LOCAL2 Reserved for local use.
- LOG_LOCAL3 Reserved for local use.
- LOG_LOCAL4 Reserved for local use.
- LOG_LOCAL5 Reserved for local use.
- LOG_LOCAL6 Reserved for local use.
- LOG_LOCAL7 Reserved for local use.

The following shall be declared as macros for constructing the maskpri argument to setlogmask().
The following macros expand to an expression of type int when the argument pri is an expression of type int:

- LOG_MASK(pri) A mask for priority pri.

The following constants shall be defined as possible values for the priority argument of syslog():
The following shall be declared as functions and may also be defined as macros. Function prototypes shall be provided.

```c
void closelog(void);
void openlog(const char *, int, int);
int setlogmask(int);
void syslog(int, const char *, ...);
```

**APPLICATION USAGE**
None.

**RATIONALE**
None.

**FUTURE DIRECTIONS**
None.

**SEE ALSO**
The System Interfaces volume of IEEE Std 1003.1-2001, `closelog()`

**CHANGE HISTORY**
First released in Issue 4, Version 2.

**Issue 5**
Moved from X/Open UNIX to BASE.
NAME

tar.h — extended tar definitions

SYNOPSIS

#include <tar.h>

DESCRIPTION

The `<tar.h>` header shall define header block definitions as follows.

General definitions:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>TMAGIC</td>
<td>&quot;ustar&quot;</td>
<td>ustar plus null byte.</td>
</tr>
<tr>
<td>TMLGLEN</td>
<td>6</td>
<td>Length of the above.</td>
</tr>
<tr>
<td>TVERSION</td>
<td>&quot;00&quot;</td>
<td>00 without a null byte.</td>
</tr>
<tr>
<td>TVERSLEN</td>
<td>2</td>
<td>Length of the above.</td>
</tr>
</tbody>
</table>

Typeflag field definitions:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>REGTYPE</td>
<td>'0'</td>
<td>Regular file.</td>
</tr>
<tr>
<td>AREGTYPE</td>
<td>'\0'</td>
<td>Regular file.</td>
</tr>
<tr>
<td>LNKTYPE</td>
<td>'1'</td>
<td>Link.</td>
</tr>
<tr>
<td>SYMTYPE</td>
<td>'2'</td>
<td>Symbolic link.</td>
</tr>
<tr>
<td>CHRTYPE</td>
<td>'3'</td>
<td>Character special.</td>
</tr>
<tr>
<td>BLKTYPE</td>
<td>'4'</td>
<td>Block special.</td>
</tr>
<tr>
<td>DIRTYPE</td>
<td>'5'</td>
<td>Directory.</td>
</tr>
<tr>
<td>FIFO</td>
<td>'6'</td>
<td>FIFO special.</td>
</tr>
<tr>
<td>CONT</td>
<td>'7'</td>
<td>Reserved.</td>
</tr>
</tbody>
</table>

Mode field bit definitions (octal):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>TSUID</td>
<td>04000</td>
<td>Set UID on execution.</td>
</tr>
<tr>
<td>TSGID</td>
<td>02000</td>
<td>Set GID on execution.</td>
</tr>
<tr>
<td>TSVTX</td>
<td>01000</td>
<td>On directories, restricted deletion flag.</td>
</tr>
<tr>
<td>TUREAD</td>
<td>00400</td>
<td>Read by owner.</td>
</tr>
<tr>
<td>TUWRITE</td>
<td>00200</td>
<td>Write by owner special.</td>
</tr>
<tr>
<td>TUEXEC</td>
<td>00100</td>
<td>Execute/search by owner.</td>
</tr>
<tr>
<td>TGREAD</td>
<td>00040</td>
<td>Read by group.</td>
</tr>
<tr>
<td>TGWRITE</td>
<td>00020</td>
<td>Write by group.</td>
</tr>
<tr>
<td>TGEXEC</td>
<td>00010</td>
<td>Execute/search by group.</td>
</tr>
<tr>
<td>TOREAD</td>
<td>00004</td>
<td>Read by other.</td>
</tr>
<tr>
<td>TOWRITE</td>
<td>00002</td>
<td>Write by other.</td>
</tr>
<tr>
<td>TOEXEC</td>
<td>00001</td>
<td>Execute/search by other.</td>
</tr>
</tbody>
</table>
APPLICATION USAGE
None.

RATIONALE
None.

FUTURE DIRECTIONS
None.

SEE ALSO
The Shell and Utilities volume of IEEE Std 1003.1-2001, pax

CHANGE HISTORY

Issue 6
The SEE ALSO section now refers to pax since the Shell and Utilities volume of IEEE Std 1003.1-2001 no longer contains the tar utility.
NAME
termios.h — define values for termios

SYNOPSIS
#include <termios.h>

DESCRIPTION
The <termios.h> header contains the definitions used by the terminal I/O interfaces (see Chapter 11 (on page 187) for the structures and names defined).

The termios Structure
The following data types shall be defined through typedef:

c_t Used for terminal special characters.
speed_t Used for terminal baud rates.
tcflag_t Used for terminal modes.

The above types shall be all unsigned integer types.

The implementation shall support one or more programming environments in which the widths of cc_t, speed_t, and tcflag_t are no greater than the width of type long. The names of these programming environments can be obtained using the confstr() function or the getconf utility.

The termios structure shall be defined, and shall include at least the following members:
tcflag_t c_iflag Input modes.
tcflag_t c_oflag Output modes.
tcflag_t c_cflag Control modes.
tcflag_t c_lflag Local modes.
c_t c_cc[NCCS] Control characters.

A definition shall be provided for:

NCCS Size of the array c_cc for control characters.

The following subscript names for the array c_cc shall be defined:

<table>
<thead>
<tr>
<th>Subscript Usage</th>
<th>Canonical Mode</th>
<th>Non-Canonical Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VEOF</td>
<td></td>
<td></td>
<td>EOF character.</td>
</tr>
<tr>
<td>VEOL</td>
<td></td>
<td></td>
<td>EOL character.</td>
</tr>
<tr>
<td>VERASE</td>
<td></td>
<td></td>
<td>ERASE character.</td>
</tr>
<tr>
<td>VINTR</td>
<td></td>
<td>VINTR</td>
<td>INTR character.</td>
</tr>
<tr>
<td>VQUIT</td>
<td></td>
<td>VQUIT</td>
<td>QUIT character.</td>
</tr>
<tr>
<td>VSTART</td>
<td></td>
<td>VSTART</td>
<td>START character.</td>
</tr>
<tr>
<td>VSTOP</td>
<td></td>
<td>VSTOP</td>
<td>STOP character.</td>
</tr>
<tr>
<td>VSUSP</td>
<td></td>
<td>VSUSP</td>
<td>SUSP character.</td>
</tr>
<tr>
<td>VTIME</td>
<td></td>
<td>VTIME</td>
<td>TIME value.</td>
</tr>
</tbody>
</table>

The subscript values shall be unique, except that the VMIN and VTIME subscripts may have the same values as the VEOF and VEOL subscripts, respectively.

The following flags shall be provided.
### Input Modes

- **c_iflag** field describes the basic terminal input control:
  - **BRKINT** Signal interrupt on break.
  - **ICRNL** Map CR to NL on input.
  - **IGNBRK** Ignore break condition.
  - **IGNCR** Ignore CR.
  - **IGNPAR** Ignore characters with parity errors.
  - **INLCR** Map NL to CR on input.
  - **INPCK** Enable input parity check.
  - **ISTRIP** Strip character.
  - **IXANY** Enable any character to restart output.
  - **IXOFF** Enable start/stop input control.
  - **IXON** Enable start/stop output control.
  - **PARMRK** Mark parity errors.

### Output Modes

- **c_oflag** field specifies the system treatment of output:
  - **OPOST** Post-process output.
  - **ONLCR** Map NL to CR-NL on output.
  - **OCRNL** Map CR to NL on output.
  - **ONOCR** No CR output at column 0.
  - **ONLRET** NL performs CR function.
  - **OFILL** Use fill characters for delay.
  - **NLDLY** Select newline delays:
    - **NL0** Newline type 0.
    - **NL1** Newline type 1.
  - **CRDLY** Select carriage-return delays:
    - **CR0** Carriage-return delay type 0.
    - **CR1** Carriage-return delay type 1.
    - **CR2** Carriage-return delay type 2.
    - **CR3** Carriage-return delay type 3.
  - **TABDLY** Select horizontal-tab delays:
    - **TAB0** Horizontal-tab delay type 0.
    - **TAB1** Horizontal-tab delay type 1.
    - **TAB2** Horizontal-tab delay type 2.
<table>
<thead>
<tr>
<th>Constant</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TAB3</td>
<td>Expand tabs to spaces.</td>
</tr>
<tr>
<td>BSDLY</td>
<td>Select backspace delays:</td>
</tr>
<tr>
<td>BS0</td>
<td>Backspace-delay type 0.</td>
</tr>
<tr>
<td>BS1</td>
<td>Backspace-delay type 1.</td>
</tr>
<tr>
<td>VTDLY</td>
<td>Select vertical-tab delays:</td>
</tr>
<tr>
<td>VT0</td>
<td>Vertical-tab delay type 0.</td>
</tr>
<tr>
<td>VT1</td>
<td>Vertical-tab delay type 1.</td>
</tr>
<tr>
<td>FFDLY</td>
<td>Select form-feed delays:</td>
</tr>
<tr>
<td>FF0</td>
<td>Form-feed delay type 0.</td>
</tr>
<tr>
<td>FF1</td>
<td>Form-feed delay type 1.</td>
</tr>
</tbody>
</table>

### Baud Rate Selection

The input and output baud rates are stored in the `termios` structure. These are the valid values for objects of type `speed_t`. The following values shall be defined, but not all baud rates need be supported by the underlying hardware.

<table>
<thead>
<tr>
<th>Baud Rate</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>B0</td>
<td>Hang up</td>
</tr>
<tr>
<td>B50</td>
<td>50 baud</td>
</tr>
<tr>
<td>B75</td>
<td>75 baud</td>
</tr>
<tr>
<td>B110</td>
<td>110 baud</td>
</tr>
<tr>
<td>B134</td>
<td>134.5 baud</td>
</tr>
<tr>
<td>B150</td>
<td>150 baud</td>
</tr>
<tr>
<td>B200</td>
<td>200 baud</td>
</tr>
<tr>
<td>B300</td>
<td>300 baud</td>
</tr>
<tr>
<td>B600</td>
<td>600 baud</td>
</tr>
<tr>
<td>B1200</td>
<td>1200 baud</td>
</tr>
<tr>
<td>B1800</td>
<td>1800 baud</td>
</tr>
<tr>
<td>B2400</td>
<td>2400 baud</td>
</tr>
<tr>
<td>B4800</td>
<td>4800 baud</td>
</tr>
<tr>
<td>B9600</td>
<td>9600 baud</td>
</tr>
<tr>
<td>B19200</td>
<td>19200 baud</td>
</tr>
<tr>
<td>B38400</td>
<td>38400 baud</td>
</tr>
</tbody>
</table>
Control Modes

The `c_cflag` field describes the hardware control of the terminal; not all values specified are required to be supported by the underlying hardware:

- **CSIZE** Character size:
  - CS5 5 bits
  - CS6 6 bits
  - CS7 7 bits
  - CS8 8 bits

- **CSTOPB** Send two stop bits, else one.

- **CREAD** Enable receiver.

- **PARENB** Parity enable.

- **PARODD** Odd parity, else even.

- **HUPCL** Hang up on last close.

- **CLOCAL** Ignore modem status lines.

The implementation shall support the functionality associated with the symbols CS7, CS8, CSTOPB, PARODD, and PARENB.

Local Modes

The `c_lflag` field of the argument structure is used to control various terminal functions:

- **ECHO** Enable echo.

- **ECHOE** Echo erase character as error-correcting backspace.

- **ECHOK** Echo KILL.

- **IEXTEN** Enable extended input character processing.

- **ISIG** Enable signals.

- **NOFLSH** Disable flush after interrupt or quit.

- **TOSTOP** Send SIGTTOU for background output.

Attribute Selection

The following symbolic constants for use with `tcsetattr()` are defined:

- **TCSANOW** Change attributes immediately.

- **TCSADRAIN** Change attributes when output has drained.

- **TCSAFLUSH** Change attributes when output has drained; also flush pending input.
The following symbolic constants for use with tcflush() shall be defined:

- TCIFLUSH: Flush pending input.
- TCIOFLUSH: Flush both pending input and untransmitted output.
- TCOFLUSH: Flush untransmitted output.

The following symbolic constants for use with tcflow() shall be defined:

- TCIOFF: Transmit a STOP character, intended to suspend input data.
- TCION: Transmit a START character, intended to restart input data.
- TCOOFF: Suspend output.
- TCOON: Restart output.

The following shall be declared as functions and may also be defined as macros. Function prototypes shall be provided:

- speed_t cfgetispeed(const struct termios *);
- speed_t cfgetospeed(const struct termios *);
- int cfsetispeed(struct termios *, speed_t);
- int cfsetospeed(struct termios *, speed_t);
- int tcdrain(int);
- int tcflow(int, int);
- int tcflush(int, int);
- int tcgetattr(int, struct termios *);
- pid_t tcgetsid(int);
- int tcsendbreak(int, int);
- int tcsetattr(int, int, const struct termios *);

The following names are reserved for XSI-conformant systems to use as an extension to the above; therefore strictly conforming applications shall not use them:

- CBAUD
- DEFECHO
- ECHOCTL
- ECHOKE
- ECHOPRT
- EXTAB
- EMBRK
- EREPRINT
- ESTATUS
- FDISCARD
- VDISCARD
- VLNEXT
- VLSUSP
- LOBLK
- VREPRINT
- SWTCH
- VWERASE

None.

None.

CHANGE HISTORY

First released in Issue 3.

Included for alignment with the ISO POSIX-1 standard.

**Issue 6**

The LEGACY symbols IUCLC, OLCUC, and XCASE are removed.

FIPS 151-2 requirements for the symbols CS7, CS8, CSTOPB, PARODD, and PARENB are reaffirmed.

IEEE Std 1003.1-2001/Cor 1-2002, item XBD/TC1/D6/19 is applied, changing ECHOK to ECHOKE in the APPLICATION USAGE section.
The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-2001 defers to the ISO C standard.

The `<tgmath.h>` header shall include the headers `<math.h>` and `<complex.h>` and shall define several type-generic macros.

Of the functions contained within the `<math.h>` and `<complex.h>` headers without an `f` (`float`) or `l` (`long double`) suffix, several have one or more parameters whose corresponding real type is `double`. For each such function, except `modf()`, there shall be a corresponding type-generic macro. The parameters whose corresponding real type is `double` in the function synopsis are generic parameters. Use of the macro invokes a function whose corresponding real type and type domain are determined by the arguments for the generic parameters.

Use of the macro invokes a function whose generic parameters have the corresponding real type determined as follows:

- First, if any argument for generic parameters has type `long double`, the type determined is `long double`.
- Otherwise, if any argument for generic parameters has type `double` or is of integer type, the type determined is `double`.
- Otherwise, the type determined is `float`.

For each unsuffixed function in the `<math.h>` header for which there is a function in the `<complex.h>` header with the same name except for a `c` prefix, the corresponding type-generic macro (for both functions) has the same name as the function in the `<math.h>` header. The corresponding type-generic macro for `fabs()` and `cabs()` is `fabs()`.

<td><code>cabs()</code></td>
<td><code>fabs()</code></td>
</tr>
</tbody>
</table>
If at least one argument for a generic parameter is complex, then use of the macro invokes a complex function; otherwise, use of the macro invokes a real function.

For each unsuffixed function in the `<math.h>` header without a c-prefixed counterpart in the `<complex.h>` header, the corresponding type-generic macro has the same name as the function. These type-generic macros are:

- `atan2()`, `fma()`, `llround()`, `remainder()`
- `cbrt()`, `fmax()`, `log10()`, `remquo()`
- `ceil()`, `fmin()`, `log1p()`, `rint()`
- `copysign()`, `fmod()`, `log2()`, `round()`
- `erf()`, `frexp()`, `logb()`, `scalbn()`
- `erfc()`, `hypot()`, `lrint()`, `scalbln()`
- `exp2()`, `ilogb()`, `lround()`, `tgamma()`
- `expm1()`, `ldexp()`, `nearbyint()`, `trunc()`
- `fdim()`, `lgamma()`, `nextafter()`
- `floor()`, `llrint()`, `nexttoward()`

If all arguments for generic parameters are real, then use of the macro invokes a real function; otherwise, use of the macro results in undefined behavior.

For each unsuffixed function in the `<complex.h>` header that is not a c-prefixed counterpart to a function in the `<math.h>` header, the corresponding type-generic macro has the same name as the function. These type-generic macros are:

- `carg()`, `cimag()`
- `conj()`
- `creal()`

Use of the macro with any real or complex argument invokes a complex function.

**APPLICATION USAGE**

With the declarations:

```c
#include <tgmath.h>
int n;
float f;
double d;
long double ld;
float complex fc;
double complex dc;
long double complex ldc;
```

functions invoked by use of type-generic macros are shown in the following table:

<table>
<thead>
<tr>
<th>Macro</th>
<th>Use</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>exp(n)</code></td>
<td><code>exp(n)</code>, the function</td>
</tr>
<tr>
<td><code>acosh(f)</code></td>
<td><code>acoshf(f)</code></td>
</tr>
<tr>
<td><code>sin(d)</code></td>
<td><code>sin(d)</code>, the function</td>
</tr>
<tr>
<td><code>atan(ld)</code></td>
<td><code>atanl(ld)</code></td>
</tr>
</tbody>
</table>
RATIONAL

Type-generic macros allow calling a function whose type is determined by the argument type, as is the case for C operators such as `+` and `*`. For example, with a type-generic `cos()` macro, the expression `cos((float)x)` will have type `float`. This feature enables writing more portably efficient code and alleviates need for awkward casting and suffixing in the process of porting or adjusting precision. Generic math functions are a widely appreciated feature of Fortran.

The only arguments that affect the type resolution are the arguments corresponding to the parameters that have type `double` in the synopsis. Hence the type of a type-generic call to `nexttoward()`, whose second parameter is `long double` in the synopsis, is determined solely by the type of the first argument.

The term “type-generic” was chosen over the proposed alternatives of intrinsic and overloading. The term is more specific than intrinsic, which already is widely used with a more general meaning, and reflects a closer match to Fortran’s generic functions than to C++ overloading.

The macros are placed in their own header in order not to silently break old programs that include the `<math.h>` header; for example, with:

```c
printf("%e", sin(x))
```

`modf(double, double *)` is excluded because no way was seen to make it safe without complicating the type resolution.

The implementation might, as an extension, endow appropriate ones of the macros that IEEE Std 1003.1-2001 specifies only for real arguments with the ability to invoke the complex functions.

IEEE Std 1003.1-2001 does not prescribe any particular implementation mechanism for generic macros. It could be implemented simply with built-in macros. The generic macro for `sqrt()`, for example, could be implemented with:

```c
#undef sqrt
#define sqrt(x) __BUILTIN_GENERIC_sqrt(x)
```

Generic macros are designed for a useful level of consistency with C++ overloaded math functions.
The great majority of existing C programs are expected to be unaffected when the `<tgmath.h>` header is included instead of the `<math.h>` or `<complex.h>` headers. Generic macros are similar to the ISO/IEC 9899: 1999 standard library masking macros, though the semantic types of return values differ.

The ability to overload on integer as well as floating types would have been useful for some functions; for example, `copysign()` . Overloading with different numbers of arguments would have allowed reusing names; for example, `remainder()` for `remquo()` . However, these facilities would have complicated the specification; and their natural consistent use, such as for a floating `abs()` or a two-argument `atan()` , would have introduced further inconsistencies with the ISO/IEC 9899: 1999 standard for insufficient benefit.

The ISO C standard in no way limits the implementation's options for efficiency, including inlining library functions.

**FUTURE DIRECTIONS**

None.

**SEE ALSO**

`<math.h>`, `<complex.h>`, the System Interfaces volume of IEEE Std 1003.1-2001, `cabs()`, `fabs()`, `modf()`

**CHANGE HISTORY**

The `<time.h>` header shall declare the structure `tm`, which shall include at least the following members:

- `int tm_sec` Seconds [0,60].
- `int tm_min` Minutes [0,59].
- `int tm_hour` Hour [0,23].
- `int tm_mday` Day of month [1,31].
- `int tm_mon` Month of year [0,11].
- `int tm_year` Years since 1900.
- `int tm_wday` Day of week [0,6] (Sunday =0).
- `int tm_yday` Day of year [0,365].
- `int tm_isdst` Daylight Savings flag.

The value of `tm_isdst` shall be positive if Daylight Savings Time is in effect, 0 if Daylight Savings Time is not in effect, and negative if the information is not available.

The `<time.h>` header shall define the following symbolic names:

- `NULL` Null pointer constant.
- `CLOCKS_PER_SEC` A number used to convert the value returned by the `clock()` function into seconds.
- `CLOCK_PROCESS_CPUTIME_ID` The identifier of the CPU-time clock associated with the process making a `clock()` or `timer()` function call.
- `CLOCK_THREAD_CPUTIME_ID` The identifier of the CPU-time clock associated with the thread making a `clock()` or `timer()` function call.

The `<time.h>` header shall declare the structure `timespec`, which has at least the following members:

- `time_t tv_sec` Seconds.
- `long tv_nsec` Nanoseconds.

The `<time.h>` header shall also declare the `itimerspec` structure, which has at least the following members:

- `struct timespec it_interval` Timer period.
- `struct timespec it_value` Timer expiration.

The following manifest constants shall be defined:

- `CLOCK_REALTIME` The identifier of the system-wide realtime clock.
- `CLOCK_BOOTTIME` The identifier of the system-wide boot clock.
- `CLOCK_MONOTONIC` The identifier of the monotonic clock.
- `CLOCK_MONOTONIC_RAW` The identifier of the monotonic clock with raw time.
- `CLOCK_MONOTONIC_ID` The identifier of the monotonic clock.
- `CLOCK_THREAD_CPUTIME_ID` The identifier of the CPU-time clock associated with the thread.
- `CLOCK_PROCESS_CPUTIME_ID` The identifier of the CPU-time clock associated with the process.
CLOCK_MONOTONIC

The identifier for the system-wide monotonic clock, which is defined as a
clock whose value cannot be set via clock_settime() and which cannot
have backward clock jumps. The maximum possible clock jump shall be
implementation-defined.

The clock_t, size_t, time_t, clockid_t, and timer_t types shall be defined as described in
<sys/types.h>.

Although the value of CLOCKS_PER_SEC is required to be 1 million on all XSI-conformant
systems, it may be variable on other systems, and it should not be assumed that
CLOCKS_PER_SEC is a compile-time constant.

The <time.h> header shall provide a declaration for getdate_err.

The following shall be declared as functions and may also be defined as macros. Function
prototypes shall be provided.

13763 MON  The identifier for the system-wide monotonic clock, which is defined as a
13764  clock whose value cannot be set via clock_settime() and which cannot
13765  have backward clock jumps. The maximum possible clock jump shall be
13766  implementation-defined.
13767  The clock_t, size_t, time_t, clockid_t, and timer_t types shall be defined as described in
13768  <sys/types.h>.
13769  Although the value of CLOCKS_PER_SEC is required to be 1 million on all XSI-conformant
13770  systems, it may be variable on other systems, and it should not be assumed that
13771  CLOCKS_PER_SEC is a compile-time constant.
13772  The <time.h> header shall provide a declaration for getdate_err.
13773  The following shall be declared as functions and may also be defined as macros. Function
13774  prototypes shall be provided.
13775  
13776  char *asctime(const struct tm *);
13777  char *asctime_r(const struct tm *restrict, char *restrict);
13778  clock_t clock(void);
13779  int clock_getcpuclockid(pid_t, clockid_t *);
13780  int clock_getres(clockid_t, struct timespec *);
13781  int clock_gettime(clockid_t, struct timespec *);
13782  int clock_nanosleep(clockid_t, int, const struct timespec *,
13783  struct timespec *);
13784  int clock_settime(clockid_t, const struct timespec *);
13785  char *ctime(const time_t *);
13786  char *ctime_r(const time_t *, char *);
13787  double difftime(time_t, time_t);
13788  struct tm *getdate(const char *);
13789  struct tm *gmtime(const time_t *);
13790  struct tm *gmtime_r(const time_t *, struct tm *restrict);
13791  struct tm *localtime(const time_t *);
13792  struct tm *localtime_r(const time_t *, restrict, struct tm *restrict);
13793  time_t mktime(struct tm *);
13794  int nanosleep(const struct timespec *, struct timespec *);
13795  size_t strftime(char *, const struct tm *, const char *,
13796  const struct tm *restrict);
13797  char *strptime(const char *, const char *, struct tm *);
13798  struct tm *restrict);
13799  time_t time(time_t *);
13800  int timer_create(clockid_t, struct sigevent *, timer_t *);
13801  int timer_delete(timer_t);
13802  int timer_gettime(timer_t, struct itimerspec *);
13803  int timer_gettime(timer_t, const struct itimerspec *,
13804  struct itimerspec *restrict);
13805  int timer_settime(timer_t, int, const struct itimerspec *,
13806  struct itimerspec *restrict);
13807  void tzset(void);
The following shall be declared as variables:

```c
extern int daylight;
extern long timezone;
extern char *tzname[];
```

Inclusion of the `<time.h>` header may make visible all symbols from the `<signal.h>` header.

**APPLICATION USAGE**

The range `[0,60]` for `tm_sec` allows for the occasional leap second.

`tm_year` is a signed value; therefore, years before 1900 may be represented.

To obtain the number of clock ticks per second returned by the `times()` function, applications should call `sysconf(_SC_CLK_TCK)`.

**RATIONALE**

The range `[0,60]` seconds allows for positive or negative leap seconds. The formal definition of UTC does not permit double leap seconds, so all mention of double leap seconds has been removed, and the range shortened from the former `[0,61]` seconds seen in previous versions of POSIX.

**FUTURE DIRECTIONS**

None.

**SEE ALSO**

`<signal.h>`, `<sys/types.h>`, the System Interfaces volume of IEEE Std 1003.1-2001, `asctime()`, `clock()`, `clock_gettime()`, `ctime()`, `difftime()`, `getdate()`, `gmtime()`, `localtime()`, `mktime()`, `nanosleep()`, `strftime()`, `strptime()`, `sysconf()`, `time()`, `timer_create()`, `timer_delete()`, `timer_getoverrun()`, `tzname`, `tzset()`, `utime()`

**CHANGE HISTORY**

First released in Issue 1. Derived from Issue 1 of the SVID.

**Issue 5**

The DESCRIPTION is updated for alignment with the POSIX Realtime Extension and the POSIX Threads Extension.

**Issue 6**

The Open Group Corrigendum U035/6 is applied. In the DESCRIPTION, the types `clockid_t` and `timer_t` have been described.

The following changes are made for alignment with the ISO POSIX-1:1996 standard:

- The POSIX timer-related functions are marked as part of the Timers option.
- The symbolic name CLK_TCK is removed. Application usage is added describing how its equivalent functionality can be obtained using `sysconf()`.
- The `clock_gettime()` function and manifest constants `CLOCK_PROCESS_CPUTIME_ID` and `CLOCK_THREAD_CPUTIME_ID` are added for alignment with IEEE Std 1003.1d-1999.
- The manifest constant `CLOCK_MONOTONIC` and the `clock_nanosleep()` function are added for alignment with IEEE Std 1003.1j-2000.

The following changes are made for alignment with the ISO/IEC 9899:1999 standard:

- The range for seconds is changed from `[0,61]` to `[0,60]`
- The `restrict` keyword is added to the prototypes for `asctime_r()`, `gmtime_r()`, `localtime_r()`, `strftime()`, `strptime()`, `timer_create()`, and `timer_settime()`.
IEEE PASC Interpretation 1003.1 #84 is applied adding the statement that symbols from the
<stdio.h> header may be made visible when the <time.h> header is included.

Extensions beyond the ISO C standard are marked.
NAME

trace.h — tracing

SYNOPSIS

```c
#include <trace.h>
```

DESCRIPTION

The `<trace.h>` header shall define the `posix_trace_event_info` structure that includes at least the following members:

```c
trace_event_id_t  posix_trace_event_id
pid_t             posix_pid
void *            *posix_prog_address
int               posix_truncation_status
struct timespec   posix_timestamp
pthread_t         posix_thread_id
```

The `<trace.h>` header shall define the `posix_trace_status_info` structure that includes at least the following members:

```c
int    posix_stream_status
int    posix_stream_full_status
int    posix_stream_overrun_status
int    posix_stream_flush_status
int    posix_stream_flush_error
int    posix_log_overrun_status
int    posix_log_full_status
```

The `<trace.h>` header shall define the following symbols:

```c
POSIX_TRACE_ALL_EVENTS
POSIX_TRACE_APPEND
POSIX_TRACE_CLOSE_FOR_CHILD
POSIX_TRACE_FILTER
POSIX_TRACE_FLUSH
POSIX_TRACE_FLUSH_START
POSIX_TRACE_FLUSH_STOP
POSIX_TRACE_FLUSHING
POSIX_TRACE_FULL
POSIX_TRACE_LOOP
POSIX_TRACE_NO_OVERRUN
POSIX_TRACE_NOT_FLUSHING
POSIX_TRACE_NOT_FULL
POSIX_TRACE_INHERITED
POSIX_TRACE_NOT_TRUNCATED
POSIX_TRACE_OVERFLOW
POSIX_TRACE_OVERRUN
POSIX_TRACE_RESUME
POSIX_TRACE_RUNNING
POSIX_TRACE_START
POSIX_TRACE_STOP
POSIX_TRACE_SUSPENDED
POSIX_TRACE_SYSTEM_EVENTS
```
POSIX_TRACE_TRUNCATED_READ
POSIX_TRACE_TRUNCATED_RECORD
POSIX_TRACE_UNNAMED_USER_EVENT
POSIX_TRACE_UNTIL_FULL
POSIX_TRACE_WOPID_EVENTS

The following types shall be defined as described in `<sys/types.h>`:

```
trace_attr_t
trace_id_t
trace_event_id_t
trace_event_set_t
```

The following shall be declared as functions and may also be defined as macros. Function prototypes shall be provided.

```
int posix_trace_attr_destroy(trace_attr_t *);
int posix_trace_attr_getclockres(const trace_attr_t *,
    struct timespec *);

NAME
ucontext.h — user context

SYNOPSIS
XSI
#include <ucontext.h>

DESCRIPTION
The <ucontext.h> header shall define the mcontext_t type through typedef.
The <ucontext.h> header shall define the ucontext_t type as a structure that shall include at least
the following members:

- ucontext_t *uc_link: Pointer to the context that is resumed when this context returns.
- sigset_t uc_sigmask: The set of signals that are blocked when this context is active.
- stack_t uc_stack: The stack used by this context.
- mcontext_t uc_mcontext: A machine-specific representation of the saved context.

The types sigset_t and stack_t shall be defined as in <signal.h>.
The following shall be declared as functions and may also be defined as macros, Function prototypes shall be provided.

- int getcontext(ucontext_t *);
- int setcontext(const ucontext_t *);
- void makecontext(ucontext_t *, void (*)(void), int, ...);
- int swapcontext(ucontext_t *restrict, const ucontext_t *restrict);

APPLICATION USAGE
None.

RATIONALE
None.

FUTURE DIRECTIONS
None.

SEE ALSO
<ucontext.h>, the System Interfaces volume of IEEE Std 1003.1-2001, getcontext(), makecontext(),
sigaction(), sigprocmask(), sigaltstack()

CHANGE HISTORY
First released in Issue 4, Version 2.
NAME
ulimit.h — ulimit commands

SYNOPSIS
XSI
#include <ulimit.h>

DESCRIPTION
The <ulimit.h> header shall define the symbolic constants used by the ulimit() function.

Symbolic constants:
UL_GETFSIZE Get maximum file size.
UL_SETFSIZE Set maximum file size.

The following shall be declared as a function and may also be defined as a macro. A function
prototype shall be provided.
long ulimit(int, ...);

APPLICATION USAGE
None.

RATIONALE
None.

FUTURE DIRECTIONS
None.

SEE ALSO
The System Interfaces volume of IEEE Std 1003.1-2001, ulimit()

CHANGE HISTORY
First released in Issue 3.
NAME
unistd.h — standard symbolic constants and types

SYNOPSIS
#include <unistd.h>

DESCRIPTION
The <unistd.h> header defines miscellaneous symbolic constants and types, and declares
miscellaneous functions. The actual values of the constants are unspecified except as shown. The
contents of this header are shown below.

Version Test Macros
The following symbolic constants shall be defined:

_POSIX_VERSION
Integer value indicating version of IEEE Std 1003.1 (C-language binding) to which the
implementation conforms. For implementations conforming to IEEE Std 1003.1-2001, the
value shall be 200112L.

_POSIX2_VERSION
Integer value indicating version of the Shell and Utilities volume of IEEE Std 1003.1 to
which the implementation conforms. For implementations conforming to
IEEE Std 1003.1-2001, the value shall be 200112L.

The following symbolic constant shall be defined only if the implementation supports the XSI
option; see Section 2.1.4 (on page 21).

_XOPEN_VERSION
Integer value indicating version of the X/Open Portability Guide to which the
implementation conforms. The value shall be 600.

Constants for Options and Option Groups
The following symbolic constants, if defined in <unistd.h>, shall have a value of −1, 0, or greater,
unless otherwise specified below. If these are undefined, the fpathconf(), pathconf(), or sysconf()
functions can be used to determine whether the option is provided for a particular invocation of
the application.

If a symbolic constant is defined with the value −1, the option is not supported. Headers, data
types, and function interfaces required only for the option need not be supplied. An application
that attempts to use anything associated only with the option is considered to be requiring an
extension.

If a symbolic constant is defined with a value greater than zero, the option shall always be
supported when the application is executed. All headers, data types, and functions shall be
present and shall operate as specified.

If a symbolic constant is defined with the value zero, all headers, data types, and functions shall
be present. The application can check at runtime to see whether the option is supported by
calling fpathconf(), pathconf(), or sysconf() with the indicated name parameter.

Unless explicitly specified otherwise, the behavior of functions associated with an unsupported
option is unspecified, and an application that uses such functions without first checking
fpathconf(), pathconf(), or sysconf() is considered to be requiring an extension.

For conformance requirements, refer to Chapter 2 (on page 17).
The implementation supports the Advisory Information option. If this symbol has a value other than −1 or 0, it shall have the value 200112L.

The implementation supports the Asynchronous Input and Output option. If this symbol has a value other than −1 or 0, it shall have the value 200112L.

The implementation supports the Barriers option. If this symbol has a value other than −1 or 0, it shall have the value 200112L.

The use of chown() and fchown() is restricted to a process with appropriate privileges, and to changing the group ID of a file only to the effective group ID of the process or to one of its supplementary group IDs. This symbol shall always be set to a value other than −1.

The implementation supports the Clock Selection option. If this symbol has a value other than −1 or 0, it shall have the value 200112L.

The implementation supports the Process CPU-Time Clocks option. If this symbol has a value other than −1 or 0, it shall have the value 200112L.

The implementation supports the File Synchronization option. If this symbol has a value other than −1 or 0, it shall have the value 200112L.

The implementation supports the IPv6 option. If this symbol has a value other than −1 or 0, it shall have the value 200112L.

The implementation supports job control. This symbol shall always be set to a value greater than zero.

The implementation supports the Memory Mapped Files option. If this symbol has a value other than −1 or 0, it shall have the value 200112L.

The implementation supports the Process Memory Locking option. If this symbol has a value other than −1 or 0, it shall have the value 200112L.

The implementation supports the Range Memory Locking option. If this symbol has a value other than −1 or 0, it shall have the value 200112L.

The implementation supports the Memory Protection option. If this symbol has a value other than −1 or 0, it shall have the value 200112L.

The implementation supports the Message Passing option. If this symbol has a value other than −1 or 0, it shall have the value 200112L.

The implementation supports the Monotonic Clock option. If this symbol has a value other than −1 or 0, it shall have the value 200112L.
than −1 or 0, it shall have the value 200112L.

_POSIX_NO_TRUNC
Pathname components longer than \{NAME_MAX\} generate an error. This symbol shall always be set to a value other than −1.

_POSIX_PRIORITIZED_IO
The implementation supports the Prioritized Input and Output option. If this symbol has a value other than −1 or 0, it shall have the value 200112L.

_POSIX_PRIORITY_SCHEDULING
The implementation supports the Process Scheduling option. If this symbol has a value other than −1 or 0, it shall have the value 200112L.

_POSIX_RAW_SOCKETS
The implementation supports the Raw Sockets option. If this symbol has a value other than −1 or 0, it shall have the value 200112L.

_POSIX_READER_WRITER_LOCKS
The implementation supports the Read-Write Locks option. This is always set to a value greater than zero if the Threads option is supported. If this symbol has a value other than −1 or 0, it shall have the value 200112L.

_POSIX_REALTIME_SIGNALS
The implementation supports the Realtime Signals Extension option. If this symbol has a value other than −1 or 0, it shall have the value 200112L.

_POSIX_REGEXP
The implementation supports the Regular Expression Handling option. This symbol shall always be set to a value greater than zero.

_POSIX_SAVED_IDS
Each process has a saved set-user-ID and a saved set-group-ID. This symbol shall always be set to a value greater than zero.

_POSIX_SEMAPHORES
The implementation supports the Semaphores option. If this symbol has a value other than −1 or 0, it shall have the value 200112L.

_POSIX_SHARED_MEMORY_OBJECTS
The implementation supports the Shared Memory Objects option. If this symbol has a value other than −1 or 0, it shall have the value 200112L.

_POSIX_SHELL
The implementation supports the POSIX shell. This symbol shall always be set to a value greater than zero.

_POSIX_SPAWN
The implementation supports the Spawn option. If this symbol has a value other than −1 or 0, it shall have the value 200112L.

_POSIX_SPINLOCKS
The implementation supports the Spin Locks option. If this symbol has a value other than −1 or 0, it shall have the value 200112L.

_POSIX_SPORADIC_SERVER
The implementation supports the Process Sporadic Server option. If this symbol has a value other than −1 or 0, it shall have the value 200112L.
The implementation supports the Synchronized Input and Output option. If this symbol has a value other than −1 or 0, it shall have the value 200112L.

The implementation supports the Thread Stack Address Attribute option. If this symbol has a value other than −1 or 0, it shall have the value 200112L.

The implementation supports the Thread Stack Size Attribute option. If this symbol has a value other than −1 or 0, it shall have the value 200112L.

The implementation supports the Thread CPU-Time Clocks option. If this symbol has a value other than −1 or 0, it shall have the value 200112L.

The implementation supports the Thread Priority Inheritance option. If this symbol has a value other than −1 or 0, it shall have the value 200112L.

The implementation supports the Thread Priority Protection option. If this symbol has a value other than −1 or 0, it shall have the value 200112L.

The implementation supports the Thread Execution Scheduling option. If this symbol has a value other than −1 or 0, it shall have the value 200112L.

The implementation supports the Thread Process-Shared Synchronization option. If this symbol has a value other than −1 or 0, it shall have the value 200112L.

The implementation supports the Thread-Safe Functions option. If this symbol has a value other than −1 or 0, it shall have the value 200112L.

The implementation supports the Thread Sporadic Server option. If this symbol has a value other than −1 or 0, it shall have the value 200112L.

The implementation supports the Threads option. If this symbol has a value other than −1 or 0, it shall have the value 200112L.

The implementation supports the Timeouts option. If this symbol has a value other than −1 or 0, it shall have the value 200112L.

The implementation supports the Timers option. If this symbol has a value other than −1 or 0, it shall have the value 200112L.

The implementation supports the Trace option. If this symbol has a value other than −1 or 0, it shall have the value 200112L.

The implementation supports the Trace Event Filter option. If this symbol has a value other than −1 or 0, it shall have the value 200112L.
POSIX_TRACE_INHERIT
The implementation supports the Trace Inherit option. If this symbol has a value other than −1 or 0, it shall have the value 200112L.

POSIX_TRACE_LOG
The implementation supports the Trace Log option. If this symbol has a value other than −1 or 0, it shall have the value 200112L.

POSIX_TYPED_MEMORY_OBJECTS
The implementation supports the Typed Memory Objects option. If this symbol has a value other than −1 or 0, it shall have the value 200112L.

_POSIX_VDISABLE
This symbol shall be defined to be the value of a character that shall disable terminal special character handling as described in <termios.h>. This symbol shall always be set to a value other than −1.

_POSIX2_C_BIND
The implementation supports the C-Language Binding option. This symbol shall always have the value 200112L.

_POSIX2_C_DEV
The implementation supports the C-Language Development Utilities option. If this symbol has a value other than −1 or 0, it shall have the value 200112L.

_POSIX2_CHAR_TERM
The implementation supports at least one terminal type.

_POSIX2_FORT_DEV
The implementation supports the FORTRAN Development Utilities option. If this symbol has a value other than −1 or 0, it shall have the value 200112L.

_POSIX2_FORT_RUN
The implementation supports the FORTRAN Runtime Utilities option. If this symbol has a value other than −1 or 0, it shall have the value 200112L.

_POSIX2_LOCALEDEF
The implementation supports the creation of locales by the localedef utility. If this symbol has a value other than −1 or 0, it shall have the value 200112L.

_POSIX2_PBS
The implementation supports the Batch Environment Services and Utilities option. If this symbol has a value other than −1 or 0, it shall have the value 200112L.

_POSIX2_PBS_ACCOUNTING
The implementation supports the Batch Accounting option. If this symbol has a value other than −1 or 0, it shall have the value 200112L.

_POSIX2_PBS_CHECKPOINT
The implementation supports the Batch Checkpoint/Restart option. If this symbol has a value other than −1 or 0, it shall have the value 200112L.

_POSIX2_PBS_LOCATE
The implementation supports the Locate Batch Job Request option. If this symbol has a value other than −1 or 0, it shall have the value 200112L.

_POSIX2_PBS_MESSAGE
The implementation supports the Batch Job Message Request option. If this symbol has a value other than −1 or 0, it shall have the value 200112L.

</tbody>
</table>
The implementation supports the Issue 4, Version 2 Shared Memory Option Group. This symbol shall always be set to a value other than −1.

The implementation supports the XSI STREAMS Option Group.

The implementation supports the XSI extension.

Execution-Time Symbolic Constants

If any of the following constants are not defined in the `<unistd.h>` header, the value shall vary depending on the file to which it is applied.

If any of the following constants are defined to have value −1 in the `<unistd.h>` header, the implementation shall not provide the option on any file; if any are defined to have a value other than −1 in the `<unistd.h>` header, the implementation shall provide the option on all applicable files.

All of the following constants, whether defined in `<unistd.h>` or not, may be queried with respect to a specific file using the `pathconf()` or `fpathconf()` functions:

- `_POSIX_ASYNC_IO`
  Asynchronous input or output operations may be performed for the associated file.

- `_POSIX_PRIO_IO`
  Prioritized input or output operations may be performed for the associated file.

- `_POSIX_SYNC_IO`
  Synchronized input or output operations may be performed for the associated file.

Constants for Functions

The following symbolic constant shall be defined:

- `NULL` Null pointer

The following symbolic constants shall be defined for the `access()` function:

- `F_OK` Test for existence of file.

- `R_OK` Test for read permission.

- `W_OK` Test for write permission.

- `X_OK` Test for execute (search) permission.

The constants `F_OK, R_OK, W_OK, and X_OK` and the expressions `R_OK | W_OK, R_OK | X_OK, and R_OK | W_OK | X_OK` shall all have distinct values.

The following symbolic constants shall be defined for the `confstr()` function:

- `_CS_PATH`
  This is the value for the `PATH` environment variable that finds all standard utilities.

- `_CS_POSIX_V6_ILP32_OFF32_CFLAGS`
  If `sysconf(_SC_V6_ILP32_OFF32)` returns −1, the meaning of this value is unspecified. Otherwise, this value is the set of initial options to be given to the `c99` utility to build an application using a programming model with 32-bit `int, long, pointer, and off_t` types.
If `sysconf(_SC_V6_ILP32_OFF32)` returns −1, the meaning of this value is unspecified.
Otherwise, this value is the set of final options to be given to the `c99` utility to build an
application using a programming model with 32-bit `int`, `long`, `pointer`, and `off_t` types.

If `sysconf(_SC_V6_ILP32_OFF32)` returns −1, the meaning of this value is unspecified.
Otherwise, this value is the set of libraries to be given to the `c99` utility to build an
application using a programming model with 32-bit `int`, `long`, `pointer`, and `off_t` types.

If `sysconf(_SC_V6_ILP32_OFFBIG)` returns −1, the meaning of this value is unspecified.
Otherwise, this value is the set of initial options to be given to the `c99` utility to build an
application using a programming model with 32-bit `int`, `long`, and `pointer` types, and an
`off_t` type using at least 64 bits.

If `sysconf(_SC_V6_ILP32_OFFBIG)` returns −1, the meaning of this value is unspecified.
Otherwise, this value is the set of libraries to be given to the `c99` utility to build an
application using a programming model with 32-bit `int`, `long`, and `pointer` types, and an
`off_t` type using at least 64 bits.

If `sysconf(_SC_V6_LP64_OFF64)` returns −1, the meaning of this value is unspecified.
Otherwise, this value is the set of initial options to be given to the `c99` utility to build an
application using a programming model with 32-bit `int` and 64-bit `long`, `pointer`, and `off_t` types.

If `sysconf(_SC_V6_LP64_OFF64)` returns −1, the meaning of this value is unspecified.
Otherwise, this value is the set of final options to be given to the `c99` utility to build an
application using a programming model with 32-bit `int` and 64-bit `long`, `pointer`, and `off_t` types.

If `sysconf(_SC_V6_LP64_OFF64)` returns −1, the meaning of this value is unspecified.
Otherwise, this value is the set of libraries to be given to the `c99` utility to build an
application using a programming model with 32-bit `int` and 64-bit `long`, `pointer`, and `off_t` types.

If `sysconf(_SC_V6_LPBIG_OFFBIG)` returns −1, the meaning of this value is unspecified.
Otherwise, this value is the set of initial options to be given to the `c99` utility to build an
application using a programming model with an `int` type using at least 32 bits and `long`,
`pointer`, and `off_t` types using at least 64 bits.

If `sysconf(_SC_V6_LPBIG_OFFBIG)` returns −1, the meaning of this value is unspecified.
Otherwise, this value is the set of final options to be given to the `c99` utility to build an
application using a programming model with an `int` type using at least 32 bits and `long`,
`pointer`, and `off_t` types using at least 64 bits.
_CS_POSIX_V6_LPBIG_OFFBIG_LIBS

If `sysconf(_SC_POSIX_V6_LPBIG_OFFBIG)` returns \(-1\), the meaning of this value is unspecified. Otherwise, this value is the set of libraries to be given to the `c99` utility to build an application using a programming model with an `int` type using at least 32 bits and `long`, `pointer`, and `off_t` types using at least 64 bits.

_`CS_POSIX_V6_WIDTH_RESTRICTED_ENVS`

This value is a <newline>-separated list of names of programming environments supported by the implementation in which the widths of the `blksize_t`, `cc_t`, `mode_t`, `nfds_t`, `pid_t`, `ptrdiff_t`, `size_t`, `speed_t`, `ssize_t`, `suseconds_t`, `tcflag_t`, `useconds_t`, `wchar_t`, and `wint_t` types are no greater than the width of type `long`.

XSI

The following symbolic constants are reserved for compatibility with Issue 5:

</table>

The following symbolic constants shall be defined for the `lseek()` and `fcntl()` functions and shall have distinct values:

- SEEK_CUR: Set file offset to current plus `offset`.
- SEEK_END: Set file offset to EOF plus `offset`.
- SEEK_SET: Set file offset to `offset`.

The following symbolic constants shall be defined as possible values for the `function` argument to the `lockf()` function:

- F_LOCK: Lock a section for exclusive use.
- F_TEST: Test section for locks by other processes.
- F_TLOCK: Test and lock a section for exclusive use.
- F_ULOCK: Unlock locked sections.

The following symbolic constants shall be defined for `pathconf()`:

Base Definitions, Issue 6 — Copyright © 2001-2003, IEEE and The Open Group. All rights reserved.
The two constants _SC_PAGESIZE and _SC_PAGE_SIZE may be defined to have the same value.

The following symbolic constants shall be defined for file streams:

- STDERR_FILENO  File number of stderr; 2.
- STDIN_FILENO   File number of stdin; 0.
- STDOUT_FILENO  File number of stdout; 1.

**Type Definitions**

The size_t, ssize_t, uid_t, gid_t, off_t, pid_t, and useconds_t types shall be defined as described in <sys/types.h>.

The intptr_t type shall be defined as described in <inttypes.h>.
The following shall be declared as functions and may also be defined as macros. Function prototypes shall be provided.

```c
int access(const char *, int);
unsigned alarm(unsigned);
int chdir(const char *);
int chown(const char *, uid_t, gid_t);
int close(int);
size_t confstr(int, char *, size_t);
char *crypt(const char *, const char *);
char *ctermid(char *);
int dup(int);
dup2(int, int);
void encrypt(char[64], int);
```
14672 int nice(int);
14673 long pathconf(const char *, int);
14674 int pause(void);
14675 int pipe(const int[2]);
14676 XSI ssize_t pread(int, void *, size_t, off_t);
14677 ssize_t pwrite(int, const void *, size_t, off_t);
14678 ssize_t read(int, void *, size_t);
14679 ssize_t readlink(const char *restrict, char *restrict, size_t);
14680 int rmdir(const char *);
14681 int setegid(gid_t);
14682 int seteuid(uid_t);
14683 int setgid(gid_t);
14684 int setpgid(pid_t, pid_t);
14685 XSI pid_t setpgid(void);
14686 int setregid(gid_t, gid_t);
14687 int setreuid(uid_t, uid_t);
14688 pid_t setsid(void);
14689 int setuid(uid_t);
14690 unsigned sleep(unsigned);
14691 XSI void swab(const void *restrict, void *restrict, ssize_t);
14692 int symlink(const char *, const char *);
14693 void sync(void);
14694 long sysconf(int);
14695 pid_t tcgetpgrp(int);
14696 int tcsetpgrp(int, pid_t);
14697 XSI int truncate(const char *, off_t);
14698 char *ttystatus(int);
14699 int ttystatus_r(int, char *, size_t);
14700 XSI useconds_t ualarm(useconds_t, useconds_t);
14701 int unlink(const char *);
14702 XSI int usleep(useconds_t);
14703 pid_t vfork(void);
14704 ssize_t write(int, const void *, size_t);

Implementations may also include the pthread_atfork() prototype as defined in <pthread.h> (on page 289).

The following external variables shall be declared:

extern int optind, opterr, optopt;
extern char *optarg;

**APPLICATION USAGE**

IEEE Std 1003.1-2001 only describes the behavior of systems that claim conformance to it. However, application developers who want to write applications that adapt to other versions of IEEE Std 1003.1 (or to systems that do not conform to any POSIX standard) may find it useful to code them so as to conditionally compile different code depending on the value of _POSIX_VERSION, for example:

```c
#if _POSIX_VERSION >= 200112L
  /* Use the newer function that copes with large files. */
  off_t pos=ftello(fp);
#else
  /* Either this is an old version of POSIX, or _POSIX_VERSION is not even defined, so use the traditional function. */
```
Earlier versions of IEEE Std 1003.1 and of the Single UNIX Specification can be identified by the following macros:

- **POSIX.1-1988 standard**
  - `_POSIX_VERSION` = 198808L

- **POSIX.1-1990 standard**
  - `_POSIX_VERSION` = 199009L

- **ISO POSIX-1: 1996 standard**
  - `_POSIX_VERSION` = 199506L

- **Single UNIX Specification, Version 1**
  - `_XOPEN_UNIX` and `_XOPEN_VERSION` = 4

- **Single UNIX Specification, Version 2**
  - `_XOPEN_UNIX` and `_XOPEN_VERSION` = 500

IEEE Std 1003.1-2001 does not make any attempt to define application binary interaction with the underlying operating system. However, application developers may find it useful to query `_SC_VERSION` at runtime via `sysconf()` to determine whether the current version of the operating system supports the necessary functionality as in the following program fragment:

```c
if (sysconf(_SC_VERSION) < 200112L) {
  fprintf(stderr, "POSIX.1-2001 system required, terminating \n");
  exit(1);
}
```

New applications should not use `_XOPEN_SHM` or `_XOPEN_ENH_I18N`.

**RATIONALE**

As IEEE Std 1003.1-2001 evolved, certain options became sufficiently standardized that it was concluded that simply requiring one of the option choices was simpler than retaining the option. However, for backwards-compatibility, the option flags (with required constant values) are retained.

**Version Test Macros**

The standard developers considered altering the definition of `_POSIX_VERSION` and removing `_SC_VERSION` from the specification of `sysconf()` since the utility to an application was deemed by some to be minimal, and since the implementation of the functionality is potentially problematic. However, they recognized that support for existing application binaries is a concern to manufacturers, application developers, and the users of implementations conforming to IEEE Std 1003.1-2001.

While the example using `_SC_VERSION` in the APPLICATION USAGE section does not provide the greatest degree of imaginable utility to the application developer or user, it is arguably better than a core file or some other equally obscure result. (It is also possible for implementations to encode and recognize application binaries compiled in various POSIX.1-conforming environments, and modify the semantics of the underlying system to conform to the expectations of the application.) For the reasons outlined in the preceding paragraphs and in the APPLICATION USAGE section, the standard developers elected to retain the `_POSIX_VERSION` and `_SC_VERSION` functionality.
IEEE Std 1003.1-2001 now includes support in certain areas for the newly adopted policy governing options and stubs. This policy provides flexibility for implementations in how they support options. It also specifies how conforming applications can adapt to different implementations that support different sets of options. It allows the following:

1. If an implementation has no interest in supporting an option, it does not have to provide anything associated with that option beyond the announcement that it does not support it.
2. An implementation can support a partial or incompatible version of an option (as a non-standard extension) as long as it does not claim to support the option.
3. An application can determine whether the option is supported. A strictly conforming application must check this announcement mechanism before first using anything associated with the option.

There is an important implication of this policy. IEEE Std 1003.1-2001 cannot dictate the behavior of interfaces associated with an option when the implementation does not claim to support the option. In particular, it cannot require that a function associated with an unsupported option will fail if it does not perform as specified. However, this policy does not prevent a standard from requiring certain functions to always be present, but that they shall always fail on some implementations. The `setpgid()` function in the POSIX.1-1990 standard, for example, is considered appropriate.

The POSIX standards include various options, and the C-language binding support for an option implies that the implementation must supply data types and function interfaces. An application must be able to discover whether the implementation supports each option.

Any application must consider the following three cases for each option:

1. Option never supported.
   - The implementation advertises at compile time that the option will never be supported. In this case, it is not necessary for the implementation to supply any of the data types or function interfaces that are provided only as part of the option. The implementation might provide data types and functions that are similar to those defined by IEEE Std 1003.1-2001, but there is no guarantee for any particular behavior.

2. Option always supported.
   - The implementation advertises at compile time that the option will always be supported. In this case, all data types and function interfaces shall be available and shall operate as specified.

3. Option might or might not be supported.
   - Some implementations might not provide a mechanism to specify support of options at compile time. In addition, the implementation might be unable or unwilling to specify support or non-support at compile time. In either case, any application that might use the option at runtime must be able to compile and execute. The implementation must provide, at compile time, all data types and function interfaces that are necessary to allow this. In this situation, there must be a mechanism that allows the application to query, at runtime, whether the option is supported. If the application attempts to use the option when it is not supported, the result is unspecified unless explicitly specified otherwise in IEEE Std 1003.1-2001.
FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 5

The DESCRIPTION is updated for alignment with the POSIX Realtime Extension and the POSIX Threads Extension.

The symbolic constants _XOPEN_REALTIME and _XOPEN_REALTIME_THREADS are added. _POSIX2_C_BIND, _XOPEN_ENH_I18N, and _XOPEN_SHM must now be set to a value other than −1 by a conforming implementation.

Large File System extensions are added.

The type of the argument to sbrk() is changed from int to intptr_t.

_XBS_ constants are added to the list of constants for Options and Option Groups, to the list of constants for the confstr() function, and to the list of constants to the sysconf() function. These are all marked EX.

Issue 6

_POSIX2_C_VERSION is removed.

The Open Group Corrigendum U026/4 is applied, adding the prototype for fdatasync().

The Open Group Corrigendum U026/1 is applied, adding the symbols _SC_XOPEN_LEGACY, _SC_XOPEN_REALTIME, and _SC_XOPEN_REALTIME_THREADS.

The symbols _XOPEN_STREAMS and _SC_XOPEN_STREAMS are added to support the XSI STREAMS Option Group.

Text in the DESCRIPTION relating to conformance requirements is moved elsewhere in IEEE Std 1003.1-2001.

The legacy symbol _SC_PASS_MAX is removed.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The _CS_POSIX_* and _CS_XBS5_* constants are added for the confstr() function.
- The _SC_XBS5_* constants are added for the sysconf() function.
- The symbolic constants F_ULOCK, F_LOCK, F_TLOCK, and F_TEST are added.
- The uid_t, gid_t, off_t, pid_t, and useconds_t types are mandated.

The gethostname() prototype is added for sockets.
A new section is added for System-Wide Options.

Function prototypes for `setegid()` and `seteuid()` are added.

Option symbolic constants are added for `_POSIX_ADVISORY_INFO`, `_POSIX_CPUTIME`, `_POSIX_SPAWN`, `_POSIX_Sporadic_SERVER`, `_POSIX_THREAD_CPUTIME`, `_POSIX_THREAD_Sporadic_SERVER`, and `_POSIX_TIMEOUTS`, and `pathconf()` variables are added for `_PC_ALLOC_SIZE_MIN`, `_PC_REC_INCR_XFER_SIZE`, `_PC_REC_MAX_XFER_SIZE`, `_PC_REC_MIN_XFER_SIZE`, and `_PC_REC_XFER_ALIGN` for alignment with IEEE Std 1003.1d-1999.

The following are added for alignment with IEEE Std 1003.1j-2000:

- Option symbolic constants `_POSIX_BARRIERS`, `_POSIX_CLOCK_SELECTION`, `_POSIX_MONOTONIC_CLOCK`, `_POSIX_READER_WRITER_LOCKS`, `_POSIX_SPIN_LOCKS`, and `_POSIX_TYPED_MEMORY_OBJECTS`
- `sysconf()` variables `_SC_BARRIERS`, `_SC_CLOCK_SELECTION`, `_SC_MONOTONIC_CLOCK`, `_SC_READER_WRITER_LOCKS`, `_SC_SPIN_LOCKS`, and `_SC_TYPED_MEMORY_OBJECTS`

The `_SC_XBS5` macros associated with the ISO/IEC 9899:1990 standard are marked LEGACY, and new equivalent `_SC_V6` macros associated with the ISO/IEC 9899:1999 standard are introduced.

The `getcwd()` function is marked LEGACY.

The `restrict` keyword is added to the prototypes for `readlink()` and `swab()`.

Constants for options are now harmonized, so when supported they take the year of approval of IEEE Std 1003.1-2001 as the value.

The following are added for alignment with IEEE Std 1003.1q-2000:

- Optional symbolic constants `_POSIX_TRACE`, `_POSIX_TRACE_EVENT_FILTER`, `_POSIX_TRACE_LOG`, and `_POSIX_TRACE_INHERIT`
- The `sysconf()` symbol constants `_SC_TRACE`, `_SC_TRACE_EVENT_FILTER`, `_SC_TRACE_LOG`, and `_SC_TRACE_INHERIT`

The `brk()` and `sbrk()` legacy functions are removed.

The Open Group Base Resolution bwg2001-006 is applied, which reworks the XSI versioning information.

The Open Group Base Resolution bwg2001-008 is applied, changing the `namelen` parameter for `gethostbyname()` from `socklen_t` to `size_t`.

IEEE Std 1003.1-2001/Cor 1-2002, item XBD/TC1/D6/2 is applied, changing “Thread Stack Address Size” to “Thread Stack Size Attribute”.

IEEE Std 1003.1-2001/Cor 1-2002, item XBD/TC1/D6/20 is applied, adding the `_POSIX_IPV6`, `_SC_V6`, and `_SC_RAW_SOCKETS` symbols.

IEEE Std 1003.1-2001/Cor 1-2002, item XBD/TC1/D6/21 is applied, correcting the description in “Constants for Functions” for the `_CS_POSIX_V6_LP64_OFF64_CFLAGS`, `_CS_POSIX_V6_LP64_OFF64_LDFLAGS`, and `_CS_POSIX_V6_LP64_OFF64_LIBS` symbols.

IEEE Std 1003.1-2001/Cor 1-2002, item XBD/TC1/D6/22 is applied, removing the shading for the `_PC` and `_SC` constants, since these are mandatory on all implementations.

IEEE Std 1003.1-2001/Cor 1-2002, item XBD/TC1/D6/24 is applied, correcting the shading and margin code for the fsync() function.

IEEE Std 1003.1-2001/Cor 1-2002, item XBD/TC1/D6/25 is applied, adding the following text to the APPLICATION USAGE section: “New applications should not use _XOPEN_SHM or _XOPEN_ENH_I18N.”
NAME
utime.h — access and modification times structure

SYNOPSIS
#include <utime.h>

DESCRIPTION
The <utime.h> header shall declare the structure utimbuf, which shall include the following members:

time_t actime Access time.
time_t modtime Modification time.

The times shall be measured in seconds since the Epoch.

The type time_t shall be defined as described in <sys/types.h>.

The following shall be declared as a function and may also be defined as a macro. A function prototype shall be provided.

int utime(const char *, const struct utimbuf *);

APPLICATION USAGE
None.

RATIONALE
None.

FUTURE DIRECTIONS
None.

SEE ALSO
/sys/types.h>, the System Interfaces volume of IEEE Std 1003.1-2001, utime()

CHANGE HISTORY
First released in Issue 3.

Issue 6
The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The time_t type is defined.
NAME
utmpx.h — user accounting database definitions

SYNOPSIS
XSI
#include <utmpx.h>

DESCRIPTION
The <utmpx.h> header shall define the utmpx structure that shall include at least the following members:

char ut_user[] User login name.
char ut_id[] Unspecified initialization process identifier.
char ut_line[] Device name.
pid_t ut_pid Process ID.
short ut_type Type of entry.
struct timeval ut_tv Time entry was made.

The pid_t type shall be defined through typedef as described in <sys/types.h>.
The timeval structure shall be defined as described in <sys/time.h>.
Inclusion of the <utmpx.h> header may also make visible all symbols from <sys/time.h>.
The following symbolic constants shall be defined as possible values for the ut_type member of the utmpx structure:

EMPTY No valid user accounting information.
BOOT_TIME Identifies time of system boot.
OLD_TIME Identifies time when system clock changed.
NEW_TIME Identifies time after system clock changed.
USER_PROCESS Identifies a process.
INIT_PROCESS Identifies a process spawned by the init process.
LOGIN_PROCESS Identifies the session leader of a logged-in user.
DEAD_PROCESS Identifies a session leader who has exited.

The following shall be declared as functions and may also be defined as macros. Function prototypes shall be provided.

void endutxent(void);
struct utmpx *getutxent(void);
struct utmpx *getutxid(const struct utmpx *);
struct utmpx *getutxline(const struct utmpx *);
struct utmpx *pututxline(const struct utmpx *);
void setutxent(void);
APPLICATION USAGE
None.

RATIONALE
None.

FUTURE DIRECTIONS
None.

CHANGE HISTORY
First released in Issue 4, Version 2.
NAME
wchar.h — wide-character handling

SYNOPSIS
#include <wchar.h>

DESCRIPTION
Some of the functionality described on this reference page extends the ISO C standard:
Applications shall define the appropriate feature test macro (see the System Interfaces volume of
IEEE Std 1003.1-2001, Section 2.2, The Compilation Environment) to enable the visibility of these
symbols in this header.

The <wchar.h> header shall define the following types:

wchar_t As described in <stddef.h>.

wint_t An integer type capable of storing any valid value of wchar_t or WEOF.

wchar_t A scalar type of a data object that can hold values which represent locale-specific character classification.

mbstate_t An object type other than an array type that can hold the conversion state information necessary to convert between sequences of (possibly multi-byte) characters and wide characters. If a codeset is being used such that an mbstate_t needs to preserve more than 2 levels of reserved state, the results are unspecified.

FILE As described in <stdio.h>.

size_t As described in <stddef.h>.

va_list As described in <stdarg.h>.

The implementation shall support one or more programming environments in which the width of wint_t is no greater than the width of type long. The names of these programming environments can be obtained using the confstr() function or the getconf utility.

The following shall be declared as functions and may also be defined as macros. Function prototypes shall be provided.

wint_t btowc(int);
wint_t fgetwc(FILE *);
wchar_t *fgetws(wchar_t *restrict, int, FILE *restrict);

FILE *fputwc(wchar_t, FILE *);
fputws(const wchar_t *restrict, FILE *restrict);

int fwide(FILE *, int);

int fwprintf(FILE *restrict, const wchar_t *restrict, ...);

int fwscanf(FILE *restrict, const wchar_t *restrict, ...);

wint_t getwc(FILE *);

wint_t getwchar(void);

int iswalnum(wint_t);
int iswalpha(wint_t);
int iswcntrl(wint_t);

int iswctype(wint_t, wctype_t);
int iswdigit(wint_t);
int iswgraph(wint_t);
int iswlower(wint_t);
int iswprint(wint_t);
int iswpunct(wint_t);
# Headers

<int iswspace(wint_t);>
<int iswupper(wint_t);>
<int iswxwixdigit(wint_t);>
<size_t mbrlen(const char * restrict, size_t, mbstate_t * restrict);>
<size_t mbtowc(wchar_t * restrict, const char * restrict, size_t, mbstate_t * restrict);>

<wchar_t * wcsrchr(const wchar_t *, wchar_t);>
<size_t wcsrtombs(char * restrict, const wchar_t ** restrict, size_t, mbstate_t * restrict);>
<size_t wcsstr(const wchar_t *, const wchar_t * restrict, const wchar_t * restrict);>
<double wcstod(const wchar_t *, restrict, wchar_t ** restrict);>
<float wcstof(const wchar_t *, restrict, wchar_t ** restrict);>
<wchar_t * wcstok(const wchar_t *, restrict, wchar_t ** restrict, wchar_t ** restrict);>
<long wcstol(const wchar_t *, restrict, wchar_t ** restrict, int);>
<long double wcstold(const wchar_t *, restrict, wchar_t ** restrict);>
<long long wcstoll(const wchar_t *, restrict, wchar_t ** restrict, int);>
unsigned long wcstoul(const wchar_t *restrict, wchar_t **restrict, int);

unsigned long long wcstoull(const wchar_t *restrict, wchar_t **restrict, int);

wchar_t *wcs同年(const wchar_t *, const wchar_t *);

int wcswidth(const wchar_t *, size_t);

size_t wcsxfrm(wchar_t *restrict, const wchar_t *restrict, size_t);

int wctob(wint_t);

wchar_t *wctype(const char *);

int wcwidth(wchar_t);

wchar_t *wmemchr(const wchar_t *, wchar_t, size_t);

int wmemcmp(const wchar_t *, const wchar_t *, size_t);

wchar_t *wmemcpy(wchar_t *restrict, const wchar_t *restrict, size_t);

wchar_t *wmemmove(wchar_t *, const wchar_t *, size_t);

wchar_t *wmemset(wchar_t *, wchar_t, size_t);

int wprintf(const wchar_t *restrict, ...);

int wscanf(const wchar_t *restrict, ...);

The <wchar.h> header shall define the following macros:

WCHAR_MAX The maximum value representable by an object of type wchar_t.

WCHAR_MIN The minimum value representable by an object of type wchar_t.

WEOF Constant expression of type wint_t that is returned by several WP functions to indicate end-of-file.

NULL As described in <stddef.h>.

The tag tm shall be declared as naming an incomplete structure type, the contents of which are described in the header <time.h>.

Inclusion of the <wchar.h> header may make visible all symbols from the headers <ctype.h>, <string.h>, <stdarg.h>, <stddef.h>, <stdio.h>, <stdlib.h>, and <time.h>.

APPLICATION USAGE

The iswblank() function was a late addition to the ISO C standard and was introduced at the same time as the ISO C standard introduced <wctype.h>, which contains all of the isw*() functions. The Open Group Base Specifications had previously aligned with the MSE working draft and had introduced the rest of the isw*() functions into <wchar.h>. For backwards-compatibility, the original set of isw*() functions, without iswblank(), are permitted (as an XSI extension) in <wchar.h>. For maximum portability, applications should include <wctype.h> in order to obtain declarations for the isw*() functions.

RATIONALE

In the ISO C standard, the symbols referenced as XSI extensions are in <wctype.h>. Their presence here is thus an extension.

FUTURE DIRECTIONS

None.

15121 CHANGE HISTORY
15122 First released in Issue 4.
15123 Issue 5  
15124 Issue 6
   The Open Group Corrigendum U021/10 is applied. The prototypes for wcswidth() and
   wcwidth() are marked as extensions.
   The Open Group Corrigendum U028/5 is applied, correcting the prototype for the mbsinit()
   function.
   The following changes are made for alignment with the ISO/IEC 9899:1999 standard:
      • Various function prototypes are updated to add the restrict keyword.
      • The functions vfwscanf(), vswscanf(), wcstof(), wcstold(), wcstoll(), and wcstoull() are added.
   The type wctype_t, the isw*(), to*w(), and wctype() functions are marked as XSI extensions.
15130 IEEE Std 1003.1-2001/Cor 1-2002, item XBD/TC1/D6/26 is applied, adding the APPLICATION
15131 USAGE section.
NAME
wctype.h — wide-character classification and mapping utilities

SYNOPSIS
#include <wctype.h>

DESCRIPTION
Some of the functionality described on this reference page extends the ISO C standard.
Applications shall define the appropriate feature test macro (see the System Interfaces volume of
IEEE Std 1003.1-2001, Section 2.2, The Compilation Environment) to enable the visibility of these
symbols in this header.

The <wctype.h> header shall define the following types:

wint_t        As described in <wchar.h>.

wctrans_t     A scalar type that can hold values which represent locale-specific character
mappings.

wctype_t       As described in <wchar.h>.

The following shall be declared as functions and may also be defined as macros. Function
prototypes shall be provided.

int iswalnum(wint_t);
int iswalpha(wint_t);
int iswblank(wint_t);
int iswcntrl(wint_t);
int iswdigit(wint_t);
int iswgraph(wint_t);
int iswlower(wint_t);
int iswprint(wint_t);
int iswpunct(wint_t);
int iswspace(wint_t);
int iswupper(wint_t);
int iswxdigit(wint_t);
int iswctype(wint_t, wctype_t);
wint_t towctrans(wint_t, wctrans_t);
wint_t towlower(wint_t);
wint_t towupper(wint_t);

The <wctype.h> header shall define the following macro name:

WEOF                   Constant expression of type wint_t that is returned by several MSE functions
to indicate end-of-file.

For all functions described in this header that accept an argument of type wint_t, the value is
representable as a wchar_t or equals the value of WEOF. If this argument has any other value,
the behavior is undefined.

The behavior of these functions shall be affected by the LC_CTYPE category of the current locale.

Inclusion of the <wctype.h> header may make visible all symbols from the headers <ctype.h>,
<stdarg.h>, <stdbool.h>, <stdio.h>, <stdlib.h>, <string.h>, <time.h>, and <wchar.h>.
APPLICATION USAGE
None.

RATIONALE
None.

FUTURE DIRECTIONS
None.

CHANGE HISTORY

Issue 6
The iswblank() function is added for alignment with the ISO/IEC 9899:1999 standard.
**NAME**

wordexp.h — word-expansion types

**SYNOPSIS**

```c
#include <wordexp.h>
```

**DESCRIPTION**

The `<wordexp.h>` header shall define the structures and symbolic constants used by the `wordexp()` and `wordfree()` functions.

The structure type `wordexp_t` shall contain at least the following members:

- `size_t we_wordc`: Count of words matched by `words`.
- `char **we_wordv`: Pointer to list of expanded words.
- `size_t we_offs`: Slots to reserve at the beginning of `we_wordv`.

The `flags` argument to the `wordexp()` function shall be the bitwise-inclusive OR of the following flags:

- `WRDE_APPEND`: Append words to those previously generated.
- `WRDE_DOOFS`: Number of null pointers to prepend to `we_wordv`.
- `WRDE_NOCMD`: Fail if command substitution is requested.
- `WRDE_REUSE`: The `pwordexp` argument was passed to a previous successful call to `wordexp()`, and has not been passed to `wordfree()`. The result is the same as if the application had called `wordfree()` and then called `wordexp()` without `WRDE_REUSE`.
- `WRDE_SHOWERR`: Do not redirect `stderr` to `/dev/null`.
- `WRDE_UNDEF`: Report error on an attempt to expand an undefined shell variable.

The following constants shall be defined as error return values:

- `WRDE_BADCHAR`: One of the unquoted characters—`<newline>, ' | ', '&', ';', '<', '>', '
  '(', ')', '{', '}'—appears in `words` in an inappropriate context.
- `WRDE_BADVAL`: Reference to undefined shell variable when `WRDE_UNDEF` is set in `flags`.
- `WRDE_CMDSUB`: Command substitution requested when `WRDE_NOCMD` was set in `flags`.
- `WRDE_NOSPACE`: Attempt to allocate memory failed.
- `OB_XSI`: `WRDE_NOSYS` Reserved.
- `WRDE_SYNTAX`: Shell syntax error, such as unbalanced parentheses or unterminated string.

The `<wordexp.h>` header shall define the following type:

```c
size_t As described in `<stddef.h>`.
```

The following shall be declared as functions and may also be defined as macros. Function prototypes shall be provided.

```c
int wordexp(const char *restrict, wordexp_t *restrict, int);
void wordfree(wordexp_t *);
```

The implementation may define additional macros or constants using names beginning with `WRDE_`.

CHANGE HISTORY

Issue 6
The restrict keyword is added to the prototype for wordexp().
The WRDE_NOSYS constant is marked obsolescent.

Abstract

This standard defines a standard operating system interface and environment, including a command interpreter (or “shell”), and common utility programs to support applications portability at the source code level. This standard is intended to be used by both applications developers and system implementors and comprises four major components (each in an associated volume):

- General terms, concepts, and interfaces common to all volumes of this standard, including utility conventions and C-language header definitions, are included in the Base Definitions volume.
- Definitions for system service functions and subroutines, language-specific system services for the C programming language, function issues, including portability, error handling, and error recovery, are included in the System Interfaces volume.
- Definitions for a standard source code-level interface to command interpretation services (a “shell”) and common utility programs for application programs are included in the Shell and Utilities volume.
- Extended rationale that did not fit well into the rest of the document structure, which contains historical information concerning the contents of this standard and why features were included or discarded by the standard developers, is included in the Rationale (Informative) volume.

The following areas are outside the scope of this standard:

- Graphics interfaces
- Database management system interfaces
- Record I/O considerations
- Object or binary code portability
- System configuration and resource availability

This standard describes the external characteristics and facilities that are of importance to applications developers, rather than the internal construction techniques employed to achieve these capabilities. Special emphasis is placed on those functions and facilities that are needed in a wide variety of commercial applications.

Keywords

application program interface (API), argument, asynchronous, basic regular expression (BRE), batch job, batch system, built-in utility, byte, child, command language interpreter, CPU, extended regular expression (ERE), FIFO, file access control mechanism, input/output (I/O), job control, network, portable operating system interface (POSIX®), parent, shell, stream, string, synchronous, system, thread, X/Open System Interface (XSI)
IEEE

IEEE Standards documents are developed within the IEEE Societies and the Standards Coordinating Committees of the IEEE Standards Association (IEEE-SA) Standards Board. The IEEE develops its standards through a consensus development process, approved by the American National Standards Institute, which brings together volunteers representing varied viewpoints and interests to achieve the final product. Volunteers are not necessarily members of the Institute and serve without compensation. While the IEEE administers the process and establishes rules to promote fairness in the consensus development process, the IEEE does not independently evaluate, test, or verify the accuracy of any of the information contained in its standards.

Use of an IEEE Standard is wholly voluntary. The IEEE disclaims liability for any personal injury, property, or other damage, of any nature whatsoever, whether special, indirect, consequential, or compensatory, directly or indirectly resulting from the publication, use of, or reliance upon this, or any other IEEE Standard document.

The IEEE does not warrant or represent the accuracy or content of the material contained herein, and expressly disclaims any express or implied warranty, including any implied warranty of merchantability or fitness for a specific purpose, or that the use of the material contained herein is free from patent infringement. IEEE Standards documents are supplied “AS IS”.

The existence of an IEEE Standard does not imply that there are no other ways to produce, test, measure, purchase, market, or provide other goods and services related to the scope of the IEEE Standard. Furthermore, the viewpoint expressed at the time a standard is approved and issued is subject to change brought about through developments in the state of the art and comments received from users of the standard. Every IEEE Standard is subjected to review at least every five years for revision or reaffirmation. When a document is more than five years old and has not been reaffirmed, it is reasonable to conclude that its contents, although still of some value, do not wholly reflect the present state of the art. Users are cautioned to check to determine that they have the latest edition of any IEEE Standard.

In publishing and making this document available, the IEEE is not suggesting or rendering professional or other services for, or on behalf of, any person or entity. Nor is the IEEE undertaking to perform any duty owed by any other person or entity to another. Any person utilizing this, and any other IEEE Standards document, should rely upon the advice of a competent professional in determining the exercise of reasonable care in any given circumstances.

Interpretations: Occasionally questions may arise regarding the meaning of portions of standards as they relate to specific applications. When the need for interpretations is brought to the attention of the IEEE, the Institute will initiate action to prepare appropriate responses. Since IEEE Standards represent a consensus of concerned interests, it is important to ensure that any interpretation has also received the concurrence of a balance of interests. For this reason, IEEE and the members of its societies and Standards Coordinating Committees are not able to provide an instant response to interpretation requests except in those cases where the matter has previously received formal consideration.

Comments for revision of IEEE Standards are welcome from any interested party, regardless of membership affiliation with the IEEE. Suggestions for changes in documents should be in the form of a proposed change of text, together with appropriate supporting comments. Comments on standards and requests for interpretations should be addressed to:

Secretary, IEEE-SA Standards Board, 445 Hoes Lane, P.O. Box 1331, Piscataway, NJ 08855-1331, U.S.A.

Attention is called to the possibility that implementation of this standard may require use of subject matter covered by patent rights. By publication of this standard, no position is taken with respect to the existence or validity of any patent rights in connection therewith. The IEEE shall not be responsible for identifying patents for which a license may be required by an IEEE Standard or for conducting inquiries into the legal validity or scope of those patents that are brought to its attention.

A patent holder has filed a statement of assurance that it will grant licenses under these rights without compensation or under reasonable rates and non-discriminatory, reasonable terms and conditions to all applicants desiring to obtain such licenses. The IEEE makes no representation as to the reasonableness of rates and/or terms and conditions of the license agreements offered by patent holders. Further information may be obtained from the IEEE Standards Department.

Authorization to photocopy portions of any individual standard for internal or personal use is granted in the U.S. by the Institute of Electrical and Electronics Engineers, Inc., provided that the appropriate fee is paid to the Copyright Clearance Center. Permission to photocopy portions of any individual standard for educational classroom use can also be obtained through the Copyright Clearance Center. To arrange for payment of the licensing fee, please contact:

Copyright Clearance Center, Customer Service, 222 Rosewood Drive, Danvers, MA 01923, U.S.A., Tel.: +1 978 750 8400

Amendments, corrigenda, and interpretations for this standard, or information about the IEEE standards development process, may be found at http://standards.ieee.org.

Full catalog and ordering information on all IEEE publications is available from the IEEE Online Catalog & Store at http://shop.ieee.org/store.

1. For this standard, please send comments via the Austin Group as requested on page iii.
2. Please refer to the special provisions for this standard on page iii concerning permissions from both copyright holders and arrangements to cover photocopying and reproduction across the world, as well as by commercial organizations wishing to license the material for use in product documentation.
The Open Group

The Open Group, a vendor and technology-neutral consortium, is committed to delivering greater business efficiency by bringing together buyers and suppliers of information technology to lower the time, cost, and risks associated with integrating new technology across the enterprise.

The Open Group’s mission is to offer all organizations concerned with open information infrastructures a forum to share knowledge, integrate open initiatives, and certify approved products and processes in a manner in which they continue to trust our impartiality.

In the global eCommerce world of today, no single economic entity can achieve independence while still ensuring interoperability. The assurance that products will interoperate with each other across differing systems and platforms is essential to the success of eCommerce and business workflow. The Open Group, with its proven testing and certification program, is the international guarantor of interoperability in the new century.

The Open Group provides opportunities to exchange information and shape the future of IT. The Open Group’s members include some of the largest and most influential organizations in the world. The flexible structure of The Open Groups membership allows for almost any organization, no matter what their size, to join and have a voice in shaping the future of the IT world.

More information is available on The Open Group web site at http://www.opengroup.org.

The Open Group has over 15 years’ experience in developing and operating certification programs and has extensive experience developing and facilitating industry adoption of test suites used to validate conformance to an open standard or specification. The Open Group portfolio of test suites includes the Westwood family of tests for this standard and the associated certification program for Version 3 of the Single UNIX Specification, as well tests for CDE, CORBA, Motif, Linux, LDAP, POSIX.1, POSIX.2, POSIX Realtime, Sockets, UNIX, XPG4, XNFS, XTI, and X11. The Open Group test tools are essential for proper development and maintenance of standards-based products, ensuring conformance of products to industry-standard APIs, applications portability, and interoperability. In-depth testing identifies defects at the earliest possible point in the development cycle, saving costs in development and quality assurance.

More information is available at http://www.opengroup.org/testing.

The Open Group publishes a wide range of technical documentation, the main part of which is focused on development of Technical and Product Standards and Guides, but which also includes white papers, technical studies, branding and testing documentation, and business titles. Full details and a catalog are available at http://www.opengroup.org/pubs.

As with all live documents, Technical Standards and Specifications require revision to align with new developments and associated international standards. To distinguish between revised specifications which are fully backwards compatible and those which are not:

- A new Version indicates there is no change to the definitive information contained in the previous publication of that title, but additions/extensions are included. As such, it replaces the previous publication.
- A new Issue indicates there is substantive change to the definitive information contained in the previous publication of that title, and there may also be additions/extensions. As such, both previous and new documents are maintained as current publications.

Readers should note that Corrigenda may apply to any publication. Corrigenda information is published at http://www.opengroup.org/corrigenda.

Full catalog and ordering information on all Open Group publications is available at http://www.opengroup.org/pubs.

Structure of the Standard

This standard was originally developed by the Austin Group, a joint working group of members of the IEEE, members of The Open Group, and members of ISO/IEC Joint Technical Committee 1, as one of the four volumes of IEEE Std 1003.1-2001. The standard was approved by ISO and IEC and published in four parts, correlating to the original volumes.

A mapping of the parts to the volumes is shown below:

<table>
<thead>
<tr>
<th>ISO/IEC 9945 Part</th>
<th>IEEE Std 1003.1 Volume</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>9945-1</td>
<td>Base Definitions</td>
<td>Includes general terms, concepts, and interfaces common to all parts of ISO/IEC 9945, including utility conventions and C-language header definitions.</td>
</tr>
<tr>
<td>9945-2</td>
<td>System Interfaces</td>
<td>Includes definitions for system service functions and subroutines, language-specific system services for the C programming language, function issues, including portability, error handling, and error recovery.</td>
</tr>
<tr>
<td>9945-3</td>
<td>Shell and Utilities</td>
<td>Includes definitions for a standard source code-level interface to command interpretation services (a “shell”) and common utility programs for application programs.</td>
</tr>
<tr>
<td>9945-4</td>
<td>Rationale</td>
<td>Includes extended rationale that did not fit well into the rest of the document structure, containing historical information concerning the contents of ISO/IEC 9945 and why features were included or discarded by the standard developers.</td>
</tr>
</tbody>
</table>

All four parts comprise the entire standard, and are intended to be used together to accommodate significant internal referencing among them. POSIX-conforming systems are required to support all four parts.
Introduction

Note: This introduction is not part of IEEE Std 1003.1-2001, Standard for Information Technology — Portable Operating System Interface (POSIX).

This standard has been jointly developed by the IEEE and The Open Group. It is simultaneously an IEEE Standard, an ISO/IEC Standard, and an Open Group Technical Standard.

The Austin Group

This standard was developed, and is maintained, by a joint working group of members of the IEEE Portable Applications Standards Committee, members of The Open Group, and members of ISO/IEC Joint Technical Committee 1. This joint working group is known as the Austin Group.³ The Austin Group arose out of discussions amongst the parties which started in early 1998, leading to an initial meeting and formation of the group in September 1998. The purpose of the Austin Group has been to revise, combine, and update the following standards: ISO/IEC 9945-1, ISO/IEC 9945-2, IEEE Std 1003.1, IEEE Std 1003.2, and the Base Specifications of The Open Group Single UNIX Specification.

After two initial meetings, an agreement was signed in July 1999 between The Open Group and the Institute of Electrical and Electronics Engineers (IEEE), Inc., to formalize the project with the first draft of the revised specifications being made available at the same time. Under this agreement, The Open Group and IEEE agreed to share joint copyright of the resulting work. The Open Group has provided the chair and secretariat for the Austin Group.

The base document for the revision was The Open Group’s Base volumes of its Single UNIX Specification, Version 2. These were selected since they were a superset of the existing POSIX.1 and POSIX.2 specifications and had some organizational aspects that would benefit the audience for the new revision.

The approach to specification development has been one of “write once, adopt everywhere”, with the deliverables being a set of specifications that carry the IEEE POSIX designation, The Open Group’s Technical Standard designation, and an ISO/IEC designation. This set of specifications forms the core of the Single UNIX Specification, Version 3.

This unique development has combined both the industry-led efforts and the formal standardization activities into a single initiative, and included a wide spectrum of participants. The Austin Group continues as the maintenance body for this document.

Anyone wishing to participate in the Austin Group should contact the chair with their request. There are no fees for participation or membership. You may participate as an observer or as a contributor. You do not have to attend face-to-face meetings to participate; electronic participation is most welcome. For more information on the Austin Group and how to participate, see http://www.opengroup.org/austin.

³ The Austin Group is named after the location of the inaugural meeting held at the IBM facility in Austin, Texas in September 1998.
Introduction

Background
The developers of this standard represent a cross section of hardware manufacturers, vendors of operating systems and other software development tools, software designers, consultants, academics, authors, applications programmers, and others.

Conceptually, this standard describes a set of fundamental services needed for the efficient construction of application programs. Access to these services has been provided by defining an interface, using the C programming language, a command interpreter, and common utility programs that establish standard semantics and syntax. Since this interface enables application writers to write portable applications—it was developed with that goal in mind—it has been designated POSIX, an acronym for Portable Operating System Interface.

Although originated to refer to the original IEEE Std 1003.1-1988, the name POSIX more correctly refers to a family of related standards: IEEE Std 1003.n and the parts of ISO/IEC 9945. In earlier editions of the IEEE standard, the term POSIX was used as a synonym for IEEE Std 1003.1-1988. A preferred term, POSIX.1, emerged. This maintained the advantages of readability of the symbol “POSIX” without being ambiguous with the POSIX family of standards.

Audience
The intended audience for this standard is all persons concerned with an industry-wide standard operating system based on the UNIX system. This includes at least four groups of people:

1. Persons buying hardware and software systems
2. Persons managing companies that are deciding on future corporate computing directions
3. Persons implementing operating systems, and especially
4. Persons developing applications where portability is an objective

Purpose
Several principles guided the development of this standard:

• Application-Oriented

The basic goal was to promote portability of application programs across UNIX system environments by developing a clear, consistent, and unambiguous standard for the interface specification of a portable operating system based on the UNIX system documentation. This standard codifies the common, existing definition of the UNIX system.

• Interface, Not Implementation

This standard defines an interface, not an implementation. No distinction is made between library functions and system calls; both are referred to as functions. No details of the implementation of any function are given (although historical practice is sometimes indicated in the RATIONALE section). Symbolic names are given for constants (such as signals and error numbers) rather than numbers.

4. The name POSIX was suggested by Richard Stallman. It is expected to be pronounced pahz-icks, as in positive, not poh-six, or other variations. The pronunciation has been published in an attempt to promulgate a standardized way of referring to a standard operating system interface.
• Source, Not Object, Portability
  This standard has been written so that a program written and translated for execution on one
  conforming implementation may also be translated for execution on another conforming
  implementation. This standard does not guarantee that executable (object or binary) code
  will execute under a different conforming implementation than that for which it was
  translated, even if the underlying hardware is identical.

• The C Language
  The system interfaces and header definitions are written in terms of the standard C language
  as specified in the ISO C standard.

• No Superuser, No System Administration
  There was no intention to specify all aspects of an operating system. System administration
  facilities and functions are excluded from this standard, and functions usable only by the
  superuser have not been included. Still, an implementation of the standard interface may also
  implement features not in this standard. This standard is also not concerned with hardware
  constraints or system maintenance.

• Minimal Interface, Minimally Defined
  In keeping with the historical design principles of the UNIX system, the mandatory core
  facilities of this standard have been kept as minimal as possible. Additional capabilities have
  been added as optional extensions.

• Broadly Implementable
  The developers of this standard endeavored to make all specified functions implementable
  across a wide range of existing and potential systems, including:
  1. All of the current major systems that are ultimately derived from the original UNIX
     system code (Version 7 or later)
  2. Compatible systems that are not derived from the original UNIX system code
  3. Emulations hosted on entirely different operating systems
  4. Networked systems
  5. Distributed systems
  6. Systems running on a broad range of hardware
  No direct references to this goal appear in this standard, but some results of it are mentioned
  in the Rationale (Informative) volume.

• Minimal Changes to Historical Implementations
  When the original version of IEEE Std 1003.1 was published, there were no known historical
  implementations that did not have to change. However, there was a broad consensus on a set
  of functions, types, definitions, and concepts that formed an interface that was common to
  most historical implementations.
  The adoption of the 1988 and 1990 IEEE system interface standards, the 1992 IEEE shell and
  utilities standard, the various Open Group (formerly X/Open) specifications, and the
  subsequent revisions and addenda to all of them have consolidated this consensus, and this
  revision reflects the significantly increased level of consensus arrived at since the original
  versions. The earlier standards and their modifications specified a number of areas where
  consensus had not been reached before, and these are now reflected in this revision. The
  authors of the original versions tried, as much as possible, to follow the principles below
when creating new specifications:

1. By standardizing an interface like one in an historical implementation; for example, directories

2. By specifying an interface that is readily implementable in terms of, and backwards-compatible with, historical implementations, such as the extended tar format defined in the pax utility

3. By specifying an interface that, when added to an historical implementation, will not conflict with it; for example, the sigaction() function

This revision tries to minimize the number of changes required to implementations which conform to the earlier versions of the approved standards to bring them into conformance with the current standard. Specifically, the scope of this work excluded doing any "new" work, but rather collecting into a single document what had been spread across a number of documents, and presenting it in what had been proven in practice to be a more effective way. Some changes to prior conforming implementations were unavoidable, primarily as a consequence of resolving conflicts found in prior revisions, or which became apparent when bringing the various pieces together.

However, since it references the 1999 version of the ISO C standard, and no longer supports "Common Usage C", there are a number of unavoidable changes. Applications portability is similarly affected.

This standard is specifically not a codification of a particular vendor’s product.

It should be noted that implementations will have different kinds of extensions. Some will reflect "historical usage" and will be preserved for execution of pre-existing applications. These functions should be considered "obsolete" and the standard functions used for new applications. Some extensions will represent functions beyond the scope of this standard. These need to be used with careful management to be able to adapt to future extensions of this standard and/or port to implementations that provide these services in a different manner.

• Minimal Changes to Existing Application Code

A goal of this standard was to minimize additional work for the developers of applications. However, because every known historical implementation will have to change at least slightly to conform, some applications will have to change.

This Standard

This standard defines the Portable Operating System Interface (POSIX) requirements and consists of the following volumes:

• Base Definitions
• Shell and Utilities
• System Interfaces (this volume)
• Rationale (Informative)
This Volume

The System Interfaces volume describes the interfaces offered to application programs by POSIX-conformant systems. Readers are expected to be experienced C language programmers, and to be familiar with the Base Definitions volume.

This volume is structured as follows:

- Chapter 1 explains the status of this volume and its relationship to other formal standards.
- Chapter 2 contains important concepts, terms, and caveats relating to the rest of this volume.
- Chapter 3 defines the functional interfaces to the POSIX-conformant system.

Comprehensive references are available in the index.

Typographical Conventions

The following typographical conventions are used throughout this standard. In the text, this standard is referred to as IEEE Std 1003.1-2001, which is technically identical to The Open Group Base Specifications, Issue 6.

The typographical conventions listed here are for ease of reading only. Editorial inconsistencies in the use of typography are unintentional and have no normative meaning in this standard.
<table>
<thead>
<tr>
<th>Reference</th>
<th>Example</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>User Input and Example Code</td>
<td>echo Hello, World</td>
<td>5</td>
</tr>
<tr>
<td>Utility Name</td>
<td>awk</td>
<td></td>
</tr>
<tr>
<td>Utility Operand</td>
<td>file_name</td>
<td></td>
</tr>
<tr>
<td>Utility Option</td>
<td>−c</td>
<td></td>

</tbody>
</table>

Notes:

1. Conversion specifications, specifier characters, and modifier characters are used primarily in date-related functions and utilities and the fprintf and fscanf formatting functions.

2. Unless otherwise noted, the quotes shall not be used as input or output. When used in a list item, the quotes are omitted. For literal characters, ‘\’ (or any of the other sequences such as ‘’’) is the same as the C constant ‘\’ (or ‘’’).

3. The style selected for some of the special characters, such as <newline>, matches the form of the input given to the localedef utility. Generally, the characters selected for this special treatment are those that are not visually distinct, such as the control characters <tab> or <newline>.

4. Names surrounded by braces represent symbolic limits or configuration values which may be declared in appropriate headers by means of the C #define construct.

5. Brackets shown in this font, " [ "] , are part of the syntax and do not indicate optional items. In syntax the ‘ | ’ symbol is used to separate alternatives, and ellipses (" . . . ") are used to show that additional arguments are optional.

Shading is used to identify extensions and options; see Section 1.8.1 (on page 3).

Footnotes and notes within the body of the normative text are for information only (informative).

Informative sections (such as Rationale, Change History, Application Usage, and so on) are denoted by continuous shading bars in the margins.

Ranges of values are indicated with parentheses or brackets as follows:

- (a,b) means the range of all values from a to b, including neither a nor b.
- [a,b] means the range of all values from a to b, including a and b.
- (a,b] means the range of all values from a to b, including a, but not b.
- (a,b) means the range of all values from a to b, including b, but not a.

Notes:

1. Symbolic limits are used in this volume instead of fixed values for portability. The values of most of these constants are defined in the Base Definitions volume, <limits.h> or <unistd.h>.

2. The values of errors are defined in the Base Definitions volume, <errno.h>.
IEEE Std 1003.1-2001 was prepared by the Austin Group, sponsored by the Portable Applications Standards Committee of the IEEE Computer Society, The Open Group, and ISO/SC22 WG15.

The Austin Group

At the time of approval, the membership of the Austin Group was as follows:

Andrew Josey, Chair
Donald W. Cragun, Organizational Representative, IEEE PASC
Nicholas Stoughton, Organizational Representative, ISO/SC22 WG15
Mark Brown, Organizational Representative, The Open Group
Cathy Hughes, Technical Editor

The Open Group

When The Open Group approved the Base Specifications, Issue 6 on 12 September 2001, the membership of The Open Group Base Working Group was as follows:

Andrew Josey, Chair
Finnbarr P. Murphy, Vice-Chair
Mark Brown, Austin Group Liaison
Cathy Hughes, Technical Editor

Base Working Group Members

Bouazza Bachar  Joanna Farley  Frank Prindle
Mark Brown      Andrew Gollan  Andrew K. Roach
Donald W. Cragun  Gary Miller  Nicholas Stoughton
Larry Dwyer      Finnbarr P. Murphy  Kenjiro Tsuji
Participants

IEEE

When the IEEE Standards Board approved IEEE Std 1003.1-2001 on 6 December 2001, the membership of the committees was as follows:

Portable Applications Standards Committee (PASC)

Lowell G. Johnson, Chair
Joseph M. Gwinn, Vice-Chair
Jay Ashford, Functional Chair
Andrew Josey, Functional Chair
Curtis Royster Jr., Functional Chair
Nicholas Stoughton, Secretary

Balloting Committee

The following members of the balloting committee voted on IEEE Std 1003.1-2001. Balloters may have voted for approval, disapproval, or abstention:

Harold C. Adams  Steven A. Haaser  Frank Prindle
Pierre-Jean Arcos  Charles E. Hammons  Francois Riche
Jay Ashford  Chris J. Harding  John D. Riley
Theodore P. Baker  Barry Hedquist  Andrew K. Roach
Robert Barned  Vincent E. Henley  Helmut Roth
David J. Blackwood  Karl Heubaum  Jaideep Roy
Shirley Bockstahler-Brandt  Niklas Holsti  Curtis Royster Jr.
James Bottomley  Thomas Hosmer  Stephen C. Schwarm
Mark Brown  Jim D. Isaak  Richard Seibel

1.1 Scope

1.2 Conformance

1.3 Normative References

1.4 Change History

Change history is described in the Rationale (Informative) volume of IEEE Std 1003.1-2001, and in the CHANGE HISTORY section of reference pages.

1.5 Terminology

This section appears in the Base Definitions volume of IEEE Std 1003.1-2001, but is repeated here for convenience:

For the purposes of IEEE Std 1003.1-2001, the following terminology definitions apply:

- **can**
  Describes a permissible optional feature or behavior available to the user or application. The feature or behavior is mandatory for an implementation that conforms to IEEE Std 1003.1-2001. An application can rely on the existence of the feature or behavior.

- **implementation-defined**
  Describes a value or behavior that is not defined by IEEE Std 1003.1-2001 but is selected by an implementor. The value or behavior may vary among implementations that conform to IEEE Std 1003.1-2001. An application should not rely on the existence of the value or behavior. An application that relies on such a value or behavior cannot be assured to be portable across conforming implementations.

  The implementor shall document such a value or behavior so that it can be used correctly by an application.

- **legacy**
  Describes a feature or behavior that is being retained for compatibility with older applications, but which has limitations which make it inappropriate for developing portable
applications. New applications should use alternative means of obtaining equivalent functionality.

**may**
Describes a feature or behavior that is optional for an implementation that conforms to IEEE Std 1003.1-2001. An application should not rely on the existence of the feature or behavior. An application that relies on such a feature or behavior cannot be assured to be portable across conforming implementations.

To avoid ambiguity, the opposite of *may* is expressed as *need not*, instead of *may not*.

**shall**
For an implementation that conforms to IEEE Std 1003.1-2001, describes a feature or behavior that is mandatory. An application can rely on the existence of the feature or behavior.

For an application or user, describes a behavior that is mandatory.

**should**
For an implementation that conforms to IEEE Std 1003.1-2001, describes a feature or behavior that is recommended but not mandatory. An application should not rely on the existence of the feature or behavior. An application that relies on such a feature or behavior cannot be assured to be portable across conforming implementations.

For an application, describes a feature or behavior that is recommended programming practice for optimum portability.

**undefined**
Describes the nature of a value or behavior not defined by IEEE Std 1003.1-2001 which results from use of an invalid program construct or invalid data input.

The value or behavior may vary among implementations that conform to IEEE Std 1003.1-2001. An application should not rely on the existence or validity of the value or behavior. An application that relies on any particular value or behavior cannot be assured to be portable across conforming implementations.

**unspecified**
Describes the nature of a value or behavior not specified by IEEE Std 1003.1-2001 which results from use of a valid program construct or valid data input.

The value or behavior may vary among implementations that conform to IEEE Std 1003.1-2001. An application should not rely on the existence or validity of the value or behavior. An application that relies on any particular value or behavior cannot be assured to be portable across conforming implementations.
1.6 Definitions

1.7 Relationship to Other Formal Standards

Great care has been taken to ensure that this volume of IEEE Std 1003.1-2001 is fully aligned with the following standards:

- ISO C (1999)
- ISO/IEC 9899:1999, Programming Languages — C.

Parts of the ISO/IEC 9899:1999 standard (hereinafter referred to as the ISO C standard) are referenced to describe requirements also mandated by this volume of IEEE Std 1003.1-2001. Some functions and headers included within this volume of IEEE Std 1003.1-2001 have a version in the ISO C standard; in this case CX markings are added as appropriate to show where the ISO C standard has been extended (see Section 1.8.1). Any conflict between this volume of IEEE Std 1003.1-2001 and the ISO C standard is unintentional.

This volume of IEEE Std 1003.1-2001 also allows, but does not require, mathematics functions to support IEEE Std 754-1985 and IEEE Std 854-1987.

1.8 Portability

Some of the utilities in the Shell and Utilities volume of IEEE Std 1003.1-2001 and functions in the System Interfaces volume of IEEE Std 1003.1-2001 describe functionality that might not be fully portable to systems meeting the requirements for POSIX conformance (see the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 2, Conformance).

Where optional, enhanced, or reduced functionality is specified, the text is shaded and a code in the margin identifies the nature of the option, extension, or warning (see Section 1.8.1). For maximum portability, an application should avoid such functionality.

1.8.1 Codes

Margin codes and their meanings are listed in the Base Definitions volume of IEEE Std 1003.1-2001, but are repeated here for convenience:

- ADV Advisory Information
  The functionality described is optional. The functionality described is also an extension to the ISO C standard.
  Where applicable, functions are marked with the ADV margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the ADV margin legend.

- AIO Asynchronous Input and Output
  The functionality described is optional. The functionality described is also an extension to the ISO C standard.
  Where applicable, functions are marked with the AIO margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the AIO margin legend.

- BAR Barriers
  The functionality described is optional. The functionality described is also an extension to the
ISO C standard.
Where applicable, functions are marked with the BAR margin legend in the SYNOPSIS section.
Where additional semantics apply to a function, the material is identified by use of the BAR margin legend.

**Batch Environment Services and Utilities**
The functionality described is optional.
Where applicable, utilities are marked with the BE margin legend in the SYNOPSIS section.
Where additional semantics apply to a utility, the material is identified by use of the BE margin legend.

**C-Language Development Utilities**
The functionality described is optional.
Where applicable, utilities are marked with the CD margin legend in the SYNOPSIS section.
Where additional semantics apply to a utility, the material is identified by use of the CD margin legend.

**Process CPU-Time Clocks**
The functionality described is optional. The functionality described is also an extension to the ISO C standard.
Where applicable, functions are marked with the CPT margin legend in the SYNOPSIS section.
Where additional semantics apply to a function, the material is identified by use of the CPT margin legend.

**Clock Selection**
The functionality described is optional. The functionality described is also an extension to the ISO C standard.
Where applicable, functions are marked with the CS margin legend in the SYNOPSIS section.
Where additional semantics apply to a function, the material is identified by use of the CS margin legend.

**Extension to the ISO C standard**
The functionality described is an extension to the ISO C standard. Application writers may make use of an extension as it is supported on all IEEE Std 1003.1-2001-conforming systems.
With each function or header from the ISO C standard, a statement to the effect that “any conflict is unintentional” is included. That is intended to refer to a direct conflict. IEEE Std 1003.1-2001 acts in part as a profile of the ISO C standard, and it may choose to further constrain behaviors allowed to vary by the ISO C standard. Such limitations are not considered conflicts.
Where additional semantics apply to a function or header, the material is identified by use of the CX margin legend.

**FORTRAN Development Utilities**
The functionality described is optional.
Where applicable, utilities are marked with the FD margin legend in the SYNOPSIS section.
Where additional semantics apply to a utility, the material is identified by use of the FD margin legend.

**FORTRAN Runtime Utilities**
The functionality described is optional.
Where applicable, utilities are marked with the FR margin legend in the SYNOPSIS section.
Where additional semantics apply to a utility, the material is identified by use of the FR margin legend.

**FSC**
File Synchronization
The functionality described is optional. The functionality described is also an extension to the ISO C standard.

Where applicable, functions are marked with the FSC margin legend in the SYNOPSIS section.
Where additional semantics apply to a function, the material is identified by use of the FSC margin legend.

**IP6**
IPV6
The functionality described is optional. The functionality described is also an extension to the ISO C standard.

Where applicable, functions are marked with the IP6 margin legend in the SYNOPSIS section.
Where additional semantics apply to a function, the material is identified by use of the IP6 margin legend.

Refer to the Base Definitions volume of IEEE Std 1003.1-2001, Section 1.5.2, Margin Code Notation.

**MC1**
Advisory Information and either Memory Mapped Files or Shared Memory Objects
The functionality described is optional. The functionality described is also an extension to the ISO C standard.

This is a shorthand notation for combinations of multiple option codes.

Where applicable, functions are marked with the MC1 margin legend in the SYNOPSIS section.
Where additional semantics apply to a function, the material is identified by use of the MC1 margin legend.

Refer to the Base Definitions volume of IEEE Std 1003.1-2001, Section 1.5.2, Margin Code Notation.

**MC2**
Memory Mapped Files, Shared Memory Objects, or Memory Protection
The functionality described is optional. The functionality described is also an extension to the ISO C standard.

This is a shorthand notation for combinations of multiple option codes.

Where applicable, functions are marked with the MC2 margin legend in the SYNOPSIS section.
Where additional semantics apply to a function, the material is identified by use of the MC2 margin legend.

Refer to the Base Definitions volume of IEEE Std 1003.1-2001, Section 1.5.2, Margin Code Notation.

**MC3**
Memory Mapped Files, Shared Memory Objects, or Typed Memory Objects
The functionality described is optional. The functionality described is also an extension to the ISO C standard.

This is a shorthand notation for combinations of multiple option codes.

Where applicable, functions are marked with the MC3 margin legend in the SYNOPSIS section.
Where additional semantics apply to a function, the material is identified by use of the MC3 margin legend.

Refer to the Base Definitions volume of IEEE Std 1003.1-2001, Section 1.5.2, Margin Code Notation.

**MF**
Memory Mapped Files
The functionality described is optional. The functionality described is also an extension to the
ISO C standard.

Where applicable, functions are marked with the MF margin legend in the SYNOPSIS section.
Where additional semantics apply to a function, the material is identified by use of the MF margin legend.

Process Memory Locking
The functionality described is optional. The functionality described is also an extension to the ISO C standard.
Where applicable, functions are marked with the ML margin legend in the SYNOPSIS section.
Where additional semantics apply to a function, the material is identified by use of the ML margin legend.

Range Memory Locking
The functionality described is optional. The functionality described is also an extension to the ISO C standard.
Where applicable, functions are marked with the MLR margin legend in the SYNOPSIS section.
Where additional semantics apply to a function, the material is identified by use of the MLR margin legend.

Monotonic Clock
The functionality described is optional. The functionality described is also an extension to the ISO C standard.
Where applicable, functions are marked with the MON margin legend in the SYNOPSIS section.
Where additional semantics apply to a function, the material is identified by use of the MON margin legend.

Memory Protection
The functionality described is optional. The functionality described is also an extension to the ISO C standard.
Where applicable, functions are marked with the MPR margin legend in the SYNOPSIS section.
Where additional semantics apply to a function, the material is identified by use of the MPR margin legend.

Message Passing
The functionality described is optional. The functionality described is also an extension to the ISO C standard.
Where applicable, functions are marked with the MSG margin legend in the SYNOPSIS section.
Where additional semantics apply to a function, the material is identified by use of the MSG margin legend.

IEC 60559 Floating-Point Option
The functionality described is optional. The functionality described is also an extension to the ISO C standard.
Where applicable, functions are marked with the MX margin legend in the SYNOPSIS section.
Where additional semantics apply to a function, the material is identified by use of the MX margin legend.

Obsolescent
The functionality described may be withdrawn in a future version of this volume of IEEE Std 1003.1-2001. Strictly Conforming POSIX Applications and Strictly Conforming XSI Applications shall not use obsolescent features.
238 Where applicable, the material is identified by use of the OB margin legend.

239 Output Format Incompletely Specified
The functionality described is an XSI extension. The format of the output produced by the utility
is not fully specified. It is therefore not possible to post-process this output in a consistent
fashion. Typical problems include unknown length of strings and unspecified field delimiters.

Where applicable, the material is identified by use of the OF margin legend.

244 Optional Header
In the SYNOPSIS section of some interfaces in the System Interfaces volume of
IEEE Std 1003.1-2001 an included header is marked as in the following example:

#include <sys/types.h>
#include <grp.h>
struct group *getgrnam(const char *name);

The OH margin legend indicates that the marked header is not required on XSI-conformant
systems.

252 Prioritized Input and Output
The functionality described is optional. The functionality described is also an extension to the
ISO C standard.

Where applicable, functions are marked with the PIO margin legend in the SYNOPSIS section.
Where additional semantics apply to a function, the material is identified by use of the PIO
margin legend.

258 Process Scheduling
The functionality described is optional. The functionality described is also an extension to the
ISO C standard.

Where applicable, functions are marked with the PS margin legend in the SYNOPSIS section.
Where additional semantics apply to a function, the material is identified by use of the PS
margin legend.

264 Raw Sockets
The functionality described is optional. The functionality described is also an extension to the
ISO C standard.

Where applicable, functions are marked with the RS margin legend in the SYNOPSIS section.
Where additional semantics apply to a function, the material is identified by use of the RS
margin legend.

270 Realtime Signals Extension
The functionality described is optional. The functionality described is also an extension to the
ISO C standard.

Where applicable, functions are marked with the RTS margin legend in the SYNOPSIS section.
Where additional semantics apply to a function, the material is identified by use of the RTS
margin legend.

276 Software Development Utilities
The functionality described is optional.

Where applicable, utilities are marked with the SD margin legend in the SYNOPSIS section.
Where additional semantics apply to a utility, the material is identified by use of the SD margin
legend.
Semaphores
The functionality described is optional. The functionality described is also an extension to the
ISO C standard.
Where applicable, functions are marked with the SEM margin legend in the SYNOPSIS section.
Where additional semantics apply to a function, the material is identified by use of the SEM
margin legend.

Shared Memory Objects
The functionality described is optional. The functionality described is also an extension to the
ISO C standard.
Where applicable, functions are marked with the SHM margin legend in the SYNOPSIS section.
Where additional semantics apply to a function, the material is identified by use of the SHM
margin legend.

Synchronized Input and Output
The functionality described is optional. The functionality described is also an extension to the
ISO C standard.
Where applicable, functions are marked with the SIO margin legend in the SYNOPSIS section.
Where additional semantics apply to a function, the material is identified by use of the SIO
margin legend.

Spin Locks
The functionality described is optional. The functionality described is also an extension to the
ISO C standard.
Where applicable, functions are marked with the SPI margin legend in the SYNOPSIS section.
Where additional semantics apply to a function, the material is identified by use of the SPI
margin legend.

Spawn
The functionality described is optional. The functionality described is also an extension to the
ISO C standard.
Where applicable, functions are marked with the SPN margin legend in the SYNOPSIS section.
Where additional semantics apply to a function, the material is identified by use of the SPN
margin legend.

Process Sporadic Server
The functionality described is optional. The functionality described is also an extension to the
ISO C standard.
Where applicable, functions are marked with the SS margin legend in the SYNOPSIS section.
Where additional semantics apply to a function, the material is identified by use of the SS
margin legend.

Thread CPU-Time Clocks
The functionality described is optional. The functionality described is also an extension to the
ISO C standard.
Where applicable, functions are marked with the TCT margin legend in the SYNOPSIS section.
Where additional semantics apply to a function, the material is identified by use of the TCT
margin legend.

Trace Event Filter
The functionality described is optional. The functionality described is also an extension to the
ISO C standard.
Where applicable, functions are marked with the TEF margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the TEF margin legend.

**THR** Threads
The functionality described is optional. The functionality described is also an extension to the ISO C standard.

Where applicable, functions are marked with the THR margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the THR margin legend.

**TMO** Timeouts
The functionality described is optional. The functionality described is also an extension to the ISO C standard.

Where applicable, functions are marked with the TMO margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the TMO margin legend.

**TMR** Timers
The functionality described is optional. The functionality described is also an extension to the ISO C standard.

Where applicable, functions are marked with the TMR margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the TMR margin legend.

**TPI** Thread Priority Inheritance
The functionality described is optional. The functionality described is also an extension to the ISO C standard.

Where applicable, functions are marked with the TPI margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the TPI margin legend.

**TPP** Thread Priority Protection
The functionality described is optional. The functionality described is also an extension to the ISO C standard.

Where applicable, functions are marked with the TPP margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the TPP margin legend.

**TPS** Thread Execution Scheduling
The functionality described is optional. The functionality described is also an extension to the ISO C standard.

Where applicable, functions are marked with the TPS margin legend for the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the TPS margin legend.

**TRC** Trace
The functionality described is optional. The functionality described is also an extension to the ISO C standard.

Where applicable, functions are marked with the TRC margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the TRC margin legend.

371 TRI Trace Inherit
The functionality described is optional. The functionality described is also an extension to the ISO C standard.
Where applicable, functions are marked with the TRI margin legend in the SYNOPSIS section.
Where additional semantics apply to a function, the material is identified by use of the TRI margin legend.

377 TRL Trace Log
The functionality described is optional. The functionality described is also an extension to the ISO C standard.
Where applicable, functions are marked with the TRL margin legend in the SYNOPSIS section.
Where additional semantics apply to a function, the material is identified by use of the TRL margin legend.

383 TSA Thread Stack Address Attribute
The functionality described is optional. The functionality described is also an extension to the ISO C standard.
Where applicable, functions are marked with the TSA margin legend for the SYNOPSIS section.
Where additional semantics apply to a function, the material is identified by use of the TSA margin legend.

389 TSF Thread-Safe Functions
The functionality described is optional. The functionality described is also an extension to the ISO C standard.
Where applicable, functions are marked with the TSF margin legend in the SYNOPSIS section.
Where additional semantics apply to a function, the material is identified by use of the TSF margin legend.

395 TSH Thread Process-Shared Synchronization
The functionality described is optional. The functionality described is also an extension to the ISO C standard.
Where applicable, functions are marked with the TSH margin legend in the SYNOPSIS section.
Where additional semantics apply to a function, the material is identified by use of the TSH margin legend.

401 TSP Thread Sporadic Server
The functionality described is optional. The functionality described is also an extension to the ISO C standard.
Where applicable, functions are marked with the TSP margin legend in the SYNOPSIS section.
Where additional semantics apply to a function, the material is identified by use of the TSP margin legend.

407 TSS Thread Stack Size Attribute
The functionality described is optional. The functionality described is also an extension to the ISO C standard.
Where applicable, functions are marked with the TSS margin legend in the SYNOPSIS section.
Where additional semantics apply to a function, the material is identified by use of the TSS margin legend.

413 TYM Typed Memory Objects
The functionality described is optional. The functionality described is also an extension to the ISO C standard.
Introduction

Portability

Where applicable, functions are marked with the TYM margin legend in the SYNOPSIS section.
Where additional semantics apply to a function, the material is identified by use of the TYM margin legend.

**UP**

User Portability Utilities

The functionality described is optional.
Where applicable, utilities are marked with the UP margin legend in the SYNOPSIS section.
Where additional semantics apply to a utility, the material is identified by use of the UP margin legend.

**XSI**

Extension

The functionality described is an XSI extension. Functionality marked XSI is also an extension to the ISO C standard. Application writers may confidently make use of an extension on all systems supporting the X/Open System Interfaces Extension.

If an entire SYNOPSIS section is shaded and marked XSI, all the functionality described in that reference page is an extension. See the Base Definitions volume of IEEE Std 1003.1-2001, Section 3.439, XSI.

**XSR**

XSI STREAMS

The functionality described is optional. The functionality described is also an extension to the ISO C standard.

Where applicable, functions are marked with the XSR margin legend in the SYNOPSIS section.
Where additional semantics apply to a function, the material is identified by use of the XSR margin legend.

1.9 Format of Entries

The entries in Chapter 3 are based on a common format as follows. The only sections relating to conformance are the SYNOPSIS, DESCRIPTION, RETURN VALUE, and ERRORS sections.

**NAME**

This section gives the name or names of the entry and briefly states its purpose.

**SYNOPSIS**

This section summarizes the use of the entry being described. If it is necessary to include a header to use this function, the names of such headers are shown, for example:

```
#include <stdio.h>
```

**DESCRIPTION**

This section describes the functionality of the function or header.

**RETURN VALUE**

This section indicates the possible return values, if any.

If the implementation can detect errors, “successful completion” means that no error has been detected during execution of the function. If the implementation does detect an error, the error is indicated.

For functions where no errors are defined, “successful completion” means that if the implementation checks for errors, no error has been detected. If the implementation can detect errors, and an error is detected, the indicated return value is returned and `errno` may be set.
ERRORS
This section gives the symbolic names of the error values returned by a function or stored into a variable accessed through the symbol \texttt{errno} if an error occurs.

“No errors are defined” means that error values returned by a function or stored into a variable accessed through the symbol \texttt{errno}, if any, depend on the implementation.

EXAMPLES
This section is informative.

This section gives examples of usage, where appropriate. In the event of conflict between an example and a normative part of this volume of IEEE Std 1003.1-2001, the normative material is to be taken as correct.

APPLICATION USAGE
This section is informative.

This section gives warnings and advice to application writers about the entry. In the event of conflict between warnings and advice and a normative part of this volume of IEEE Std 1003.1-2001, the normative material is to be taken as correct.

RATIONALE
This section is informative.

This section contains historical information concerning the contents of this volume of IEEE Std 1003.1-2001 and why features were included or discarded by the standard developers.

FUTURE DIRECTIONS
This section is informative.

This section provides comments which should be used as a guide to current thinking; there is not necessarily a commitment to adopt these future directions.

SEE ALSO
This section is informative.

This section gives references to related information.

CHANGE HISTORY
This section is informative.

This section shows the derivation of the entry and any significant changes that have been made to it.
Chapter 2

General Information

This chapter covers information that is relevant to all the functions specified in Chapter 3 and the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 13, Headers.

2.1 Use and Implementation of Functions

Each of the following statements shall apply unless explicitly stated otherwise in the detailed descriptions that follow:

1. If an argument to a function has an invalid value (such as a value outside the domain of the function, or a pointer outside the address space of the program, or a null pointer), the behavior is undefined.

2. Any function declared in a header may also be implemented as a macro defined in the header, so a function should not be declared explicitly if its header is included. Any macro definition of a function can be suppressed locally by enclosing the name of the function in parentheses, because the name is then not followed by the left parenthesis that indicates expansion of a macro function name. For the same syntactic reason, it is permitted to take the address of a function even if it is also defined as a macro. The use of the C-language

#define construct to remove any such macro definition shall also ensure that an actual function is referred to.

3. Any invocation of a function that is implemented as a macro shall expand to code that evaluates each of its arguments exactly once, fully protected by parentheses where necessary, so it is generally safe to use arbitrary expressions as arguments. Likewise, those function-like macros described in the following sections may be invoked in an expression anywhere a function with a compatible return type could be called.

4. Provided that a function can be declared without reference to any type defined in a header, it is also permissible to declare the function explicitly and use it without including its associated header.

5. If a function that accepts a variable number of arguments is not declared (explicitly or by including its associated header), the behavior is undefined.

2.2 The Compilation Environment

2.2.1 POSIX.1 Symbols

Certain symbols in this volume of IEEE Std 1003.1-2001 are defined in headers (see the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 13, Headers). Some of those headers could also define symbols other than those defined by IEEE Std 1003.1-2001, potentially conflicting with symbols used by the application. Also, IEEE Std 1003.1-2001 defines symbols that are not permitted by other standards to appear in those headers without some control on the visibility of those symbols.

Symbols called “feature test macros” are used to control the visibility of symbols that might be included in a header. Implementations, future versions of IEEE Std 1003.1-2001, and other standards may define additional feature test macros.
In the compilation of an application that \texttt{#defines} a feature test macro specified by IEEE Std 1003.1-2001, no header defined by IEEE Std 1003.1-2001 shall be included prior to the definition of the feature test macro. This restriction also applies to any implementation-provided header in which these feature test macros are used. If the definition of the macro does not precede the \texttt{#include}, the result is undefined.

Feature test macros shall begin with the underscore character (‘\_’).

\subsection*{2.2.1.1 \texttt{The \_POSIX\_C\_SOURCE Feature Test Macro}}

A POSIX-conforming application should ensure that the feature test macro \_POSIX\_C\_SOURCE is defined before inclusion of any header.

When an application includes a header described by IEEE Std 1003.1-2001, and when this feature test macro is defined to have the value 200112L:

1. All symbols required by IEEE Std 1003.1-2001 to appear when the header is included shall be made visible.
2. Symbols that are explicitly permitted, but not required, by IEEE Std 1003.1-2001 to appear in that header (including those in reserved name spaces) may be made visible.
3. Additional symbols not required or explicitly permitted by IEEE Std 1003.1-2001 to be in that header shall not be made visible, except when enabled by another feature test macro.

Identifiers in IEEE Std 1003.1-2001 may only be undefined using the \texttt{#undef} directive as described in Section 2.1 (on page 13) or Section 2.2.2. These \texttt{#undef} directives shall follow all \texttt{#include} directives of any header in IEEE Std 1003.1-2001.

\textbf{Note:} The POSIX.1-1990 standard specified a macro called \_POSIX\_SOURCE. This has been superseded by \_POSIX\_C\_SOURCE.

\subsection*{2.2.1.2 \texttt{The \_XOPEN\_SOURCE Feature Test Macro}}

An XSI-conforming application should ensure that the feature test macro \_XOPEN\_SOURCE is defined with the value 600 before inclusion of any header. This is needed to enable the functionality described in Section 2.2.1.1 and in addition to enable the XSI extension.

Since this volume of IEEE Std 1003.1-2001 is aligned with the ISO C standard, and since all functionality enabled by \_POSIX\_C\_SOURCE set equal to 200112L is enabled by \_XOPEN\_SOURCE set equal to 600, there should be no need to define \_POSIX\_C\_SOURCE if \_XOPEN\_SOURCE is so defined. Therefore, if \_XOPEN\_SOURCE is set equal to 600 and \_POSIX\_C\_SOURCE is set equal to 200112L, the behavior is the same as if only \_XOPEN\_SOURCE is defined and set equal to 600. However, should \_POSIX\_C\_SOURCE be set to a value greater than 200112L, the behavior is unspecified.

\subsection*{2.2.2 \texttt{The Name Space}}

All identifiers in this volume of IEEE Std 1003.1-2001, except environ, are defined in at least one of the headers, as shown in the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 13, Headers. When \_XOPEN\_SOURCE or \_POSIX\_C\_SOURCE is defined, each header defines or declares some identifiers, potentially conflicting with identifiers used by the application. The set of identifiers visible to the application consists of precisely those identifiers from the header pages of the included headers, as well as additional identifiers reserved for the implementation.

In addition, some headers may make visible identifiers from other headers as indicated on the relevant header pages.
Implementations may also add members to a structure or union without controlling the visibility of those members with a feature test macro, as long as a user-defined macro with the same name cannot interfere with the correct interpretation of the program. The identifiers reserved for use by the implementation are described below:

1. Each identifier with external linkage described in the header section is reserved for use as an identifier with external linkage if the header is included.

2. Each macro described in the header section is reserved for any use if the header is included.

3. Each identifier with file scope described in the header section is reserved for use as an identifier with file scope in the same name space if the header is included.

The prefixes posix_, POSIX_, and _POSIX_ are reserved for use by IEEE Std 1003.1-2001 and other POSIX standards. Implementations may add symbols to the headers shown in the following table, provided the identifiers for those symbols begin with the corresponding reserved prefixes in the following table, and do not use the reserved prefixes posix_, POSIX_, or _POSIX_.

**Note:** The notation [A−Z] indicates any uppercase letter in the portable character set. The notation [a−z] indicates any lowercase letter in the portable character set. Commas and spaces in the lists of prefixes and complete names in the above table are not part of any prefix or complete name.

If any header in the following table is included, macros with the prefixes shown may be defined. After the last inclusion of a given header, an application may use identifiers with the corresponding prefixes for its own purpose, provided their use is preceded by a `#undef` of the corresponding macro.

The following are used to reserve complete names for the `<stdint.h>` header:

- INT[0-9A-Za-z_]*_MIN
- INT[0-9A-Za-z_]*_MAX
- INT[0-9A-Za-z_]*_C
- UINT[0-9A-Za-z_]*_MIN
- UINT[0-9A-Za-z_]*_MAX
- UINT[0-9A-Za-z_]*_C

**Note:** The notation [0–9] indicates any digit. The notation [A–Z] indicates any uppercase letter in the portable character set. The notation [0–9a–z_] indicates any digit, any lowercase letter in the portable character set, or underscore.
The following reserved names are used as exact matches for `<termios.h>`:

CBAUD  EXTB  VDSUSP
DEFECHO  FLUSHO  VLNEXT
ECHOCTL  LOBLK  VREPRINT
ECHOKE  PENDIN  VSTATUS
ECHOPRT  SWTCH  VWERASE
EXTA  VDISCARD

The following identifiers are reserved regardless of the inclusion of headers:

1. All identifiers that begin with an underscore and either an uppercase letter or another underscore are always reserved for any use by the implementation.
2. All identifiers that begin with an underscore are always reserved for use as identifiers with file scope in both the ordinary identifier and tag name spaces.
3. All identifiers in the table below are reserved for use as identifiers with external linkage. Some of these identifiers do not appear in this volume of IEEE Std 1003.1-2001, but are reserved for future use by the ISO C standard.

The Compilation Environment

General Information

The notation \([a-z]\) indicates any lowercase letter in the portable character set. The notation \('[a-z]*\) indicates any combination of digits, letters in the portable character set, or underscore.

4. All functions and external identifiers defined in the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 13, Headers are reserved for use as identifiers with external linkage.

5. All the identifiers defined in this volume of IEEE Std 1003.1-2001 that have external linkage are always reserved for use as identifiers with external linkage.

No other identifiers are reserved.

Applications shall not declare or define identifiers with the same name as an identifier reserved in the same context. Since macro names are replaced whenever found, independent of scope and
name space, macro names matching any of the reserved identifier names shall not be defined by
an application if any associated header is included.

Except that the effect of each inclusion of `<assert.h>` depends on the definition of NDEBUG,
headers may be included in any order, and each may be included more than once in a given
scope, with no difference in effect from that of being included only once.

If used, the application shall ensure that a header is included outside of any external declaration
or definition, and it shall be first included before the first reference to any type or macro it
defines, or to any function or object it declares. However, if an identifier is declared or defined in
more than one header, the second and subsequent associated headers may be included after the
initial reference to the identifier. Prior to the inclusion of a header, the application shall not
define any macros with names lexically identical to symbols defined by that header.

### 2.3 Error Numbers

Most functions can provide an error number. The means by which each function provides its
error numbers is specified in its description.

Some functions provide the error number in a variable accessed through the symbol `errno`. The
symbol `errno`, defined by including the `<errno.h>` header, expands to a modifiable lvalue of type
`int`. It is unspecified whether `errno` is a macro or an identifier declared with external linkage. If a
macro definition is suppressed in order to access an actual object, or a program defines an
identifier with the name `errno`, the behavior is undefined.

The value of `errno` should only be examined when it is indicated to be valid by a function's return
value. No function in this volume of IEEE Std 1003.1-2001 shall set `errno` to zero. For each thread
of a process, the value of `errno` shall not be affected by function calls or assignments to `errno` by
other threads.

Some functions return an error number directly as the function value. These functions return a
value of zero to indicate success.

If more than one error occurs in processing a function call, any one of the possible errors may be
returned, as the order of detection is undefined.

Implementations may support additional errors not included in this list, may generate errors
included in this list under circumstances other than those described here, or may contain
extensions or limitations that prevent some errors from occurring. The ERRORS section on each
reference page specifies whether an error shall be returned, or whether it may be returned.
Implementations shall not generate a different error number from the ones described here for
error conditions described in this volume of IEEE Std 1003.1-2001, but may generate additional
errors unless explicitly disallowed for a particular function.

Each implementation shall document, in the conformance document, situations in which each of
the optional conditions defined in IEEE Std 1003.1-2001 is detected. The conformance document
may also contain statements that one or more of the optional error conditions are not detected.

For functions under the Threads option for which [EINTR] is not listed as a possible error
condition in this volume of IEEE Std 1003.1-2001, an implementation shall not return an error
code of [EINTR].

The following symbolic names identify the possible error numbers, in the context of the
functions specifically defined in this volume of IEEE Std 1003.1-2001; these general descriptions
are more precisely defined in the ERRORS sections of the functions that return them. Only these
symbolic names should be used in programs, since the actual value of the error number is
unspecified. All values listed in this section shall be unique integer constant expressions with type \texttt{int} suitable for use in \texttt{#if} preprocessing directives, except as noted below. The values for all these names shall be found in the \texttt{<errno.h>} header defined in the Base Definitions volume of IEEE Std 1003.1-2001. The actual values are unspecified by this volume of IEEE Std 1003.1-2001.

\[E2BIG\]
Argument list too long. The sum of the number of bytes used by the new process image’s argument list and environment list is greater than the system-imposed limit of \{ARG\_MAX\} bytes.

or:

Lack of space in an output buffer.

or:

Argument is greater than the system-imposed maximum.

\[EACCES\]
Permission denied. An attempt was made to access a file in a way forbidden by its file access permissions.

\[EADDRINUSE\]
Address in use. The specified address is in use.

\[EADDRNOTAVAIL\]
Address not available. The specified address is not available from the local system.

\[EAFNOSUPPORT\]
Address family not supported. The implementation does not support the specified address family, or the specified address is not a valid address for the address family of the specified socket.

\[EAGAIN\]
Resource temporarily unavailable. This is a temporary condition and later calls to the same routine may complete normally.

\[EALREADY\]
Connection already in progress. A connection request is already in progress for the specified socket.

\[EBADF\]
Bad file descriptor. A file descriptor argument is out of range, refers to no open file, or a read (write) request is made to a file that is only open for writing (reading).

\[EBADMSG\]
Bad message. During a \texttt{read()}, \texttt{getmsg()}, \texttt{getpmsg()}, or \texttt{ioctl()} \texttt{I\_RECVFD} request to a STREAMS device, a message arrived at the head of the STREAM that is inappropriate for the function receiving the message.

\texttt{read()}  
Message waiting to be read on a STREAM is not a data message.

\texttt{getmsg()} or \texttt{getpmsg()}  
A file descriptor was received instead of a control message.

\texttt{ioctl()}  
Control or data information was received instead of a file descriptor when \texttt{I\_RECVFD} was specified.

or:
Bad Message. The implementation has detected a corrupted message.

[EBUSY]
Resource busy. An attempt was made to make use of a system resource that is not currently available, as it is being used by another process in a manner that would have conflicted with the request being made by this process.

[ECANCELED]
Operation canceled. The associated asynchronous operation was canceled before completion.

[ECHILD]
No child process. A wait() or waitpid() function was executed by a process that had no existing or unwaited-for child process.

[ECONNABORTED]
Connection aborted. The connection has been aborted.

[ECONNREFUSED]
Connection refused. An attempt to connect to a socket was refused because there was no process listening or because the queue of connection requests was full and the underlying protocol does not support retransmissions.

[ECONNRESET]
Connection reset. The connection was forcibly closed by the peer.

[EDEADLK]
Resource deadlock would occur. An attempt was made to lock a system resource that would have resulted in a deadlock situation.

[EDESTADDRREQ]
Destination address required. No bind address was established.

[EDOM]
Domain error. An input argument is outside the defined domain of the mathematical function (defined in the ISO C standard).

[EDQUOT]
Reserved.

[EEXIST]
File exists. An existing file was mentioned in an inappropriate context; for example, as a new link name in the link() function.

[EFAULT]
Bad address. The system detected an invalid address in attempting to use an argument of a call. The reliable detection of this error cannot be guaranteed, and when not detected may result in the generation of a signal, indicating an address violation, which is sent to the process.

[EFBIG]
File too large. The size of a file would exceed the maximum file size of an implementation or offset maximum established in the corresponding file description.

[EHOSTUNREACH]
Host is unreachable. The destination host cannot be reached (probably because the host is down or a remote router cannot reach it).

[EIDRM]
Identifier removed. Returned during XSI interprocess communication if an identifier has
been removed from the system.

[EILSEQ]
Illegal byte sequence. A wide-character code has been detected that does not correspond to
a valid character, or a byte sequence does not form a valid wide-character code (defined in
the ISO C standard).

[EINPROGRESS]
Operation in progress. This code is used to indicate that an asynchronous operation has not
yet completed.

or:
O_NONBLOCK is set for the socket file descriptor and the connection cannot be
immediately established.

[EINTR]
Interrupted function call. An asynchronous signal was caught by the process during the
execution of an interruptible function. If the signal handler performs a normal return, the
interrupted function call may return this condition (see the Base Definitions volume of

EINVAL
Invalid argument. Some invalid argument was supplied; for example, specifying an
undefined signal in a `signal()` function or a `kill()` function.

[EIO]
Input/output error. Some physical input or output error has occurred. This error may be
reported on a subsequent operation on the same file descriptor. Any other error-causing
operation on the same file descriptor may cause the [EIO] error indication to be lost.

[EISCONN]
Socket is connected. The specified socket is already connected.

[EISDIR]
Is a directory. An attempt was made to open a directory with write mode specified.

[ELOOP]
Symbolic link loop. A loop exists in symbolic links encountered during pathname
resolution. This error may also be returned if more than {SYMLOOP_MAX} symbolic links
are encountered during pathname resolution.

[EMFILE]
Too many open files. An attempt was made to open more than the maximum number of file
descriptors allowed in this process.

[EMFILE]
Too many links. An attempt was made to have the link count of a single file exceed
{LINK_MAX}.

[EMSGSIZE]
Message too large. A message sent on a transport provider was larger than an internal
message buffer or some other network limit.

or:
Inappropriate message buffer length.

[EMULTIHOP]
Reserved.
General Information

Error Numbers

[ENAMETOOLONG]
Filename too long. The length of a pathname exceeds \{PATH_MAX\}, or a pathname component is longer than \{NAME_MAX\}. This error may also occur when pathname substitution, as a result of encountering a symbolic link during pathname resolution, results in a pathname string the size of which exceeds \{PATH_MAX\}.

[ENETDOWN]
Network is down. The local network interface used to reach the destination is down.

[ENETRESET]
The connection was aborted by the network.

[ENETUNREACH]
Network unreachable. No route to the network is present.

[ENFILE]
Too many files open in system. Too many files are currently open in the system. The system has reached its predefined limit for simultaneously open files and temporarily cannot accept requests to open another one.

[ENOBUFFS]
No buffer space available. Insufficient buffer resources were available in the system to perform the socket operation.

[ENODATA]
No message available. No message is available on the STREAM head read queue.

[ENODEV]
No such device. An attempt was made to apply an inappropriate function to a device; for example, trying to read a write-only device such as a printer.

[ENOENT]
No such file or directory. A component of a specified pathname does not exist, or the pathname is an empty string.

[ENOEXEC]
Executable file format error. A request is made to execute a file that, although it has the appropriate permissions, is not in the format required by the implementation for executable files.

[ENOLCK]
No locks available. A system-imposed limit on the number of simultaneous file and record locks has been reached and no more are currently available.

[ENOLINK]
Reserved.

[ENOMEM]
Not enough space. The new process image requires more memory than is allowed by the hardware or system-imposed memory management constraints.

[ENOMEMSG]
No message of the desired type. The message queue does not contain a message of the required type during XSI interprocess communication.

[ENOPROTOOPT]
Protocol not available. The protocol option specified to \texttt{setsockopt()} is not supported by the implementation.
1020 [ENOSPC]
   No space left on a device. During the write() function on a regular file or when extending a directory, there is no free space left on the device.

1023 [XSR][ENOSR]
   No STREAM resources. Insufficient STREAMS memory resources are available to perform a STREAMS-related function. This is a temporary condition; it may be recovered from if other processes release resources.

1027 [XSR][ENOSTR]
   Not a STREAM. A STREAM function was attempted on a file descriptor that was not associated with a STREAMS device.

1030 [ENOSYS]
   Function not implemented. An attempt was made to use a function that is not available in this implementation.

1033 [ENOTCONN]
   Socket not connected. The socket is not connected.

1035 [ENOTDIR]
   Not a directory. A component of the specified pathname exists, but it is not a directory, when a directory was expected.

1038 [ENOTEMPTY]
   Directory not empty. A directory other than an empty directory was supplied when an empty directory was expected.

1041 [ENOTSOCK]
   Not a socket. The file descriptor does not refer to a socket.

1043 [ENOTSUP]
   Not supported. The implementation does not support this feature of the Realtime Option Group.

1046 [ENOTTY]
   Inappropriate I/O control operation. A control function has been attempted for a file or special file for which the operation is inappropriate.

1049 [ENXIO]
   No such device or address. Input or output on a special file refers to a device that does not exist, or makes a request beyond the capabilities of the device. It may also occur when, for example, a tape drive is not on-line.

1054 [EOPNOTSUPP]
   Operation not supported on socket. The type of socket (address family or protocol) does not support the requested operation.

1057 [EOVERFLOW]
   Value too large to be stored in data type. An operation was attempted which would generate a value that is outside the range of values that can be represented in the relevant data type or that are allowed for a given data item.

1060 [EPERM]
   Operation not permitted. An attempt was made to perform an operation limited to processes with appropriate privileges or to the owner of a file or other resource.

1063 [EPIPE]
   Broken pipe. A write was attempted on a socket, pipe, or FIFO for which there is no process
General Information

Error Numbers

to read the data.

[EPROTO]
Protocol error. Some protocol error occurred. This error is device-specific, but is generally
not related to a hardware failure.

[EPROTONOSUPPORT]
Protocol not supported. The protocol is not supported by the address family, or the protocol
is not supported by the implementation.

[EPROTOTYPE]
Protocol wrong type for socket. The socket type is not supported by the protocol.

[ERANGE]
Result too large or too small. The result of the function is too large (overflow) or too small
(underflow) to be represented in the available space (defined in the ISO C standard).

[EROFS]
Read-only file system. An attempt was made to modify a file or directory on a file system
that is read-only.

[ESPIPE]
Invalid seek. An attempt was made to access the file offset associated with a pipe or FIFO.

[ESRCH]
No such process. No process can be found corresponding to that specified by the given
process ID.

[ESTALE]
Reserved.

[ETIME]
STREAM ioctl() timeout. The timer set for a STREAMS ioctl() call has expired. The cause of
this error is device-specific and could indicate either a hardware or software failure, or a
timeout value that is too short for the specific operation. The status of the ioctl() operation
is unspecified.

[ETIMEDOUT]
Connection timed out. The connection to a remote machine has timed out. If the connection
timed out during execution of the function that reported this error (as opposed to timing
out prior to the function being called), it is unspecified whether the function has completed
some or all of the documented behavior associated with a successful completion of the
function.

or:

Operation timed out. The time limit associated with the operation was exceeded before the
operation completed.

[ETXTBSY]
Text file busy. An attempt was made to execute a pure-procedure program that is currently
open for writing, or an attempt has been made to open for writing a pure-procedure
program that is being executed.

[EWOULDBLOCK]
Operation would block. An operation on a socket marked as non-blocking has encountered
a situation such as no data available that otherwise would have caused the function to
suspend execution.
A conforming implementation may assign the same values for \[\text{EWOULDBLOCK}\] and \[\text{EAGAIN}\].

[EXDEV]

Improper link. A link to a file on another file system was attempted.

### 2.3.1 Additional Error Numbers

Additional implementation-defined error numbers may be defined in `<errno.h>`.

### 2.4 Signal Concepts

#### 2.4.1 Signal Generation and Delivery

A signal is said to be “generated” for (or sent to) a process or thread when the event that causes the signal first occurs. Examples of such events include detection of hardware faults, timer expiration, signals generated via the `sigevent` structure and terminal activity, as well as invocations of the `kill()` and `sigqueue()` functions. In some circumstances, the same event generates signals for multiple processes.

At the time of generation, a determination shall be made whether the signal has been generated for the process or for a specific thread within the process. Signals which are generated by some action attributable to a particular thread, such as a hardware fault, shall be generated for the thread that caused the signal to be generated. Signals that are generated in association with a process ID or process group ID or an asynchronous event, such as terminal activity, shall be generated for the process.

Each process has an action to be taken in response to each signal defined by the system (see Section 2.4.3 (on page 30)). A signal is said to be “delivered” to a process when the appropriate action for the process and signal is taken. A signal is said to be “accepted” by a process when the signal is selected and returned by one of the `sigwait()` functions.

During the time between the generation of a signal and its delivery or acceptance, the signal is said to be “pending”. Ordinarily, this interval cannot be detected by an application. However, a signal can be “blocked” from delivery to a thread. If the action associated with a blocked signal is anything other than to ignore the signal, and if that signal is generated for the thread, the signal shall remain pending until it is unblocked, it is accepted when it is selected and returned by a call to the `sigwait()` function, or the action associated with it is set to ignore the signal.

Signals generated for the process shall be delivered to exactly one of those threads within the process which is in a call to a `sigwait()` function selecting that signal or has not blocked delivery of the signal. If there are no threads in a call to a `sigwait()` function selecting that signal, and if all threads within the process block delivery of the signal, the signal shall remain pending until a thread calls a `sigwait()` function selecting that signal, a thread unblocks delivery of the signal, or the action associated with the signal is set to ignore the signal. If the action associated with a blocked signal is to ignore the signal and if that signal is generated for the process, it is unspecified whether the signal is discarded immediately upon generation or remains pending.

Each thread has a “signal mask” that defines the set of signals currently blocked from delivery to it. The signal mask for a thread shall be initialized from that of its parent or creating thread, or from the corresponding thread in the parent process if the thread was created as the result of a call to `fork()`. The `pthread_sigmask()`, `sigaction()`, `sigprocmask()`, and `sigsuspend()` functions control the manipulation of the signal mask.
The determination of which action is taken in response to a signal is made at the time the signal is delivered, allowing for any changes since the time of generation. This determination is independent of the means by which the signal was originally generated. If a subsequent occurrence of a pending signal is generated, it is implementation-defined as to whether the signal is delivered or accepted more than once in circumstances other than those in which queuing is required under the Realtime Signals Extension option. The order in which multiple, simultaneously pending signals outside the range SIGRTMIN to SIGRTMAX are delivered to or accepted by a process is unspecified.

When any stop signal (SIGSTOP, SIGTSTP, SIGTTIN, SIGTTOU) is generated for a process, any pending SIGCONT signals for that process shall be discarded. Conversely, when SIGCONT is generated for a process, all pending stop signals for that process shall be discarded. When SIGCONT is generated for a process that is stopped, the process shall be continued, even if the SIGCONT signal is blocked or ignored. If SIGCONT is blocked and not ignored, it shall remain pending until it is either unblocked or a stop signal is generated for the process.

An implementation shall document any condition not specified by this volume of IEEE Std 1003.1-2001 under which the implementation generates signals.

2.4.2 Realtime Signal Generation and Delivery

This section describes extensions to support realtime signal generation and delivery. This functionality is dependent on support of the Realtime Signals Extension option (and the rest of this section is not further shaded for this option).

Some signal-generating functions, such as high-resolution timer expiration, asynchronous I/O completion, interprocess message arrival, and the `sigqueue()` function, support the specification of an application-defined value, either explicitly as a parameter to the function or in a `sigevent` structure parameter. The `sigevent` structure is defined in `<signal.h>` and contains at least the following members:

<table>
<thead>
<tr>
<th>Member Type</th>
<th>Member Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>int</td>
<td><code>sigev_notify</code></td>
<td>Notification type.</td>
</tr>
<tr>
<td>int</td>
<td><code>sigev_signo</code></td>
<td>Signal number.</td>
</tr>
<tr>
<td>union signal</td>
<td><code>sigev_value</code></td>
<td>Signal value.</td>
</tr>
<tr>
<td>void(*)(unsigned signalling)</td>
<td><code>sigev_notify_function</code></td>
<td>Notification function.</td>
</tr>
<tr>
<td>(pthread_attr_*)</td>
<td><code>sigev_notify_attributes</code></td>
<td>Notification attributes.</td>
</tr>
</tbody>
</table>

The `sigev_notify` member specifies the notification mechanism to use when an asynchronous event occurs. This volume of IEEE Std 1003.1-2001 defines the following values for the `sigev_notify` member:

- **SIGEV_NONE**: No asynchronous notification shall be delivered when the event of interest occurs.
- **SIGEV_SIGNAL**: The signal specified in `sigev_signo` shall be generated for the process when the event of interest occurs. If the implementation supports the Realtime Signals Extension option and if the SA_SIGINFO flag is set for that signal number, then the signal shall be queued to the process and the value specified in `sigev_value` shall be the `si_value` component of the generated signal. If SA_SIGINFO is not set for that signal number, it is unspecified whether the signal is queued and what value, if any, is sent.
- **SIGEV_THREAD**: A notification function shall be called to perform notification.
An implementation may define additional notification mechanisms.

The `sigev_signo` member specifies the signal to be generated. The `sigev_value` member is the application-defined value to be passed to the signal-catching function at the time of the signal delivery or to be returned at signal acceptance as the `si_value` member of the `siginfo_t` structure.

The `sigval` union is defined in `<signal.h>` and contains at least the following members:

<table>
<thead>
<tr>
<th>Member Type</th>
<th>Member Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>int</td>
<td><code>sival_int</code></td>
<td>Integer signal value.</td>
</tr>
<tr>
<td>void*</td>
<td><code>sival_ptr</code></td>
<td>Pointer signal value.</td>
</tr>
</tbody>
</table>

The `sival_int` member shall be used when the application-defined value is of type `int`; the `sival_ptr` member shall be used when the application-defined value is a pointer.

When a signal is generated by the `sigqueue()` function or any signal-generating function that supports the specification of an application-defined value, the signal shall be marked pending and, if the SA_SIGINFO flag is set for that signal, the signal shall be queued to the process along with the application-specified signal value. Multiple occurrences of signals so generated are queued in FIFO order. It is unspecified whether signals so generated are queued when the SA_SIGINFO flag is not set for that signal.

Signals generated by the `kill()` function or other events that cause signals to occur, such as detection of hardware faults, `alarm()` timer expiration, or terminal activity, and for which the implementation does not support queuing, shall have no effect on signals already queued for the same signal number.

When multiple unblocked signals, all in the range SIGRTMIN to SIGRTMAX, are pending, the behavior shall be as if the implementation delivers the pending unblocked signal with the lowest signal number within that range. No other ordering of signal delivery is specified.

If, when a pending signal is delivered, there are additional signals queued to that signal number, the signal shall remain pending. Otherwise, the pending indication shall be reset.

Multi-threaded programs can use an alternate event notification mechanism. When a notification is processed, and the `sigev_notify` member of the `sigevent` structure has the value `SIGEV_THREAD`, the function `sigev_notify_function` is called with parameter `sigev_value`.

The function shall be executed in an environment as if it were the `start_routine` for a newly created thread with thread attributes specified by `sigev_notify_attributes`. If `sigev_notify_attributes` is NULL, the behavior shall be as if the thread were created with the `detachstate` attribute set to `PTHREAD_CREATE_DETACHED`. Supplying an attributes structure with a `detachstate` attribute of `PTHREAD_CREATE_JOINABLE` results in undefined behavior. The signal mask of this thread is implementation-defined.

### 2.4.3 Signal Actions

There are three types of action that can be associated with a signal: `SIG_DFL`, `SIG_IGN`, or a pointer to a function. Initially, all signals shall be set to `SIG_DFL` or `SIG_IGN` prior to entry of the `main()` routine (see the `exec` functions). The actions prescribed by these values are as follows:

- **SIG_DFL**: Signal-specific default action.
- **SIG_IGN**: The default actions for the signals defined in this volume of IEEE Std 1003.1-2001 RTS are specified under `<signal.h>`. If the Realtime Signals Extension option is supported, the default actions for the realtime signals in the range SIGRTMIN to SIGRTMAX shall be to terminate the process abnormally.
If the default action is to stop the process, the execution of that process is temporarily suspended. When a process stops, a SIGCHLD signal shall be generated for its parent process, unless the parent process has set the SA_NOCLDSTOP flag. While a process is stopped, any additional signals that are sent to the process shall not be delivered until the process is continued, except SIGKILL which always terminates the receiving process. A process that is a member of an orphaned process group shall not be allowed to stop in response to the SIGTSTP, SIGTTIN, or SIGTTOU signals. In cases where delivery of one of these signals would stop such a process, the signal shall be discarded.

Setting a signal action to SIG_DFL for a signal that is pending, and whose default action is to ignore the signal (for example, SIGCHLD), shall cause the pending signal to be discarded, whether or not it is blocked. If the Realtime Signals Extension option is supported, any queued values pending shall be discarded and the resources used to queue them shall be released and returned to the system for other use.

The default action for SIGCONT is to resume execution at the point where the process was stopped, after first handling any pending unblocked signals.

When a stopped process is continued, a SIGCHLD signal may be generated for its parent process, unless the parent process has set the SA_NOCLDSTOP flag.

SIG_IGN Ignore signal.

Delivery of the signal shall have no effect on the process. The behavior of a process is undefined after it ignores a SIGFPE, SIGILL, SIGSEGV, or SIGBUS signal that was not generated by kill(), sigqueue(), or raise().

The system shall not allow the action for the signals SIGKILL or SIGSTOP to be set to SIG_IGN.

Setting a signal action to SIG_IGN for a signal that is pending shall cause the pending signal to be discarded, whether or not it is blocked.

If a process sets the action for the SIGCHLD signal to SIG_IGN, the behavior is unspecified, except as specified below.

If the action for the SIGCHLD signal is set to SIG_IGN, child processes of the calling processes shall not be transformed into zombie processes when they terminate. If the calling process subsequently waits for its children, and the process has no unwaited-for children that were transformed into zombie processes, it shall block until all of its children terminate, and wait(), waitid(), and waitpid() shall fail and set errno to [ECHILD].

If the Realtime Signals Extension option is supported, any queued values pending shall be discarded and the resources used to queue them shall be released and made available to queue other signals.

pointer to a function

Catch signal.

On delivery of the signal, the receiving process is to execute the signal-catching function at the specified address. After returning from the signal-catching function, the receiving process shall resume execution at the point at which it was interrupted.

If the SA_SIGINFO flag for the signal is cleared, the signal-catching function shall be entered as a C-language function call as follows:
### Signal Concepts

**General Information**

#### 1287

```
void func(int signo);
```

If the SA_SIGINFO flag for the signal is set, the signal-catching function shall be entered as a C-language function call as follows:

```c
void func(int signo, siginfo_t *info, void *context);
```

where `func` is the specified signal-catching function, `signo` is the signal number of the signal being delivered, and `info` is a pointer to a `siginfo_t` structure defined in `<signal.h>` containing at least the following members:

<table>
<thead>
<tr>
<th>Member Type</th>
<th>Member Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>int</td>
<td>si_signo</td>
<td>Signal number.</td>
</tr>
<tr>
<td>int</td>
<td>si_code</td>
<td>Cause of the signal.</td>
</tr>
<tr>
<td>union signal</td>
<td>si_value</td>
<td>Signal value.</td>
</tr>
</tbody>
</table>

The `si_signo` member shall contain the signal number. This shall be the same as the `signo` parameter. The `si_code` member shall contain a code identifying the cause of the signal. The following values are defined for `si_code`:

- **SI_USER**: The signal was sent by the `kill()` function. The implementation may set `si_code` to SI_USER if the signal was sent by the `raise()` or `abort()` functions or any similar functions provided as implementation extensions.

- **SI_QUEUE**: The signal was sent by the `sigqueue()` function.

- **SI_TIMER**: The signal was generated by the expiration of a timer set by `timer_settime()`.

- **SI_ASYNCIO**: The signal was generated by the completion of an asynchronous I/O request.

- **SI_MESGQ**: The signal was generated by the arrival of a message on an empty message queue.

If the signal was not generated by one of the functions or events listed above, the `si_code` shall be set to an implementation-defined value that is not equal to any of the values defined above.

If the Realtime Signals Extension is supported, and `si_code` is one of SI_QUEUE, SI_TIMER, SI_ASYNCIO, or SI_MESGQ, then `si_value` shall contain the application-specified signal value. Otherwise, the contents of `si_value` are undefined.

The behavior of a process is undefined after it returns normally from a signal-catching function for a SIGBUS, SIGFPE, SIGILL, or SIGSEGV signal that was not generated by `kill()`, `sigqueue()`, or `raise()`.

The system shall not allow a process to catch the signals SIGKILL and SIGSTOP.

If a process establishes a signal-catching function for the SIGCHLD signal while it has a terminated child process for which it has not waited, it is unspecified whether a SIGCHLD signal is generated to indicate that child process.

When signal-catching functions are invoked asynchronously with process execution, the behavior of some of the functions defined by this volume of IEEE Std 1003.1-2001 is unspecified if they are called from a signal-catching function.
The following table defines a set of functions that shall be either reentrant or non-interruptible by signals and shall be async-signal-safe. Therefore applications may invoke them, without restriction, from signal-catching functions:

<table>
<thead>
<tr>

</tbody>
</table>

All functions not in the above table are considered to be unsafe with respect to signals. In the presence of signals, all functions defined by this volume of IEEE Std 1003.1-2001 shall behave as defined when called from or interrupted by a signal-catching function, with a single exception: when a signal interrupts an unsafe function and the signal-catching function calls an unsafe function, the behavior is undefined.

When a signal is delivered to a thread, if the action of that signal specifies termination, stop, or continue, the entire process shall be terminated, stopped, or continued, respectively.
2.4.4 Signal Effects on Other Functions

Signals affect the behavior of certain functions defined by this volume of IEEE Std 1003.1-2001 if delivered to a process while it is executing such a function. If the action of the signal is to terminate the process, the process shall be terminated and the function shall not return. If the action of the signal is to stop the process, the process shall stop until continued or terminated. Generation of a SIGCONT signal for the process shall cause the process to be continued, and the original function shall continue at the point the process was stopped. If the action of the signal is to invoke a signal-catching function, the signal-catching function shall be invoked; in this case the original function is said to be “interrupted” by the signal. If the signal-catching function executes a return statement, the behavior of the interrupted function shall be as described individually for that function, except as noted for unsafe functions. Signals that are ignored shall not affect the behavior of any function; signals that are blocked shall not affect the behavior of any function until they are unblocked and then delivered, except as specified for the sigpending() and sigwait() functions.

2.5 Standard I/O Streams

A stream is associated with an external file (which may be a physical device) by “opening” a file, which may involve “creating” a new file. Creating an existing file causes its former contents to be discarded if necessary. If a file can support positioning requests (such as a disk file, as opposed to a terminal), then a “file position indicator” associated with the stream is positioned at the start (byte number 0) of the file, unless the file is opened with append mode, in which case it is implementation-defined whether the file position indicator is initially positioned at the beginning or end of the file. The file position indicator is maintained by subsequent reads, writes, and positioning requests, to facilitate an orderly progression through the file. All input takes place as if bytes were read by successive calls to fgetc(); all output takes place as if bytes were written by successive calls to fputc().

When a stream is “unbuffered”, bytes are intended to appear from the source or at the destination as soon as possible; otherwise, bytes may be accumulated and transmitted as a block. When a stream is “fully buffered”, bytes are intended to be transmitted as a block when a buffer is filled. When a stream is “line buffered”, bytes are intended to be transmitted as a block when a newline byte is encountered. Furthermore, bytes are intended to be transmitted as a block when a buffer is filled, when input is requested on an unbuffered stream, or when input is requested on a line-buffered stream that requires the transmission of bytes. Support for these characteristics is implementation-defined, and may be affected via setbuf() and setvbuf().

A file may be disassociated from a controlling stream by “closing” the file. Output streams are flushed (any unwritten buffer contents are transmitted) before the stream is disassociated from the file. The value of a pointer to a FILE object is unspecified after the associated file is closed (including the standard streams).

A file may be subsequently reopened, by the same or another program execution, and its contents reclamed or modified (if it can be repositioned at its start). If the main() function returns to its original caller, or if the exit() function is called, all open files are closed (hence all output streams are flushed) before program termination. Other paths to program termination, such as calling abort(), need not close all files properly.

The address of the FILE object used to control a stream may be significant; a copy of a FILE object need not necessarily serve in place of the original.

At program start-up, three streams are predefined and need not be opened explicitly: standard input (for reading conventional input), standard output (for writing conventional output), and...
standard error (for writing diagnostic output). When opened, the standard error stream is not fully buffered; the standard input and standard output streams are fully buffered if and only if the stream can be determined not to refer to an interactive device.

2.5.1 Interaction of File Descriptors and Standard I/O Streams

This section describes the interaction of file descriptors and standard I/O streams. This functionality is an extension to the ISO C standard (and the rest of this section is not further CX shaded).

An open file description may be accessed through a file descriptor, which is created using functions such as `open()` or `pipe()`, or through a stream, which is created using functions such as `fopen()` or `popen()`. Either a file descriptor or a stream is called a "handle" on the open file description to which it refers; an open file description may have several handles.

Handles can be created or destroyed by explicit user action, without affecting the underlying open file description. Some of the ways to create them include `fcntl()`, `dup()`, `fdopen()`, `fileno()`, and `fork()`. They can be destroyed by at least `fclose()`, `close()`, and the `exec` functions.

A file descriptor that is never used in an operation that could affect the file offset (for example, `read()`, `write()`, or `lseek()`)) is not considered a handle for this discussion, but could give rise to one (for example, as a consequence of `fdopen()`, `dup()`, or `fork()`). This exception does not include the file descriptor underlying a stream, whether created with `fopen()` or `fdopen()`, so long as it is not used directly by the application to affect the file offset. The `read()` and `write()` functions implicitly affect the file offset; `lseek()` explicitly affects it.

The result of function calls involving any one handle (the "active handle") is defined elsewhere in this volume of IEEE Std 1003.1-2001, but if two or more handles are used, and any one of them is a stream, the application shall ensure that their actions are coordinated as described below. If this is not done, the result is undefined.

A handle which is a stream is considered to be closed when either an `fclose()` or `freopen()` is executed on it (the result of `freopen()` is a new stream, which cannot be a handle on the same open file description as its previous value), or when the process owning that stream terminates with `exit()`, `abort()`, or due to a signal. A file descriptor is closed by `close()`, `_exit()`, or the `exec` functions when `FD_CLOEXEC` is set on that file descriptor.

For a handle to become the active handle, the application shall ensure that the actions below are performed between the last use of the handle (the current active handle) and the first use of the second handle (the future active handle). The second handle then becomes the active handle. All activity by the application affecting the file offset on the first handle shall be suspended until it again becomes the active file handle. (If a stream function has as an underlying function one that affects the file offset, the stream function shall be considered to affect the file offset.)

The handles need not be in the same process for these rules to apply.

Note that after a `fork()`, two handles exist where one existed before. The application shall ensure that, if both handles can ever be accessed, they are both in a state where the other could become the active handle first. The application shall prepare for a `fork()` exactly as if it were a change of active handle. (If the only action performed by one of the processes is one of the `exec` functions or `_exit()` (not `exit()`), the handle is never accessed in that process.)

For the first handle, the first applicable condition below applies. After the actions required below are taken, if the handle is still open, the application can close it.

- If it is a file descriptor, no action is required.
• If the only further action to be performed on any handle to this open file descriptor is to close it, no action need be taken.
• If it is a stream which is unbuffered, no action need be taken.
• If it is a stream which is line buffered, and the last byte written to the stream was a <newline> (that is, as if a:
  
putc('\n')
was the most recent operation on that stream), no action need be taken.
• If it is a stream which is open for writing or appending (but not also open for reading), the application shall either perform an fflush(), or the stream shall be closed.
• If the stream is open for reading and it is at the end of the file (feof() is true), no action need be taken.
• If the stream is open with a mode that allows reading and the underlying open file description refers to a device that is capable of seeking, the application shall either perform an fflush(), or the stream shall be closed.

Otherwise, the result is undefined.

For the second handle:
• If any previous active handle has been used by a function that explicitly changed the file offset, except as required above for the first handle, the application shall perform an lseek() or fseek() (as appropriate to the type of handle) to an appropriate location.

If the active handle ceases to be accessible before the requirements on the first handle, above, have been met, the state of the open file description becomes undefined. This might occur during functions such as a fork() or _exit().

The exec functions make inaccessible all streams that are open at the time they are called, independent of which streams or file descriptors may be available to the new process image.

When these rules are followed, regardless of the sequence of handles used, implementations shall ensure that an application, even one consisting of several processes, shall yield correct results: no data shall be lost or duplicated when writing, and all data shall be written in order, except as requested by seeks. It is implementation-defined whether, and under what conditions, all input is seen exactly once.

If the rules above are not followed, the result is unspecified.

Each function that operates on a stream is said to have zero or more “underlying functions”. This means that the stream function shares certain traits with the underlying functions, but does not require that there be any relation between the implementations of the stream function and its underlying functions.

2.5.2 Stream Orientation and Encoding Rules

For conformance to the ISO/IEC 9899:1999 standard, the definition of a stream includes an “orientation”. After a stream is associated with an external file, but before any operations are performed on it, the stream is without orientation. Once a wide-character input/output function has been applied to a stream without orientation, the stream shall become “wide-oriented”. Similarly, once a byte input/output function has been applied to a stream without orientation, the stream shall become “byte-oriented”. Only a call to the freopen() function or the fwide() function can otherwise alter the orientation of a stream.
A successful call to `freopen`() shall remove any orientation. The three predefined streams standard input, standard output, and standard error shall be unoriented at program start-up.

Byte input/output functions cannot be applied to a wide-oriented stream, and wide-character input/output functions cannot be applied to a byte-oriented stream. The remaining stream operations shall not affect and shall not be affected by a stream's orientation, except for the following additional restriction:

- For wide-oriented streams, after a successful call to a file-positioning function that leaves the file position indicator prior to the end-of-file, a wide-character output function can overwrite a partial character; any file contents beyond the byte(s) written are henceforth undefined.

Each wide-oriented stream has an associated `mbstate_t` object that stores the current parse state of the stream. A successful call to `fgetpos()` shall store a representation of the value of this `mbstate_t` object as part of the value of the `fpos_t` object. A later successful call to `fsetpos()` using the same stored `fpos_t` value shall restore the value of the associated `mbstate_t` object as well as the position within the controlled stream.

Implementations that support multiple encoding rules associate an encoding rule with the stream. The encoding rule shall be determined by the setting of the `LC_CTYPE` category in the current locale at the time when the stream becomes wide-oriented. As with the stream's orientation, the encoding rule associated with a stream cannot be changed once it has been set, except by a successful call to `freopen()` which clears the encoding rule and resets the orientation to unoriented.

Although wide-oriented streams are conceptually sequences of wide characters, the external file associated with a wide-oriented stream is a sequence of (possibly multi-byte) characters generalized as follows:

- Multi-byte encodings within files may contain embedded null bytes (unlike multi-byte encodings valid for use internal to the program).
- A file need not begin nor end in the initial shift state.

Moreover, the encodings used for characters may differ among files. Both the nature and choice of such encodings are implementation-defined.

The wide-character input functions read characters from the stream and convert them to wide characters as if they were read by successive calls to the `fgetwc()` function. Each conversion shall occur as if by a call to the `mbtowc()` function, with the conversion state described by the stream's own `mbstate_t` object, except the encoding rule associated with the stream is used instead of the encoding rule implied by the `LC_CTYPE` category of the current locale.

The wide-character output functions convert wide characters to (possibly multi-byte) characters and write them to the stream as if they were written by successive calls to the `fputwc()` function. Each conversion shall occur as if by a call to the `wcrtomb()` function, with the conversion state described by the stream's own `mbstate_t` object, except the encoding rule associated with the stream is used instead of the encoding rule implied by the `LC_CTYPE` category of the current locale.

An "encoding error" shall occur if the character sequence presented to the underlying `mbtowc()` function does not form a valid (generalized) character, or if the code value passed to the underlying `wcrtomb()` function does not correspond to a valid (generalized) character. The wide-character input/output functions and the byte input/output functions store the value of the macro `[EILSEQ]` in `errno` if and only if an encoding error occurs.
2.6 STREAMS

STREAMS functionality is provided on implementations supporting the XSI STREAMS Option Group. This functionality is dependent on support of the XSI STREAMS option (and the rest of this section is not further shaded for this option).

STREAMS provides a uniform mechanism for implementing networking services and other character-based I/O. The STREAMS function provides direct access to protocol modules. STREAMS modules are unspecified objects. Access to STREAMS modules is provided by interfaces in IEEE Std 1003.1-2001. Creation of STREAMS modules is outside the scope of IEEE Std 1003.1-2001.

A STREAM is typically a full-duplex connection between a process and an open device or pseudo-device. However, since pipes may be STREAMS-based, a STREAM can be a full-duplex connection between two processes. The STREAM itself exists entirely within the implementation and provides a general character I/O function for processes. It optionally includes one or more intermediate processing modules that are interposed between the process end of the STREAM (STREAM head) and a device driver at the end of the STREAM (STREAM end).

STREAMS I/O is based on messages. There are three types of message:

- **Data messages** containing actual data for input or output
- **Control data** containing instructions for the STREAMS modules and underlying implementation
- **Other messages**, which include file descriptors

The interface between the STREAM and the rest of the implementation is provided by a set of functions at the STREAM head. When a process calls write(), writev(), putmsg(), putpmsg(), or ioctl(), messages are sent down the STREAM, and read(), readv(), getmsg(), or getpmsg() accepts data from the STREAM and passes it to a process. Data intended for the device at the downstream end of the STREAM is packaged into messages and sent downstream, while data and signals from the device are composed into messages by the device driver and sent upstream to the STREAM head.

When a STREAMS-based device is opened, a STREAM shall be created that contains the STREAM head and the STREAM end (driver). If pipes are STREAMS-based in an implementation, when a pipe is created, two STREAMS shall be created, each containing a STREAM head. Other modules are added to the STREAM using ioctl(). New modules are "pushed" onto the STREAM one at a time in last-in, first-out (LIFO) style, as though the STREAM was a push-down stack.

**Priority**

Message types are classified according to their queuing priority and may be **normal** (non-priority), **priority**, or **high-priority** messages. A message belongs to a particular priority band that determines its ordering when placed on a queue. Normal messages have a priority band of 0 and shall always be placed at the end of the queue following all other messages in the queue. High-priority messages are always placed at the head of a queue, but shall be discarded if there is already a high-priority message in the queue. Their priority band shall be ignored; they are high-priority by virtue of their type. Priority messages have a priority band greater than 0. Priority messages are always placed after any messages of the same or higher priority. High-priority and priority messages are used to send control and data information outside the normal flow of control. By convention, high-priority messages shall not be affected by flow control. Normal and priority messages have separate flow controls.
Message Parts

A process may access STREAMS messages that contain a data part, control part, or both. The data part is that information which is transmitted over the communication medium and the control information is used by the local STREAMS modules. The other types of messages are used between modules and are not accessible to processes. Messages containing only a data part are accessible via `putmsg()`, `putpmsg()`, `getmsg()`, `getpmsg()`, `read()`, `readv()`, `write()`, or `writev()`.

Messages containing a control part with or without a data part are accessible via calls to `putmsg()`, `putpmsg()`, `getmsg()`, or `getpmsg()`.

2.6.1 Accessing STREAMS

A process accesses STREAMS-based files using the standard functions `close()`, `ioctl()`, `getmsg()`, `getpmsg()`, `open()`, `pipe()`, `poll()`, `putmsg()`, `putpmsg()`, `read()`, or `write()`. Refer to the applicable function definitions for general properties and errors.

Calls to `ioctl()` shall perform control functions on the STREAM associated with the file descriptor `fildes`. The control functions may be performed by the STREAM head, a STREAMS module, or the STREAMS driver for the STREAM.

STREAMS modules and drivers can detect errors, sending an error message to the STREAM head, thus causing subsequent functions to fail and set `errno` to the value specified in the message. In addition, STREAMS modules and drivers can elect to fail a particular `ioctl()` request alone by sending a negative acknowledgement message to the STREAM head. This shall cause just the pending `ioctl()` request to fail and set `errno` to the value specified in the message.

2.7 XSI Interprocess Communication

This section describes extensions to support interprocess communication. This functionality is dependent on support of the XSI extension (and the rest of this section is not further shaded for this option).

The following message passing, semaphore, and shared memory services form an XSI interprocess communication facility. Certain aspects of their operation are common, and are defined as follows.

<table>
<thead>
<tr>
<th>IPC Functions</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>msgctl()</code></td>
</tr>
<tr>
<td><code>msgget()</code></td>
</tr>
<tr>
<td><code>msgrcv()</code></td>
</tr>
<tr>
<td><code>msgsnd()</code></td>
</tr>
<tr>
<td><code>semctl()</code></td>
</tr>
<tr>
<td><code>semget()</code></td>
</tr>
<tr>
<td><code>semop()</code></td>
</tr>
<tr>
<td><code>shmdt()</code></td>
</tr>
<tr>
<td><code>shmctl()</code></td>
</tr>
<tr>
<td><code>shmget()</code></td>
</tr>
<tr>
<td><code>shmget()</code></td>
</tr>
</tbody>
</table>

Another interprocess communication facility is provided by functions in the Realtime Option Group; see Section 2.8 (on page 41).
2.7.1 IPC General Description

Each individual shared memory segment, message queue, and semaphore set shall be identified by a unique positive integer, called, respectively, a shared memory identifier, `shmid`, a semaphore identifier, `semid`, and a message queue identifier, `msqid`. The identifiers shall be returned by calls to `shmget()`, `semget()`, and `msgget()`, respectively.

Associated with each identifier is a data structure which contains data related to the operations which may be or may have been performed; see the Base Definitions volume of IEEE Std 1003.1-2001, `<sys/shm.h>`, `<sys/sem.h>`, and `<sys/msg.h>` for their descriptions.

Each of the data structures contains both ownership information and an `ipc_perm` structure (see the Base Definitions volume of IEEE Std 1003.1-2001, `<sys/ipc.h>`) which are used in conjunction to determine whether or not read/write (read/alter for semaphores) permissions should be granted to processes using the IPC facilities. The `mode` member of the `ipc_perm` structure acts as a bit field which determines the permissions.

The values of the bits are given below in octal notation.

<table>
<thead>
<tr>
<th>Bit</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0400</td>
<td>Read by user.</td>
</tr>
<tr>
<td>0200</td>
<td>Write by user.</td>
</tr>
<tr>
<td>0040</td>
<td>Read by group.</td>
</tr>
<tr>
<td>0020</td>
<td>Write by group.</td>
</tr>
<tr>
<td>0004</td>
<td>Read by others.</td>
</tr>
<tr>
<td>0002</td>
<td>Write by others.</td>
</tr>
</tbody>
</table>

The name of the `ipc_perm` structure is `shm_perm`, `sem_perm`, or `msg_perm`, depending on which service is being used. In each case, read and write/alter permissions shall be granted to a process if one or more of the following are true ("xxx" is replaced by `shm`, `sem`, or `msg`, as appropriate):

- The process has appropriate privileges.
- The effective user ID of the process matches `xxx_perm.cuid` or `xxx_perm.uid` in the data structure associated with the IPC identifier, and the appropriate bit of the `user` field in `xxx_perm.mode` is set.
- The effective user ID of the process does not match `xxx_perm.cuid` or `xxx_perm.uid` but the effective group ID of the process matches `xxx_perm.cgid` or `xxx_perm.gid` in the data structure associated with the IPC identifier, and the appropriate bit of the `group` field in `xxx_perm.mode` is set.
- The effective user ID of the process does not match `xxx_perm.cuid` or `xxx_perm.uid` and the effective group ID of the process does not match `xxx_perm.cgid` or `xxx_perm.gid` in the data structure associated with the IPC identifier, but the appropriate bit of the `other` field in `xxx_perm.mode` is set.

Otherwise, the permission shall be denied.
2.8 Realtime

This section defines functions to support the source portability of applications with realtime requirements. The presence of many of these functions is dependent on support for implementation options described in the text.

The specific functional areas included in this section and their scope include the following. Full definitions of these terms can be found in the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 3, Definitions.

- Semaphores
- Process Memory Locking
- Memory Mapped Files and Shared Memory Objects
- Priority Scheduling
- Realtime Signal Extension
- Timers
- Interprocess Communication
- Synchronized Input and Output
- Asynchronous Input and Output

All the realtime functions defined in this volume of IEEE Std 1003.1-2001 are portable, although some of the numeric parameters used by an implementation may have hardware dependencies.

2.8.1 Realtime Signals

Realtime signal generation and delivery is dependent on support for the Realtime Signals Extension option.

See Section 2.4.2 (on page 29).

2.8.2 Asynchronous I/O

The functionality described in this section is dependent on support of the Asynchronous Input and Output option (and the rest of this section is not further shaded for this option).

An asynchronous I/O control block structure `aiocb` is used in many asynchronous I/O functions. It is defined in the Base Definitions volume of IEEE Std 1003.1-2001, `<aio.h>` and has at least the following members:

<table>
<thead>
<tr>
<th>Member Type</th>
<th>Member Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>int</td>
<td>aio_fildes</td>
<td>File descriptor.</td>
</tr>
<tr>
<td></td>
<td>aio_offset</td>
<td>File offset.</td>
</tr>
<tr>
<td>volatile void*</td>
<td>aio_buf</td>
<td>Location of buffer.</td>
</tr>
<tr>
<td>size_t</td>
<td>aio_nbytes</td>
<td>Length of transfer.</td>
</tr>
<tr>
<td>int</td>
<td>aio_reaprio</td>
<td>Request priority offset.</td>
</tr>
<tr>
<td>struct sigevent</td>
<td>aio_sigevent</td>
<td>Signal number and value.</td>
</tr>
<tr>
<td>int</td>
<td>aio_lio_opcode</td>
<td>Operation to be performed.</td>
</tr>
</tbody>
</table>

The `aio_fildes` element is the file descriptor on which the asynchronous operation is performed.

If O_APPEND is not set for the file descriptor `aio_fildes` and if `aio_fildes` is associated with a device that is capable of seeking, then the requested operation takes place at the absolute position in the file as given by `aio_offset`, as if `seek()` were called immediately prior to the
operation with an offset argument equal to aio_offset and a whence argument equal to SEEK_SET. If O_APPEND is set for the file descriptor, or if aio_fildes is associated with a device that is incapable of seeking, write operations append to the file in the same order as the calls were made, with the following exception: under implementation-defined circumstances, such as operation on a multi-processor or when requests of differing priorities are submitted at the same time, the ordering restriction may be relaxed. Since there is no way for a strictly conforming application to determine whether this relaxation applies, all strictly conforming applications which rely on ordering of output shall be written in such a way that they will operate correctly if the relaxation applies. After a successful call to enqueue an asynchronous I/O operation, the value of the file offset for the file is unspecified. The aio_nbytes and aio_buf elements are the same as the nbyte and buf arguments defined by read() and write(), respectively.

If _POSIX_PRIORITIZED_IO and _POSIX_PRIORITY_SCHEDULING are defined, then asynchronous I/O is queued in priority order, with the priority of each asynchronous operation based on the current scheduling priority of the calling process. The aio_reqprio member can be used to lower (but not raise) the asynchronous I/O operation priority and is within the range zero through [AIO_PRIO_DELTA_MAX], inclusive. Unless both _POSIX_PRIORITIZED_IO and _POSIX_PRIORITY_SCHEDULING are defined, the order of processing asynchronous I/O requests is unspecified. When both _POSIX_PRIORITIZED_IO and _POSIX_PRIORITY_SCHEDULING are defined, the order of processing of requests submitted by processes whose schedulers are not SCHED_FIFO, SCHED_RR, or SCHED_SPORADIC is unspecified. The priority of an asynchronous request is computed as (process scheduling priority) minus aio_reqprio. The priority assigned to each asynchronous I/O request is an indication of the desired order of execution of the request relative to other asynchronous I/O requests for this file. If _POSIX_PRIORITIZED_IO is defined, requests issued with the same priority to a character special file are processed by the underlying device in FIFO order; the order of processing of requests of the same priority issued to files that are not character special files is unspecified. Numerically higher priority values indicate requests of higher priority. The value of aio_reqprio has no effect on process scheduling priority. When prioritized asynchronous I/O requests to the same file are blocked waiting for a resource required for that I/O operation, the higher-priority I/O requests shall be granted the resource before lower-priority I/O requests are granted the resource. The relative priority of asynchronous I/O and synchronous I/O is implementation-defined. If _POSIX_PRIORITIZED_IO is defined, the implementation shall define for which files I/O prioritization is supported.

The aio_sigevent determines how the calling process shall be notified upon I/O completion, as specified in Section 2.4.1 (on page 28). If aio_sigevent.sigev_notify is SIGEV_NONE, then no signal shall be posted upon I/O completion, but the error status for the operation and the return status for the operation shall be set appropriately.

The aio_lio_opcode field is used only by the lio_listio() call. The lio_listio() call allows multiple asynchronous I/O operations to be submitted at a single time. The function takes as an argument an array of pointers to aiocb structures. Each aiocb structure indicates the operation to be performed (read or write) via the aio_lio_opcode field.

The address of the aiocb structure is used as a handle for retrieving the error status and return status of the asynchronous operation while it is in progress.

The aiocb structure and the data buffers associated with the asynchronous I/O operation are being used by the system for asynchronous I/O while, and only while, the error status of the asynchronous operation is equal to [EINPROGRESS]. Applications shall not modify the aiocb structure while the structure is being used by the system for asynchronous I/O.

The return status of the asynchronous operation is the number of bytes transferred by the I/O operation. If the error status is set to indicate an error completion, then the return status is set to
the return value that the corresponding `read()`, `write()`, or `fsync()` call would have returned. When the error status is not equal to [EINPROGRESS], the return status shall reflect the return status of the corresponding synchronous operation.

### 2.8.3 Memory Management

#### 2.8.3.1 Memory Locking

Range memory locking operations are defined in terms of pages. Implementations may restrict the size and alignment of range lockings to be on page-size boundaries. The page size, in bytes, is the value of the configurable system variable `PAGESIZE`. If an implementation has no restrictions on size or alignment, it may specify a 1-byte page size.

Memory locking guarantees the residence of portions of the address space. It is implementation-defined whether locking memory guarantees fixed translation between virtual addresses (as seen by the process) and physical addresses. Per-process memory locks are not inherited across a `fork()`, and all memory locks owned by a process are unlocked upon `exec` or process termination. Unmapping of an address range removes any memory locks established on that address range by this process.

#### 2.8.3.2 Memory Mapped Files

The functionality described in this section is dependent on support of the Memory Mapped Files option (and the rest of this section is not further shaded for this option).

Range memory mapping operations are defined in terms of pages. Implementations may restrict the size and alignment of range mappings to be on page-size boundaries. The page size, in bytes, is the value of the configurable system variable `PAGESIZE`. If an implementation has no restrictions on size or alignment, it may specify a 1-byte page size.

Memory mapped files provide a mechanism that allows a process to access files by directly incorporating file data into its address space. Once a file is mapped into a process address space, the data can be manipulated as memory. If more than one process maps a file, its contents are shared among them. If the mappings allow shared write access, then data written into the memory object through the address space of one process appears in the address spaces of all processes that similarly map the same portion of the memory object.

Shared memory objects are named regions of storage that may be independent of the file system and can be mapped into the address space of one or more processes to allow them to share the associated memory.

An `unlink()` of a file or `shm_unlink()` of a shared memory object, while causing the removal of the name, does not unmap any mappings established for the object. Once the name has been removed, the contents of the memory object are preserved as long as it is referenced. The memory object remains referenced as long as a process has the memory object open or has some area of the memory object mapped.

#### 2.8.3.3 Memory Protection

The functionality described in this section is dependent on support of the Memory Protection and Memory Mapped Files option (and the rest of this section is not further shaded for these options).

When an object is mapped, various application accesses to the mapped region may result in signals. In this context, SIGBUS is used to indicate an error using the mapped object, and SIGSEGV is used to indicate a protection violation or misuse of an address.
• A mapping may be restricted to disallow some types of access.

• Write attempts to memory that was mapped without write access, or any access to memory mapped PROT_NONE, shall result in a SIGSEGV signal.

• References to unmapped addresses shall result in a SIGSEGV signal.

• Reference to whole pages within the mapping, but beyond the current length of the object, shall result in a SIGBUS signal.

• The size of the object is unaffected by access beyond the end of the object (even if a SIGBUS is not generated).

2.8.3.4 Typed Memory Objects

The functionality described in this section is dependent on support of the Typed Memory Objects option (and the rest of this section is not further shaded for this option).

Implementations may support the Typed Memory Objects option without supporting the Memory Mapped Files option or the Shared Memory Objects option. Typed memory objects are implementation-configurable named storage pools accessible from one or more processors in a system, each via one or more ports, such as backplane buses, LANs, I/O channels, and so on. Each valid combination of a storage pool and a port is identified through a name that is defined at system configuration time, in an implementation-defined manner; the name may be independent of the file system. Using this name, a typed memory object can be opened and mapped into process address space. For a given storage pool and port, it is necessary to support both dynamic allocation from the pool as well as mapping at an application-supplied offset within the pool; when dynamic allocation has been performed, subsequent deallocation must be supported. Lastly, accessing typed memory objects from different ports requires a method for obtaining the offset and length of contiguous storage of a region of typed memory (dynamically allocated or not); this allows typed memory to be shared among processes and/or processors while being accessed from the desired port.

2.8.4 Process Scheduling

The functionality described in this section is dependent on support of the Process Scheduling option (and the rest of this section is not further shaded for this option).

Scheduling Policies

The scheduling semantics described in this volume of IEEE Std 1003.1-2001 are defined in terms of a conceptual model that contains a set of thread lists. No implementation structures are necessarily implied by the use of this conceptual model. It is assumed that no time elapses during operations described using this model, and therefore no simultaneous operations are possible. This model discusses only processor scheduling for runnable threads, but it should be noted that greatly enhanced predictability of realtime applications results if the sequencing of other resources takes processor scheduling policy into account.

There is, conceptually, one thread list for each priority. A runnable thread will be on the thread list for that thread’s priority. Multiple scheduling policies shall be provided. Each non-empty thread list is ordered, contains a head as one end of its order, and a tail as the other. The purpose of a scheduling policy is to define the allowable operations on this set of lists (for example, moving threads between and within lists).

Each process shall be controlled by an associated scheduling policy and priority. These parameters may be specified by explicit application execution of the sched_setscheduler() or sched_setparam() functions.
Each thread shall be controlled by an associated scheduling policy and priority. These parameters may be specified by explicit application execution of the `pthread_setschedparam()` function.

Associated with each policy is a priority range. Each policy definition shall specify the minimum priority range for that policy. The priority ranges for each policy may but need not overlap the priority ranges of other policies.

A conforming implementation shall select the thread that is defined as being at the head of the highest priority non-empty thread list to become a running thread, regardless of its associated policy. This thread is then removed from its thread list.

Four scheduling policies are specifically required. Other implementation-defined scheduling policies may be defined. The following symbols are defined in the Base Definitions volume of IEEE Std 1003.1-2001, `<sched.h>`:

- **SCHED_FIFO** — First in, first out (FIFO) scheduling policy.
- **SCHED_RR** — Round robin scheduling policy.
- **SCHED_SPORADIC** — Sporadic server scheduling policy.
- **SCHED_OTHER** — Another scheduling policy.

The values of these symbols shall be distinct.

### SCHED_FIFO

Conforming implementations shall include a scheduling policy called the FIFO scheduling policy.

Threads scheduled under this policy are chosen from a thread list that is ordered by the time its threads have been on the list without being executed; generally, the head of the list is the thread that has been on the list the longest time, and the tail is the thread that has been on the list the shortest time.

Under the SCHED_FIFO policy, the modification of the definitional thread lists is as follows:

1. When a running thread becomes a preempted thread, it becomes the head of the thread list for its priority.
2. When a blocked thread becomes a runnable thread, it becomes the tail of the thread list for its priority.
3. When a running thread calls the `sched_setscheduler()` function, the process specified in the function call is modified to the specified policy and the priority specified by the `param` argument.
4. When a running thread calls the `sched_setparam()` function, the priority of the process specified in the function call is modified to the priority specified by the `param` argument.
5. When a running thread calls the `pthread_setschedparam()` function, the thread specified in the function call is modified to the specified policy and the priority specified by the `param` argument.
6. When a running thread calls the `pthread_setschedprio()` function, the thread specified in the function call is modified to the priority specified by the `prio` argument.
7. If a thread whose policy or priority has been modified other than by `pthread_setschedprio()` is a running thread or is runnable, it then becomes the tail of the thread list for its new priority.
8. If a thread whose policy or priority has been modified by `pthread_setschedprio()` is a
running thread or is runnable, the effect on its position in the thread list depends on the
direction of the modification, as follows:
a. If the priority is raised, the thread becomes the tail of the thread list.
b. If the priority is unchanged, the thread does not change position in the thread list.
c. If the priority is lowered, the thread becomes the head of the thread list.

9. When a running thread issues the `sched_yield()` function, the thread becomes the tail of the
thread list for its priority.

10. At no other time is the position of a thread with this scheduling policy within the thread
lists affected.

For this policy, valid priorities shall be within the range returned by the `sched_get_priority_max()`
and `sched_get_priority_min()` functions when SCHED_FIFO is provided as the parameter.
Conforming implementations shall provide a priority range of at least 32 priorities for this
policy.

**SCHED_RR**

Conforming implementations shall include a scheduling policy called the “round robin”
scheduling policy. This policy shall be identical to the SCHED_FIFO policy with the additional
condition that when the implementation detects that a running thread has been executing as a
running thread for a time period of the length returned by the `sched_rr_get_interval()` function or
longer, the thread shall become the tail of its thread list and the head of that thread list shall be
removed and made a running thread.

The effect of this policy is to ensure that if there are multiple SCHED_RR threads at the same
priority, one of them does not monopolize the processor. An application should not rely only on
the use of SCHED_RR to ensure application progress among multiple threads if the application
includes threads using the SCHED_FIFO policy at the same or higher priority levels or
SCHED_RR threads at a higher priority level.

A thread under this policy that is preempted and subsequently resumes execution as a running
thread completes the unexpired portion of its round robin interval time period.

For this policy, valid priorities shall be within the range returned by the `sched_get_priority_max()`
and `sched_get_priority_min()` functions when SCHED_RR is provided as the parameter.
Conforming implementations shall provide a priority range of at least 32 priorities for this
policy.

**SCHED_SPORADIC**

The functionality described in this section is dependent on support of the Process Sporadic
Server or Thread Sporadic Server options (and the rest of this section is not further shaded for
these options).

If `_POSIX_SPORADIC_SERVER` or `_POSIX_THREAD_SPORADIC_SERVER` is defined, the
implementation shall include a scheduling policy identified by the value SCHED_SPORADIC.

The sporadic server policy is based primarily on two parameters: the replenishment period and
the available execution capacity. The replenishment period is given by the `sched_ss_repl_period`
member of the `sched_param` structure. The available execution capacity is initialized to the
value given by the `sched_ss_init_budget` member of the same parameter. The sporadic server
policy is identical to the SCHED_FIFO policy with some additional conditions that cause the
thread’s assigned priority to be switched between the values specified by the `sched_priority` and
The priority assigned to a thread using the sporadic server scheduling policy is determined in the following manner: if the available execution capacity is greater than zero and the number of pending replenishment operations is strictly less than \texttt{sched\_ss\_max\_repl}, the thread is assigned the priority specified by \texttt{sched\_priority}; otherwise, the assigned priority shall be \texttt{sched\_ss\_low\_priority}. If the value of \texttt{sched\_priority} is less than or equal to the value of \texttt{sched\_ss\_low\_priority}, the results are undefined. When active, the thread shall belong to the thread list corresponding to its assigned priority level, according to the mentioned priority assignment. The modification of the available execution capacity and, consequently of the assigned priority, is done as follows:

1. When the thread at the head of the \texttt{sched\_priority} list becomes a running thread, its execution time shall be limited to at most its available execution capacity, plus the resolution of the execution time clock used for this scheduling policy. This resolution shall be implementation-defined.

2. Each time the thread is inserted at the tail of the list associated with \texttt{sched\_priority}—because as a blocked thread it became runnable with priority \texttt{sched\_priority} or because a replenishment operation was performed—the time at which this operation is done is posted as the \texttt{activation\_time}.

3. When the running thread with assigned priority equal to \texttt{sched\_priority} becomes a preempted thread, it becomes the head of the thread list for its priority, and the execution time consumed is subtracted from the available execution capacity. If the available execution capacity would become negative by this operation, it shall be set to zero.

4. When the running thread with assigned priority equal to \texttt{sched\_priority} becomes a blocked thread, the execution time consumed is subtracted from the available execution capacity, and a replenishment operation is scheduled, as described in 6 and 7. If the available execution capacity would become negative by this operation, it shall be set to zero.

5. When the running thread with assigned priority equal to \texttt{sched\_priority} reaches the limit imposed on its execution time, it becomes the tail of the thread list for \texttt{sched\_ss\_low\_priority}, the execution time consumed is subtracted from the available execution capacity (which becomes zero), and a replenishment operation is scheduled, as described in 6 and 7.

6. Each time a replenishment operation is scheduled, the amount of execution capacity to be replenished, \texttt{replenish\_amount}, is set equal to the execution time consumed by the thread since the \texttt{activation\_time}. The replenishment is scheduled to occur at \texttt{activation\_time} plus \texttt{sched\_ss\_repl\_period}. If the scheduled time obtained is before the current time, the replenishment operation is carried out immediately. Several replenishment operations may be pending at the same time, each of which will be serviced at its respective scheduled time. With the above rules, the number of replenishment operations simultaneously pending for a given thread that is scheduled under the sporadic server policy shall not be greater than \texttt{sched\_ss\_max\_repl}.

7. A replenishment operation consists of adding the corresponding \texttt{replenish\_amount} to the available execution capacity at the scheduled time. If, as a consequence of this operation, the execution capacity would become larger than \texttt{sched\_ss\_initial\_budget}, it shall be rounded down to a value equal to \texttt{sched\_ss\_initial\_budget}. Additionally, if the thread was runnable or running, and had assigned priority equal to \texttt{sched\_ss\_low\_priority}, then it becomes the tail of the thread list for \texttt{sched\_priority}.

Execution time is defined in Section 2.2.2 (on page 14).
For this policy, changing the value of a CPU-time clock via `clock_settime()` shall have no effect on its behavior.

For this policy, valid priorities shall be within the range returned by the `sched_get_priority_min()` and `sched_get_priority_max()` functions when `SCHED_SPORADIC` is provided as the parameter. Conforming implementations shall provide a priority range of at least 32 distinct priorities for this policy.

**SCHED_OTHER**

Conforming implementations shall include one scheduling policy identified as `SCHED_OTHER` (which may execute identically with either the FIFO or round robin scheduling policy). The effect of scheduling threads with the `SCHED_OTHER` policy in a system in which other threads are executing under `SCHED_FIFO`, `SCHED_RR`, or `SCHED_SPORADIC` is implementation-defined.

This policy is defined to allow strictly conforming applications to be able to indicate in a portable manner that they no longer need a realtime scheduling policy.

For threads executing under this policy, the implementation shall use only priorities within the range returned by the `sched_get_priority_max()` and `sched_get_priority_min()` functions when `SCHED_OTHER` is provided as the parameter.

### 2.8.5 Clocks and Timers

**TMR**

The functionality described in this section is dependent on support of the Timers option (and the rest of this section is not further shaded for this option).

The `<time.h>` header defines the types and manifest constants used by the timing facility.

#### Time Value Specification Structures

Many of the timing facility functions accept or return time value specifications. A time value structure `timespec` specifies a single time value and includes at least the following members:

<table>
<thead>
<tr>
<th>Member Type</th>
<th>Member Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>time_t</code></td>
<td><code>tv_sec</code></td>
<td>Seconds.</td>
</tr>
<tr>
<td><code>long</code></td>
<td><code>tv_nsec</code></td>
<td>Nanoseconds.</td>
</tr>
</tbody>
</table>

The `tv_nsec` member is only valid if greater than or equal to zero, and less than the number of nanoseconds in a second (1,000 million). The time interval described by this structure is `(tv_sec * 10^9 + tv_nsec)` nanoseconds.

A time value structure `itimerspec` specifies an initial timer value and a repetition interval for use by the per-process timer functions. This structure includes at least the following members:

<table>
<thead>
<tr>
<th>Member Type</th>
<th>Member Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>struct timespec</code></td>
<td><code>it_interval</code></td>
<td>Timer period.</td>
</tr>
<tr>
<td></td>
<td><code>it_value</code></td>
<td>Timer expiration.</td>
</tr>
</tbody>
</table>

If the value described by `it_value` is non-zero, it indicates the time to or time of the next timer expiration (for relative and absolute timer values, respectively). If the value described by `it_value` is zero, the timer shall be disarmed.

If the value described by `it_interval` is non-zero, it specifies an interval which shall be used in reloading the timer when it expires; that is, a periodic timer is specified. If the value described by...
it_interval is zero, the timer is disarmed after its next expiration; that is, a one-shot timer is
specified.

Timer Event Notification Control Block

Per-process timers may be created that notify the process of timer expirations by queuing a
realtime extended signal. The sigevent structure, defined in the Base Definitions volume of
IEEE Std 1003.1-2001, <signal.h>, is used in creating such a timer. The sigevent structure
contains the signal number and an application-specific data value which shall be used when
notifying the calling process of timer expiration events.

Manifest Constants

The following constants are defined in the Base Definitions volume of IEEE Std 1003.1-2001,
<time.h>:

CLOCK_REALTIME The identifier for the system-wide realtime clock.

TIMER_ABSTIME Flag indicating time is absolute with respect to the clock associated
with a timer.

CLOCK_MONOTONIC The identifier for the system-wide monotonic clock, which is defined
as a clock whose value cannot be set via clock_settime() and which
cannot have backward clock jumps. The maximum possible clock
jump is implementation-defined.

CLOCK_MONOTONIC The maximum allowable resolution for CLOCK_REALTIME and CLOCK_MONOTONIC clocks
and all time services based on these clocks is represented by _POSIX_CLOCKRES_MIN and
shall be defined as 20 ms (1/50 of a second). Implementations may support smaller values of
resolution for these clocks to provide finer granularity time bases. The actual resolution
supported by an implementation for a specific clock is obtained using the clock_getres() function.
If the actual resolution supported for a time service based on one of these clocks differs from the
resolution supported for that clock, the implementation shall document this difference.

The minimum allowable maximum value for CLOCK_REALTIME and CLOCK_MONOTONIC
and all absolute time services based on them is the same as that defined by the ISO C
standard for the time_t type. If the maximum value supported by a time service based on one of
these clocks differs from the maximum value supported by that clock, the implementation shall
document this difference.

Execution Time Monitoring

If _POSIX_CPUTIME is defined, process CPU-time clocks shall be supported in addition to the
clocks described in Manifest Constants.

If _POSIX_THREAD_CPUTIME is defined, thread CPU-time clocks shall be supported.

CPU-time clocks measure execution or CPU time, which is defined in the Base Definitions
volume of IEEE Std 1003.1-2001, Section 3.117, CPU Time (Execution Time). The mechanism
used to measure execution time is described in the Base Definitions volume of

If _POSIX_CPUTIME is defined, the following constant of the type clockid_t is defined in
<time.h>:

CLOCK_PROCESS_CPUTIME_ID When this value of the type clockid_t is used in a clock() or timer*() function call, it is
interpreted as the identifier of the CPU-time clock associated with the process making the
If _POSIX_THREAD_CPUTIME is defined, the following constant of the type clockid_t is defined in <time.h>:

CLOCK_THREAD_CPUTIME_ID

When this value of the type clockid_t is used in a clock() or timer() function call, it is interpreted as the identifier of the CPU-time clock associated with the thread making the function call.

2.9 Threads

The functionality described in this section is dependent on support of the Threads option (and the rest of this section is not further shaded for this option).

This section defines functionality to support multiple flows of control, called “threads”, within a process. For the definition of threads, see the Base Definitions volume of IEEE Std 1003.1-2001, Section 3.393, Thread.

The specific functional areas covered by threads and their scope include:

- Thread management: the creation, control, and termination of multiple flows of control in the same process under the assumption of a common shared address space
- Synchronization primitives optimized for tightly coupled operation of multiple control flows in a common, shared address space

2.9.1 Thread-Safety

All functions defined by this volume of IEEE Std 1003.1-2001 shall be thread-safe, except that the following functions¹ need not be thread-safe.

1. The functions in the table are not shaded to denote applicable options. Individual reference pages should be consulted.
The `ctermid()` and `tmpnam()` functions need not be thread-safe if passed a NULL argument. The `wcrtomb()` and `wcsrtombs()` functions need not be thread-safe if passed a NULL argument.

Implementations shall provide internal synchronization as necessary in order to satisfy this requirement.

### 2.9.2 Thread IDs

Although implementations may have thread IDs that are unique in a system, applications should only assume that thread IDs are usable and unique within a single process. The effect of calling any of the functions defined in this volume of IEEE Std 1003.1-2001 and passing as an argument the thread ID of a thread from another process is unspecified. A conforming implementation is free to reuse a thread ID after the thread terminates if it was created with the `detachstate` attribute set to `PTHREAD_CREATE_DETACHED` or if `pthread_detach()` or `pthread_join()` has been called for that thread. If a thread is detached, its thread ID is invalid for use as an argument in a call to `pthread_detach()` or `pthread_join()`.

### 2.9.3 Thread Mutexes

A thread that has blocked shall not prevent any unblocked thread that is eligible to use the same processing resources from eventually making forward progress in its execution. Eligibility for processing resources is determined by the scheduling policy.

A thread shall become the owner of a mutex, `m`, when one of the following occurs:

- It returns successfully from `pthread_mutex_lock()` with `m` as the `mutex` argument.
- It returns successfully from `pthread_mutex_trylock()` with `m` as the `mutex` argument.
- It returns successfully from `pthread_mutex_timedlock()` with `m` as the `mutex` argument.
- It returns (successfully or not) from `pthread_cond_wait()` with `m` as the `mutex` argument (except as explicitly indicated otherwise for certain errors).
- It returns (successfully or not) from `pthread_cond_timedwait()` with `m` as the `mutex` argument (except as explicitly indicated otherwise for certain errors).

The thread shall remain the owner of `m` until one of the following occurs:

- It executes `pthread_mutex_unlock()` with `m` as the `mutex` argument.
- It blocks in a call to `pthread_cond_wait()` with `m` as the `mutex` argument.
- It blocks in a call to `pthread_cond_timedwait()` with `m` as the `mutex` argument.

The implementation shall behave as if at all times there is at most one owner of any mutex.

A thread that becomes the owner of a mutex is said to have “acquired” the mutex and the mutex is said to have become “locked”; when a thread gives up ownership of a mutex it is said to have “released” the mutex and the mutex is said to have become “unlocked.”
2.9.4 Thread Scheduling

The functionality described in this section is dependent on support of the Thread Execution Scheduling option (and the rest of this section is not further shaded for this option).

Thread Scheduling Attributes

In support of the scheduling function, threads have attributes which are accessed through the `pthread_attr_t` thread creation attributes object.

The `contentionscope` attribute defines the scheduling contention scope of the thread to be either `PTHREAD_SCOPE_PROCESS` or `PTHREAD_SCOPE_SYSTEM`.

The `inheritsched` attribute specifies whether a newly created thread is to inherit the scheduling attributes of the creating thread or to have its scheduling values set according to the other scheduling attributes in the `pthread_attr_t` object.

The `schedpolicy` attribute defines the scheduling policy for the thread. The `schedparam` attribute defines the scheduling parameters for the thread. The interaction of threads having different policies within a process is described as part of the definition of those policies.

If the Thread Execution Scheduling option is defined, and the `schedpolicy` attribute specifies one of the priority-based policies defined under this option, the `schedparam` attribute contains the scheduling priority of the thread. A conforming implementation ensures that the priority value in `schedparam` is in the range associated with the scheduling policy when the thread attributes object is used to create a thread, or when the scheduling attributes of a thread are dynamically modified. The meaning of the priority value in `schedparam` is the same as that of `priority`.

If `_POSIX_THREAD_SPORADIC_SERVER` is defined, the `schedparam` attribute supports four new members that are used for the sporadic server scheduling policy. These members are `sched_ss_low_priority`, `sched_ss_repl_period`, `sched_ss_init_budget`, and `sched_ss_max_repl`. The meaning of these attributes is the same as in the definitions that appear under Section 2.8.4 (on page 44).

When a process is created, its single thread has a scheduling policy and associated attributes equal to the process’ policy and attributes. The default scheduling contention scope value is implementation-defined. The default values of other scheduling attributes are implementation-defined.

Thread Scheduling Contention Scope

The scheduling contention scope of a thread defines the set of threads with which the thread competes for use of the processing resources. The scheduling operation selects at most one thread to execute on each processor at any point in time and the thread’s scheduling attributes (for example, `priority`), whether under process scheduling contention scope or system scheduling contention scope, are the parameters used to determine the scheduling decision.

The scheduling contention scope, in the context of scheduling a mixed scope environment, affects threads as follows:

- A thread created with `PTHREAD_SCOPE_SYSTEM` scheduling contention scope contends for resources with all other threads in the same scheduling allocation domain relative to their system scheduling attributes. The system scheduling attributes of a thread created with `PTHREAD_SCOPE_SYSTEM` scheduling contention scope are the scheduling attributes with which the thread was created. The system scheduling attributes of a thread created with `PTHREAD_SCOPE_PROCESS` scheduling contention scope are the implementation-defined mapping into system attribute space of the scheduling attributes with which the thread was created.
Threads created with PTHREAD_SCOPE_PROCESS scheduling contention scope contend directly with other threads within their process that were created with PTHREAD_SCOPE_PROCESS scheduling contention scope. The contention is resolved based on the threads' scheduling attributes and policies. It is unspecified how such threads are scheduled relative to threads in other processes or threads with PTHREAD_SCOPE_SYSTEM scheduling contention scope.

Conforming implementations shall support the PTHREAD_SCOPE_PROCESS scheduling contention scope, the PTHREAD_SCOPE_SYSTEM scheduling contention scope, or both.

### Scheduling Allocation Domain

Implementations shall support scheduling allocation domains containing one or more processors. It should be noted that the presence of multiple processors does not automatically indicate a scheduling allocation domain size greater than one. Conforming implementations on multi-processors may map all or any subset of the CPUs to one or multiple scheduling allocation domains, and could define these scheduling allocation domains on a per-thread, per-process, or per-system basis, depending on the types of applications intended to be supported by the implementation. The scheduling allocation domain is independent of scheduling contention scope, as the scheduling contention scope merely defines the set of threads with which a thread contends for processor resources, while scheduling allocation domain defines the set of processors for which it contends. The semantics of how this contention is resolved among threads for processors is determined by the scheduling policies of the threads.

The choice of scheduling allocation domain size and the level of application control over scheduling allocation domains is implementation-defined. Conforming implementations may change the size of scheduling allocation domains and the binding of threads to scheduling allocation domains at any time.

For application threads with scheduling allocation domains of size equal to one, the scheduling rules defined for SCHED_FIFO and SCHED_RR shall be used; see Scheduling Policies (on page 44). All threads with system scheduling contention scope, regardless of the processes in which they reside, compete for the processor according to their priorities. Threads with process scheduling contention scope compete only with other threads with process scheduling contention scope within their process.

For application threads with scheduling allocation domains of size greater than one, the rules defined for SCHED_FIFO, SCHED_RR, and SCHED_SPORADIC shall be used in an implementation-defined manner. Each thread with system scheduling contention scope competes for the processors in its scheduling allocation domain in an implementation-defined manner according to its priority. Threads with process scheduling contention scope are scheduled relative to other threads within the same scheduling contention scope in the process.

If _POSIX_THREAD_SPORADIC_SERVER is defined, the rules defined for SCHED_SPORADIC in Scheduling Policies (on page 44) shall be used in an implementation-defined manner for application threads whose scheduling allocation domain size is greater than one.
2218 Scheduling Documentation
2219 If _POSIX_PRIORITY_SCHEDULING is defined, then any scheduling policies beyond
2220 SCHED_OTHER, SCHED_FIFO, SCHED_RR, and SCHED_SPORADIC, as well as the effects of
2221 the scheduling policies indicated by these other values, and the attributes required in order to
2222 support such a policy, are implementation-defined. Furthermore, the implementation shall
2223 document the effect of all processor scheduling allocation domain values supported for these
2224 policies.

2225 2.9.5 Thread Cancellation
2226 The thread cancellation mechanism allows a thread to terminate the execution of any other
2227 thread in the process in a controlled manner. The target thread (that is, the one that is being
2228 canceled) is allowed to hold cancellation requests pending in a number of ways and to perform
2229 application-specific cleanup processing when the notice of cancellation is acted upon.
2230 Cancellation is controlled by the cancellation control functions. Each thread maintains its own
2231 cancelability state. Cancellation may only occur at cancellation points or when the thread is
2232 asynchronously cancelable.
2233 The thread cancellation mechanism described in this section depends upon programs having set
2234 deferred cancelability state, which is specified as the default. Applications shall also carefully
2235 follow static lexical scoping rules in their execution behavior. For example, use of setjmp(),
2236 return, goto, and so on, to leave user-defined cancellation scopes without doing the necessary
2237 scope pop operation results in undefined behavior.
2238 Use of asynchronous cancelability while holding resources which potentially need to be released
2239 may result in resource loss. Similarly, cancellation scopes may only be safely manipulated
2240 (pushed and popped) when the thread is in the deferred or disabled cancelability states.

2241 2.9.5.1 Cancelability States
2242 The cancelability state of a thread determines the action taken upon receipt of a cancellation
2243 request. The thread may control cancellation in a number of ways.
2244 Each thread maintains its own cancelability state, which may be encoded in two bits:
2245 1. Cancelability-Enable: When cancelability is PTHREAD_CANCEL_DISABLE (as defined in
2246 the Base Definitions volume of IEEE Std 1003.1-2001, <pthread.h>), cancellation requests
2247 against the target thread are held pending. By default, cancelability is set to
2248 PTHREAD_CANCEL_ENABLE (as defined in <pthread.h>).
2249
2250 2. Cancelability Type: When cancelability is enabled and the cancelability type is
2251 PTHREAD_CANCELASYNCHRONOUS (as defined in <pthread.h>), new or pending
2252 cancellation requests may be acted upon at any time. When cancelability is enabled and
2253 the cancelability type is PTHREAD_CANCEL_DEFERRED (as defined in <pthread.h>),
2254 cancellation requests are held pending until a cancellation point (see below) is reached. If
2255 cancelability is disabled, the setting of the cancelability type has no immediate effect as all
2256 cancellation requests are held pending; however, once cancelability is enabled again the
2257 new type is in effect. The cancelability type is PTHREAD_CANCELDIFFERRED in all
2258 newly created threads including the thread in which main() was first invoked.
Cancellation points shall occur when a thread is executing the following functions:

- accept()
- aio_suspend()
- clock_nanosleep()
- close()
- connect()
- creat()
- fcntl()
- fsync()
- getmsg()
- getpmsg()
- lockf()
- mq_receive()
- mq_send()
- mq_timedreceive()
- pthread_cond_timedwait()
- pthread_cond_wait()
- pthread_join()
- pthread_testcancel()
- putmsg()
- putpmsg()
- read()
- readv()
- recv()
- recvfrom()
- recvmsg()
- sem_timedwait()
- sem_wait()
- send()
- sendmsg()
- sendto()
- sigpause()
- sigsuspend()
- sigwait()
- sigwaitinfo()
- sleep()
- system()
- tcdrain()
- usleep()
- wait()
- waitid()
- write()
- writev()
A cancellation point may also occur when a thread is executing the following functions:

- catclose()
- ftell()
- getwc()
- pthread_rwlock_wrlock()
- catgets()
- ftello()
- getwchar()
- pute()
- catopen()
- fwrite()
- getwd()
- pute_unlocked()
- closedir()
- fprintf()
- glob()
- putchar()
- closelog()
- fwrite()
- iconv_close()
- putchar_unlocked()
- ctermid()
- fscanf()
- iconv_open()
- puts()
- dbrn_close()
- getchar()
- mkstemp()
- putw()
- dbrn_delete()
- getchar_unlocked()
- lseek()
- putw()
- dbrn_fetch()
- getc()
- mkstemp()
- putw()
- dbrn_nextkey()
- getchar_unlocked()
- nftw()
- readdir()
- dbm_open()
- getcwd()
- opendir()
- readdir_r()
- dbrn_store()
- getdate()
- openlog()
- remove()
- dlclose()
- getgid()
- pclock()
- rename()
- dlopen()
- getpid()
- perror()
- rewind()
- endgrent()
- getgrgid_r()
- popen()
- rewindedir()
- endhostent()
- getgrnam()
- posix_fadvise()
- scanf()
- endnetent()
- getgrnam_r()
- posix_fallocate()
- seekdir()
- endprotoent()
- gethostbyaddr()
- posix_madvise()
- semap()
- endw4ent()
- gethostbyname()
- posix_spawn()
- setgrent()
- endw4cent()
- gethostent()
- posix_spawnp()
- sethostent()
- enduxent()
- gethostname()
- posix_trace_clear()
- setnetent()
- fclose()
- getlogin()
- posix_trace_close()
- setprotoent()
- fcntl()
- getlogin_r()
- posix_trace_create()
- setseent()
- fget()
- getnetbyaddr()
- posix_trace_create_withlog()
- setutxent()
- fgetpos()
- getnetent()
- posix_trace_eventtypelist_getnext_id()
- setutxent()
- fgets()
- getprotobynumber()
- posix_trace_flush()
- syslog()
- fgetwc()
- getprotoent()
- posix_trace_get_attr()
- tmpfile()
- fgets()
- getprotobynumber()
- posix_trace_get_filter()
- tmpnam()
- fopen()
- getprotoent()
- posix_trace_get_status()
- ttyname()
- fprintf()
- getpwnam()
- posix_trace_getnext_event()
- ttynamespace()
- fprintf()
- getpwnam_r()
- posix_trace_open()
- ungetc()
- fprintf()
- getpwnam_r()
- posix_trace_rewind()
- ungetw()
- fprintf()
- getpwnam_r()
- posix_trace_set_filter()
- unlink()
- fprintf()
- gets()
- posix_trace_shutdown()
- vfprintf()
- fread()
- getservbyaddr()
- posix_trace_timedgetnext_event()
- vsprintf()
- freopen()
- getservbyname()
- posix_type_mem_open()
- vsprintf()
- fscanf()
- getservent()
- printf()
- vsprintf()
- fseek()
- getutxent()
- pthread_rwlock_rdlock()
- wscanf()
- fseeko()
- getutxid()
- pthread_rwlock_timedrdlock()
- wscanf()
- fsetpos()
- getutxline()
- pthread_rwlock_timedwrlock()

An implementation shall not introduce cancellation points into any other functions specified in this volume of IEEE Std 1003.1-2001.

For any value of the cmd argument.
The side effects of acting upon a cancellation request while suspended during a call of a function are the same as the side effects that may be seen in a single-threaded program when a call to a function is interrupted by a signal and the given function returns [EINTR]. Any such side effects occur before any cancellation cleanup handlers are called.

Whenever a thread has cancelability enabled and a cancellation request has been made with that thread as the target, and the thread then calls any function that is a cancellation point (such as pthread_testcancel() or read()), the cancellation request shall be acted upon before the function returns. If a thread has cancelability enabled and a cancellation request is made with the thread as a target while the thread is suspended at a cancellation point, the thread shall be awakened and the cancellation request shall be acted upon. However, if the thread is suspended at a cancellation point and the event for which it is waiting occurs before the cancellation request is acted upon, it is unspecified whether the cancellation request is acted upon or whether the cancellation request remains pending and the thread resumes normal execution.

2.9.5.3 Thread Cancellation Cleanup Handlers

Each thread maintains a list of cancellation cleanup handlers. The programmer uses the pthread_cleanup_push() and pthread_cleanup_pop() functions to place routines on and remove routines from this list.

When a cancellation request is acted upon, the routines in the list are invoked one by one in LIFO sequence; that is, the last routine pushed onto the list (Last In) is the first to be invoked (First Out). The thread invokes the cancellation cleanup handler with cancellation disabled until the last cancellation cleanup handler returns. When the cancellation cleanup handler for a scope is invoked, the storage for that scope remains valid. If the last cancellation cleanup handler returns, thread execution is terminated and a status of PTHREAD_CANCELED is made available to any threads joining with the target. The symbolic constant PTHREAD_CANCELED expands to a constant expression of type (void *) whose value matches no pointer to an object in memory nor the value NULL.

The cancellation cleanup handlers are also invoked when the thread calls pthread_exit().

A side effect of acting upon a cancellation request while in a condition variable wait is that the mutex is re-acquired before calling the first cancellation cleanup handler. In addition, the thread is no longer considered to be waiting for the condition and the thread shall not have consumed any pending condition signals on the condition.

A cancellation cleanup handler cannot exit via longjmp() or siglongjmp().

2.9.5.4 Async-Cancel Safety

The pthread_cancel(), pthread_setcancelstate(), and pthread_setcanceltype() functions are defined to be async-cancel safe.

No other functions in this volume of IEEE Std 1003.1-2001 are required to be async-cancel-safe.

### 2.9.6 Thread Read-Write Locks

Multiple readers, single writer (read-write) locks allow many threads to have simultaneous read-only access to data while allowing only one thread to have exclusive write access at any given time. They are typically used to protect data that is read more frequently than it is changed.

One or more readers acquire read access to the resource by performing a read lock operation on the associated read-write lock. A writer acquires exclusive write access by performing a write lock operation. Basically, all readers exclude any writers and a writer excludes all readers and any other writers.

A thread that has blocked on a read-write lock (for example, has not yet returned from a `pthread_rwlock_rdlock()` or `pthread_rwlock_wrlock()` call) shall not prevent any unblocked thread that is eligible to use the same processing resources from eventually making forward progress in its execution. Eligibility for processing resources shall be determined by the scheduling policy.

Read-write locks can be used to synchronize threads in the current process and other processes if they are allocated in memory that is writable and shared among the cooperating processes and have been initialized for this behavior.

### 2.9.7 Thread Interactions with Regular File Operations

All of the functions `chmod()`, `close()`, `fchmod()`, `fcntl()`, `fstat()`, `ftruncate()`, `lseek()`, `open()`, `read()`, `readlink()`, `stat()`, `symlink()`, and `write()` shall be atomic with respect to each other in the effects specified in IEEE Std 1003.1-2001 when they operate on regular files. If two threads each call one of these functions, each call shall either see all of the specified effects of the other call, or none of them.

### 2.10 Sockets

A socket is an endpoint for communication using the facilities described in this section. A socket is created with a specific socket type, described in Section 2.10.6 (on page 59), and is associated with a specific protocol, detailed in Section 2.10.3 (on page 59). A socket is accessed via a file descriptor obtained when the socket is created.

#### 2.10.1 Address Families

All network protocols are associated with a specific address family. An address family provides basic services to the protocol implementation to allow it to function within a specific network environment. These services may include packet fragmentation and reassembly, routing, addressing, and basic transport. An address family is normally comprised of a number of protocols, one per socket type. Each protocol is characterized by an abstract socket type. It is not required that an address family support all socket types. An address family may contain multiple protocols supporting the same socket abstraction.

Section 2.10.17 (on page 66), Section 2.10.19 (on page 67), and Section 2.10.20 (on page 67), respectively, describe the use of sockets for local UNIX connections, for Internet protocols based on IPv4, and for Internet protocols based on IPv6.
2.10.2 Addressing

An address family defines the format of a socket address. All network addresses are described using a general structure, called a `sockaddr`, as defined in the Base Definitions volume of IEEE Std 1003.1-2001, `<sys/socket.h>`. However, each address family imposes finer and more specific structure, generally defining a structure with fields specific to the address family. The field `sa_family` in the `sockaddr` structure contains the address family identifier, specifying the format of the `sa_data` area. The size of the `sa_data` area is unspecified.

2.10.3 Protocols

A protocol supports one of the socket abstractions detailed in Section 2.10.6. Selecting a protocol involves specifying the address family, socket type, and protocol number to the `socket()` function. Certain semantics of the basic socket abstractions are protocol-specific. All protocols are expected to support the basic model for their particular socket type, but may, in addition, provide non-standard facilities or extensions to a mechanism.

2.10.4 Routing

Sockets provides packet routing facilities. A routing information database is maintained, which is used in selecting the appropriate network interface when transmitting packets.

2.10.5 Interfaces

Each network interface in a system corresponds to a path through which messages can be sent and received. A network interface usually has a hardware device associated with it, though certain interfaces such as the loopback interface, do not.

2.10.6 Socket Types

A socket is created with a specific type, which defines the communication semantics and which allows the selection of an appropriate communication protocol. Four types are defined: `SOCK_RAW`, `SOCK_STREAM`, `SOCK_SEQPACKET`, and `SOCK_DGRAM`. Implementations may specify additional socket types.

The `SOCK_STREAM` socket type provides reliable, sequenced, full-duplex octet streams between the socket and a peer to which the socket is connected. A socket of type `SOCK_STREAM` must be in a connected state before any data may be sent or received. Record boundaries are not maintained; data sent on a stream socket using output operations of one size may be received using input operations of smaller or larger sizes without loss of data. Data may be buffered; successful return from an output function does not imply that the data has been delivered to the peer or even transmitted from the local system. If data cannot be successfully transmitted within a given time then the connection is considered broken, and subsequent operations shall fail. A SIGPIPE signal is raised if a thread sends on a broken stream (one that is no longer connected). Support for an out-of-band data transmission facility is protocol-specific.

The `SOCK_SEQPACKET` socket type is similar to the `SOCK_STREAM` type, and is also connection-oriented. The only difference between these types is that record boundaries are maintained using the `SOCK_SEQPACKET` type. A record can be sent using one or more output operations and received using one or more input operations, but a single operation never transfers parts of more than one record. Record boundaries are visible to the receiver via the `MSG_EOR` flag in the received message flags returned by the `recvmsg()` function. It is protocol-specific whether a maximum record size is imposed.

The `SOCK_DGRAM` socket type supports connectionless data transfer which is not necessarily acknowledged or reliable. Datagrams may be sent to the address specified (possibly multicast or...
broadcast) in each output operation, and incoming datagrams may be received from multiple
sources. The source address of each datagram is available when receiving the datagram. An
application may also pre-specify a peer address, in which case calls to output functions shall
send to the pre-specified peer. If a peer has been specified, only datagrams from that peer shall
be received. A datagram must be sent in a single output operation, and must be received in a
single input operation. The maximum size of a datagram is protocol-specific; with some
protocols, the limit is implementation-defined. Output datagrams may be buffered within the
system; thus, a successful return from an output function does not guarantee that a datagram is
actually sent or received. However, implementations should attempt to detect any errors
possible before the return of an output function, reporting any error by an unsuccessful return
value.

2.10.7 Socket I/O Mode

The I/O mode of a socket is described by the O_NONBLOCK file status flag which pertains to
the open file description for the socket. This flag is initially off when a socket is created, but may
be set and cleared by the use of the F_SETFL command of the fcntl() function.

When the O_NONBLOCK flag is set, functions that would normally block until they are
complete shall either return immediately with an error, or shall complete asynchronously to the
execution of the calling process. Data transfer operations (the read(), write(), send(), and recv()
functions) shall complete immediately, transfer only as much as is available, and then return
without blocking, or return an error indicating that no transfer could be made without blocking.
The connect() function initiates a connection and shall return without blocking when
O_NONBLOCK is set; it shall return the error [EINPROGRESS] to indicate that the connection
was initiated successfully, but that it has not yet completed.

2.10.8 Socket Owner

The owner of a socket is unset when a socket is created. The owner may be set to a process ID or
process group ID using the F_SETOWN command of the fcntl() function.

2.10.9 Socket Queue Limits

The transmit and receive queue sizes for a socket are set when the socket is created. The default
sizes used are both protocol-specific and implementation-defined. The sizes may be changed
using the setsockopt() function.

2.10.10 Pending Error

Errors may occur asynchronously, and be reported to the socket in response to input from the
network protocol. The socket stores the pending error to be reported to a user of the socket at the
next opportunity. The error is returned in response to a subsequent send(), recv(), or getsockopt()
operation on the socket, and the pending error is then cleared.
2.10.11 Socket Receive Queue

A socket has a receive queue that buffers data when it is received by the system until it is removed by a receive call. Depending on the type of the socket and the communication provider, the receive queue may also contain ancillary data such as the addressing and other protocol data associated with the normal data in the queue, and may contain out-of-band or expedited data. The limit on the queue size includes any normal, out-of-band data, datagram source addresses, and ancillary data in the queue. The description in this section applies to all sockets, even though some elements cannot be present in some instances.

The contents of a receive buffer are logically structured as a series of data segments with associated ancillary data and other information. A data segment may contain normal data or out-of-band data, but never both. A data segment may complete a record if the protocol supports records (always true for types SOCK_SEQPACKET and SOCK_DGRAM). A record may be stored as more than one segment; the complete record might never be present in the receive buffer at one time, as a portion might already have been returned to the application, and another portion might not yet have been received from the communications provider. A data segment may contain ancillary protocol data, which is logically associated with the segment. Ancillary data is received as if it were queued along with the first normal data octet in the segment (if any). A segment may contain ancillary data only, with no normal or out-of-band data. For the purposes of this section, a datagram is considered to be a data segment that terminates a record, and that includes a source address as a special type of ancillary data. Data segments are placed into the queue as data is delivered to the socket by the protocol. Normal data segments are placed at the end of the queue as they are delivered. If a new segment contains the same type of data as the preceding segment and includes no ancillary data, and if the preceding segment does not terminate a record, the segments are logically merged into a single segment.

The receive queue is logically terminated if an end-of-file indication has been received or a connection has been terminated. A segment shall be considered to be terminated if another segment follows it in the queue, if the segment completes a record, or if an end-of-file or other connection termination has been reported. The last segment in the receive queue shall also be considered to be terminated while the socket has a pending error to be reported.

A receive operation shall never return data or ancillary data from more than one segment.

2.10.12 Socket Out-of-Band Data State

The handling of received out-of-band data is protocol-specific. Out-of-band data may be placed in the socket receive queue, either at the end of the queue or before all normal data in the queue. In this case, out-of-band data is returned to an application program by a normal receive call. Out-of-band data may also be queued separately rather than being placed in the socket receive queue, in which case it shall be returned only in response to a receive call that requests out-of-band data. It is protocol-specific whether an out-of-band data mark is placed in the receive queue to demarcate data preceding the out-of-band data and following the out-of-band data. An out-of-band data mark is logically an empty data segment that cannot be merged with other segments in the queue. An out-of-band data mark is never returned in response to an input operation. The sockatmark( ) function can be used to test whether an out-of-band data mark is the first element in the queue. If an out-of-band data mark is the first element in the queue when an input function is called without the MSG_PEEK option, the mark is removed from the queue and the following data (if any) is processed as if the mark had not been present.
2.10.13 Connection Indication Queue

Sockets that are used to accept incoming connections maintain a queue of outstanding connection indications. This queue is a list of connections that are awaiting acceptance by the application; see `listen()`.

2.10.14 Signals

One category of event at the socket interface is the generation of signals. These signals report protocol events or process errors relating to the state of the socket. The generation or delivery of a signal does not change the state of the socket, although the generation of the signal may have been caused by a state change.

The `SIGPIPE` signal shall be sent to a thread that attempts to send data on a socket that is no longer able to send. In addition, the send operation fails with the error `[EPIPE]`.

If a socket has an owner, the `SIGURG` signal is sent to the owner of the socket when it is notified of expedited or out-of-band data. The socket state at this time is protocol-dependent, and the status of the socket is specified in Section 2.10.17 (on page 66), Section 2.10.19 (on page 67), and Section 2.10.20 (on page 67). Depending on the protocol, the expedited data may or may not have arrived at the time of signal generation.

2.10.15 Asynchronous Errors

If any of the following conditions occur asynchronously for a socket, the corresponding value listed below shall become the pending error for the socket:

- `[ECONNABORTED]`  
The connection was aborted locally.

- `[ECONNREFUSED]`  
For a connection-mode socket attempting a non-blocking connection, the attempt to connect was forcefully rejected. For a connectionless-mode socket, an attempt to deliver a datagram was forcefully rejected.

- `[ECONNRESET]`  
The peer has aborted the connection.

- `[EHOSTDOWN]`  
The destination host has been determined to be down or disconnected.

- `[EHOSTUNREACH]`  
The destination host is not reachable.

- `[EMSGSIZE]`  
For a connectionless-mode socket, the size of a previously sent datagram prevented delivery.

- `[ENETDOWN]`  
The local network connection is not operational.

- `[ENETRESET]`  
The connection was aborted by the network.

- `[ENETUNREACH]`  
The destination network is not reachable.
There are a number of socket options which either specialize the behavior of a socket or provide useful information. These options may be set at different protocol levels and are always present at the uppermost "socket" level.

Socket options are manipulated by two functions, `getsockopt()` and `setsockopt()`. These functions allow an application program to customize the behavior and characteristics of a socket to provide the desired effect.

All of the options have default values. The type and meaning of these values is defined by the protocol level to which they apply. Instead of using the default values, an application program may choose to customize one or more of the options. However, in the bulk of cases, the default values are sufficient for the application.

Some of the options are used to enable or disable certain behavior within the protocol modules (for example, turn on debugging) while others may be used to set protocol-specific information (for example, IP time-to-live on all the application’s outgoing packets). As each of the options is introduced, its effect on the underlying protocol modules is described.

Table 2-1 shows the value for the socket level.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SOL_SOCKET</td>
<td>Options are intended for the sockets level.</td>
</tr>
</tbody>
</table>

Table 2-2 (on page 64) lists those options present at the socket level; that is, when the `level` parameter of the `getsockopt()` or `setsockopt()` function is SOL_SOCKET, the types of the option value parameters associated with each option, and a brief synopsis of the meaning of the option value parameter. Unless otherwise noted, each may be examined with `getsockopt()` and set with `setsockopt()` on all types of socket.
The SO_BROADCAST option requests permission to send broadcast datagrams on the socket. Support for SO_BROADCAST is protocol-specific. The default for SO_BROADCAST is that the ability to send broadcast datagrams on a socket is disabled.

The SO_DEBUG option enables debugging in the underlying protocol modules. This can be useful for tracing the behavior of the underlying protocol modules during normal system operation. The semantics of the debug reports are implementation-defined. The default value for SO_DEBUG is for debugging to be turned off.

The SO_DONTROUTE option requests that outgoing messages bypass the standard routing facilities. The destination must be on a directly-connected network, and messages are directed to the appropriate network interface according to the destination address. It is protocol-specific whether this option has any effect and how the outgoing network interface is chosen. Support for this option with each protocol is implementation-defined.

The SO_ERROR option is used only on getsockopt(). When this option is specified, getsockopt() shall return any pending error on the socket and clear the error status. It shall return a value of 0 if there is no pending error. SO_ERROR may be used to check for asynchronous errors on connected connectionless-mode sockets or for other types of asynchronous errors. SO_ERROR has no default value.

### Table 2-2 Socket-Level Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Parameter Type</th>
<th>Parameter Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>SO_BROADCAST</td>
<td>int</td>
<td>Non-zero requests permission to transmit broadcast datagrams (SOCK_DGRAM sockets only).</td>
</tr>
<tr>
<td>SO_DEBUG</td>
<td>int</td>
<td>Non-zero requests debugging in underlying protocol modules.</td>
</tr>
<tr>
<td>SO_DONTROUTE</td>
<td>int</td>
<td>Non-zero requests bypass of normal routing; route based on destination address only.</td>
</tr>
<tr>
<td>SO_ERROR</td>
<td>int</td>
<td>Requests and clears pending error information on the socket (getsockopt() only).</td>
</tr>
<tr>
<td>SO_KEEPALIVE</td>
<td>int</td>
<td>Non-zero requests periodic transmission of keepalive messages (protocol-specific).</td>
</tr>
<tr>
<td>SO_LINGER</td>
<td>struct linger</td>
<td>Specify actions to be taken for queued, unsent data on close(): linger on/off and linger time in seconds.</td>
</tr>
<tr>
<td>SO_OOBINLINE</td>
<td>int</td>
<td>Non-zero requests that out-of-band data be placed into normal data input queue as received.</td>
</tr>
<tr>
<td>SO_RCVBUF</td>
<td>int</td>
<td>Size of receive buffer (in bytes).</td>
</tr>
<tr>
<td>SO_RCVLOWAT</td>
<td>int</td>
<td>Minimum amount of data to return to application for input operations (in bytes).</td>
</tr>
<tr>
<td>SO_RCVTIMEO</td>
<td>struct timeval</td>
<td>Timeout value for a socket receive operation.</td>
</tr>
<tr>
<td>SO_REUSEADDR</td>
<td>int</td>
<td>Non-zero requests reuse of local addresses in bind() (protocol-specific).</td>
</tr>
<tr>
<td>SO_SNDBUF</td>
<td>int</td>
<td>Size of send buffer (in bytes).</td>
</tr>
<tr>
<td>SO_SNDELOWAT</td>
<td>int</td>
<td>Minimum amount of data to send for output operations (in bytes).</td>
</tr>
<tr>
<td>SO_SNDTIMEO</td>
<td>struct timeval</td>
<td>Timeout value for a socket send operation.</td>
</tr>
<tr>
<td>SO_TYPE</td>
<td>int</td>
<td>Identify socket type (getsockopt() only).</td>
</tr>
</tbody>
</table>
The SO_KEEPALIVE option enables the periodic transmission of messages on a connected socket. The behavior of this option is protocol-specific. The default value for SO_KEEPALIVE is zero, specifying that this capability is turned off.

The SO_LINGER option controls the action of the interface when unsent messages are queued on a socket and a close() is performed. The details of this option are protocol-specific. The default value for SO_LINGER is zero, or off, for the l_onoff element of the option value and zero seconds for the linger time specified by the l_linger element.

The SO_OOBINLINE option is valid only on protocols that support out-of-band data. The SO_OOBINLINE option requests that out-of-band data be placed in the normal data input queue as received; it is then accessible using the read() or recv() functions without the MSG_OOB flag set. The default for SO_OOBINLINE is off; that is, for out-of-band data not to be placed in the normal data input queue.

The SO_RCVBUF option requests that the buffer space allocated for receive operations on this socket be set to the value, in bytes, of the option value. Applications may wish to increase buffer size for high volume connections, or may decrease buffer size to limit the possible backlog of incoming data. The default value for the SO_RCVBUF option value is implementation-defined, and may vary by protocol.

The maximum value for the option for a socket may be obtained by the use of the fpathconf() function, using the value _PC_SOCK_MAXBUF.

The SO_RCVLOWAT option sets the minimum number of bytes to process for socket input operations. In general, receive calls block until any (non-zero) amount of data is received, then return the smaller of the amount available or the amount requested. The default value for SO_RCVLOWAT is 1, and does not affect the general case. If SO_RCVLOWAT is set to a larger value, blocking receive calls normally wait until they have received the smaller of the low water mark value or the requested amount. Receive calls may still return less than the low water mark if an error occurs, a signal is caught, or the type of data next in the receive queue is different from that returned (for example, out-of-band data). As mentioned previously, the default value for SO_RCVLOWAT is 1 byte. It is implementation-defined whether the SO_RCVLOWAT option can be set.

The SO_RCVTIMEO option is an option to set a timeout value for input operations. It accepts a timeval structure with the number of seconds and microseconds specifying the limit on how long to wait for an input operation to complete. If a receive operation has blocked for this much time without receiving additional data, it shall return with a partial count or errno shall be set to [EWOULDBLOCK] if no data were received. The default for this option is the value zero, which indicates that a receive operation will not time out. It is implementation-defined whether the SO_RCVTIMEO option can be set.

The SO_REUSEADDR option indicates that the rules used in validating addresses supplied in a bind() should allow reuse of local addresses. Operation of this option is protocol-specific. The default value for SO_REUSEADDR is off; that is, reuse of local addresses is not permitted.

The SO_SNDBUF option requests that the buffer space allocated for send operations on this socket be set to the value, in bytes, of the option value. The default value for the SO_SNDBUF option value is implementation-defined, and may vary by protocol. The maximum value for the option for a socket may be obtained by the use of the fpathconf() function, using the value _PC_SOCK_MAXBUF.

The SO_SNDOLOWAT option sets the minimum number of bytes to process for socket output operations. Most output operations process all of the data supplied by the call, delivering data to the protocol for transmission and blocking as necessary for flow control. Non-blocking output operations process as much data as permitted subject to flow control without blocking, but
Sockets General Information

process no data if flow control does not allow the smaller of the send low water mark value or the entire request to be processed. A select() operation testing the ability to write to a socket shall return true only if the send low water mark could be processed. The default value for SO_SNDLOWAT is implementation-defined and protocol-specific. It is implementation-defined whether the SO_SNDLOWAT option can be set.

The SO_SNDTIMEO option is an option to set a timeout value for the amount of time that an output function shall block because flow control prevents data from being sent. As noted in Table 2-2 (on page 64), the option value is a timeval structure with the number of seconds and microseconds specifying the limit on how long to wait for an output operation to complete. If a send operation has blocked for this much time, it shall return with a partial count or errno set to [EWOULDBLOCK] if no data were sent. The default for this option is the value zero, which indicates that a send operation will not time out. It is implementation-defined whether the SO_SNDTIMEO option can be set.

The SO_TYPE option is used only on getsockopt(). When this option is specified, getsockopt() shall return the type of the socket (for example, SOCK_STREAM). This option is useful to servers that inherit sockets on start-up. SO_TYPE has no default value.

2.10.17 Use of Sockets for Local UNIX Connections

Support for UNIX domain sockets is mandatory.

UNIX domain sockets provide process-to-process communication in a single system.

2.10.17.1 Headers

The symbolic constant AF_UNIX defined in the <sys/socket.h> header is used to identify the UNIX domain address family. The <sys/un.h> header contains other definitions used in connection with UNIX domain sockets. See the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 13, Headers.

The sockaddr_storage structure defined in <sys/socket.h> shall be large enough to accommodate a sockaddr_un structure (see the <sys/un.h> header defined in the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 13, Headers) and shall be aligned at an appropriate boundary so that pointers to it can be cast as pointers to sockaddr_un structures and used to access the fields of those structures without alignment problems. When a sockaddr_storage structure is cast as a sockaddr_un structure, the ss_family field maps onto the sun_family field.

2.10.18 Use of Sockets over Internet Protocols

When a socket is created in the Internet family with a protocol value of zero, the implementation shall use the protocol listed below for the type of socket created.

SOCK_STREAM IPPROTO_TCP.
SOCK_DGRAM IPPROTO_UDP.
SOCK_RAW IPPROTO_RAW.
SOCK_SEQPACKET Unspecified.

A raw interface to IP is available by creating an Internet socket of type SOCK_RAW. The default protocol for type SOCK_RAW shall be identified in the IP header with the value IPPROTO_RAW. Applications should not use the default protocol when creating a socket with type SOCK_RAW, but should identify a specific protocol by value. The ICMP control protocol is accessible from a raw socket by specifying a value of IPPROTO_ICMP for protocol.
2.10.19 Use of Sockets over Internet Protocols Based on IPv4

Support for sockets over Internet protocols based on IPv4 is mandatory.

2.10.19.1 Headers

The symbolic constant AF_INET defined in the <sys/socket.h> header is used to identify the IPv4 Internet address family. The <netinet/in.h> header contains other definitions used in connection with IPv4 Internet sockets. See the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 13, Headers.

The sockaddr_storage structure defined in <sys/socket.h> shall be large enough to accommodate a sockaddr_in structure (see the <netinet/in.h> header defined in the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 13, Headers) and shall be aligned at an appropriate boundary so that pointers to it can be cast as pointers to sockaddr_in structures and used to access the fields of those structures without alignment problems. When a sockaddr_storage structure is cast as a sockaddr_in structure, the ss_family field maps onto the sin_family field.

2.10.20 Use of Sockets over Internet Protocols Based on IPv6

IPv6 This section describes extensions to support sockets over Internet protocols based on IPv6. This functionality is dependent on support of the IPV6 option (and the rest of this section is not further shaded for this option).

To enable smooth transition from IPv4 to IPv6, the features defined in this section may, in certain circumstances, also be used in connection with IPv4; see Section 2.10.20.2 (on page 68).

2.10.20.1 Addressing

IPv6 overcomes the addressing limitations of previous versions by using 128-bit addresses instead of 32-bit addresses. The IPv6 address architecture is described in RFC 2373.

There are three kinds of IPv6 address:

Unicast

Identifies a single interface.

A unicast address can be global, link-local (designed for use on a single link), or site-local (designed for systems not connected to the Internet). Link-local and site-local addresses need not be globally unique.

Anycast

Identifies a set of interfaces such that a packet sent to the address can be delivered to any member of the set.

An anycast address is similar to a unicast address; the nodes to which an anycast address is assigned must be explicitly configured to know that it is an anycast address.

Multicast

Identifies a set of interfaces such that a packet sent to the address should be delivered to every member of the set.

An application can send multicast datagrams by simply specifying an IPv6 multicast address in the address argument of sendto(). To receive multicast datagrams, an application must join the multicast group (using setsockopt() with IPV6_JOIN_GROUP) and must bind to the socket the UDP port on which datagrams will be received. Some applications should also bind the multicast group address to the socket, to prevent other datagrams destined to that port from being delivered to the socket.
A multicast address can be global, node-local, link-local, site-local, or organization-local.

The following special IPv6 addresses are defined:

- **Unspecified**
  - An address that is not assigned to any interface and is used to indicate the absence of an address.

- **Loopback**
  - A unicast address that is not assigned to any interface and can be used by a node to send packets to itself.

Two sets of IPv6 addresses are defined to correspond to IPv4 addresses:

- **IPv4-compatible addresses**
  - These are assigned to nodes that support IPv6 and can be used when traffic is “tunneled” through IPv4.

- **IPv4-mapped addresses**
  - These are used to represent IPv4 addresses in IPv6 address format; see Section 2.10.20.2.

Note that the unspecified address and the loopback address must not be treated as IPv4-compatible addresses.

### 2.10.20.2 Compatibility with IPv4

The API provides the ability for IPv6 applications to interoperate with applications using IPv4, by using IPv4-mapped IPv6 addresses. These addresses can be generated automatically by the getaddrinfo() function when the specified host has only IPv4 addresses.

Applications can use AF_INET6 sockets to open TCP connections to IPv4 nodes, or send UDP packets to IPv4 nodes, by simply encoding the destination’s IPv4 address as an IPv4-mapped IPv6 address, and passing that address, within a sockaddr_in6 structure, in the connect(), sendto(), or sendmsg() function. When applications use AF_INET6 sockets to accept TCP connections from IPv4 nodes, or receive UDP packets from IPv4 nodes, the system shall return the peer’s address to the application in the accept(), recvfrom(), recvmsg(), or getpeername() function using a sockaddr_in6 structure encoded this way. If a node has an IPv4 address, then the implementation shall allow applications to communicate using that address via an AF_INET6 socket. In such a case, the address will be represented at the API by the corresponding IPv4-mapped IPv6 address. Also, the implementation may allow an AF_INET6 socket bound to in6addr_any to receive inbound connections and packets destined to one of the node’s IPv4 addresses.

An application can use AF_INET6 sockets to bind to a node’s IPv4 address by specifying the address as an IPv4-mapped IPv6 address in a sockaddr_in6 structure in the bind() function. For an AF_INET6 socket bound to a node’s IPv4 address, the system shall return the address in the getsockname() function as an IPv4-mapped IPv6 address in a sockaddr_in6 structure.

### 2.10.20.3 Interface Identification

Each local interface is assigned a unique positive integer as a numeric index. Indexes start at 1; zero is not used. There may be gaps so that there is no current interface for a particular positive index. Each interface also has a unique implementation-defined name.
2.10.20.4 Options

The following options apply at the IPPROTO_IPV6 level:

**IPV6_JOIN_GROUP**
When set via `setsockopt()`, it joins the application to a multicast group on an interface (identified by its index) and addressed by a given multicast address, enabling packets sent to that address to be read via the socket. If the interface index is specified as zero, the system selects the interface (for example, by looking up the address in a routing table and using the resulting interface).

An attempt to read this option using `getsockopt()` shall result in an [EOPNOTSUPP] error.

The parameter type of this option is a pointer to an `ipv6_mreq` structure.

**IPV6_LEAVE_GROUP**
When set via `setsockopt()`, it removes the application from the multicast group on an interface (identified by its index) and addressed by a given multicast address.

An attempt to read this option using `getsockopt()` shall result in an [EOPNOTSUPP] error.

The parameter type of this option is a pointer to an `ipv6_mreq` structure.

**IPV6_MULTICAST_HOPS**
The value of this option is the hop limit for outgoing multicast IPv6 packets sent via the socket. Its possible values are the same as those of IPV6_UNICAST_HOPS. If the IPV6_MULTICAST_HOPS option is not set, a value of 1 is assumed. This option can be set via `setsockopt()` and read via `getsockopt()`.

The parameter type of this option is a pointer to an `int`. (Default value: 1)

**IPV6_MULTICAST_IF**
The index of the interface to be used for outgoing multicast packets. It can be set via `setsockopt()` and read via `getsockopt()`.

The parameter type of this option is a pointer to an `unsigned int`. (Default value: 0)

**IPV6_MULTICAST_LOOP**
This option controls whether outgoing multicast packets should be delivered back to the local application when the sending interface is itself a member of the destination multicast group. If it is set to 1 they are delivered. If it is set to 0 they are not. Other values result in an [EINVAL] error. This option can be set via `setsockopt()` and read via `getsockopt()`.

The parameter type of this option is a pointer to an `unsigned int` which is used as a Boolean value. (Default value: 1)

**IPV6_UNICAST_HOPS**
The value of this option is the hop limit for outgoing unicast IPv6 packets sent via the socket. If the option is not set, or is set to −1, the system selects a default value. Attempts to set a value less than −1 or greater than 255 shall result in an [EINVAL] error. This option can be set via `setsockopt()` and read via `getsockopt()`.

The parameter type of this option is a pointer to an `int`. (Default value: Unspecified)

**IPV6_V6ONLY**
This socket option restricts AF_INET6 sockets to IPv6 communications only. AF_INET6 sockets may be used for both IPv4 and IPv6 communications. Some applications may want to restrict their use of an AF_INET6 socket to IPv6 communications only. For these
applications, the IPv6_V6ONLY socket option is defined. When this option is turned on, the socket can be used to send and receive IPv6 packets only. This is an IPPROTO_IPV6-level option.

The parameter type of this option is a pointer to an int which is used as a Boolean value. (Default value: 0)

An [EOPNOTSUPP] error shall result if IPV6_JOIN_GROUP or IPV6_LEAVE_GROUP is used with getsockopt().

2.10.20.5 Headers

The symbolic constant AF_INET6 is defined in the <sys/socket.h> header to identify the IPv6 Internet address family. See the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 13, Headers.

The sockaddr_storage structure defined in <sys/socket.h> shall be large enough to accommodate a sockaddr_in6 structure (see the <netinet/in.h> header defined in the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 13, Headers) and shall be aligned at an appropriate boundary so that pointers to it can be cast as pointers to sockaddr_in6 structures and used to access the fields of those structures without alignment problems. When a sockaddr_storage structure is cast as a sockaddr_in6 structure, the ss_family field maps onto the sin6_family field.

The <netinet/in.h>, <arpa/inet.h>, and <netdb.h> headers contain other definitions used in connection with IPv6 Internet sockets; see the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 13, Headers.

2.11 Tracing

This section describes extensions to support tracing of user applications. This functionality is dependent on support of the Trace option (and the rest of this section is not further shaded for this option).

The tracing facilities defined in IEEE Std 1003.1-2001 allow a process to select a set of trace event types, to activate a trace stream of the selected trace events as they occur in the flow of execution, and to retrieve the recorded trace events.

The tracing operation relies on three logically different components: the traced process, the controller process, and the analyzer process. During the execution of the traced process, when a trace point is reached, a trace event is recorded into the trace streams created for that process in which the associated trace event type identifier is not being filtered out. The controller process controls the operation of recording the trace events into the trace stream. It shall be able to:

- Initialize the attributes of a trace stream
- Create the trace stream (for a specified traced process) using those attributes
- Start and stop tracing for the trace stream
- Filter the type of trace events to be recorded, if the Trace Event Filter option is supported
- Shut a trace stream down

These operations can be done for an active trace stream. The analyzer process retrieves the traced events either at runtime, when the trace stream has not yet been shut down, but is still recording trace events; or after opening a trace log that had been previously recorded and shut down. These three logically different operations can be performed by the same process, or can be
A trace stream identifier can be created by a call to `posix_trace_create()`, `posix_trace_create_withlog()`, or `posix_trace_open()`. The `posix_trace_create()` and `posix_trace_create_withlog()` functions should be used by a controller process. The `posix_trace_open()` should be used by an analyzer process.

The tracing functions can serve different purposes. One purpose is debugging the possibly pre-instrumented code, while another is post-mortem fault analysis. These two potential uses differ in that the first requires pre-filtering capabilities to avoid overwhelming the trace stream and permits focusing on expected information; while the second needs comprehensive trace capabilities in order to be able to record all types of information.

The events to be traced belong to two classes:

1. User trace events (generated by the application instrumentation)
2. System trace events (generated by the operating system)

The trace interface defines several system trace event types associated with control of and operation of the trace stream. This small set of system trace events includes the minimum required to interpret correctly the trace event information present in the stream. Other desirable system trace events for some particular application profile may be implemented and are encouraged; for example, process and thread scheduling, signal occurrence, and so on.

Each traced process shall have a mapping of the trace event names to trace event type identifiers that have been defined for that process. Each active trace stream shall have a mapping that incorporates all the trace event type identifiers predefined by the trace system plus all the mappings of trace event names to trace event type identifiers of the processes that are being traced into that trace stream. These mappings are defined from the instrumented application by calling the `posix_trace_eventid_open()` function and from the controller process by calling the `posix_trace_trid_eventid_open()` function. For a pre-recorded trace stream, the list of trace event types is obtained from the pre-recorded trace log.

The `st_ctime` and `st_mtime` fields of a file associated with an active trace stream shall be marked for update every time any of the tracing operations modifies that file.

The `st_atime` field of a file associated with a trace stream shall be marked for update every time any of the tracing operations causes data to be read from that file.

Results are undefined if the application performs any operation on a file descriptor associated with an active or pre-recorded trace stream until `posix_trace_shutdown()` or `posix_trace_close()` is called for that trace stream.

The main purpose of this option is to define a complete set of functions and concepts that allow a conforming application to be traced from creation to termination, whatever its realtime constraints and properties.

### 2.11.1 Tracing Data Definitions

#### 2.11.1.1 Structures

The `<trace.h>` header shall define the `posix_trace_status_info` and `posix_trace_event_info` structures described below. Implementations may add extensions to these structures.
Tracing

posix_trace_status_info Structure

To facilitate control of a trace stream, information about the current state of an active trace stream can be obtained dynamically. This structure is returned by a call to the posix_trace_get_status() function.

The posix_trace_status_info structure defined in <trace.h> shall contain at least the following members:

<table>
<thead>
<tr>
<th>Member Type</th>
<th>Member Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>int</td>
<td>posix_stream_status</td>
<td>The operating mode of the trace stream.</td>
</tr>
<tr>
<td>int</td>
<td>posix_stream_full_status</td>
<td>The full status of the trace stream.</td>
</tr>
<tr>
<td>int</td>
<td>posix_stream_overrun_status</td>
<td>Indicates whether trace events were lost in the trace stream.</td>
</tr>
</tbody>
</table>

If the Trace Log option is supported in addition to the Trace option, the posix_trace_status_info structure defined in <trace.h> shall contain at least the following additional members:

<table>
<thead>
<tr>
<th>Member Type</th>
<th>Member Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>int</td>
<td>posix_stream_flush_status</td>
<td>Indicates whether a flush is in progress.</td>
</tr>
<tr>
<td>int</td>
<td>posix_stream_flush_error</td>
<td>Indicates whether any error occurred during the last flush operation.</td>
</tr>
<tr>
<td>int</td>
<td>posix_log_overrun_status</td>
<td>Indicates whether trace events were lost in the trace log.</td>
</tr>
<tr>
<td>int</td>
<td>posix_log_full_status</td>
<td>The full status of the trace log.</td>
</tr>
</tbody>
</table>

The posix_stream_status member indicates the operating mode of the trace stream and shall have one of the following values defined by manifest constants in the <trace.h> header:

POSIX_TRACE_RUNNING
Tracing is in progress; that is, the trace stream is accepting trace events.

POSIX_TRACE_SUSPENDED
The trace stream is not accepting trace events. The tracing operation has not yet started or has stopped, either following a posix_trace_stop() function call or because the trace resources are exhausted.

The posix_stream_full_status member indicates the full status of the trace stream, and it shall have one of the following values defined by manifest constants in the <trace.h> header:

POSIX_TRACE_FULL
The space in the trace stream for trace events is exhausted.

POSIX_TRACE_NOT_FULL
There is still space available in the trace stream.

The combination of the posix_stream_status and posix_stream_full_status members also indicates the actual status of the stream. The status shall be interpreted as follows:

POSIX_TRACE_RUNNING and POSIX_TRACE_NOT_FULL
This status combination indicates that tracing is in progress, and there is space available for recording more trace events.

POSIX_TRACE_RUNNING and POSIX_TRACE_FULL
This status combination indicates that tracing is in progress and that the trace stream is full of trace events. This status combination cannot occur unless the stream-full-policy is set to
POSIX_TRACE_LOOP. The trace stream contains trace events recorded during a moving
time window of prior trace events, and some older trace events may have been overwritten
and thus lost.

POSIX_TRACE_SUSPENDED and POSIX_TRACE_NOT_FULL
This status combination indicates that tracing has not yet been started, has been stopped by
the posix_trace_stop() function, or has been cleared by the posix_trace_clear() function.

POSIX_TRACE_SUSPENDED and POSIX_TRACE_FULL
This status combination indicates that tracing has been stopped by the implementation
because the stream-full-policy attribute was POSIX_TRACE_UNTIL_FULL and trace
resources were exhausted, or that the trace stream was stopped by the function
posix_trace_stop() at a time when trace resources were exhausted.

The posix_stream_overrun_status member indicates whether trace events were lost in the trace
stream, and shall have one of the following values defined by manifest constants in the
<trace.h> header:

POSIX_TRACE_OVERRUN
At least one trace event was lost and thus was not recorded in the trace stream.

POSIX_TRACE_NO_OVERRUN
No trace events were lost.

When the corresponding trace stream is created, the posix_stream_overrun_status member shall be
set to POSIX_TRACE_NO_OVERRUN.

Whenever an overrun occurs, the posix_stream_overrun_status member shall be set to
POSIX_TRACE_OVERRUN.

An overrun occurs when:
• The policy is POSIX_TRACE_LOOP and a recorded trace event is overwritten.
• The policy is POSIX_TRACE_UNTIL_FULL and the trace stream is full when a trace event is
generated.
• If the Trace Log option is supported, the policy is POSIX_TRACE_FLUSH and at least one
trace event is lost while flushing the trace stream to the trace log.

The posix_stream_overrun_status member is reset to zero after its value is read.

If the Trace Log option is supported in addition to the Trace option, the posix_stream_flush_status,
posix_stream_flush_error, posix_log_overrun_status, and posix_log_full_status members are defined
as follows; otherwise, they are undefined.

The posix_stream_flush_status member indicates whether a flush operation is being performed
and shall have one of the following values defined by manifest constants in the header
<trace.h>:

POSIX_TRACE_FLUSHING
The trace stream is currently being flushed to the trace log.

POSIX_TRACE_NOT_FLUSHING
No flush operation is in progress.

The posix_stream_flush_status member shall be set to POSIX_TRACE_FLUSHING if a flush
operation is in progress either due to a call to the posix_trace_flush() function (explicit or caused
by a trace stream shutdown operation) or because the trace stream has become full with the
stream-full-policy attribute set to POSIX_TRACE_FLUSH. The posix_stream_flush_status member
shall be set to POSIX_TRACE_NOT_FLUSHING if no flush operation is in progress.
The `posix_stream_flush_error` member shall be set to zero if no error occurred during flushing. If an error occurred during a previous flushing operation, the `posix_stream_flush_error` member shall be set to the value of the first error that occurred. If more than one error occurs while flushing, error values after the first shall be discarded. The `posix_stream_flush_error` member is reset to zero after its value is read.

The `posix_log_overrun_status` member indicates whether trace events were lost in the trace log, and shall have one of the following values defined by manifest constants in the `<trace.h>` header:

- `POSIX_TRACE_OVERRUN`: At least one trace event was lost.
- `POSIX_TRACE_NO_OVERRUN`: No trace events were lost.

When the corresponding trace stream is created, the `posix_log_overrun_status` member shall be set to `POSIX_TRACE_NO_OVERRUN`. Whenever an overrun occurs, this status shall be set to `POSIX_TRACE_OVERRUN`. The `posix_log_overrun_status` member is reset to zero after its value is read.

The `posix_log_full_status` member indicates the full status of the trace log, and it shall have one of the following values defined by manifest constants in the `<trace.h>` header:

- `POSIX_TRACE_FULL`: The space in the trace log is exhausted.
- `POSIX_TRACE_NOT_FULL`: There is still space available in the trace log.

The `posix_log_full_status` member is only meaningful if the `log-full-policy` attribute is either `POSIX_TRACE_UNTIL_FULL` or `POSIX_TRACE_LOOP`.

For an active trace stream without log, that is created by the `posix_trace_create()` function, the `posix_log_overrun_status` member shall be set to `POSIX_TRACE_NO_OVERRUN` and the `posix_log_full_status` member shall be set to `POSIX_TRACE_NOT_FULL`.

### `posix_trace_event_info` Structure

The trace event structure `posix_trace_event_info` contains the information for one recorded trace event. This structure is returned by the set of functions `posix_trace_getnext_event()`, `posix_trace_timedgetnext_event()`, and `posix_trace_trygetnext_event()`.

The `posix_trace_event_info` structure defined in `<trace.h>` shall contain at least the following members:

<table>
<thead>
<tr>
<th>Member Type</th>
<th>Member Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>trace_event_id_t</code></td>
<td><code>posix_event_id</code></td>
<td>Trace event type identification.</td>
</tr>
<tr>
<td><code>pid_t</code></td>
<td><code>posix_pid</code></td>
<td>Process ID of the process that generated the trace event.</td>
</tr>
<tr>
<td><code>void *</code></td>
<td><code>posix_prog_address</code></td>
<td>Address at which the trace point was invoked.</td>
</tr>
<tr>
<td><code>int</code></td>
<td><code>posix_truncation_status</code></td>
<td>Status about the truncation of the data associated with this trace event.</td>
</tr>
<tr>
<td><code>struct timespec</code></td>
<td><code>posix_timestamp</code></td>
<td>Time at which the trace event was generated.</td>
</tr>
</tbody>
</table>

In addition, if the Trace option and the Threads option are both supported, the `posix_trace_event_info` structure defined in `<trace.h>` shall contain the following additional member:
The `posix_event_id` member represents the identification of the trace event type and its value is not directly defined by the user. This identification is returned by a call to one of the following functions: `posix_trace_trid_eventid_open()`, `posix_trace_eventtypelist_getnext_id()` , or `posix_trace_eventid_open()` . The name of the trace event type can be obtained by calling `posix_trace_eventid_get_name()` .

The `posix_pid` is the process identifier of the traced process which generated the trace event. If the `posix_event_id` member is one of the implementation-defined system trace events and that trace event is not associated with any process, the `posix_pid` member shall be set to zero.

For a user trace event, the `posix_prog_address` member is the process mapped address of the point at which the associated call to the `posix_trace_event()` function was made. For a system trace event, if the trace event is caused by a system service explicitly called by the application, the `posix_prog_address` member shall be the address of the process at the point where the call to that system service was made.

The `posix_truncation_status` member defines whether the data associated with a trace event has been truncated at the time the trace event was generated, or at the time the trace event was read from the trace stream, or (if the Trace Log option is supported) from the trace log (see the `event` argument from the `posix_trace_getnext_event()` function). The `posix_truncation_status` member shall have one of the following values defined by manifest constants in the `<trace.h>` header:

- `POSIX_TRACE_NOT_TRUNCATED` All the traced data is available.
- `POSIX_TRACE_TRUNCATED_RECORD` Data was truncated at the time the trace event was generated.
- `POSIX_TRACE_TRUNCATED_READ` Data was truncated at the time the trace event was read from a trace stream or a trace log because the reader’s buffer was too small. This truncation status overrides the `POSIX_TRACE_TRUNCATED_RECORD` status.

The `posix_timestamp` member shall be the time at which the trace event was generated. The clock used is implementation-defined, but the resolution of this clock can be retrieved by a call to the `posix_trace_attr_getclockres()` function.

If the Threads option is supported in addition to the Trace option:

- The `posix_thread_id` member is the identifier of the thread that generated the trace event. If the `posix_event_id` member is one of the implementation-defined system trace events and that trace event is not associated with any thread, the `posix_thread_id` member shall be set to zero.

Otherwise, this member is undefined.

### 2.11.1.2 Trace Stream Attributes

Trace streams have attributes that compose the `posix_trace Attr_t` trace stream attributes object. This object shall contain at least the following attributes:

- The `generation-version` attribute identifies the origin and version of the trace system.
Tracing

3111 • The trace-name attribute is a character string defined by the trace controller, and that
3112 identifies the trace stream.
3113 • The creation-time attribute represents the time of the creation of the trace stream.
3114 • The clock-resolution attribute defines the clock resolution of the clock used to generate
3115 timestamps.
3116 • The stream-min-size attribute defines the minimum size in bytes of the trace stream strictly
3117 reserved for the trace events.
3118 • The stream-full-policy attribute defines the policy followed when the trace stream is full; its
3119 value is POSIX_TRACE_LOOP, POSIX_TRACE_UNTIL_FULL, or POSIX_TRACE_FLUSH.
3120 • The max-data-size attribute defines the maximum record size in bytes of a trace event.
3121 In addition, if the Trace option and the Trace Inherit option are both supported, the
3122 posix_trace_attr_t trace stream creation attributes object shall contain at least the following
3123 attributes:
3124 • The inheritance attribute specifies whether a newly created trace stream will inherit tracing in
3125 its parent’s process trace stream. It is either POSIX_TRACE_INHERITED or
3126 POSIX_TRACE_CLOSE_FOR_CHILD.
3127 In addition, if the Trace option and the Trace Log option are both supported, the
3128 posix_trace_attr_t trace stream creation attributes object shall contain at least the following
3129 attribute:
3130 • If the file type corresponding to the trace log supports the POSIX_TRACE_LOOP or the
3131 POSIX_TRACE_UNTIL_FULL policies, the log-max-size attribute defines the maximum size
3132 in bytes of the trace log associated with an active trace stream. Other stream data—for
3133 example, trace attribute values—shall not be included in this size.
3134 • The log-full-policy attribute defines the policy of a trace log associated with an active trace
3135 stream to be POSIX_TRACE_LOOP, POSIX_TRACE_UNTIL_FULL, or
3136 POSIX_TRACE_APPEND.

2.11.2 Trace Event Type Definitions

2.11.2.1 System Trace Event Type Definitions

The following system trace event types, defined in the <trace.h> header, track the invocation of
the trace operations:

• POSIX_TRACE_START shall be associated with a trace start operation.
• POSIX_TRACE_STOP shall be associated with a trace stop operation.
• If the Trace Event Filter option is supported, POSIX_TRACE_FILTER shall be associated with
a trace event type filter change operation.

The following system trace event types, defined in the <trace.h> header, report operational trace
events:

• POSIX_TRACE_OVERFLOW shall mark the beginning of a trace overflow condition.
• POSIX_TRACE_RESUME shall mark the end of a trace overflow condition.
• If the Trace Log option is supported, POSIX_TRACE_FLUSH_START shall mark the
beginning of a flush operation.
If the Trace Log option is supported, POSIX_TRACE_FLUSH_STOP shall mark the end of a flush operation.

If an implementation-defined trace error condition is reported, it shall be marked POSIX_TRACE_ERROR.

The interpretation of a trace stream or a trace log by a trace analyzer process relies on the information recorded for each trace event, and also on system trace events that indicate the invocation of trace control operations and trace system operational trace events.

The POSIX_TRACE_START and POSIX_TRACE_STOP trace events specify the time windows during which the trace stream is running.

- The POSIX_TRACE_STOP trace event with an associated data that is equal to zero indicates a call of the function `posix_trace_stop()`.
- The POSIX_TRACE_STOP trace event with an associated data that is different from zero indicates an automatic stop of the trace stream (see `posix_trace_attr_getstreamfullpolicy()`).

The POSIX_TRACE_FILTER trace event indicates that a trace event type filter value changed while the trace stream was running.

The POSIX_TRACE_ERROR serves to inform the analyzer process that an implementation-defined internal error of the trace system occurred.

The POSIX_TRACE_OVERFLOW trace event shall be reported with a timestamp equal to the timestamp of the first trace event overwritten. This is an indication that some generated trace events have been lost.

The POSIX_TRACE_RESUME trace event shall be reported with a timestamp equal to the timestamp of the first valid trace event reported after the overflow condition ends and shall be reported before this first valid trace event. This is an indication that the trace system is reliably recording trace events after an overflow condition.

Each of these trace event types shall be defined by a constant trace event name and a `trace_event_id_t` constant; trace event data is associated with some of these trace events.

If the Trace option is supported and the Trace Event Filter option and the Trace Log option are not supported, the following predefined system trace events in Table 2-3 shall be defined:

<table>
<thead>
<tr>
<th>Event Name</th>
<th>Constant</th>
<th>Associated Data</th>
<th>Data Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>posix_trace_error</td>
<td>POSIX_TRACE_ERROR</td>
<td>error</td>
<td>int</td>
</tr>
<tr>
<td>posix_trace_start</td>
<td>POSIX_TRACE_START</td>
<td>None.</td>
<td></td>
</tr>
<tr>
<td>posix_trace_stop</td>
<td>POSIX_TRACE_STOP</td>
<td>auto</td>
<td>int</td>
</tr>
<tr>
<td>posix_trace_overflow</td>
<td>POSIX_TRACE_OVERFLOW</td>
<td>None.</td>
<td></td>
</tr>
<tr>
<td>posix_trace_resume</td>
<td>POSIX_TRACE_RESUME</td>
<td>None.</td>
<td></td>
</tr>
</tbody>
</table>

If the Trace option and the Trace Event Filter option are both supported, and if the Trace Log option is not supported, the following predefined system trace events in Table 2-4 (on page 78) shall be defined:
### Table 2-4 Trace and Trace Event Filter Options: System Trace Events

<table>
<thead>
<tr>
<th>Event Name</th>
<th>Constant</th>
<th>Associated Data</th>
</tr>
</thead>
<tbody>
<tr>
<td>posix_trace_error</td>
<td>POSIX_TRACE_ERROR</td>
<td>error</td>
</tr>
<tr>
<td>posix_trace_start</td>
<td>POSIX_TRACE_START</td>
<td>event_filter</td>
</tr>
<tr>
<td>posix_trace_stop</td>
<td>POSIX_TRACE_STOP</td>
<td>auto</td>
</tr>
<tr>
<td>posix_trace_filter</td>
<td>POSIX_TRACE_FILTER</td>
<td>old_event_filter, new_event_filter</td>
</tr>
<tr>
<td>posix_trace_overflow</td>
<td>POSIX_TRACE_OVERFLOW</td>
<td>None.</td>
</tr>
<tr>
<td>posix_trace_resume</td>
<td>POSIX_TRACE_RESUME</td>
<td>None.</td>
</tr>
</tbody>
</table>

If the Trace option and the Trace Log option are both supported, and if the Trace Event Filter option is not supported, the following predefined system trace events in Table 2-5 shall be defined:

### Table 2-5 Trace and Trace Log Options: System Trace Events

<table>
<thead>
<tr>
<th>Event Name</th>
<th>Constant</th>
<th>Associated Data</th>
</tr>
</thead>
<tbody>
<tr>
<td>posix_trace_error</td>
<td>POSIX_TRACE_ERROR</td>
<td>error</td>
</tr>
<tr>
<td>posix_trace_start</td>
<td>POSIX_TRACE_START</td>
<td>None.</td>
</tr>
<tr>
<td>posix_trace_stop</td>
<td>POSIX_TRACE_STOP</td>
<td>auto</td>
</tr>
<tr>
<td>posix_trace_filter</td>
<td>POSIX_TRACE_FILTER</td>
<td>None.</td>
</tr>
<tr>
<td>posix_trace_overflow</td>
<td>POSIX_TRACE_OVERFLOW</td>
<td>None.</td>
</tr>
<tr>
<td>posix_trace_resume</td>
<td>POSIX_TRACE_RESUME</td>
<td>None.</td>
</tr>
</tbody>
</table>

If the Trace option, the Trace Event Filter option, and the Trace Log option are all supported, the following predefined system trace events in Table 2-6 (on page 79) shall be defined:
Table 2-6  Trace, Trace Log, and Trace Event Filter Options: System Trace Events

<table>
<thead>
<tr>
<th>Event Name</th>
<th>Constant</th>
<th>Associated Data</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Data Type</td>
<td></td>
</tr>
<tr>
<td>posix_trace_error</td>
<td>POSIX_TRACE_ERROR</td>
<td>error</td>
</tr>
<tr>
<td></td>
<td>int</td>
<td></td>
</tr>
<tr>
<td>posix_trace_start</td>
<td>POSIX_TRACE_START</td>

2.11.2.2 User Trace Event Type Definitions

The user trace event POSIX_TRACE_UNNAMED_USEREVENT is defined in the <trace.h> header. If the limit of per-process user trace event names represented by (TRACE_USER_EVENT_MAX) has already been reached, this predefined user event shall be returned when the application tries to register more events than allowed. The data associated with this trace event is application-defined.

The following predefined user trace event in Table 2-7 shall be defined:

Table 2-7  Trace Option: User Trace Event

<table>

<tr>
<th>Event Name</th>
<th>Constant</th>
</tr>
</thead>
<tbody>
<tr>
<td>posix_trace_unnamed_userevent</td>
<td>POSIX_TRACE_UNNAMED_USEREVENT</td>
</tr>
</tbody>
</table>

2.11.3 Trace Functions

The trace interface is built and structured to improve portability through use of trace data of opaque type. The object-oriented approach for the manipulation of trace attributes and trace event type identifiers requires definition of many constructor and selector functions which operate on these opaque types. Also, the trace interface must support several different tracing roles. To facilitate reading the trace interface, the trace functions are grouped into small functional sets supporting the three different roles:

- A trace controller process requires functions to set up and customize all the resources needed to run a trace stream, including:
  - Attribute initialization and destruction (posix_trace_attr_init())
  - Identification information manipulation (posix_trace_attr_getgenversion())
  - Trace system behavior modification (posix_trace_attr_getinherited())
  - Trace stream and trace log size set (posix_trace_attr_getmaxusereventsize())
— Trace stream creation, flush, and shutdown (posix_trace_create())
— Trace stream and trace log clear (posix_trace_clear())
— Trace event type identifier manipulation (posix_trace_trid_eventid_open())
— Trace event type identifier list exploration (posix_trace_eventtypelist_getnext_id())
— Trace event type set manipulation (posix_trace_eventset_empty())
— Trace event type filter set (posix_trace_set_filter())
— Trace stream start and stop (posix_trace_start())
— Trace stream information and status read (posix_trace_get_attr())

• A traced process requires functions to instrument trace points:
  — Trace event type identifiers definition and trace points insertion (posix_trace_event())

• A trace analyzer process requires functions to retrieve information from a trace stream and trace log:
  — Identification information read (posix_trace_attr_getgenversion())
  — Trace system behavior information read (posix_trace_attr_getinherited())
  — Trace stream and trace log size get (posix_trace_attr_getmaxusereventsizes())
  — Trace event type identifier manipulation (posix_trace_trid_eventid_open())
  — Trace event type identifier list exploration (posix_trace_eventtypelist_getnext_id())
  — Trace log open, rewind, and close (posix_trace_open())
  — Trace stream information and status read (posix_trace_get_attr())
  — Trace event read (posix_trace_getnext_event())

### 2.12 Data Types

All of the data types used by various functions are defined by the implementation. The following table describes some of these types. Other types referenced in the description of a function, not mentioned here, can be found in the appropriate header for that function.

<table>
<thead>
<tr>
<th>Defined Type</th>
<th>Description</th>
</tr>

This chapter describes the functions, macros, and external variables to support applications portability at the C-language source level.
NAME
FD_CLR — macros for synchronous I/O multiplexing

SYNOPSIS
#include <sys/time.h>

FD_CLR(int fd, fd_set *fdset);
FD_ISSET(int fd, fd_set *fdset);
FD_SET(int fd, fd_set *fdset);
FD_ZERO(fd_set *fdset);

DESCRIPTION
Refer to pselect().
NAME
_exit, _exit — terminate a process

SYNOPSIS
#include <stdlib.h>
void _Exit(int status);
#include <unistd.h>
void _exit(int status);

DESCRIPTION
Refer to exit().
NAME

_longjmp, _setjmp — non-local goto

SYNOPSIS

XSI
#include <setjmp.h>

void _longjmp(jmp_buf env, int val);
int _setjmp(jmp_buf env);

DESCRIPTION
The _longjmp() and _setjmp() functions shall be equivalent to longjmp() and setjmp(),
respectively, with the additional restriction that _longjmp() and _setjmp() shall not manipulate
the signal mask.

If _longjmp() is called even though env was never initialized by a call to _setjmp(), or when the
last such call was in a function that has since returned, the results are undefined.

RETURN VALUE
Refer to longjmp() and setjmp().

ERRORS
No errors are defined.

EXAMPLES
None.

APPLICATION USAGE
If _longjmp() is executed and the environment in which _setjmp() was executed no longer exists,
errors can occur. The conditions under which the environment of the _setjmp() no longer exists
include exiting the function that contains the _setjmp() call, and exiting an inner block with
temporary storage. This condition might not be detectable, in which case the _longjmp() occurs
and, if the environment no longer exists, the contents of the temporary storage of an inner block
are unpredictable. This condition might also cause unexpected process termination. If the
function has returned, the results are undefined.

Passing longjmp() a pointer to a buffer not created by setjmp(), passing _longjmp() a pointer to a
buffer not created by _setjmp(), passing siglongjmp() a pointer to a buffer not created by
sigsetjmp(), or passing any of these three functions a buffer that has been modified by the user
can cause all the problems listed above, and more.

The _longjmp() and _setjmp() functions are included to support programs written to historical
system interfaces. New applications should use siglongjmp() and sigsetjmp() respectively.

RATIONALE
None.

FUTURE DIRECTIONS
The _longjmp() and _setjmp() functions may be marked LEGACY in a future version.

NAME
_tolower — transliterate uppercase characters to lowercase

SYNOPSIS
XSI
#include <ctype.h>
int _tolower(int c);

DESCRIPTION
The _tolower() macro shall be equivalent to tolower(c) except that the application shall ensure
that the argument c is an uppercase letter.

RETURN VALUE
Upon successful completion, _tolower() shall return the lowercase letter corresponding to the
argument passed.

ERRORS
No errors are defined.

EXAMPLES
None.

APPLICATION USAGE
None.

RATIONALE
None.

FUTURE DIRECTIONS
None.

NAME
a64l, l64a — convert between a 32-bit integer and a radix-64 ASCII string

SYNOPSIS
XSI
#include <stdlib.h>

long a64l(const char *s);
char *l64a(long value);

DESCRIPTION
These functions maintain numbers stored in radix-64 ASCII characters. This is a notation by which 32-bit integers can be represented by up to six characters; each character represents a digit in radix-64 notation. If the type long contains more than 32 bits, only the low-order 32 bits shall be used for these operations.

The characters used to represent digits are ‘.’ (dot) for 0, ‘/’ for 1, ‘0’ through ‘9’ for [2,11], ‘A’ through ‘Z’ for [12,37], and ‘a’ through ‘z’ for [38,63].

The a64l() function shall take a pointer to a radix-64 representation, in which the first digit is the least significant, and return the corresponding long value. If the string pointed to by s contains more than six characters, a64l() shall use the first six. If the first six characters of the string contain a null terminator, a64l() shall use only characters preceding the null terminator. The a64l() function shall scan the character string from left to right with the least significant digit on the left, decoding each character as a 6-bit radix-64 number. If the type long contains more than 32 bits, the resulting value is sign-extended. The behavior of a64l() is unspecified if s is a null pointer or the string pointed to by s was not generated by a previous call to l64a().

The l64a() function shall take a long argument and return a pointer to the corresponding radix-64 representation. The behavior of l64a() is unspecified if value is negative.

The value returned by l64a() may be a pointer into a static buffer. Subsequent calls to l64a() may overwrite the buffer.

The l64a() function need not be reentrant. A function that is not required to be reentrant is not required to be thread-safe.

RETURN VALUE
Upon successful completion, a64l() shall return the long value resulting from conversion of the input string. If a string pointed to by s is an empty string, a64l() shall return 0L.

The l64a() function shall return a pointer to the radix-64 representation. If value is 0L, l64a() shall return a pointer to an empty string.

ERRORS
No errors are defined.

EXAMPLES
None.

APPLICATION USAGE
If the type long contains more than 32 bits, the result of a64l(l64a(x)) is x in the low-order 32 bits.

RATIONALE
This is not the same encoding as used by either encoding variant of the uuencode utility.
FUTURE DIRECTIONS
None.

SEE ALSO
stdout(), the Base Definitions volume of IEEE Std 1003.1-2001, <stdlib.h>, the Shell and Utilities
volume of IEEE Std 1003.1-2001, uuencode

CHANGE HISTORY
First released in Issue 4, Version 2.

Issue 5
Moved from X/OPEN UNIX extension to BASE.
Normative text previously in the APPLICATION USAGE section is moved to the
DESCRIPTION.
A note indicating that these functions need not be reentrant is added to the DESCRIPTION.
NAME
abort — generate an abnormal process abort

SYNOPSIS
#include <stdlib.h>

void abort(void);

DESCRIPTION
The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-2001 defers to the ISO C standard.
The abort() function shall cause abnormal process termination to occur, unless the signal SIGABRT is being caught and the signal handler does not return.
The abnormal termination processing shall include the default actions defined for SIGABRT and may include an attempt to effect fclose() on all open streams.
The SIGABRT signal shall be sent to the calling process as if by means of raise() with the argument SIGABRT.
The status made available to wait() or waitpid() by abort() shall be that of a process terminated by the SIGABRT signal. The abort() function shall override blocking or ignoring the SIGABRT signal.

RETURN VALUE
The abort() function shall not return.

ERRORS
No errors are defined.

EXAMPLES
None.

APPLICATION USAGE
Catching the signal is intended to provide the application writer with a portable means to abort processing, free from possible interference from any implementation-defined functions.

RATIONALE
The ISO/IEC 9899:1999 standard requires the abort() function to be async-signal-safe. Since IEEE Std 1003.1-2001 defers to the ISO C standard, this required a change to the DESCRIPTION from “shall include the effect of fclose()” to “may include an attempt to effect fclose().”
The revised wording permits some backwards-compatibility and avoids a potential deadlock situation.
The Open Group Base Resolution bwg2002-003 is applied, removing the following XSI shaded paragraph from the DESCRIPTION:
“On XSI-conformant systems, in addition the abnormal termination processing shall include the effect of fclose() on message catalog descriptors.”
There were several reasons to remove this paragraph:
• No special processing of open message catalogs needs to be performed prior to abnormal process termination.
• The main reason to specifically mention that abort() includes the effect of fclose() on open streams is to flush output queued on the stream. Message catalogs in this context are read-only and, therefore, do not need to be flushed.
• The effect of `fclose()` on a message catalog descriptor is unspecified. Message catalog descriptors are allowed, but not required to be implemented using a file descriptor, but there is no mention in IEEE Std 1003.1-2001 of a message catalog descriptor using a standard I/O stream FILE object as would be expected by `fclose()`.

**FUTURE DIRECTIONS**
None.

**SEE ALSO**
`exit()`, `kill()`, `raise()`, `signal()`, `wait()`, `waitpid()`, the Base Definitions volume of IEEE Std 1003.1-2001, `<stdlib.h>`

**CHANGE HISTORY**
First released in Issue 1. Derived from Issue 1 of the SVID.

**Issue 6**
Extensions beyond the ISO C standard are marked.
Changes are made to the DESCRIPTION for alignment with the ISO/IEC 9899: 1999 standard.
The Open Group Base Resolution bwg2002-003 is applied.
IEEE Std 1003.1-2001/C1-2002, item XSH/TC1/D6/10 is applied, changing the DESCRIPTION of abnormal termination processing and adding to the RATIONALE section.
abs()

NAME
abs — return an integer absolute value

SYNOPSIS
#include <stdlib.h>

int abs(int i);

DESCRIPTION
CX The functionality described on this reference page is aligned with the ISO C standard. Any
collision between the requirements described here and the ISO C standard is unintentional. This
The abs() function shall compute the absolute value of its integer operand, i. If the result cannot
be represented, the behavior is undefined.

RETURN VALUE
The abs() function shall return the absolute value of its integer operand.

ERRORS
No errors are defined.

EXAMPLES
None.

APPLICATION USAGE
In two's-complement representation, the absolute value of the negative integer with largest
magnitude [INT_MIN] might not be representable.

RATIONALE
None.

FUTURE DIRECTIONS
None.

Extensions beyond the ISO C standard are marked.
NAME
accept — accept a new connection on a socket

SYNOPSIS
#include <sys/socket.h>

int accept(int socket, struct sockaddr *restrict address,
socklen_t *restrict address_len);

DESCRIPTION
The accept() function shall extract the first connection on the queue of pending connections,
create a new socket with the same socket type protocol and address family as the specified
socket, and allocate a new file descriptor for that socket.

The accept() function takes the following arguments:
socket Specifies a socket that was created with socket(), has been bound to an address
with bind(), and has issued a successful call to listen().
address Either a null pointer, or a pointer to a sockaddr structure where the address of
the connecting socket shall be returned.
address_len Points to a socklen_t structure which on input specifies the length of the
supplied sockaddr structure, and on output specifies the length of the stored
address.

If address is not a null pointer, the address of the peer for the accepted connection shall be stored
in the sockaddr structure pointed to by address, and the length of this address shall be stored in
the object pointed to by address_len.

If the actual length of the address is greater than the length of the supplied sockaddr structure,
the stored address shall be truncated.

If the protocol permits connections by unbound clients, and the peer is not bound, then the value
stored in the object pointed to by address is unspecified.

If the listen queue is empty of connection requests and O_NONBLOCK is not set on the file
descriptor for the socket, accept() shall block until a connection is present. If the listen() queue is
empty of connection requests and O_NONBLOCK is set on the file descriptor for the socket,
accept() shall fail and set errno to [EAGAIN] or [EWOULDBLOCK].

The accepted socket cannot itself accept more connections. The original socket remains open and
can accept more connections.

RETURN VALUE
Upon successful completion, accept() shall return the non-negative file descriptor of the accepted
socket. Otherwise, −1 shall be returned and errno set to indicate the error.

ERRORS
The accept() function shall fail if:

[EAGAIN] or [EWOULDBLOCK]
O_NONBLOCK is set for the socket file descriptor and no connections are
present to be accepted.

[EBADF] The socket argument is not a valid file descriptor.

[ECONNABORTED] A connection has been aborted.
accept()  

The accept() function was interrupted by a signal that was caught before a valid connection arrived.

The socket is not accepting connections.

[OPEN_MAX] file descriptors are currently open in the calling process.

The maximum number of file descriptors in the system are already open.

The socket argument does not refer to a socket.

The socket type of the specified socket does not support accepting connections.

The accept() function may fail if:

No buffer space is available.

There was insufficient memory available to complete the operation.

A protocol error has occurred; for example, the STREAMS protocol stack has not been initialized.

EXAMPLES

None.

APPLICATION USAGE

When a connection is available, select() indicates that the file descriptor for the socket is ready for reading.

RATIONALE

None.

FUTURE DIRECTIONS

None.

SEE ALSO

bind(), connect(), listen(), socket(), the Base Definitions volume of IEEE Std 1003.1-2001, <sys/socket.h>

CHANGE HISTORY

First released in Issue 6. Derived from the XNS, Issue 5.2 specification.

The restrict keyword is added to the accept() prototype for alignment with the ISO/IEC 9899:1999 standard.
NAME
access — determine accessibility of a file

SYNOPSIS
#include <unistd.h>
int access(const char *path, int amode);

DESCRIPTION
The access() function shall check the file named by the pathname pointed to by the path argument for accessibility according to the bit pattern contained in amode, using the real user ID in place of the effective user ID and the real group ID in place of the effective group ID.

The value of amode is either the bitwise-inclusive OR of the access permissions to be checked (R_OK, W_OK, X_OK) or the existence test (F_OK).

If any access permissions are checked, each shall be checked individually, as described in the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 3, Definitions. If the process has appropriate privileges, an implementation may indicate success for X_OK even if none of the execute file permission bits are set.

RETURN VALUE
If the requested access is permitted, access() succeeds and shall return 0; otherwise, –1 shall be returned and errno shall be set to indicate the error.

ERRORS
The access() function shall fail if:

[EACCES] Permission bits of the file mode do not permit the requested access, or search permission is denied on a component of the path prefix.

[ELOOP] A loop exists in symbolic links encountered during resolution of the path argument.

[ENAMETOOLONG] The length of the path argument exceeds {PATH_MAX} or a pathname component is longer than {NAME_MAX}.

[ENOENT] A component of path does not name an existing file or path is an empty string.

[ENOTDIR] A component of the path prefix is not a directory.

[EROFS] Write access is requested for a file on a read-only file system.

The access() function may fail if:

[EINVAL] The value of the amode argument is invalid.

[ELOOP] More than {SYMLOOP_MAX} symbolic links were encountered during resolution of the path argument.

[ENAMETOOLONG] As a result of encountering a symbolic link in resolution of the path argument, the length of the substituted pathname string exceeded {PATH_MAX}.

[ETXTBSY] Write access is requested for a pure procedure (shared text) file that is being executed.
EXAMPLES

Testing for the Existence of a File

The following example tests whether a file named \texttt{myfile} exists in the \texttt{/tmp} directory.

```c
#include <unistd.h>
...
int result;
const char *filename = "/tmp/myfile";
result = access (filename, F_OK);
```

APPLICATION USAGE

Additional values of \texttt{amode} other than the set defined in the description may be valid; for example, if a system has extended access controls.

RATIONALE

In early proposals, some inadequacies in the \texttt{access()} function led to the creation of an \texttt{eaccess()} function because:

1. Historical implementations of \texttt{access()} do not test file access correctly when the process' real user ID is superuser. In particular, they always return zero when testing execute permissions without regard to whether the file is executable.
2. The superuser has complete access to all files on a system. As a consequence, programs started by the superuser and switched to the effective user ID with lesser privileges cannot use \texttt{access()} to test their file access permissions.

However, the historical model of \texttt{eaccess()} does not resolve problem (1), so this volume of IEEE Std 1003.1-2001 now allows \texttt{access()} to behave in the desired way because several implementations have corrected the problem. It was also argued that problem (2) is more easily solved by using \texttt{open()}, \texttt{chdir()}, or one of the \texttt{exec} functions as appropriate and responding to the error, rather than creating a new function that would not be as reliable. Therefore, \texttt{eaccess()} is not included in this volume of IEEE Std 1003.1-2001.

The sentence concerning appropriate privileges and execute permission bits reflects the two possibilities implemented by historical implementations when checking superuser access for \texttt{X_OK}.

New implementations are discouraged from returning \texttt{X_OK} unless at least one execution permission bit is set.

FUTURE DIRECTIONS

None.

SEE ALSO

\texttt{chmod()}, \texttt{stat()}, the Base Definitions volume of IEEE Std 1003.1-2001, \texttt{<unistd.h>}

CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 6

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The [ELOOP] mandatory error condition is added.
- A second [ENAMETOOLONG] is added as an optional error condition.
- The [ETXTBSY] optional error condition is added.

The following changes were made to align with the IEEE P1003.1a draft standard:
- The [ELOOP] optional error condition is added.
acos()

NAME
acos, acosf, acosl — arc cosine functions

SYNOPSIS
#include <math.h>

double acos(double x);
float acosf(float x);
long double acosl(long double x);

DESCRIPTION
The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-2001 defers to the ISO C standard.

These functions shall compute the principal value of the arc cosine of their argument x. The value of x should be in the range [-1,1].

An application wishing to check for error situations should set errno to zero and call feclearexcept(FE_ALL_EXCEPT) before calling these functions. On return, if errno is non-zero or fetestexcept(FE_INVALID | FE_DIVBYZERO | FE_OVERFLOW | FE_UNDERFLOW) is non-zero, an error has occurred.

RETURN VALUE
Upon successful completion, these functions shall return the arc cosine of x, in the range [0, \pi] radians.

For finite values of x not in the range [-1,1], a domain error shall occur, and either a NaN (if supported), or an implementation-defined value shall be returned.

If x is NaN, a NaN shall be returned.

If x is +1, +0 shall be returned.

If x is ±Inf, a domain error shall occur, and either a NaN (if supported), or an implementation-defined value shall be returned.

ERRORS
These functions shall fail if:

Domain Error The x argument is finite and is not in the range [-1,1], or is ±Inf.

If the integer expression (math_errhandling & MATH_ERRNO) is non-zero, then errno shall be set to [EDOM]. If the integer expression (math_errhandling & MATH_ERREXCEPT) is non-zero, then the invalid floating-point exception shall be raised.

EXAMPLES
None.

APPLICATION USAGE
On error, the expressions (math_errhandling & MATH_ERRNO) and (math_errhandling & MATH_ERREXCEPT) are independent of each other, but at least one of them must be non-zero.

RATIONALE
None.
**FUTURE DIRECTIONS**

None.

**CHANGE HISTORY**

First released in Issue 1. Derived from Issue 1 of the SVID.

**Issue 5**

The DESCRIPTION is updated to indicate how an application should check for an error. This text was previously published in the APPLICATION USAGE section.

**Issue 6**

The `acosf()` and `acosl()` functions are added for alignment with the ISO/IEC 9899:1999 standard.

The DESCRIPTION, RETURN VALUE, ERRORS, and APPLICATION USAGE sections are revised to align with the ISO/IEC 9899:1999 standard.

NAME
acosh, acoshf, acoshl — inverse hyperbolic cosine functions

SYNOPSIS
#include <math.h>
double acosh(double x);
float acoshf(float x);
long double acoshl(long double x);

DESCRIPTION
The functionality described on this reference page is aligned with the ISO C standard. Any
conflict between the requirements described here and the ISO C standard is unintentional. This

These functions shall compute the inverse hyperbolic cosine of their argument x.

An application wishing to check for error situations should set errno to zero and call
feclearexcept(FE_ALL_EXCEPT) before calling these functions. On return, if errno is non-zero or
fetestexcept(FE_INVALID | FE_DIVBYZERO | FE_OVERFLOW | FE_UNDERFLOW) is non-zero, an error has occurred.

RETURN VALUE
Upon successful completion, these functions shall return the inverse hyperbolic cosine of their
argument.

MX For finite values of x < 1, a domain error shall occur, and either a NaN (if supported), or an
implementation-defined value shall be returned.

MX If x is NaN, a NaN shall be returned.

If x is +1, +0 shall be returned.

If x is +Inf, +Inf shall be returned.

If x is −Inf, a domain error shall occur, and either a NaN (if supported), or an implementation-
defined value shall be returned.

ERRORS
These functions shall fail if:

MX Domain Error The x argument is finite and less than +1.0, or is −Inf.

If the integer expression (math_errno & MATH_ERRNO) is non-zero, then errno shall be set to [EDOM]. If the integer expression (math_errno & MATH_ERREXCEPT) is non-zero, then the invalid floating-point exception shall be raised.

EXAMPLES
None.

APPLICATION USAGE
On error, the expressions (math_errno & MATH_ERRNO) and (math_errno & MATH_ERREXCEPT) are independent of each other, but at least one of them must be non-zero.

RATIONALE
None.
FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 4, Version 2.

Issue 5

Moved from X/OPEN UNIX extension to BASE.

Issue 6

The acosh() function is no longer marked as an extension.

The acoshf() and acoshl() functions are added for alignment with the ISO/IEC 9899:1999 standard.

The DESCRIPTION, RETURN VALUE, ERRORS, and APPLICATION USAGE sections are revised to align with the ISO/IEC 9899:1999 standard.

acosl()

NAME
acosl — arc cosine functions

SYNOPSIS
#include <math.h>

long double acosl(long double x);

DESCRIPTION
Refer to acos().
NAME
aio_cancel — cancel an asynchronous I/O request (REALTIME)

SYNOPSIS
#include <aio.h>

int aio_cancel(int fildes, struct aiocb *aiocbp);

DESCRIPTION
The aio_cancel() function shall attempt to cancel one or more asynchronous I/O requests currently outstanding against file descriptor fildes. The aiocbp argument points to the asynchronous I/O control block for a particular request to be canceled. If aiocbp is NULL, then all outstanding cancelable asynchronous I/O requests against fildes shall be canceled.

Normal asynchronous notification shall occur for asynchronous I/O operations that are successfully canceled. If there are requests that cannot be canceled, then the normal asynchronous completion process shall take place for those requests when they are completed.

For requested operations that are successfully canceled, the associated error status shall be set to [ECANCELED] and the return status shall be −1. For requested operations that are not successfully canceled, the aiocbp shall not be modified by aio_cancel().

If aiocbp is not NULL, then if fildes does not have the same value as the file descriptor with which the asynchronous operation was initiated, unspecified results occur.

Which operations are cancelable is implementation-defined.

RETURN VALUE
The aio_cancel() function shall return the value AIO_CANCELED to the calling process if the requested operation(s) were canceled. The value AIO_NOTCANCELED shall be returned if at least one of the requested operation(s) cannot be canceled because it is in progress. In this case, the state of the other operations, if any, referenced in the call to aio_cancel() is not indicated by the return value of aio_cancel(). The application may determine the state of affairs for these operations by using aio_error(). The value AIO_ALLDONE is returned if all of the operations have already completed. Otherwise, the function shall return −1 and set errno to indicate the error.

ERRORS
The aio_cancel() function shall fail if:

[EBADF] The fildes argument is not a valid file descriptor.

EXAMPLES
None.

APPLICATION USAGE
The aio_cancel() function is part of the Asynchronous Input and Output option and need not be available on all implementations.

RATIONALE
None.

FUTURE DIRECTIONS
None.

Issue 6

The [ENOSYS] error condition has been removed as stubs need not be provided if an implementation does not support the Asynchronous Input and Output option.

The APPLICATION USAGE section is added.
NAME
aio_error — retrieve errors status for an asynchronous I/O operation (REALTIME)

SYNOPSIS
#include <aio.h>

int aio_error(const struct aiocb *aiocbp);

DESCRIPTION
The aio_error() function shall return the error status associated with the aiocb structure
referenced by the aiocbp argument. The error status for an asynchronous I/O operation is the
errno value that would be set by the corresponding read(), write(), fdatasync(), or fsync() operation. If the operation has not yet completed, then the error status shall be equal to
[EINPROGRESS].

RETURN VALUE
If the asynchronous I/O operation has completed successfully, then 0 shall be returned. If the
asynchronous operation has completed unsuccessfully, then the error status, as described for
read(), write(), fdatasync(), and fsync(), shall be returned. If the asynchronous I/O operation has
not yet completed, then [EINPROGRESS] shall be returned.

ERRORS
The aio_error() function may fail if:

[EINVAL]  The aiocbp argument does not refer to an asynchronous operation whose
return status has not yet been retrieved.

EXAMPLES
None.

APPLICATION USAGE
The aio_error() function is part of the Asynchronous Input and Output option and need not be
available on all implementations.

RATIONALE
None.

FUTURE DIRECTIONS
None.

CHANGE HISTORY
First released in Issue 5. Included for alignment with the POSIX Realtime Extension.

Issue 6
The [ENOSYS] error condition has been removed as stubs need not be provided if an
implementation does not support the Asynchronous Input and Output option.
The APPLICATION USAGE section is added.
**NAME**

aio_fsync — asynchronous file synchronization (REALTIME)

**SYNOPSIS**

```c
#include <aio.h>

int aio_fsync(int op, struct aiocb *aiocbp);
```

**DESCRIPTION**

The `aio_fsync()` function shall asynchronously force all I/O operations associated with the file indicated by the file descriptor `aio_fildes` member of the `aiocb` structure referenced by the `aiocbp` argument and queued at the time of the call to `aio_fsync()` to the synchronized I/O completion state. The function call shall return when the synchronization request has been initiated or queued to the file or device (even when the data cannot be synchronized immediately).

If `op` is O_DSYNC, all currently queued I/O operations shall be completed as if by a call to `fdatasync();` that is, as defined for synchronized I/O data integrity completion. If `op` is O_SYNC, all currently queued I/O operations shall be completed as if by a call to `fsync();` that is, as defined for synchronized I/O file integrity completion. If the `aio_fsync()` function fails, or if the operation queued by `aio_fsync()` fails, then, as for `fsync()` and `fdatasync()`, outstanding I/O operations are not guaranteed to have been completed.

If `aio_fsync()` succeeds, then it is only the I/O that was queued at the time of the call to `aio_fsync()` that is guaranteed to be forced to the relevant completion state. The completion of subsequent I/O on the file descriptor is not guaranteed to be completed in a synchronized fashion.

The `aiocbp` argument refers to an asynchronous I/O control block. The `aiocbp` value may be used as an argument to `aio_error()` and `aio_return()` in order to determine the error status and return status, respectively, of the asynchronous operation while it is proceeding. When the request is queued, the error status for the operation is [EINPROGRESS]. When all data has been successfully transferred, the error status shall be reset to reflect the success or failure of the operation. If the operation does not complete successfully, the error status for the operation shall be set to indicate the error. The `aio_sigevent` member determines the asynchronous notification to occur as specified in Section 2.4.1 (on page 28) when all operations have achieved synchronized I/O completion. All other members of the structure referenced by `aiocbp` are ignored. If the control block referenced by `aiocbp` becomes an illegal address prior to asynchronous I/O completion, then the behavior is undefined.

If the `aio_fsync()` function fails or `aiocbp` indicates an error condition, data is not guaranteed to have been successfully transferred.

**RETURN VALUE**

The `aio_fsync()` function shall return the value 0 to the calling process if the I/O operation is successfully queued; otherwise, the function shall return the value −1 and set `errno` to indicate the error.

**ERRORS**

The `aio_fsync()` function shall fail if:

- **[EAGAIN]** The requested asynchronous operation was not queued due to temporary resource limitations.
- **[EBADF]** The `aio_fildes` member of the `aiocb` structure referenced by the `aiocbp` argument is not a valid file descriptor open for writing.
This implementation does not support synchronized I/O for this file.

A value of \texttt{op} other than \texttt{O_DSYNC} or \texttt{O_SYNC} was specified.

In the event that any of the queued I/O operations fail, \texttt{aio_fsync()} shall return the error condition defined for \texttt{read()} and \texttt{write()}. The error is returned in the error status for the asynchronous \texttt{fsync()} operation, which can be retrieved using \texttt{aio_error()}.

\textbf{EXAMPLES}

None.

\textbf{APPLICATION USAGE}

The \texttt{aio_fsync()} function is part of the Asynchronous Input and Output option and need not be available on all implementations.

\textbf{RATIONALE}

None.

\textbf{FUTURE DIRECTIONS}

None.

\textbf{SEE ALSO}

\textbf{CHANGE HISTORY}

First released in Issue 5. Included for alignment with the POSIX Realtime Extension.

\textbf{Issue 6}

The [ENOSYS] error condition has been removed as stubs need not be provided if an implementation does not support the Asynchronous Input and Output option.

The APPLICATION USAGE section is added.
NAME
aio_read — asynchronous read from a file (REALTIME)

SYNOPSIS
AIO
#include <aio.h>
int aio_read(struct aiocb *aiocbp);

DESCRIPTION
The aio_read() function shall read aiocbp->aio_nbytes from the file associated with
aiocbp->aio_fildes into the buffer pointed to by aiocbp->aio_buf. The function call shall return when
the read request has been initiated or queued to the file or device (even when the data cannot be
delivered immediately).

PIO
If prioritized I/O is supported for this file, then the asynchronous operation shall be submitted
at a priority equal to the scheduling priority of the process minus aiocbp->aio_reqprio.

The aiocbp value may be used as an argument to aio_error() and aio_return() in order to
determine the error status and return status, respectively, of the asynchronous operation while it
is proceeding. If an error condition is encountered during queuing, the function call shall return
without having initiated or queued the request. The requested operation takes place at the
absolute position in the file as given by aio_offset, as if lseek() were called immediately prior to
the operation with an offset equal to aio_offset and a whence equal to SEEK_SET. After a
successful call to enqueue an asynchronous I/O operation, the value of the file offset for the file
is unspecified.

The aiocbp->aio_lio_opcode field shall be ignored by aio_read().

The aiocbp argument points to an aiocb structure. If the buffer pointed to by aiocbp->aio_buf or
the control block pointed to by aiocbp becomes an illegal address prior to asynchronous I/O
completion, then the behavior is undefined.

Simultaneous asynchronous operations using the same aiocbp produce undefined results.

SIO
If synchronized I/O is enabled on the file associated with aiocbp->aio_fildes, the behavior of this
function shall be according to the definitions of synchronized I/O data integrity completion and
synchronized I/O file integrity completion.

For any system action that changes the process memory space while an asynchronous I/O is
outstanding to the address range being changed, the result of that action is undefined.

For regular files, no data transfer shall occur past the offset maximum established in the open
file description associated with aiocbp->aio_fildes.

RETURN VALUE
The aio_read() function shall return the value zero to the calling process if the I/O operation is
successfully queued; otherwise, the function shall return the value −1 and set errno to indicate
the error.

ERRORS
The aio_read() function shall fail if:

[EAGAIN] The requested asynchronous I/O operation was not queued due to system
resource limitations.

Each of the following conditions may be detected synchronously at the time of the call to
aio_read(), or asynchronously. If any of the conditions below are detected synchronously, the
aio_read() function shall return −1 and set errno to the corresponding value. If any of the
conditions below are detected asynchronously, the return status of the asynchronous operation...
is set to −1, and the error status of the asynchronous operation is set to the corresponding value.

[EBADF] The aiocbp->aio_fildes argument is not a valid file descriptor open for reading.

[EINVAL] The file offset value implied by aiocbp->aio_offset would be invalid, aiocbp->aio_reqprio is not a valid value, or aiocbp->aio_nbytes is an invalid value.

In the case that the aio_read() successfully queues the I/O operation but the operation is subsequently canceled or encounters an error, the return status of the asynchronous operation is one of the values normally returned by the read() function call. In addition, the error status of the asynchronous operation is set to one of the error statuses normally set by the read() function call, or one of the following values:

[EBADF] The aiocbp->aio_fildes argument is not a valid file descriptor open for reading.

[ECANCELED] The requested I/O was canceled before the I/O completed due to an explicit aio_cancel() request.

[EINVAL] The file offset value implied by aiocbp->aio_offset would be invalid.

The following condition may be detected synchronously or asynchronously:

[EOVERFLOW] The file is a regular file, aiobcp->aio_nbytes is greater than 0, and the starting offset in aiobcp->aio_offset is before the end-of-file and is at or beyond the offset maximum in the open file description associated with aiocbp->aio_fildes.

EXAMPLES

None.

APPLICATION USAGE

The aio_read() function is part of the Asynchronous Input and Output option and need not be available on all implementations.

RATIONALE

None.

FUTURE DIRECTIONS

None.

SEE ALSO

CHANGE HISTORY

First released in Issue 5. Included for alignment with the POSIX Realtime Extension.

Large File Summit extensions are added.

Issue 6

The [ENOSYS] error condition has been removed as stubs need not be provided if an implementation does not support the Asynchronous Input and Output option.

The APPLICATION USAGE section is added.
The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- In the DESCRIPTION, text is added to indicate setting of the offset maximum in the open file description. This change is to support large files.
- In the ERRORS section, the [EOVERFLOW] condition is added. This change is to support large files.
NAME
aio_return — retrieve return status of an asynchronous I/O operation (REALTIME)

SYNOPSIS
AIO #include <aio.h>

ssize_t aio_return(struct aiocb *aiocbp);

DESCRIPTION
The aio_return() function shall return the return status associated with the aiocb structure referenced by the aiocbp argument. The return status for an asynchronous I/O operation is the value that would be returned by the corresponding read(), write(), or fsync() function call. If the error status for the operation is equal to [EINPROGRESS], then the return status for the operation is undefined. The aio_return() function may be called exactly once to retrieve the return status of a given asynchronous operation; thereafter, if the same aiocb structure is used in a call to aio_return() or aio_error(), an error may be returned. When the aiocb structure referred to by aiocbp is used to submit another asynchronous operation, then aio_return() may be successfully used to retrieve the return status of that operation.

RETURN VALUE
If the asynchronous I/O operation has completed, then the return status, as described for read(), write(), and fsync(), shall be returned. If the asynchronous I/O operation has not yet completed, the results of aio_return() are undefined.

ERRORS
The aio_return() function may fail if:

[EINVAL] The aiocbp argument does not refer to an asynchronous operation whose return status has not yet been retrieved.

EXAMPLES
None.

APPLICATION USAGE
The aio_return() function is part of the Asynchronous Input and Output option and need not be available on all implementations.

RATIONALE
None.

FUTURE DIRECTIONS
None.

SEE ALSO
aio_cancel(), aio_error(), aio_fsync(), aio_read(), aio_write(), close(), exec(), exit(), fork(), lio_listio(), lseek(), read(), the Base Definitions volume of IEEE Std 1003.1-2001, <aio.h>

CHANGE HISTORY
First released in Issue 5. Included for alignment with the POSIX Realtime Extension.

Issue 6
The [ENOSYS] error condition has been removed as stubs need not be provided if an implementation does not support the Asynchronous Input and Output option.

The APPLICATION USAGE section is added.

The [EINVAL] error condition is updated as a “may fail”. This is for consistency with the DESCRIPTION.
NAME
aio_suspend — wait for an asynchronous I/O request (REALTIME)

SYNOPSIS
#include <aio.h>

int aio_suspend(const struct aiocb * const list[], int nent,
                const struct timespec *timeout);

DESCRIPTION
The aio_suspend() function shall suspend the calling thread until at least one of the asynchronous
I/O operations referenced by the list argument has completed, until a signal interrupts the
function, or, if timeout is not NULL, until the time interval specified by timeout has passed. If any
of the aiocb structures in the list correspond to completed asynchronous I/O operations (that is,
the error status for the operation is not equal to [EINPROGRESS]) at the time of the call, the
function shall return without suspending the calling thread. The list argument is an array of
pointers to asynchronous I/O control blocks. The nent argument indicates the number of
elements in the array. Each aiocb structure pointed to has been used in initiating an
asynchronous I/O request via aio_read(), aio_write(), or lio_listio(). This array may contain
NULL pointers, which are ignored. If this array contains pointers that refer to aiocb structures
that have not been used in submitting asynchronous I/O, the effect is undefined.

If the time interval indicated in the timespec structure pointed to by timeout passes before any of
the I/O operations referenced by list are completed, then aio_suspend() shall return with an
error. If the Monotonic Clock option is supported, the clock that shall be used to measure this
time interval shall be the CLOCK_MONOTONIC clock.

RETURN VALUE
If the aio_suspend() function returns after one or more asynchronous I/O operations have
completed, the function shall return zero. Otherwise, the function shall return a value of −1 and
set errno to indicate the error.

The application may determine which asynchronous I/O completed by scanning the associated
error and return status using aio_error() and aio_return(), respectively.

ERRORS
The aio_suspend() function shall fail if:

[EAGAIN] No asynchronous I/O indicated in the list referenced by list completed in the
time interval indicated by timeout.

[EINTR] A signal interrupted the aio_suspend() function. Note that, since each
asynchronous I/O operation may possibly provoke a signal when it
completes, this error return may be caused by the completion of one (or more)
of the very I/O operations being awaited.

EXAMPLES
None.

APPLICATION USAGE
The aio_suspend() function is part of the Asynchronous Input and Output option and need not
be available on all implementations.

RATIONALE
None.
FUTURE DIRECTIONS

None.

SEE ALSO

CHANGE HISTORY

First released in Issue 5. Included for alignment with the POSIX Realtime Extension.

Issue 6

The [ENOSYS] error condition has been removed as stubs need not be provided if an implementation does not support the Asynchronous Input and Output option.

The APPLICATION USAGE section is added.

The DESCRIPTION is updated for alignment with IEEE Std 1003.1j-2000 by specifying that the CLOCK_MONOTONIC clock, if supported, is used.
NAME
aio_write — asynchronous write to a file (REALTIME)

SYNOPSIS

AIO
#include <aio.h>

int aio_write(struct aiocb *aiocbp);

DESCRIPTION
The aio_write( ) function shall write aiocbp->aio_nbytes to the file associated with aiocbp->aio_fildes
from the buffer pointed to by aiocbp->aio_buf. The function shall return when the write request
has been initiated or, at a minimum, queued to the file or device.

PIO
If prioritized I/O is supported for this file, then the asynchronous operation shall be submitted
at a priority equal to the scheduling priority of the process minus aiocbp->aio_reqprio.

The aiocbp argument may be used as an argument to aio_error( ) and aio_return( ) in order to
determine the error status and return status, respectively, of the asynchronous operation while it
is proceeding.

The aiocbp argument points to an aiocb structure. If the buffer pointed to by aiocbp->aio_buf or
the control block pointed to by aiocbp becomes an illegal address prior to asynchronous I/O
completion, then the behavior is undefined.

If O_APPEND is not set for the file descriptor aiocbp->aio_fildes, then the requested operation shall take
place at the absolute position in the file as given by aiocbp->aio_offset, as if lseek( ) were called
immediately prior to the operation with an offset equal to aiocbp->aio_offset and a whence equal to
SEEK_SET. If O_APPEND is set for the file descriptor, write operations append to the file in the
same order as the calls were made. After a successful call to enqueue an asynchronous I/O
operation, the value of the file offset for the file is unspecified.

The aiocbp->aio_lio_opcode field shall be ignored by aio_write( ).

Simultaneous asynchronous operations using the same aiocbp produce undefined results.

SIO
If synchronized I/O is enabled on the file associated with aiocbp->aio_fildes, the behavior of this
function shall be according to the definitions of synchronized I/O data integrity completion, and
synchronized I/O file integrity completion.

For any system action that changes the process memory space while an asynchronous I/O is
outstanding to the address range being changed, the result of that action is undefined.

For regular files, no data transfer shall occur past the offset maximum established in the open
file description associated with aiocbp->aio_fildes.

RETURN VALUE
The aio_write( ) function shall return the value zero to the calling process if the I/O operation is
successfully queued; otherwise, the function shall return the value −1 and set errno to indicate
the error.

ERRORS
The aio_write( ) function shall fail if:

[EAGAIN] The requested asynchronous I/O operation was not queued due to system
resource limitations.

Each of the following conditions may be detected synchronously at the time of the call to
aio_write(), or asynchronously. If any of the conditions below are detected synchronously, the
aio_write() function shall return −1 and set errno to the corresponding value. If any of the
conditions below are detected asynchronously, the return status of the asynchronous operation shall be set to -1, and the error status of the asynchronous operation is set to the corresponding value.

- [EBADF] The aiocbp->aio_fildes argument is not a valid file descriptor open for writing.
- [EINVAL] The file offset value implied by aiocbp->aio_offset would be invalid, aiocbp->aio_reqprio is not a valid value, or aiocbp->aio_nbytes is an invalid value.

In the case that the aio_write() successfully queues the I/O operation, the return status of the asynchronous operation shall be one of the values normally returned by the write() function call. If the operation is successfully queued but is subsequently canceled or encounters an error, the error status for the asynchronous operation contains one of the values normally set by the write() function call, or one of the following:

- [EBADF] The aiocbp->aio_fildes argument is not a valid file descriptor open for writing.
- [EINVAL] The file offset value implied by aiocbp->aio_offset would be invalid.
- [ECANCELED] The requested I/O was canceled before the I/O completed due to an explicit aio_cancel() request.

The following condition may be detected synchronously or asynchronously:

- [EFBIG] The file is a regular file, aiocbp->aio_nbytes is greater than 0, and the starting offset in aiocbp->aio_offset is at or beyond the offset maximum in the open file description associated with aiocbp->aio_fildes.

**EXAMPLES**

None.

**APPLICATION USAGE**

The aio_write() function is part of the Asynchronous Input and Output option and need not be available on all implementations.

**RATIONALE**

None.

**FUTURE DIRECTIONS**

None.

**SEE ALSO**

aio_cancel(), aio_error(), aio_read(), aio_return(), close(), exec, exit(), fork(), lio_listio(), lseek(), write(), the Base Definitions volume of IEEE Std 1003.1-2001, <aio.h>

**CHANGE HISTORY**

First released in Issue 5. Included for alignment with the POSIX Realtime Extension.

Large File Summit extensions are added.

**Issue 6**

The [ENOSYS] error condition has been removed as stubs need not be provided if an implementation does not support the Asynchronous Input and Output option.

The APPLICATION USAGE section is added.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- In the DESCRIPTION, text is added to indicate that for regular files no data transfer occurs past the offset maximum established in the open file description associated with
aio_write()

- The [EFBIG] error is added as part of the large file support extensions.
alarm( )

NAME
alarm — schedule an alarm signal

SYNOPSIS
#include <unistd.h>
unsigned alarm(unsigned seconds);

DESCRIPTION
The alarm( ) function shall cause the system to generate a SIGALRM signal for the process after
the number of realtime seconds specified by seconds have elapsed. Processor scheduling delays
may prevent the process from handling the signal as soon as it is generated.

If seconds is 0, a pending alarm request, if any, is canceled.

Alarm requests are not stacked; only one SIGALRM generation can be scheduled in this manner.
If the SIGALRM signal has not yet been generated, the call shall result in rescheduling the time
at which the SIGALRM signal is generated.

XSI Interactions between alarm( ) and any of setitimer( ), ualarm( ), or usleep( ) are unspecified.

RETURN VALUE
If there is a previous alarm( ) request with time remaining, alarm( ) shall return a non-zero value
that is the number of seconds until the previous request would have generated a SIGALRM
signal. Otherwise, alarm( ) shall return 0.

ERRORS
The alarm( ) function is always successful, and no return value is reserved to indicate an error.

EXAMPLES
None.

APPLICATION USAGE
The fork( ) function clears pending alarms in the child process. A new process image created by
one of the exec functions inherits the time left to an alarm signal in the old process’ image.

Application writers should note that the type of the argument seconds and the return value of
alarm( ) is unsigned. That means that a Strictly Conforming POSIX System Interfaces
Application cannot pass a value greater than the minimum guaranteed value for {UINT_MAX},
which the ISO C standard sets as 65535, and any application passing a larger value is restricting
its portability. A different type was considered, but historical implementations, including those
with a 16-bit int type, consistently use either unsigned or int.

Application writers should be aware of possible interactions when the same process uses both
the alarm( ) and sleep( ) functions.

RATIONALE
Many historical implementations (including Version 7 and System V) allow an alarm to occur up
to a second early. Other implementations allow alarms up to half a second or one clock tick
early or do not allow them to occur early at all. The latter is considered most appropriate, since it
gives the most predictable behavior, especially since the signal can always be delayed for an
indefinite amount of time due to scheduling. Applications can thus choose the seconds argument
as the minimum amount of time they wish to have elapse before the signal.

The term “realtime” here and elsewhere (sleep(), times()) is intended to mean “wall clock” time
as common English usage, and has nothing to do with “realtime operating systems”. It is in
contrast to virtual time, which could be misinterpreted if just time were used.

In some implementations, including 4.3 BSD, very large values of the seconds argument are
silently rounded down to an implementation-defined maximum value. This maximum is large
There were two possible choices for alarm generation in multi-threaded applications: generation for the calling thread or generation for the process. The first option would not have been particularly useful since the alarm state is maintained on a per-process basis and the alarm that is established by the last invocation of \texttt{alarm()} is the only one that would be active.

Furthermore, allowing generation of an asynchronous signal for a thread would have introduced an exception to the overall signal model. This requires a compelling reason in order to be justified.

\textbf{FUTURE DIRECTIONS}

None.

\textbf{CHANGE HISTORY}

First released in Issue 1. Derived from Issue 1 of the SVID.

\textbf{Issue 6}

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The DESCRIPTION is updated to indicate that interactions with the \texttt{setitimer()}, \texttt{ualarm()}, and \texttt{usleep()} functions are unspecified.
NAME
asctime, asctime_r — convert date and time to a string

SYNOPSIS
#include <time.h>
char *asctime(const struct tm *timeptr);
TSF char *asctime_r(const struct tm *restrict tm, char *restrict buf);

DESCRIPTION
CX For asctime(): The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-2001 defers to the ISO C standard.
The asctime() function shall convert the broken-down time in the structure pointed to by timeptr into a string in the form:
Sun Sep 16 01:03:52 1973
using the equivalent of the following algorithm:
char *asctime(const struct tm *timeptr)
{
    static char wday_name[7][3] = {
        "Sun", "Mon", "Tue", "Wed", "Thu", "Fri", "Sat"
    };
    static char mon_name[12][3] = {
        "Jul", "Aug", "Sep", "Oct", "Nov", "Dec"
    };
    static char result[26];
    sprintf(result, ";.3s%.3s%.3d%.2d:%.2d:%.2d %d\n",
            wday_name[timeptr->tm_wday],
            mon_name[timeptr->tm_mon],
            timeptr->tm_mday, timeptr->tm_hour,
            timeptr->tm_min, timeptr->tm_sec,
            1900 + timeptr->tm_year);
    return result;
}
The tm structure is defined in the <time.h> header.

CX The asctime(), ctime(), gmtime(), and localtime() functions shall return values in one of two static objects: a broken-down time structure and an array of type char. Execution of any of the functions may overwrite the information returned in either of these objects by any of the other functions.
The asctime() function need not be reentrant. A function that is not required to be reentrant is not required to be thread-safe.

TSF The asctime_r() function shall convert the broken-down time in the structure pointed to by tm into a string (of the same form as that returned by asctime()) that is placed in the user-supplied buffer pointed to by buf (which shall contain at least 26 bytes) and then return buf.
asctime()

RETURN VALUE
4439 Upon successful completion, asctime() shall return a pointer to the string.
4440
4441 TSF Upon successful completion, asctime_r() shall return a pointer to a character string containing
4442 the date and time. This string is pointed to by the argument buf. If the function is unsuccessful,
4443 it shall return NULL.

ERRORS
4445 No errors are defined.

EXAMPLES
4446 None.

APPLICATION USAGE
4448 Values for the broken-down time structure can be obtained by calling gmtime() or localtime().
4449 This function is included for compatibility with older implementations, and does not support
4450 localized date and time formats. Applications should use strftime() to achieve maximum
4451 portability.
4452
4453 The asctime_r() function is thread-safe and shall return values in a user-supplied buffer instead
4454 of possibly using a static data area that may be overwritten by each call.

RATIONALE
4455 None.

FUTURE DIRECTIONS
4458 None.

NAME
asin, asinf, asinl — arc sine function

SYNOPSIS
#include <math.h>

double asin(double x);
float asinf(float x);
long double asinl(long double x);

DESCRIPTION
The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-2001 defers to the ISO C standard.

These functions shall compute the principal value of the arc sine of their argument x. The value of x should be in the range \([-1,1]\).

An application wishing to check for error situations should set \(errno\) to zero and call \(feclearexcept(FE_ALL_EXCEPT)\) before calling these functions. On return, if \(errno\) is non-zero or \(fetestexcept(FE_INVALID | FE_DIVBYZERO | FE_OVERFLOW | FE_UNDERFLOW)\) is non-zero, an error has occurred.

RETURN VALUE
Upon successful completion, these functions shall return the arc sine of x, in the range \([-\pi/2,\pi/2]\] radians.

For finite values of x not in the range \([-1,1]\), a domain error shall occur, and either a NaN (if supported), or an implementation-defined value shall be returned.

If x is NaN, a NaN shall be returned.

If x is ±0, x shall be returned.

If x is ±Inf, a domain error shall occur, and either a NaN (if supported), or an implementation-defined value shall be returned.

If x is subnormal, a range error may occur and x should be returned.

ERRORS
These functions shall fail if:

Domain Error The x argument is finite and is not in the range \([-1,1]\), or is ±Inf.
If the integer expression (math_errhandling & MATH_ERRNO) is non-zero, then \(errno\) shall be set to [EDOM]. If the integer expression (math_errhandling & MATH_ERREXCEPT) is non-zero, then the invalid floating-point exception shall be raised.

These functions may fail if:

Range Error The value of x is subnormal.
If the integer expression (math_errhandling & MATH_ERRNO) is non-zero, then \(errno\) shall be set to [ERANGE]. If the integer expression (math_errhandling & MATH_ERREXCEPT) is non-zero, then the underflow floating-point exception shall be raised.
EXAMPLES
None.

APPLICATION USAGE
On error, the expressions (math_errhandling & MATH_ERRNO) and (math_errhandling &
MATH_ERREXCEPT) are independent of each other, but at least one of them must be non-zero.

RATIONALE
None.

FUTURE DIRECTIONS
None.

Issue 5
The DESCRIPTION is updated to indicate how an application should check for an error. This
text was previously published in the APPLICATION USAGE section.

Issue 6
The asinf() and asinl() functions are added for alignment with the ISO/IEC 9899: 1999 standard.
The DESCRIPTION, RETURN VALUE, ERRORS, and APPLICATION USAGE sections are
revised to align with the ISO/IEC 9899: 1999 standard.
IEC 60559: 1989 standard floating-point extensions over the ISO/IEC 9899: 1999 standard are
marked.
NAME
asinh, asinhf, asinhl — inverse hyperbolic sine functions

SYNOPSIS
#include <math.h>

double asinh(double x);
float asinhf(float x);
long double asinhl(long double x);

DESCRIPTION
The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-2001 defers to the ISO C standard.

These functions shall compute the inverse hyperbolic sine of their argument x.

An application wishing to check for error situations should set errno to zero and call fegetexcept(FE_ALL_EXCEPT) before calling these functions. On return, if errno is non-zero or fetestexcept(FE_INVALID | FE_DIVBYZERO | FE_OVERFLOW | FE_UNDERFLOW) is non-zero, an error has occurred.

RETURN VALUE
Upon successful completion, these functions shall return the inverse hyperbolic sine of their argument.

If x is NaN, a NaN shall be returned.
If x is ±0, ±Inf, x shall be returned.
If x is subnormal, a range error may occur and x should be returned.

ERRORS
These functions may fail if:

If the integer expression (math_errhandling & MATH_ERRNO) is non-zero, then errno shall be set to [ERANGE]. If the integer expression (math_errhandling & MATH_ERREXCEPT) is non-zero, then the underflow floating-point exception shall be raised.

EXAMPLES
None.

APPLICATION USAGE
On error, the expressions (math_errhandling & MATH_ERRNO) and (math_errhandling & MATH_ERREXCEPT) are independent of each other, but at least one of them must be non-zero.

RATIONALE
None.

FUTURE DIRECTIONS
None.

**CHANGE HISTORY**

First released in Issue 4, Version 2.

**Issue 5**

Moved from X/OPEN UNIX extension to BASE.

**Issue 6**

The `asinh()` function is no longer marked as an extension.

The `asinhf()` and `asinhl()` functions are added for alignment with the ISO/IEC 9899:1999 standard.

The DESCRIPTION, RETURN VALUE, ERRORS, and APPLICATION USAGE sections are revised to align with the ISO/IEC 9899:1999 standard.

NAME
asinl — arc sine function

SYNOPSIS
#include <math.h>
long double asinl(long double x);

DESCRIPTION
Refer to asin().
NAME
assert — insert program diagnostics

SYNOPSIS
#include <assert.h>
void assert(scalar expression);

DESCRIPTION
The functionality described on this reference page is aligned with the ISO C standard. Any
conflict between the requirements described here and the ISO C standard is unintentional. This

The assert() macro shall insert diagnostics into programs; it shall expand to a void expression.
When it is executed, if expression (which shall have a scalar type) is false (that is, compares equal
to 0), assert() shall write information about the particular call that failed on stderr and shall call
abort().

The information written about the call that failed shall include the text of the argument, the
name of the source file, the source file line number, and the name of the enclosing function; the
latter are, respectively, the values of the preprocessing macros __FILE__ and __LINE__ and of the
identifier __func___.

Forcing a definition of the name NDEBUG, either from the compiler command line or with the
preprocessor control statement #define NDEBUG ahead of the #include <assert.h> statement,
shall stop assertions from being compiled into the program.

RETURN VALUE
The assert() macro shall not return a value.

ERRORS
No errors are defined.

EXAMPLES
None.

APPLICATION USAGE
None.

RATIONALE
None.

FUTURE DIRECTIONS
None.

The DESCRIPTION of assert() is updated for alignment with the ISO/IEC 9899:1999 standard.
NAME
atan, atanf, atanl — arc tangent function

SYNOPSIS
#include <math.h>

double atan(double x);
float atanf(float x);
long double atanl(long double x);

DESCRIPTION
CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-2001 defers to the ISO C standard.

These functions shall compute the principal value of the arc tangent of their argument \( x \).

An application wishing to check for error situations should set \textit{errno} to zero and call \textit{feclearexcept}(FE_ALL_EXCEPT) before calling these functions. On return, if \textit{errno} is non-zero or \textit{fetestexcept}(FE_INVALID | FE_DIVBYZERO | FE_OVERFLOW | FE_UNDERFLOW) is non-zero, an error has occurred.

RETURN VALUE
Upon successful completion, these functions shall return the arc tangent of \( x \) in the range \([-\pi/2,\pi/2]\) radians.

MX If \( x \) is NaN, a NaN shall be returned.
If \( x \) is ±0, \( x \) shall be returned.
If \( x \) is ±Inf, ±\( \pi/2 \) shall be returned.
If \( x \) is subnormal, a range error may occur and \( x \) should be returned.

ERRORS
These functions may fail if:

MX Range Error The value of \( x \) is subnormal.

If the integer expression (\textit{math_errhandling} & MATH_ERRNO) is non-zero, then \textit{errno} shall be set to [ERANGE]. If the integer expression (\textit{math_errhandling} & MATH_ERREXCEPT) is non-zero, then the underflow floating-point exception shall be raised.

EXAMPLES
None.

APPLICATION USAGE
On error, the expressions (\textit{math_errhandling} & MATH_ERRNO) and (\textit{math_errhandling} & MATH_ERREXCEPT) are independent of each other, but at least one of them must be non-zero.

NAME
atan2, atan2f, atan2l — arc tangent functions

SYNOPSIS
#include <math.h>

double atan2(double y, double x);
float atan2f(float y, float x);
long double atan2l(long double y, long double x);

DESCRIPTION
The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-2001 defers to the ISO C standard.

These functions shall compute the principal value of the arc tangent of \(y/x\), using the signs of both arguments to determine the quadrant of the return value.

An application wishing to check for error situations should set \(errno\) to zero and call \texttt{fclearexcept}(FE_ALL_EXCEPT) before calling these functions. On return, if \(errno\) is non-zero or \texttt{fetestexcept}(FE_INVALID | FE_DIVBYZERO | FE_OVERFLOW | FE_UNDERFLOW) is non-zero, an error has occurred.

RETURN VALUE
Upon successful completion, these functions shall return the arc tangent of \(y/x\) in the range \([-\pi, \pi]\) radians.

If \(y\) is \(\pm 0\) and \(x\) is \(< 0\), \(\pm \pi\) shall be returned.

If \(y\) is \(\pm 0\) and \(x\) is \(> 0\), \(\pm 0\) shall be returned.

If \(y\) is \(< 0\) and \(x\) is \(\pm 0\), \(-\pi/2\) shall be returned.

If \(y\) is \(> 0\) and \(x\) is \(\pm 0\), \(\pi/2\) shall be returned.

If \(x\) is \(0\), a pole error shall not occur.

If either \(x\) or \(y\) is NaN, a NaN shall be returned.

If the result underflows, a range error may occur and \(y/x\) should be returned.

If \(y\) is \(\pm 0\) and \(x\) is \(-0\), \(\pm \pi\) shall be returned.

If \(y\) is \(\pm 0\) and \(x\) is \(+0\), \(\pm 0\) shall be returned.

For finite values of \(\pm y > 0\), if \(x\) is \(-\text{Inf}\), \(\pm \pi\) shall be returned.

For finite values of \(\pm y > 0\), if \(x\) is \(+\text{Inf}\), \(\pm 0\) shall be returned.

For finite values of \(x\), if \(y\) is \(\pm\text{Inf}\), \(\pm \pi/2\) shall be returned.

If \(y\) is \(\pm\text{Inf}\) and \(x\) is \(-\text{Inf}\), \(\pm 3\pi/4\) shall be returned.

If \(y\) is \(\pm\text{Inf}\) and \(x\) is \(+\text{Inf}\), \(\pm \pi/4\) shall be returned.

If both arguments are \(0\), a domain error shall not occur.

ERRORS
These functions may fail if:

Range Error The result underflows.

If the integer expression \((\text{math_errnohand}\&\text{MATH_ERRNO})\) is non-zero, then \(errno\) shall be set to [ERANGE]. If the integer expression
(math_errno & MATH_ERREXCEPT) is non-zero, then the underflow floating-point exception shall be raised.

EXAMPLES
None.

APPLICATION USAGE
On error, the expressions (math_errno & MATH_ERRNO) and (math_errno & MATH_ERREXCEPT) are independent of each other, but at least one of them must be non-zero.

RATIONALE
None.

FUTURE DIRECTIONS
None.

NAME
atanf — arc tangent function

SYNOPSIS
#include <math.h>
float atanf(float x);

DESCRIPTION
Refer to atan().
NAME
atanh, atanhf, atanhl — inverse hyperbolic tangent functions

SYNOPSIS
#include <math.h>

double atanh(double x);
float atanhf(float x);
long double atanhl(long double x);

DESCRIPTION
The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-2001 defers to the ISO C standard.

These functions shall compute the inverse hyperbolic tangent of their argument x.

An application wishing to check for error situations should set errno to zero and call feclearexcept(FE_ALL_EXCEPT) before calling these functions. On return, if errno is non-zero or fetestexcept(FE_INVALID | FE_DIVBYZERO | FE_OVERFLOW | FE_UNDERFLOW) is non-zero, an error has occurred.

RETURN VALUE
Upon successful completion, these functions shall return the inverse hyperbolic tangent of their argument.

If x is ±1, a pole error shall occur, and atanh(), atanhf(), and atanhl() shall return the value of the macro HUGE_VAL, HUGE_VALF, and HUGE_VALL, respectively, with the same sign as the correct value of the function.

For finite |x|>1, a domain error shall occur, and either a NaN (if supported), or an implementation-defined value shall be returned.

If x is NaN, a NaN shall be returned.

If x is ±0, x shall be returned.

If x is ±Inf, a domain error shall occur, and either a NaN (if supported), or an implementation-defined value shall be returned.

If x is subnormal, a range error may occur and x should be returned.

ERRORS
These functions shall fail if:

Domain Error The x argument is finite and not in the range [-1,1], or is ±Inf.

If the integer expression (math_errhandling & MATH_ERRNO) is non-zero, then errno shall be set to [EDOM]. If the integer expression (math_errhandling & MATH_ERREXCEPT) is non-zero, then the invalid floating-point exception shall be raised.

Pole Error The x argument is ±1.

If the integer expression (math_errhandling & MATH_ERRNO) is non-zero, then errno shall be set to [ERANGE]. If the integer expression (math_errhandling & MATH_ERREXCEPT) is non-zero, then the divide-by-zero floating-point exception shall be raised.
These functions may fail if:

<table>
<thead>
<tr>
<th>MX</th>
<th>Range Error</th>
<th>The value of x is subnormal.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>If the integer expression (math_errhandling &amp; MATH_ERRNO) is non-zero, then errno shall be set to [ERANGE]. If the integer expression (math_errhandling &amp; MATH_ERREXCEPT) is non-zero, then the underflow floating-point exception shall be raised.</td>
<td></td>
</tr>
</tbody>
</table>

**EXAMPLES**

The atanh() function is no longer marked as an extension.

The atanhf() and atanhl() functions are added for alignment with the ISO/IEC 9899:1999 standard.

The DESCRIPTION, RETURN VALUE, ERRORS, and APPLICATION USAGE sections are revised to align with the ISO/IEC 9899:1999 standard.

NAME
atanl — arc tangent function

SYNOPSIS
#include <math.h>
long double atanl(long double x);

DESCRIPTION
Refer to atan().
NAME
atexit — register a function to run at process termination

SYNOPSIS
#include <stdlib.h>

int atexit(void (*func)(void));

DESCRIPTION
The functionality described on this reference page is aligned with the ISO C standard. Any
conflict between the requirements described here and the ISO C standard is unintentional. This

The atexit() function shall register the function pointed to by func, to be called without
arguments at normal program termination. At normal program termination, all functions
registered by the atexit() function shall be called, in the reverse order of their registration, except
that a function is called after any previously registered functions that had already been called at
the time it was registered. Normal termination occurs either by a call to exit() or a return from
main().

At least 32 functions can be registered with atexit().

After a successful call to any of the exec functions, any functions previously registered by atexit()shall no longer be registered.

RETURN VALUE
Upon successful completion, atexit() shall return 0; otherwise, it shall return a non-zero value.

ERRORS
No errors are defined.

EXAMPLES
None.

APPLICATION USAGE
The functions registered by a call to atexit() must return to ensure that all registered functions
are called.

The application should call sysconf() to obtain the value of {ATEXIT_MAX}, the number of
functions that can be registered. There is no way for an application to tell how many functions
have already been registered with atexit().

RATIONALE
None.

FUTURE DIRECTIONS
None.

SEE ALSO
exit(), sysconf(), the Base Definitions volume of IEEE Std 1003.1-2001, <stdlib.h>

CHANGE HISTORY
First released in Issue 4. Derived from the ANSI C standard.

Issue 6
Extensions beyond the ISO C standard are marked.

The DESCRIPTION is updated for alignment with the ISO/IEC 9899:1999 standard.
NAME
atof — convert a string to a double-precision number

SYNOPSIS
#include <stdlib.h>

double atof(const char *str);

DESCRIPTION
The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-2001 defers to the ISO C standard.

The call atof(str) shall be equivalent to:

```
strtod(str,(char **)NULL),
```

except that the handling of errors may differ. If the value cannot be represented, the behavior is undefined.

RETURN VALUE
The atof() function shall return the converted value if the value can be represented.

ERRORS
No errors are defined.

APPLICATION USAGE
The atof() function is subsumed by strtod() but is retained because it is used extensively in existing code. If the number is not known to be in range, strtod() should be used because atof() is not required to perform any error checking.

RATIONALE
None.

FUTURE DIRECTIONS
None.

SEE ALSO
strtod(), the Base Definitions volume of IEEE Std 1003.1-2001, <stdlib.h>

CHANGE HISTORY
First released in Issue 1. Derived from Issue 1 of the SVID.
NAME
atoi — convert a string to an integer

SYNOPSIS
#include <stdlib.h>
int atoi(const char *str);

DESCRIPTION
The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-2001 defers to the ISO C standard.

The call atoi(str) shall be equivalent to:
(int) strtol(str, (char **)NULL, 10)
except that the handling of errors may differ. If the value cannot be represented, the behavior is undefined.

RETURN VALUE
The atoi() function shall return the converted value if the value can be represented.

ERRORS
No errors are defined.

EXAMPLES
Converting an Argument
The following example checks for proper usage of the program. If there is an argument and the decimal conversion of this argument (obtained using atoi()) is greater than 0, then the program has a valid number of minutes to wait for an event.

#include <stdlib.h>
#include <stdio.h>
...
int minutes_to_event;
...
if (argc < 2 || ((minutes_to_event = atoi (argv[1]))) <= 0) {
    fprintf(stderr, "Usage: %s minutes\n", argv[0]); exit(1);
}
...

APPLICATION USAGE
The atoi() function is subsumed by strtol() but is retained because it is used extensively in existing code. If the number is not known to be in range, strtol() should be used because atoi() is not required to perform any error checking.

RATIONALE
None.

FUTURE DIRECTIONS
None.

NAME
atol, atoll — convert a string to a long integer

SYNOPSIS
#include <stdlib.h>
long atol(const char *str);
long long atoll(const char *nptr);

DESCRIPTION
The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-2001 defers to the ISO C standard.

The call atol(str) shall be equivalent to:
strtol(str, (char **)NULL, 10)
The call atoll(str) shall be equivalent to:
strtoll(nptr, (char **)NULL, 10)
except that the handling of errors may differ. If the value cannot be represented, the behavior is undefined.

RETURN VALUE
These functions shall return the converted value if the value can be represented.

ERRORS
No errors are defined.

EXAMPLES
None.

APPLICATION USAGE
The atol() function is subsumed by strtol() but is retained because it is used extensively in existing code. If the number is not known to be in range, strtol() should be used because atol() is not required to perform any error checking.

RATIONALE
None.

FUTURE DIRECTIONS
None.

SEE ALSO
strtol(), the Base Definitions volume of IEEE Std 1003.1-2001, <stdlib.h>

CHANGE HISTORY
First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 6
The atoll() function is added for alignment with the ISO/IEC 9899:1999 standard.
NAME
basename — return the last component of a pathname

SYNOPSIS
XSI
```c
#include <libgen.h>

char *basename(char *path);
```

DESCRIPTION
The `basename()` function shall take the pathname pointed to by `path` and return a pointer to the final component of the pathname, deleting any trailing ‘/’ characters.

If the string consists entirely of the ‘/’ character, `basename()` shall return a pointer to the string “/”. If the string is exactly “/”, it is implementation-defined whether ‘/’ or “/” is returned.

If `path` is a null pointer or points to an empty string, `basename()` shall return a pointer to the string “.”.

The `basename()` function may modify the string pointed to by `path`, and may return a pointer to static storage that may then be overwritten by a subsequent call to `basename()`.

The `basename()` function need not be reentrant. A function that is not required to be reentrant is not required to be thread-safe.

RETURN VALUE
The `basename()` function shall return a pointer to the final component of `path`.

ERRORS
No errors are defined.

EXAMPLES
Using `basename()`
The following program fragment returns a pointer to the value `lib`, which is the base name of `/usr/lib`.
```c
#include <libgen.h>
...
char *name = "/usr/lib";
char *base;
base = basename(name);
...
```

Sample Input and Output Strings for `basename()`
In the following table, the input string is the value pointed to by `path`, and the output string is the return value of the `basename()` function.

<table>
<thead>
<tr>
<th>Input String</th>
<th>Output String</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;/usr/lib&quot;</td>
<td>&quot;lib&quot;</td>
</tr>
<tr>
<td>&quot;/usr/&quot;</td>
<td>&quot;usr&quot;</td>
</tr>
<tr>
<td>&quot;/&quot;</td>
<td>&quot;/&quot;</td>
</tr>
<tr>
<td>&quot;///&quot;</td>
<td>&quot;/&quot;</td>
</tr>
<tr>
<td>&quot;/////&quot;</td>
<td>&quot;/&quot;</td>
</tr>
<tr>
<td>&quot;///usr///lib///&quot;</td>
<td>&quot;lib&quot;</td>
</tr>
</tbody>
</table>
APPLICATION USAGE
None.

CHANGE HISTORY
First released in Issue 4, Version 2.

Issue 5
Moved from X/OPEN UNIX extension to BASE.

Issue 6
In the DESCRIPTION, the note about reentrancy is expanded to cover thread-safety.
**NAME**

bcmp — memory operations (LEGACY)

**SYNOPSIS**

```c
#include <strings.h>

int bcmp(const void *s1, const void *s2, size_t n);
```

**DESCRIPTION**

The `bcmp()` function shall compare the first `n` bytes of the area pointed to by `s1` with the area pointed to by `s2`.

**RETURN VALUE**

The `bcmp()` function shall return 0 if `s1` and `s2` are identical; otherwise, it shall return non-zero. Both areas are assumed to be `n` bytes long. If the value of `n` is 0, `bcmp()` shall return 0.

**EXAMPLES**

None.

**APPLICATION USAGE**

The `memcmp()` function is preferred over this function. For maximum portability, it is recommended to replace the function call to `bcmp()` as follows:

```c
#define bcmp(b1,b2,len) memcmp((b1), (b2), (size_t)(len))
```

**RATIONALE**

None.

**FUTURE DIRECTIONS**

This function may be withdrawn in a future version.

**SEE ALSO**

`memcmp()`, the Base Definitions volume of IEEE Std 1003.1-2001, `<strings.h>`

**CHANGE HISTORY**

First released in Issue 4, Version 2.

**Issue 5**

Moved from X/OPEN UNIX extension to BASE.

**Issue 6**

This function is marked LEGACY.
NAME
bcopy — memory operations (LEGACY)

SYNOPSIS
XSI
#include <strings.h>

void bcopy(const void *s1, void *s2, size_t n);

DESCRIPTION
The bcopy() function shall copy n bytes from the area pointed to by s1 to the area pointed to by s2.

The bytes are copied correctly even if the area pointed to by s1 overlaps the area pointed to by s2.

RETURN VALUE
The bcopy() function shall not return a value.

ERRORS
No errors are defined.

EXAMPLES
None.

APPLICATION USAGE
The memmove() function is preferred over this function.

The following are approximately equivalent (note the order of the arguments):

bcopy(s1, s2, n) = memmove(s2, s1, n)

For maximum portability, it is recommended to replace the function call to bcopy() as follows:

#define bcopy(b1, b2, len) (memmove((b2), (b1), (len)), (void) 0)

RATIONALE
None.

FUTURE DIRECTIONS
This function may be withdrawn in a future version.

SEE ALSO
memmove(), the Base Definitions volume of IEEE Std 1003.1-2001, <strings.h>

CHANGE HISTORY
First released in Issue 4, Version 2.

Issue 5
Moved from X/OPEN UNIX extension to BASE.

Issue 6
This function is marked LEGACY.
NAME
bind — bind a name to a socket

SYNOPSIS
#include <sys/socket.h>

int bind(int socket, const struct sockaddr *address, socklen_t address_len);

DESCRIPTION
The bind() function shall assign a local socket address address to a socket identified by descriptor socket that has no local socket address assigned. Sockets created with the socket() function are initially unnamed; they are identified only by their address family.

The bind() function takes the following arguments:

socket Specifies the file descriptor of the socket to be bound.
address Points to a sockaddr structure containing the address to be bound to the socket. The length and format of the address depend on the address family of the socket.
address_len Specifies the length of the sockaddr structure pointed to by the address argument.

The socket specified by socket may require the process to have appropriate privileges to use the bind() function.

RETURN VALUE
Upon successful completion, bind() shall return 0; otherwise, −1 shall be returned and errno set to indicate the error.

ERRORS
The bind() function shall fail if:

[EADDRINUSE] The specified address is already in use.

[EADDRNOTAVAIL]
The specified address is not available from the local machine.

[EAFNOSUPPORT]
The specified address is not a valid address for the address family of the specified socket.

[EBADF] The socket argument is not a valid file descriptor.

[EINVAL] The socket is already bound to an address, and the protocol does not support binding to a new address; or the socket has been shut down.

[ENOTSOCK] The socket argument does not refer to a socket.

[EOPNOTSUPP] The socket type of the specified socket does not support binding to an address.

If the address family of the socket is AF_UNIX, then bind() shall fail if:

[EACCES] A component of the path prefix denies search permission, or the requested name requires writing in a directory with a mode that denies write permission.

[EDESTADDRREQ] or [EISDIR]
The address argument is a null pointer.
bind( )

[EIO] An I/O error occurred.
[ELOOP] A loop exists in symbolic links encountered during resolution of the pathname in address.
[ENOENT] A component of the pathname does not name an existing file or the pathname is an empty string.
[ENOTDIR] A component of the path prefix of the pathname in address is not a directory.
[EROFS] The name would reside on a read-only file system.

The bind( ) function may fail if:

[EACCESS] The specified address is protected and the current user does not have permission to bind to it.
[EINVAL] The address_len argument is not a valid length for the address family.
[EISCONN] The socket is already connected.
[ELOOP] More than [SYMLOOP_MAX] symbolic links were encountered during resolution of the pathname in address.
[ENAMETOOLONG] Pathname resolution of a symbolic link produced an intermediate result whose length exceeds [PATH_MAX].
[ENOBUFS] Insufficient resources were available to complete the call.

EXAMPLES
None.

APPLICATION USAGE
An application program can retrieve the assigned socket name with the getsockname( ) function.

RATIONALE
None.

FUTURE DIRECTIONS
None.

connect( ), getsockname( ), listen( ), socket( ), the Base Definitions volume of IEEE Std 1003.1-2001, <sys/socket.h>

CHANGE HISTORY
First released in Issue 6. Derived from the XNS, Issue 5.2 specification.
NAME
bsd_signal — simplified signal facilities

SYNOPSIS
#include <signal.h>

void (*bsd_signal(int sig, void (*func)(int)))(int);

DESCRIPTION
The bsd_signal() function provides a partially compatible interface for programs written to
historical system interfaces (see APPLICATION USAGE).

The function call bsd_signal(sig, func) shall be equivalent to the following:

void (*bsd_signal(int sig, void (*func)(int)))(int)
{
    struct sigaction act, oact;
    act.sa_handler = func;
    act.sa_flags = SA_RESTART;
    sigemptyset(&act.sa_mask);
    sigaddset(&act.sa_mask, sig);
    if (sigaction(sig, &act, &oact) == -1)
        return(SIG_ERR);
    return(oact.sa_handler);
}

The handler function should be declared:

void handler(int sig);

where sig is the signal number. The behavior is undefined if func is a function that takes more
than one argument, or an argument of a different type.

RETURN VALUE
Upon successful completion, bsd_signal() shall return the previous action for sig. Otherwise,
SIG_ERR shall be returned and errno shall be set to indicate the error.

ERRORS
Refer to sigaction().

EXAMPLES
None.

APPLICATION USAGE
This function is a direct replacement for the BSD signal() function for simple applications that
are installing a single-argument signal handler function. If a BSD signal handler function is being
installed that expects more than one argument, the application has to be modified to use
sigaction(). The bsd_signal() function differs from signal() in that the SA_RESTART flag is set
and the SA_RESETHAND is clear when bsd_signal() is used. The state of these flags is not
specified for signal().

It is recommended that new applications use the sigaction() function.

RATIONALE
None.
**FUTURE DIRECTIONS**

None.

**SEE ALSO**
sigaction(), sigaddset(), sigemptyset(), signal(), the Base Definitions volume of IEEE Std 1003.1-2001, `<signal.h>`

**CHANGE HISTORY**

First released in Issue 4, Version 2.

**Issue 5**

Moved from X/OPEN UNIX extension to BASE.

**Issue 6**

This function is marked obsolescent.
NAME

bsearch — binary search a sorted table

SYNOPSIS

#include <stdlib.h>

void *bsearch(const void *key, const void *base, size_t nel, size_t width, int (*compar)(const void *, const void *));

DESCRIPTION

The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-2001 defers to the ISO C standard.

The bsearch() function shall search an array of nel objects, the initial element of which is pointed to by base, for an element that matches the object pointed to by key. The size of each element in the array is specified by width. If the nel argument has the value zero, the comparison function pointed to by compar shall not be called and no match shall be found.

The comparison function pointed to by compar shall be called with two arguments that point to the key object and to an array element, in that order.

The application shall ensure that the comparison function pointed to by compar does not alter the contents of the array. The implementation may reorder elements of the array between calls to the comparison function, but shall not alter the contents of any individual element.

The implementation shall ensure that the first argument is always a pointer to the key.

When the same objects (consisting of width bytes, irrespective of their current positions in the array) are passed more than once to the comparison function, the results shall be consistent with one another. That is, the same object shall always compare the same way with the key.

The application shall ensure that the function returns an integer less than, equal to, or greater than 0 if the key object is considered, respectively, to be less than, to match, or to be greater than the array element. The application shall ensure that the array consists of all the elements that compare less than, all the elements that compare equal to, and all the elements that compare greater than the key object, in that order.

RETURN VALUE

The bsearch() function shall return a pointer to a matching member of the array, or a null pointer if no match is found. If two or more members compare equal, which member is returned is unspecified.

ERRORS

No errors are defined.

EXAMPLES

The example below searches a table containing pointers to nodes consisting of a string and its length. The table is ordered alphabetically on the string in the node pointed to by each entry.

The code fragment below reads in strings and either finds the corresponding node and prints out the string and its length, or prints an error message.

#include <stdio.h>
#include <stdlib.h>
#include <string.h>

#define TABSIZE 1000
struct node {
    char *string;
    int length;
};

struct node table[TABSIZE]; /* Table to be searched. */

struct node *node_ptr, node;
/* Routine to compare 2 nodes. */
int node_compare(const void *, const void *);
char str_space[20]; /* Space to read string into. */

node.string = str_space;
while (scanf("%s", node.string) != EOF) {
    node_ptr = (struct node *)bsearch((void *)&node,
        (void *)table, TABSIZE,
        sizeof(struct node), node_compare);
    if (node_ptr != NULL) {
        (void)printf("string = %20s, length = %d\n",
            node_ptr->string, node_ptr->length);
    } else {
        (void)printf("not found: %s\n", node.string);
    }
}

/* This routine compares two nodes based on an
   alphabetical ordering of the string field. */
int node_compare(const void *node1, const void *node2)
{
    return strcoll(((const struct node *)node1)->string,
        ((const struct node *)node2)->string);
}

APPLICATION USAGE

The pointers to the key and the element at the base of the table should be of type pointer-to-
element.

The comparison function need not compare every byte, so arbitrary data may be contained in
the elements in addition to the values being compared.

In practice, the array is usually sorted according to the comparison function.

RATIONALE

The requirement that the second argument (hereafter referred to as p) to the comparison
function is a pointer to an element of the array implies that for every call all of the following
expressions are non-zero:
bsearch()

5345  ((char *)p - (char *(base) % width == 0
5346  (char *)p >= (char *)base
5347  (char *)p < (char *)base + nel * width

5348  **FUTURE DIRECTIONS**
5349  None.

5355
5356  **Issue 6**
5357  The DESCRIPTION is updated to avoid use of the term “must” for application requirements.
5358  IEEE Std 1003.1-2001/Cor 1-2002, item XSH/TC1/D6/11 is applied, adding to the
5359  DESCRIPTION the last sentence of the first non-shaded paragraph, and the following three
5360  paragraphs. The RATIONALE section is also updated. These changes are for alignment with the
5361  ISO C standard.
NAME
btowc — single byte to wide character conversion

SYNOPSIS
#include <stdio.h>
#include <wchar.h>

wint_t btowc(int c);

DESCRIPTION
The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-2001 defers to the ISO C standard.

The btowc() function shall determine whether c constitutes a valid (one-byte) character in the initial shift state.

The behavior of this function shall be affected by the LC_CTYPE category of the current locale.

RETURN VALUE
The btowc() function shall return WEOF if c has the value EOF or if (unsigned char) c does not constitute a valid (one-byte) character in the initial shift state. Otherwise, it shall return the wide-character representation of that character.

ERRORS
No errors are defined.

EXAMPLES
None.

NAME
  cacosl — complex arc cosine functions

SYNOPSIS
  #include <complex.h>
  long double complex cacosl(long double complex z);

DESCRIPTION
  Refer to cacos().
NAME
calloc — a memory allocator

SYNOPSIS
#include <stdlib.h>

void *calloc(size_t nelem, size_t elsize);

DESCRIPTION
The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-2001 defers to the ISO C standard.

The calloc() function shall allocate unused space for an array of nelem elements each of whose size in bytes is elsize. The space shall be initialized to all bits 0.

The order and contiguity of storage allocated by successive calls to calloc() is unspecified. The pointer returned if the allocation succeeds shall be suitably aligned so that it may be assigned to a pointer to any type of object and then used to access such an object or an array of such objects in the space allocated (until the space is explicitly freed or reallocated). Each such allocation shall yield a pointer to an object disjoint from any other object. The pointer returned shall point to the start (lowest byte address) of the allocated space. If the space cannot be allocated, a null pointer shall be returned. If the size of the space requested is 0, the behavior is implementation-defined: the value returned shall be either a null pointer or a unique pointer.

RETURN VALUE
Upon successful completion with both nelem and elsize non-zero, calloc() shall return a pointer to the allocated space. If either nelem or elsize is 0, then either a null pointer or a unique pointer value that can be successfully passed to free() shall be returned. Otherwise, it shall return a null pointer and set errno to indicate the error.

ERRORS
The calloc() function shall fail if:

- [ENOMEM] Insufficient memory is available.

EXAMPLES
None.

APPLICATION USAGE
There is now no requirement for the implementation to support the inclusion of <malloc.h>.

RATIONALE
None.

FUTURE DIRECTIONS

NAME
catanl — complex arc tangent functions

SYNOPSIS
#include <complex.h>
long double complex catanl(long double complex z);

DESCRIPTION
Refer to catan().
catclose()  

NAME
   catclose — close a message catalog descriptor

SYNOPSIS
   XSI
   #include <nl_types.h>
   int catclose(nl_catd catd);

DESCRIPTION
   The catclose() function shall close the message catalog identified by catd. If a file descriptor is used to implement the type nl_catd, that file descriptor shall be closed.

RETURN VALUE
   Upon successful completion, catclose() shall return 0; otherwise, −1 shall be returned, and errno set to indicate the error.

ERRORS
   The catclose() function may fail if:

   [EBADF] The catalog descriptor is not valid.

   [EINTR] The catclose() function was interrupted by a signal.

EXAMPLES
   None.

APPLICATION USAGE
   None.

RATIONALE
   None.

FUTURE DIRECTIONS
   None.

   First released in Issue 2.
NAME

catgets — read a program message

SYNOPSIS

```c
#include <nl_types.h>

char *catgets(nl_catd catd, int set_id, int msg_id, const char *s);
```

DESCRIPTION

The `catgets()` function shall attempt to read message `msg_id`, in set `set_id`, from the message catalog identified by `catd`. The `catd` argument is a message catalog descriptor returned from an earlier call to `catopen()`. The `s` argument points to a default message string which shall be returned by `catgets()` if it cannot retrieve the identified message.

The `catgets()` function need not be reentrant. A function that is not required to be reentrant is not required to be thread-safe.

RETURN VALUE

If the identified message is retrieved successfully, `catgets()` shall return a pointer to an internal buffer area containing the null-terminated message string. If the call is unsuccessful for any reason, `s` shall be returned and `errno` may be set to indicate the error.

ERRORS

The `catgets()` function may fail if:

- `[EBADF]` The `catd` argument is not a valid message catalog descriptor open for reading.
- `[EBADMSG]` The message identified by `set_id` and `msg_id` in the specified message catalog did not satisfy implementation-defined security criteria.
- `[EINTR]` The read operation was terminated due to the receipt of a signal, and no data was transferred.
- `[EINVAL]` The message catalog identified by `catd` is corrupted.
- `[ENOMSG]` The message identified by `set_id` and `msg_id` is not in the message catalog.

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

None.

FUTURE DIRECTIONS

None.

SEE ALSO

`catclose()`, `catopen()`, the Base Definitions volume of IEEE Std 1003.1-2001, `<nl_types.h>`

CHANGE HISTORY

First released in Issue 2.

Issue 5

A note indicating that this function need not be reentrant is added to the DESCRIPTION.
In the DESCRIPTION, the note about reentrancy is expanded to cover thread-safety.
NAME

`catopen` — open a message catalog

SYNOPSIS

XSI

```c
#include <nl_types.h>

nl_catd catopen(const char *name, int oflag);
```

DESCRIPTION

The `catopen`() function shall open a message catalog and return a message catalog descriptor. The `name` argument specifies the name of the message catalog to be opened. If `name` contains a ‘/’, then `name` specifies a complete name for the message catalog. Otherwise, the environment variable `NLSPATH` is used with `name` substituted for the `%N` conversion specification (see the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 8, Environment Variables). If `NLSPATH` exists in the environment when the process starts, then if the process has appropriate privileges, the behavior of `catopen`() is undefined. If `NLSPATH` does not exist in the environment, or if a message catalog cannot be found in any of the components specified by `NLSPATH`, then an implementation-defined default path shall be used. This default may be affected by the setting of `LC_MESSAGES` if the value of `oflag` is `NL_CAT_LOCALE`, or the `LANG` environment variable if `oflag` is 0.

A message catalog descriptor shall remain valid in a process until that process closes it, or a successful call to one of the `exec` functions. A change in the setting of the `LC_MESSAGES` category may invalidate existing open catalogs.

If a file descriptor is used to implement message catalog descriptors, the `FD_CLOEXEC` flag shall be set; see `<fcntl.h>`.

If the value of the `oflag` argument is 0, the `LANG` environment variable is used to locate the catalog without regard to the `LC_MESSAGES` category. If the `oflag` argument is `NL_CAT_LOCALE`, the `LC_MESSAGES` category is used to locate the message catalog (see the Base Definitions volume of IEEE Std 1003.1-2001, Section 8.2, Internationalization Variables).

RETURN VALUE

Upon successful completion, `catopen`() shall return a message catalog descriptor for use on subsequent calls to `catgets()` and `catclose()`.

ERRORS

The `catopen`() function may fail if:

- `[EACCES]` Search permission is denied for the component of the path prefix of the message catalog or read permission is denied for the message catalog.

- `[ENOMEM]` File descriptors are currently open in the calling process.

- `[ENAMETOOLONG]` The length of a pathname of the message catalog exceeds `[PATH_MAX]` or a pathname component is longer than `[NAME_MAX]`.

- `[ENAMETOOLONG]` Pathname resolution of a symbolic link produced an intermediate result whose length exceeds `[PATH_MAX]`.

- `[ENOENT]` The message catalog does not exist or the `name` argument points to an empty string.
catopen()  

System Interfaces

5845  [ENOMEM]  Insufficient storage space is available.

5846  [ENOTDIR]  A component of the path prefix of the message catalog is not a directory.

5847  EXAMPLES

5848  None.

5849  APPLICATION USAGE

5850  Some implementations of catopen() use malloc() to allocate space for internal buffer areas. The
catopen() function may fail if there is insufficient storage space available to accommodate these
buffers.

5852  Conforming applications must assume that message catalog descriptors are not valid after a call
to one of the exec functions.

5854  Application writers should be aware that guidelines for the location of message catalogs have
not yet been developed. Therefore they should take care to avoid conflicting with catalogs used
by other applications and the standard utilities.

5856  RATIONALE

NAME

cbrt, cbrtf, cbrtl — cube root functions

SYNOPSIS

#include <math.h>

double cbrt(double x);

float cbrtf(float x);

long double cbrtl(long double x);

DESCRIPTION

The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-2001 defers to the ISO C standard.

These functions shall compute the real cube root of their argument \( x \).

RETURN VALUE

Upon successful completion, these functions shall return the cube root of \( x \).

If \( x \) is NaN, a NaN shall be returned.

If \( x \) is \( \pm 0 \) or \( \pm \text{Inf} \), \( x \) shall be returned.

ERRORS

No errors are defined.

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

For some applications, a true cube root function, which returns negative results for negative arguments, is more appropriate than \( \text{pow}(x, 1.0/3.0) \), which returns a NaN for \( x \) less than 0.

FUTURE DIRECTIONS

None.

DESCRIPTION
Refer to ccos().
NAME
ceil, ceilf, ceill — ceiling value function

SYNOPSIS
#include <math.h>
double ceil(double x);
float ceilf(float x);
long double ceill(long double x);

DESCRIPTION
The functionality described on this reference page is aligned with the ISO C standard. Any
collision between the requirements described here and the ISO C standard is unintentional. This

These functions shall compute the smallest integral value not less than x.

An application wishing to check for error situations should set errno to zero and call
feclearexcept(FE_ALL_EXCEPT) before calling these functions. On return, if errno is non-zero or
fetestexcept(FE_INVALID | FE_DIVBYZERO | FE_OVERFLOW | FE_UNDERFLOW) is non-
zero, an error has occurred.

RETURN VALUE
Upon successful completion, ceil(), ceilf(), and ceill() shall return the smallest integral value not
less than x, expressed as a type double, float, or long double, respectively.

If x is NaN, a NaN shall be returned.

If x is ±0 or ±Inf, x shall be returned.

If the correct value would cause overflow, a range error shall occur and ceil(), ceilf(), and ceill() shall return the value of the macro HUGE_VAL, HUGE_VALF, and HUGE_VALL, respectively.

ERRORS
These functions shall fail if:

Range Error The result overflows.

If the integer expression (math_errhandling & MATH_ERRNO) is non-zero, then errno shall be set to [ERANGE]. If the integer expression
(math_errhandling & MATH_ERRNO) is non-zero, then the overflow
floating-point exception shall be raised.

APPLICATION USAGE
The integral value returned by these functions need not be expressible as an int or long. The
return value should be tested before assigning it to an integer type to avoid the undefined results
of an integer overflow.

The ceil() function can only overflow when the floating-point representation has
DBL_MANT_DIG > DBL_MAX_EXP.

On error, the expressions (math_errhandling & MATH_ERRNO) and (math_errhandling & MATH_ERREXCEPT) are independent of each other, but at least one of them must be non-zero.

CHANGE HISTORY
NAME

cfgetispeed — get input baud rate

SYNOPSIS

#include <termios.h>

speed_t cfgetispeed(const struct termios *termios_p);

DESCRIPTION

The cfgetispeed() function shall extract the input baud rate from the termios structure to which the termios_p argument points. This function shall return exactly the value in the termios data structure, without interpretation.

RETURN VALUE

Upon successful completion, cfgetispeed() shall return a value of type speed_t representing the input baud rate.

ERRORS

No errors are defined.

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

The term “baud” is used historically here, but is not technically correct. This is properly “bits per second”, which may not be the same as baud. However, the term is used because of the historical usage and understanding.

The cfgetospeed(), cfgetispeed(), cfsetospeed(), and cfsetispeed() functions do not take arguments as numbers, but rather as symbolic names. There are two reasons for this:

1. Historically, numbers were not used because of the way the rate was stored in the data structure. This is retained even though a function is now used.

2. More importantly, only a limited set of possible rates is at all portable, and this constrains the application to that set.

There is nothing to prevent an implementation accepting as an extension a number (such as 126), and since the encoding of the Bxxx symbols is not specified, this can be done to avoid introducing ambiguity.

Setting the input baud rate to zero was a mechanism to allow for split baud rates. Clarifications in this volume of IEEE Std 1003.1-2001 have made it possible to determine whether split rates are supported and to support them without having to treat zero as a special case. Since this functionality is also confusing, it has been declared obsolescent. The 0 argument referred to is the literal constant 0, not the symbolic constant B0. This volume of IEEE Std 1003.1-2001 does not preclude B0 from being defined as the value 0; in fact, implementations would likely benefit from the two being equivalent. This volume of IEEE Std 1003.1-2001 does not fully specify whether the previous cfsetispeed() value is retained after a tcgetattr() as the actual value or as zero. Therefore, conforming applications should always set both the input speed and output speed when setting either.

In historical implementations, the baud rate information is traditionally kept in c_cflag. Applications should be written to presume that this might be the case (and thus not blindly copy c_cflag), but not to rely on it in case it is in some other field of the structure. Setting the c_cflag field absolutely after setting a baud rate is a non-portable action because of this. In general, the
unused parts of the flag fields might be used by the implementation and should not be blindly copied from the descriptions of one terminal device to another.

FUTURE DIRECTIONS
None.

NAME
cfsetispeed — set input baud rate

SYNOPSIS
#include <termios.h>

int cfsetispeed(struct termios *termios_p, speed_t speed);

DESCRIPTION
The cfsetispeed() function shall set the input baud rate stored in the structure pointed to by
termios_p to speed.
There shall be no effect on the baud rates set in the hardware until a subsequent successful call
to tcsetattr() with the same termios structure. Similarly, errors resulting from attempts to set
baud rates not supported by the terminal device need not be detected until the tcsetattr() function is called.

RETURN VALUE
Upon successful completion, cfsetispeed() shall return 0; otherwise, −1 shall be returned, and
errno may be set to indicate the error.

ERRORS
The cfsetispeed() function may fail if:

EINVAL The speed value is not a valid baud rate.
EINVAL The value of speed is outside the range of possible speed values as specified in
<termios.h>.

EXAMPLES
None.

APPLICATION USAGE
None.

RATIONALE

Issue 6
The following new requirements on POSIX implementations derive from alignment with the
Single UNIX Specification:

• The optional setting of errno and the [EINVAL] error conditions are added.
NAME
chdir — change working directory

SYNOPSIS
#include <unistd.h>

int chdir(const char *path);

DESCRIPTION
The chdir() function shall cause the directory named by the pathname pointed to by the path argument to become the current working directory; that is, the starting point for path searches for pathnames not beginning with '/'.

RETURN VALUE
Upon successful completion, 0 shall be returned. Otherwise, −1 shall be returned, the current working directory shall remain unchanged, and errno shall be set to indicate the error.

ERRORS
The chdir() function shall fail if:

[EACCES] Search permission is denied for any component of the pathname.

[ELOOP] A loop exists in symbolic links encountered during resolution of the path argument.

[ENAMETOOLONG] The length of the path argument exceeds {PATH_MAX} or a pathname component is longer than {NAME_MAX}.

[ENOENT] A component of path does not name an existing directory or path is an empty string.

[ENOTDIR] A component of the pathname is not a directory.

The chdir() function may fail if:

[ELOOP] More than {SYMLOOP_MAX} symbolic links were encountered during resolution of the path argument.

[ENAMETOOLONG] As a result of encountering a symbolic link in resolution of the path argument, the length of the substituted pathname string exceeded {PATH_MAX}.

EXAMPLES

Changing the Current Working Directory
The following example makes the value pointed to by directory, /tmp, the current working directory.

#include <unistd.h>

char *directory = "/tmp";
int ret;
ret = chdir(directory);
APPLICATION USAGE
None.

RATIONALE
The `chdir()` function only affects the working directory of the current process.

FUTURE DIRECTIONS
None.

SEE ALSO
`getcwd()`, the Base Definitions volume of IEEE Std 1003.1-2001, `<unistd.h>`

CHANGE HISTORY
First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 6
The APPLICATION USAGE section is added.
The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The `[ELOOP]` mandatory error condition is added.
- A second `[ENAMETOOLONG]` is added as an optional error condition.
The following changes were made to align with the IEEE P1003.1a draft standard:

- The `[ELOOP]` optional error condition is added.
NAME
chmod — change mode of a file

SYNOPSIS
#include <sys/stat.h>

int chmod(const char *path, mode_t mode);

DESCRIPTION
XSI  The chmod() function shall change S_ISUID, S_ISGID, S_ISVTX, and the file permission bits of
the file named by the pathname pointed to by the path argument to the corresponding bits in the
mode argument. The application shall ensure that the effective user ID of the process matches the
owner of the file or the process has appropriate privileges in order to do this.
XSI  S_ISUID, S_ISGID, S_ISVTX, and the file permission bits are described in <sys/stat.h>.

If the calling process does not have appropriate privileges, and if the group ID of the file does
not match the effective group ID or one of the supplementary group IDs and if the file is a
regular file, bit S_ISGID (set-group-ID on execution) in the file's mode shall be cleared upon
successful return from chmod().

Additional implementation-defined restrictions may cause the S_ISUID and S_ISGID bits in
mode to be ignored.

The effect on file descriptors for files open at the time of a call to chmod() is implementation-
defined.

Upon successful completion, chmod() shall mark for update the st_ctime field of the file.

RETURN VALUE
Upon successful completion, 0 shall be returned; otherwise, −1 shall be returned and errno set to
indicate the error. If −1 is returned, no change to the file mode occurs.

ERRORS
The chmod() function shall fail if:

[EACCES]  Search permission is denied on a component of the path prefix.

[ELOOP]  A loop exists in symbolic links encountered during resolution of the path argument.

[ENAMETOOLONG]  The length of the path argument exceeds [PATH_MAX] or a pathname
component is longer than [NAME_MAX].

[ENOTDIR]  A component of the path prefix is not a directory.

[ENOENT]  A component of path does not name an existing file or path is an empty string.

[EPERM]  The effective user ID does not match the owner of the file and the process
does not have appropriate privileges.

[EROFS]  The named file resides on a read-only file system.

The chmod() function may fail if:

[EINTR]  A signal was caught during execution of the function.

[EINVAL]  The value of the mode argument is invalid.

[ELOOP]  More than [SYMLOOP_MAX] symbolic links were encountered during
resolution of the path argument.
[ENAMETOOLONG]
As a result of encountering a symbolic link in resolution of the path argument, the length of the substituted pathname strings exceeded [PATH_MAX].

EXAMPLES

Setting Read Permissions for User, Group, and Others
The following example sets read permissions for the owner, group, and others.

```c
#include <sys/stat.h>
const char *path;
...
chmod(path, S_IRUSR|S_IRGRP|S_IROTH);
```

Setting Read, Write, and Execute Permissions for the Owner Only
The following example sets read, write, and execute permissions for the owner, and no permissions for group and others.

```c
#include <sys/stat.h>
const char *path;
...
chmod(path, S_IRWXU);
```

Setting Different Permissions for Owner, Group, and Other
The following example sets owner permissions for CHANGEFILE to read, write, and execute, group permissions to read and execute, and other permissions to read.

```c
#include <sys/stat.h>
#define CHANGEFILE "/etc/myfile"
...
chmod(CHANGEFILE, S_IRWXU|S_IRGRP|S_IXGRP|S_IROTH);
```

Setting and Checking File Permissions
The following example sets the file permission bits for a file named /home/cnd/mod1, then calls the stat() function to verify the permissions.

```c
#include <sys/types.h>
#include <sys/stat.h>
int status;
struct stat buffer
...
chmod("home/cnd/mod1", S_IRWXU|S_IRWXG|S_IROTH|S_IWOTH);
status = stat("home/cnd/mod1", &buffer);
```

APPLICATION USAGE
In order to ensure that the S_ISUID and S_ISGID bits are set, an application requiring this should use stat() after a successful chmod() to verify this.

Any file descriptors currently open by any process on the file could possibly become invalid if the mode of the file is changed to a value which would deny access to that process. One
situation where this could occur is on a stateless file system. This behavior will not occur in a conforming environment.

**RATIONALE**

This volume of IEEE Std 1003.1-2001 specifies that the S_ISGID bit is cleared by `chmod()` on a regular file under certain conditions. This is specified on the assumption that regular files may be executed, and the system should prevent users from making executable `setgid()` files perform with privileges that the caller does not have. On implementations that support execution of other file types, the S_ISGID bit should be cleared for those file types under the same circumstances.

Implementations that use the S_ISUID bit to indicate some other function (for example, mandatory record locking) on non-executable files need not clear this bit on writing. They should clear the bit for executable files and any other cases where the bit grants special powers to processes that change the file contents. Similar comments apply to the S_ISGID bit.

**FUTURE DIRECTIONS**

None.

**SEE ALSO**

`chown()` , `mkdir()` , `mkfifo()` , `open()` , `stat()` , `statvfs()` , the Base Definitions volume of IEEE Std 1003.1-2001, `<sys/stat.h>` , `<sys/types.h>`

**CHANGE HISTORY**

First released in Issue 1. Derived from Issue 1 of the SVID.

**Issue 6**

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The requirement to include `<sys/types.h>` has been removed. Although `<sys/types.h>` was required for conforming implementations of previous POSIX specifications, it was not required for UNIX applications.
- The [EINVAL] and [EINTR] optional error conditions are added.
- A second [ENAMETOOLONG] is added as an optional error condition.

The following changes were made to align with the IEEE P1003.1a draft standard:

- The [ELOOP] optional error condition is added.

The DESCRIPTION is updated to avoid use of the term “must” for application requirements.
**NAME**
chown — change owner and group of a file

**SYNOPSIS**

```c
#include <unistd.h>

int chown(const char *path, uid_t owner, gid_t group);
```

**DESCRIPTION**

The `chown()` function shall change the user and group ownership of a file.

The `path` argument points to a pathname naming a file. The user ID and group ID of the named file shall be set to the numeric values contained in `owner` and `group`, respectively.

Only processes with an effective user ID equal to the user ID of the file or with appropriate privileges may change the ownership of a file. If `_POSIX_CHOWN_RESTRICTED` is in effect for `path`:

- Changing the user ID is restricted to processes with appropriate privileges.
- Changing the group ID is permitted to a process with an effective user ID equal to the user ID of the file, but without appropriate privileges, if and only if `owner` is equal to the file's user ID or (`uid_t`)−1 and `group` is equal either to the calling process' effective group ID or to one of its supplementary group IDs.

If the specified file is a regular file, one or more of the S_IXUSR, S_IXGRP, or S_IXOTH bits of the file mode are set, and the process does not have appropriate privileges, the set-user-ID (S_ISUID) and set-group-ID (S_ISGID) bits of the file mode shall be cleared upon successful return from `chown()`. If the specified file is a regular file, one or more of the S_IXUSR, S_IXGRP, or S_IXOTH bits of the file mode are set, and the process has appropriate privileges, it is implementation-defined whether the set-user-ID and set-group-ID bits are altered. If the `chown()` function is successfully invoked on a file that is not a regular file and one or more of the S_IXUSR, S_IXGRP, or S_IXOTH bits of the file mode are set, the set-user-ID and set-group-ID bits may be cleared.

If `owner` or `group` is specified as (`uid_t`)−1 or (`gid_t`)−1, respectively, the corresponding ID of the file shall not be changed. If both `owner` and `group` are −1, the times need not be updated.

Upon successful completion, `chown()` shall mark for update the `st_ctime` field of the file.

**RETURN VALUE**

Upon successful completion, 0 shall be returned; otherwise, −1 shall be returned and `errno` set to indicate the error. If −1 is returned, no changes are made in the user ID and group ID of the file.

**ERRORS**

The `chown()` function shall fail if:

- `[EACCES]` Search permission is denied on a component of the path prefix.
- `[ELOOP]` A loop exists in symbolic links encountered during resolution of the `path` argument.
- `[ENAMETOOLONG]` The length of the `path` argument exceeds {PATH_MAX} or a pathname component is longer than {NAME_MAX}.
- `[ENOTDIR]` A component of the path prefix is not a directory.
- `[ENOENT]` A component of `path` does not name an existing file or `path` is an empty string.
The effective user ID does not match the owner of the file, or the calling
process does not have appropriate privileges and
_POSIX_CHOWN_RESTRICTED indicates that such privilege is required.

The named file resides on a read-only file system.

The chown() function may fail if:

- [EIO] An I/O error occurred while reading or writing to the file system.
- [EINTR] The chown() function was interrupted by a signal which was caught.
- [EINVAL] The owner or group ID supplied is not a value supported by the
  implementation.
- [ELOOP] More than {SYMLOOP_MAX} symbolic links were encountered during
  resolution of the path argument.
- [ENAMETOOLONG] As a result of encountering a symbolic link in resolution of the path argument,
  the length of the substituted pathname string exceeded [PATH_MAX].

None.

Although chown() can be used on some implementations by the file owner to change the owner
and group to any desired values, the only portable use of this function is to change the group of
a file to the effective GID of the calling process or to a member of its group set.

System III and System V allow a user to give away files; that is, the owner of a file may change
its user ID to anything. This is a serious problem for implementations that are intended to meet
government security regulations. Version 7 and 4.3 BSD permit only the superuser to change the
user ID of a file. Some government agencies (usually not ones concerned directly with security)
find this limitation too confining. This volume of IEEE Std 1003.1-2001 uses may to permit secure
implementations while not disallowing System V.

System III and System V allow the owner of a file to change the group ID to anything. Version 7
permits only the superuser to change the group ID of a file. 4.3 BSD permits the owner to
change the group ID of a file to its effective group ID or to any of the groups in the list of
supplementary group IDs, but to no others.

The POSIX.1-1990 standard requires that the chown() function invoked by a non-appropriate
privileged process clear the S_ISGID and the S_ISUID bits for regular files, and permits them to
be cleared for other types of files. This is so that changes in accessibility do not accidentally
cause files to become security holes. Unfortunately, requiring these bits to be cleared on non-
executable data files also clears the mandatory file locking bit (shared with S_ISUID), which is
an extension on many implementations (it first appeared in System V). These bits should only be
required to be cleared on regular files that have one or more of their execute bits set.

None.

chmod(), pathconf(), the Base Definitions volume of IEEE Std 1003.1-2001, <sys/types.h>,
<unistd.h>
CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 6

The following changes are made for alignment with the ISO POSIX-1:1996 standard:

- The wording describing the optional dependency on _POSIX_CHOWN_RESTRICTED is restored.
- The [EPERM] error is restored as an error dependent on _POSIX_CHOWN_RESTRICTED. This is since its operand is a pathname and applications should be aware that the error may not occur for that pathname if the file system does not support _POSIX_CHOWN_RESTRICTED.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The requirement to include <sys/types.h> has been removed. Although <sys/types.h> was required for conforming implementations of previous POSIX specifications, it was not required for UNIX applications.
- The value for owner of (uid_t)−1 allows the use of −1 by the owner of a file to change the group ID only. A corresponding change is made for group.
- The [ELOOP] mandatory error condition is added.
- The [EIO] and [EINTR] optional error conditions are added.
- A second [ENAMETOOLONG] is added as an optional error condition.

The following changes were made to align with the IEEE P1003.1a draft standard:

- Clarification is added that the S_ISUID and S_ISGID bits do not need to be cleared when the process has appropriate privileges.
- The [ELOOP] optional error condition is added.
NAME
cimag, cimagf, cimagl — complex imaginary functions

SYNOPSIS
#include <complex.h>

double cimag(double complex z);
float cimagf(float complex z);
long double cimagl(long double complex z);

DESCRIPTION
The functionality described on this reference page is aligned with the ISO C standard. Any
collection between the requirements described here and the ISO C standard is unintentional. This

These functions shall compute the imaginary part of z.

RETURN VALUE
These functions shall return the imaginary part value (as a real).

ERRORS
No errors are defined.

EXAMPLES
None.

APPLICATION USAGE
For a variable z of complex type:

z == creal(z) + cimag(z)*I

RATIONALE
None.

FUTURE DIRECTIONS
None.

CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID.
NAME
   clock — report CPU time used

SYNOPSIS
   #include <time.h>
   clock_t clock(void);

DESCRIPTION
   The functionality described on this reference page is aligned with the ISO C standard. Any
   conflict between the requirements described here and the ISO C standard is unintentional. This

   The clock() function shall return the implementation’s best approximation to the processor time
   used by the process since the beginning of an implementation-defined era related only to the
   process invocation.

RETURN VALUE
   To determine the time in seconds, the value returned by clock() should be divided by the value
   of the macro CLOCKS_PER_SEC. CLOCKS_PER_SEC is defined to be one million in <time.h>.
   If the processor time used is not available or its value cannot be represented, the function shall
   return the value (clock_t)−1.

ERRORS
   No errors are defined.

EXAMPLES
   None.

APPLICATION USAGE
   In order to measure the time spent in a program, clock() should be called at the start of the
   program and its return value subtracted from the value returned by subsequent calls. The value
   returned by clock() is defined for compatibility across systems that have clocks with different
   resolutions. The resolution on any particular system need not be to microsecond accuracy.
   The value returned by clock() may wrap around on some implementations. For example, on a
   machine with 32-bit values for clock_t, it wraps after 2 147 seconds or 36 minutes.

RATIONALE
   None.

FUTURE DIRECTIONS
   None.

clock_getcpuclockid()

NAME
clock_getcpuclockid — access a process CPU-time clock (ADVANCED REALTIME)

SYNOPSIS
#include <time.h>

int clock_getcpuclockid(pid_t pid, clockid_t *clock_id);

DESCRIPTION
The clock_getcpuclockid() function shall return the clock ID of the CPU-time clock of the process specified by pid. If the process described by pid exists and the calling process has permission, the clock ID of this clock shall be returned in clock_id.

If pid is zero, the clock_getcpuclockid() function shall return the clock ID of the CPU-time clock of the process making the call, in clock_id.

The conditions under which one process has permission to obtain the CPU-time clock ID of other processes are implementation-defined.

RETURN VALUE
Upon successful completion, clock_getcpuclockid() shall return zero; otherwise, an error number shall be returned to indicate the error.

ERRORS
The clock_getcpuclockid() function shall fail if:

[EPERM] The requesting process does not have permission to access the CPU-time clock for the process.

The clock_getcpuclockid() function may fail if:

[ESRCH] No process can be found corresponding to the process specified by pid.

EXAMPLES
None.

APPLICATION USAGE
The clock_getcpuclockid() function is part of the Process CPU-Time Clocks option and need not be provided on all implementations.

RATIONALE
None.

FUTURE DIRECTIONS
None.

SEE ALSO
clock_getres(), timer_create(), the Base Definitions volume of IEEE Std 1003.1-2001, <time.h>

CHANGE HISTORY
In the SYNOPSIS, the inclusion of <sys/types.h> is no longer required.
NAME

clock_getres, clock_gettime, clock_settime — clock and timer functions (REALTIME)

SYNOPSIS

#include <time.h>

int clock_getres(clockid_t clock_id, struct timespec *res);
int clock_gettime(clockid_t clock_id, struct timespec *tp);
int clock_settime(clockid_t clock_id, const struct timespec *tp);

DESCRIPTION

The clock_getres() function shall return the resolution of any clock. Clock resolutions are
implementation-defined and cannot be set by a process. If the argument res is not NULL, the
resolution of the specified clock shall be stored in the location pointed to by res. If res is NULL,
the clock resolution is not returned. If the time argument of clock_settime() is not a multiple of res,
then the value is truncated to a multiple of res.

The clock_gettime() function shall return the current value tp for the specified clock, clock_id.

The clock_settime() function shall set the specified clock, clock_id, to the value specified by tp.
Time values that are between two consecutive non-negative integer multiples of the resolution
of the specified clock shall be truncated down to the smaller multiple of the resolution.

A clock may be system-wide (that is, visible to all processes) or per-process (measuring time that
is meaningful only within a process). All implementations shall support a clock_id of
CLOCK_REALTIME as defined in <time.h>. This clock represents the realtime clock for the
system. For this clock, the values returned by clock_gettime() and specified by clock_settime()
represent the amount of time (in seconds and nanoseconds) since the Epoch. An implementation
may also support additional clocks. The interpretation of time values for these clocks is
unspecified.

If the value of the CLOCK_REALTIME clock is set via clock_settime(), the new value of the clock
shall be used to determine the time of expiration for absolute time services based upon the
CLOCK_REALTIME clock. This applies to the time at which armed absolute timers expire. If the
absolute time requested at the invocation of such a time service is before the new value of the
clock, the time service shall expire immediately as if the clock had reached the requested time
normally.

Setting the value of the CLOCK_REALTIME clock via clock_settime() shall have no effect on
threads that are blocked waiting for a relative time service based upon this clock, including the
nanosleep() function; nor on the expiration of relative timers based upon this clock.
Consequently, these time services shall expire when the requested relative interval elapses,
independently of the new or old value of the clock.

If the Monotonic Clock option is supported, all implementations shall support a clock_id of
CLOCK_MONOTONIC defined in <time.h>. This clock represents the monotonic clock for the
system. For this clock, the value returned by clock_gettime() represents the amount of time (in
seconds and nanoseconds) since an unspecified point in the past (for example, system start-up
time, or the Epoch). This point does not change after system start-up time. The value of the
CLOCK_MONOTONIC clock cannot be set via clock_settime(). This function shall fail if it is
invoked with a clock_id argument of CLOCK_MONOTONIC.

The effect of setting a clock via clock_settime() on armed per-process timers associated with a
clock other than CLOCK_REALTIME is implementation-defined.

If the value of the CLOCK_REALTIME clock is set via clock_settime(), the new value of the clock
shall be used to determine the time at which the system shall awaken a thread blocked on an
absolute `clock_nanosleep()` call based upon the CLOCK_REALTIME clock. If the absolute time
requested at the invocation of such a time service is before the new value of the clock, the call
shall return immediately as if the clock had reached the requested time normally.

Setting the value of the CLOCK_REALTIME clock via `clock_settime()` shall have no effect on any
thread that is blocked on a relative `clock_nanosleep()` call. Consequently, the call shall return
when the requested relative interval elapses, independently of the new or old value of the clock.

The appropriate privilege to set a particular clock is implementation-defined.

If `_POSIX_CPUTIME` is defined, implementations shall support clock ID values obtained by
invoking `clock_getcpuclockid()`, which represent the CPU-time clock of a given process.
Implementations shall also support the special `clockid_t` value
CLOCK_PROCESS_CPUTIME_ID, which represents the CPU-time clock of the calling process
when invoking one of the `clock_*()` or `timer_*()` functions. For these clock IDs, the values
returned by `clock_gettime()` and specified by `clock_settime()` represent the amount of execution
time of the process associated with the clock. Changing the value of a CPU-time clock via
`clock_settime()` shall have no effect on the behavior of the sporadic server scheduling policy (see
Scheduling Policies on page 44).

If `_POSIX_THREAD_CPUTIME` is defined, implementations shall support clock ID values
obtained by invoking `pthread_getcpuclockid()`, which represent the CPU-time clock of a given
thread. Implementations shall also support the special `clockid_t` value
CLOCK_THREAD_CPUTIME_ID, which represents the CPU-time clock of the calling thread
when invoking one of the `clock_*()` or `timer_*()` functions. For these clock IDs, the values
returned by `clock_gettime()` and specified by `clock_settime()` shall represent the amount of
execution time of the thread associated with the clock. Changing the value of a CPU-time clock
via `clock_settime()` shall have no effect on the behavior of the sporadic server scheduling policy
(see Scheduling Policies on page 44).

RETURN VALUE
A return value of 0 shall indicate that the call succeeded. A return value of −1 shall indicate that
an error occurred, and `errno` shall be set to indicate the error.

ERRORS
The `clock_gettime()`, `clock_settime()`, and `clock_getres()` functions shall fail if:

- `[EINVAL]` The `clock_id` argument does not specify a known clock.
- `[EINVAL]` The `tp` argument to `clock_settime()` is outside the range for the given clock ID.
- `[EINVAL]` The `tp` argument specified a nanosecond value less than zero or greater than
  or equal to 1 000 million.
- `[EINVAL]` The value of the `clock_id` argument is CLOCK_MONOTONIC.
- `[EPERM]` The requesting process does not have the appropriate privilege to set the
  specified clock.
EXAMPLES
None.

APPLICATION USAGE
These functions are part of the Timers option and need not be available on all implementations.

Note that the absolute value of the monotonic clock is meaningless (because its origin is arbitrary), and thus there is no need to set it. Furthermore, realtime applications can rely on the fact that the value of this clock is never set and, therefore, that time intervals measured with this clock will not be affected by calls to clock_settime().

RATIONALE
None.

FUTURE DIRECTIONS
None.

SEE ALSO
clock_getcpuclockid(), clock_nanosleep(), ctime(), mq_timedreceive(), mq_timedsend(), nanosleep(), pthread_mutex_timedlock(), sem_timedwait(), time(), timer_create(), timer_getoverrun(), the Base Definitions volume of IEEE Std 1003.1-2001, <time.h>

CHANGE HISTORY
First released in Issue 5. Included for alignment with the POSIX Realtime Extension.

Issue 6
The [ENOSYS] error condition has been removed as stubs need not be provided if an implementation does not support the Timers option.

The APPLICATION USAGE section is added.

The following changes were made to align with the IEEE P1003.1a draft standard:

• Clarification is added of the effect of resetting the clock resolution.

CPU-time clocks and the clock_getcpuclockid() function are added for alignment with IEEE Std 1003.1d-1999.

The following changes are added for alignment with IEEE Std 1003.1j-2000:

• The DESCRIPTION is updated as follows:
  — The value returned by clock_gettime() for CLOCK_MONOTONIC is specified.
  — The clock_settime() function failing for CLOCK_MONOTONIC is specified.
  — The effects of clock_settime() on the clock_nanosleep() function with respect to CLOCK_REALTIME are specified.

• An [EINVAL] error is added to the ERRORS section, indicating that clock_settime() fails for CLOCK_MONOTONIC.

• The APPLICATION USAGE section notes that the CLOCK_MONOTONIC clock need not and shall not be set by clock_settime() since the absolute value of the CLOCK_MONOTONIC clock is meaningless.

• The clock_nanosleep(), mq_timedreceive(), mq_timedsend(), pthread_mutex_timedlock(), sem_timedwait(), timer_create(), and timer_settime() functions are added to the SEE ALSO section.
NAME

clock_nanosleep — high resolution sleep with specifiable clock (ADVANCED REALTIME)

SYNOPSIS

```c
#include <time.h>

int clock_nanosleep(clockid_t clock_id, int flags,
                     const struct timespec *rqtp, struct timespec *rmtp);
```

DESCRIPTION

If the flag TIMER_ABSTIME is not set in the `flags` argument, the `clock_nanosleep()` function shall cause the current thread to be suspended from execution until either the time interval specified by the `rqtp` argument has elapsed, or a signal is delivered to the calling thread and its action is to invoke a signal-catch function, or the process is terminated. The clock used to measure the time shall be the clock specified by `clock_id`.

If the flag TIMER_ABSTIME is set in the `flags` argument, the `clock_nanosleep()` function shall cause the current thread to be suspended from execution until either the time value of the clock specified by `clock_id` reaches the absolute time specified by the `rqtp` argument, or a signal is delivered to the calling thread and its action is to invoke a signal-catch function, or the process is terminated. If, at the time of the call, the time value specified by `rqtp` is less than or equal to the time value of the specified clock, then `clock_nanosleep()` shall return immediately and the calling process shall not be suspended.

The suspension time caused by this function may be longer than requested because the argument value is rounded up to an integer multiple of the sleep resolution, or because of the scheduling of other activity by the system. But, except for the case of being interrupted by a signal, the suspension time for the relative `clock_nanosleep()` function (that is, with the TIMER_ABSTIME flag not set) shall not be less than the time interval specified by `rqtp`, as measured by the corresponding clock. The suspension for the absolute `clock_nanosleep()` function (that is, with the TIMER_ABSTIME flag set) shall be in effect at least until the value of the corresponding clock reaches the absolute time specified by `rqtp`, except for the case of being interrupted by a signal.

The use of the `clock_nanosleep()` function shall have no effect on the action or blockage of any signal.

The `clock_nanosleep()` function shall fail if the `clock_id` argument refers to the CPU-time clock of the calling thread. It is unspecified whether `clock_id` values of other CPU-time clocks are allowed.

RETURN VALUE

If the `clock_nanosleep()` function returns because the requested time has elapsed, its return value shall be zero.

If the `clock_nanosleep()` function returns because it has been interrupted by a signal, it shall return the corresponding error value. For the relative `clock_nanosleep()` function, if the `rmtp` argument is non-NULL, the `timespec` structure referenced by it shall be updated to contain the amount of time remaining in the interval (the requested time minus the time actually slept). If the `rmtp` argument is NULL, the remaining time is not returned. The absolute `clock_nanosleep()` function has no effect on the structure referenced by `rmtp`.

If `clock_nanosleep()` fails, it shall return the corresponding error value.
The clock_nanosleep() function shall fail if:

- [EINTR] The clock_nanosleep() function was interrupted by a signal.
- [EINVAL] The rqtp argument specified a nanosecond value less than zero or greater than or equal to 1,000 million; or the TIMER_ABSTIME flag was specified in flags and the rqtp argument is outside the range for the clock specified by clock_id; or the clock_id argument does not specify a known clock, or specifies the CPU-time clock of the calling thread.
- [ENOTSUP] The clock_id argument specifies a clock for which clock_nanosleep() is not supported, such as a CPU-time clock.

EXAMPLES

None.

APPLICATION USAGE

Calling clock_nanosleep() with the value TIMER_ABSTIME not set in the flags argument and with a clock_id of CLOCK_REALTIME is equivalent to calling nanosleep() with the same rqtp and rmtp arguments.

RATIONALE

The nanosleep() function specifies that the system-wide clock CLOCK_REALTIME is used to measure the elapsed time for this time service. However, with the introduction of the monotonic clock CLOCK_MONOTONIC a new relative sleep function is needed to allow an application to take advantage of the special characteristics of this clock.

There are many applications in which a process needs to be suspended and then activated multiple times in a periodic way; for example, to poll the status of a non-interrupting device or to refresh a display device. For these cases, it is known that precise periodic activation cannot be achieved with a relative sleep() or nanosleep() function call. Suppose, for example, a periodic process that is activated at time T0, executes for a while, and then wants to suspend itself until time T0+T, the period being T. If this process wants to use the nanosleep() function, it must first call clock_gettime() to get the current time, then calculate the difference between the current time and T0+T and, finally, call nanosleep() using the computed interval. However, the process could be preempted by a different process between the two function calls, and in this case the interval computed would be wrong; the process would wake up later than desired. This problem would not occur with the absolute clock_nanosleep() function, since only one function call would be necessary to suspend the process until the desired time. In other cases, however, a relative sleep is needed, and that is why both functionalities are required.

Although it is possible to implement periodic processes using the timers interface, this implementation would require the use of signals, and the reservation of some signal numbers. In this regard, the reasons for including an absolute version of the clock_nanosleep() function in IEEE Std 1003.1-2001 are the same as for the inclusion of the relative nanosleep().

It is also possible to implement precise periodic processes using pthread_cond_timedwait(), in which an absolute timeout is specified that takes effect if the condition variable involved is never signaled. However, the use of this interface is unnatural, and involves performing other operations on mutexes and condition variables that imply an unnecessary overhead. Furthermore, pthread_cond_timedwait() is not available in implementations that do not support threads.

Although the interface of the relative and absolute versions of the new high resolution sleep service is the same clock_nanosleep() function, the rmtp argument is only used in the relative sleep. This argument is needed in the relative clock_nanosleep() function to reissue the function
call if it is interrupted by a signal, but it is not needed in the absolute \texttt{clock_nanosleep()} function call; if the call is interrupted by a signal, the absolute \texttt{clock_nanosleep()} function can be invoked again with the same \texttt{rqtp} argument used in the interrupted call.

CHANGE HISTORY

NAME
close — close a file descriptor

SYNOPSIS
#include <unistd.h>

int close(int fildes);

DESCRIPTION
The close() function shall deallocate the file descriptor indicated by fildes. To deallocate means to make the file descriptor available for return by subsequent calls to open() or other functions that allocate file descriptors. All outstanding record locks owned by the process on the file associated with the file descriptor shall be removed (that is, unlocked).

If close() is interrupted by a signal that is to be caught, it shall return −1 with errno set to [EINTR] and the state of fildes is unspecified. If an I/O error occurred while reading from or writing to the file system during close(), it may return −1 with errno set to [EIO]; if this error is returned, the state of fildes is unspecified.

When all file descriptors associated with a pipe or FIFO special file are closed, any data remaining in the pipe or FIFO shall be discarded.

When all file descriptors associated with an open file description have been closed, the open file description shall be freed.

If the link count of the file is 0, when all file descriptors associated with the file are closed, the space occupied by the file shall be freed and the file shall no longer be accessible.

XSR If a STREAMS-based fildes is closed and the calling process was previously registered to receive a SIGPOLL signal for events associated with that STREAM, the calling process shall be unregistered for events associated with the STREAM. The last close() for a STREAM shall cause the STREAM associated with fildes to be dismantled. If O_NONBLOCK is not set and there have been no signals posted for the STREAM, and if there is data on the module's write queue, close() shall wait for an unspecified time (for each module and driver) for any output to drain before dismantling the STREAM. The time delay can be changed via an I_SETCLTIME ioctl() request. If the O_NONBLOCK flag is set, or if there are any pending signals, close() shall not wait for output to drain, and shall dismantle the STREAM immediately.

If the implementation supports STREAMS-based pipes, and fildes is associated with one end of a pipe, the last close() shall cause a hangup to occur on the other end of the pipe. In addition, if the other end of the pipe has been named by fattach(), then the last close() shall force the named end to be detached by fdetach(). If the named end has no open file descriptors associated with it and gets detached, the STREAM associated with that end shall also be dismantled.

XSI If fildes refers to the master side of a pseudo-terminal, and this is the last close, a SIGHUP signal shall be sent to the controlling process, if any, for which the slave side of the pseudo-terminal is the controlling terminal. It is unspecified whether closing the master side of the pseudo-terminal flushes all queued input and output.

XSR If fildes refers to the slave side of a STREAMS-based pseudo-terminal, a zero-length message may be sent to the master.

AIO When there is an outstanding cancelable asynchronous I/O operation against fildes when close() is called, that I/O operation may be canceled. An I/O operation that is not canceled completes as if the close() operation had not yet occurred. All operations that are not canceled shall complete as if the close() blocked until the operations completed. The close() operation itself need not block awaiting such I/O completion. Whether any I/O operation is canceled, and which I/O operation may be canceled upon close(), is implementation-defined.
If a shared memory object or a memory mapped file remains referenced at the last close (that is, a process has it mapped), then the entire contents of the memory object shall persist until the memory object becomes unreffered. If this is the last close of a shared memory object or a memory mapped file and the close results in the memory object becoming unreffered, and the memory object has been unlinked, then the memory object shall be removed.

If *fildes* refers to a socket, *close()* shall cause the socket to be destroyed. If the socket is in connection-mode, and the SO_LINGER option is set for the socket with non-zero linger time, and the socket has untransmitted data, then *close()* shall block for up to the current linger interval until all data is transmitted.

**RETURN VALUE**

Upon successful completion, 0 shall be returned; otherwise, −1 shall be returned and *errno* set to indicate the error.

**ERRORS**

The *close()* function shall fail if:

- **[EBADF]** The *fildes* argument is not a valid file descriptor.
- **[EINTR]** The *close()* function was interrupted by a signal.

The *close()* function may fail if:

- **[EIO]** An I/O error occurred while reading from or writing to the file system.

**EXAMPLES**

### Reassigning a File Descriptor

The following example closes the file descriptor associated with standard output for the current process, re-assings standard output to a new file descriptor, and closes the original file descriptor to clean up. This example assumes that the file descriptor 0 (which is the descriptor for standard input) is not closed.

```c
#include <unistd.h>
...
int pfd;
...
close(1);
dup(pfd);
close(pfd);
...
```

Incidentally, this is exactly what could be achieved using:

```c
dup2(pfd, 1);
```

### Closing a File Descriptor

In the following example, *close()* is used to close a file descriptor after an unsuccessful attempt is made to associate that file descriptor with a stream.

```c
#include <stdio.h>
#include <unistd.h>
#include <stdlib.h>
```
#define LOCKFILE "/etc/ptmp"

int pfd;
FILE *fpfd;

if ((fpfd = fdopen (pfd, "w")) == NULL) {
    close(pfd);
    unlink(LOCKFILE);
    exit(1);
}

APPLICATION USAGE
An application that had used the \texttt{stdio} routine \texttt{fopen()} to open a file should use the corresponding \texttt{fclose()} routine rather than \texttt{close()}. Once a file is closed, the file descriptor no longer exists, since the integer corresponding to it no longer refers to a file.

RATIONALE
The use of interruptible device close routines should be discouraged to avoid problems with the implicit closes of file descriptors by \texttt{exec} and \texttt{exit()}. This volume of IEEE Std 1003.1-2001 only intends to permit such behavior by specifying the [EINTR] error condition.

FUTURE DIRECTIONS
None.

SEE ALSO
Section 2.6 (on page 38), \texttt{fattach()}, \texttt{fclose()}, \texttt{fdetach()}, \texttt{fopen()}, \texttt{ioctl()}, \texttt{open()}, the Base Definitions volume of IEEE Std 1003.1-2001, \texttt{<unistd.h>}

CHANGE HISTORY
First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 5
The DESCRIPTION is updated for alignment with the POSIX Realtime Extension.

Issue 6
The DESCRIPTION related to a STREAMS-based file or pseudo-terminal is marked as part of the XSI STREAMS Option Group.
The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:
• The [EIO] error condition is added as an optional error.
• The DESCRIPTION is updated to describe the state of the \textit{fildes} file descriptor as unspecified if an I/O error occurs and an [EIO] error condition is returned.

Text referring to sockets is added to the DESCRIPTION.
The DESCRIPTION is updated for alignment with IEEE Std 1003.1j-2000 by specifying that shared memory objects and memory mapped files (and not typed memory objects) are the types of memory objects to which the paragraph on last closes applies.
IEEE Std 1003.1-2001/Cor 1-2002, item XSH/TC1/D6/12 is applied, correcting the XSH shaded text relating to the master side of a pseudo-terminal. The reason for the change is that the behavior of pseudo-terminals and regular terminals should be as much alike as possible in this case; the change achieves that and matches historical behavior.
closedir()

NAME
    closedir — close a directory stream

SYNOPSIS
    #include <dirent.h>
    int closedir(DIR *dirp);

DESCRIPTION
    The closedir() function shall close the directory stream referred to by the argument dirp. Upon return, the value of dirp may no longer point to an accessible object of the type DIR. If a file descriptor is used to implement type DIR, that file descriptor shall be closed.

RETURN VALUE
    Upon successful completion, closedir() shall return 0; otherwise, −1 shall be returned and errno set to indicate the error.

ERRORS
    The closedir() function may fail if:
    [EBADF] The dirp argument does not refer to an open directory stream.
    [EINTR] The closedir() function was interrupted by a signal.

EXAMPLES
    Closing a Directory Stream
    The following program fragment demonstrates how the closedir() function is used.

    ...  
    DIR *dir;  
    struct dirent *dp;  
    ...  
    if ((dir = opendir (".")) == NULL) {  
        ...  
    }  
    while ((dp = readdir (dir)) != NULL) {  
        ...  
    }  
    ...  
    closedir(dir);  
    ...

APPLICATION USAGE
    None.

RATIONALE
    None.

FUTURE DIRECTIONS
    None.

    opendir(), the Base Definitions volume of IEEE Std 1003.1-2001, <dirent.h>
CHANGE HISTORY

First released in Issue 2.

Issue 6

In the SYNOPSIS, the optional include of the `<sys/types.h>` header is removed.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The requirement to include `<sys/types.h>` has been removed. Although `<sys/types.h>` was required for conforming implementations of previous POSIX specifications, it was not required for UNIX applications.

- The [EINTR] error condition is added as an optional error condition.
NAME
closelog, openlog, setlogmask, syslog — control system log

SYNOPSIS
XSI
#include <syslog.h>

void closelog(void);
void openlog(const char *ident, int logopt, int facility);
int setlogmask(int maskpri);
void syslog(int priority, const char *message, ... /* arguments */);

DESCRIPTION
The syslog() function shall send a message to an implementation-defined logging facility, which
may log it in an implementation-defined system log, write it to the system console, forward it to
a list of users, or forward it to the logging facility on another host over the network. The logged
message shall include a message header and a message body. The message header contains at
least a timestamp and a tag string.

The message body is generated from the message and following arguments in the same manner
as if these were arguments to printf(), except that the additional conversion specification %m
shall be recognized; it shall convert no arguments, shall cause the output of the error message
string associated with the value of errno on entry to syslog(), and may be mixed with argument
specifications of the "%n$" form. If a complete conversion specification with the m conversion
specifier character is not just %m, the behavior is undefined. A trailing <newline> may be added
if needed.

Values of the priority argument are formed by OR’ing together a severity-level value and an
optional facility value. If no facility value is specified, the current default facility value is used.

Possible values of severity level include:
LOG_EMERG A panic condition.
LOG_ALERT A condition that should be corrected immediately, such as a corrupted system
database.
LOG_CRIT Critical conditions, such as hard device errors.
LOG_ERR Errors.
LOG_WARNING Warning messages.
LOG_NOTICE Conditions that are not error conditions, but that may require special
handling.
LOG_INFO Informational messages.
LOG_DEBUG Messages that contain information normally of use only when debugging a
program.

The facility indicates the application or system component generating the message. Possible
facility values include:
LOG_USER Messages generated by arbitrary processes. This is the default facility
identifier if none is specified.
LOG_LOCAL0 Reserved for local use.
The `openlog()` function shall set process attributes that affect subsequent calls to `syslog()`. The `ident` argument is a string that is prepended to every message. The `logopt` argument indicates logging options. Values for `logopt` are constructed by a bitwise-inclusive OR of zero or more of the following:

- **LOG_PID**: Log the process ID with each message. This is useful for identifying specific processes.
- **LOG_CONS**: Write messages to the system console if they cannot be sent to the logging facility. The `syslog()` function ensures that the process does not acquire the console as a controlling terminal in the process of writing the message.
- **LOG_NDELAY**: Open the connection to the logging facility immediately. Normally the open is delayed until the first message is logged. This is useful for programs that need to manage the order in which file descriptors are allocated.
- **LOG_ODELAY**: Delay open until `syslog()` is called.
- **LOG_NOWAIT**: Do not wait for child processes that may have been created during the course of logging the message. This option should be used by processes that enable notification of child termination using SIGCHLD, since `syslog()` may otherwise block waiting for a child whose exit status has already been collected.

The `facility` argument encodes a default facility to be assigned to all messages that do not have an explicit facility already encoded. The initial default facility is LOG_USER.

The `openlog()` and `syslog()` functions may allocate a file descriptor. It is not necessary to call `openlog()` prior to calling `syslog()`.

The `closelog()` function shall close any open file descriptors allocated by previous calls to `openlog()` or `syslog()`.

The `setlogmask()` function shall set the log priority mask for the current process to `maskpri` and return the previous mask. If the `maskpri` argument is 0, the current log mask is not modified. Calls by the current process to `syslog()` with a priority not set in `maskpri` shall be rejected. The default log mask allows all priorities to be logged. A call to `openlog()` is not required prior to calling `setlogmask()`.

Symbolic constants for use as values of the `logopt`, `facility`, `priority`, and `maskpri` arguments are defined in the `<syslog.h>` header.

**RETURN VALUE**

The `setlogmask()` function shall return the previous log priority mask. The `closelog()`, `openlog()`, and `syslog()` functions shall not return a value.
closelog()  

ERRORS
No errors are defined.

EXAMPLES

Using openlog()
The following example causes subsequent calls to syslog() to log the process ID with each message, and to write messages to the system console if they cannot be sent to the logging facility.

```c
#include <syslog.h>
char *ident = "Process demo";
int logopt = LOG_PID | LOG_CONS;
int facility = LOG_USER;
...
openlog(ident, logopt, facility);
```

Using setlogmask()
The following example causes subsequent calls to syslog() to accept error messages, and to reject all other messages.

```c
#include <syslog.h>
int result;
int mask = LOG_MASK (LOG_ERR);
...
result = setlogmask(mask);
```

Using syslog
The following example sends the message "This is a message" to the default logging facility, marking the message as an error message generated by random processes.

```c
#include <syslog.h>
char *message = "This is a message";
int priority = LOG_ERR | LOG_USER;
...
syslog(priority, message);
```

APPLICATION USAGE

CHANGE HISTORY

First released in Issue 4, Version 2.

Issue 5
Moved from X/OPEN UNIX extension to BASE.

Issue 6
IEEE Std 1003.1-2001/Cor 1-2002, item XSH/TC1/D6/13 is applied, correcting the EXAMPLES section.
confstr() — get configurable variables

SYNOPSIS
#include <unistd.h>
size_t confstr(int name, char *buf, size_t len);

DESCRIPTION
The confstr() function shall return configuration-defined string values. Its use and purpose are similar to sysconf(), but it is used where string values rather than numeric values are returned.

The name argument represents the system variable to be queried. The implementation shall support the following name values, defined in <unistd.h>. It may support others:

_XS_PATH
_CS_POSIX_V6_ILP32_OFF32_CFLAGS
_CS_POSIX_V6_ILP32_OFF32_LDFLAGS
_CS_POSIX_V6_ILP32_OFF32_LIBS
_CS_POSIX_V6_ILP32_OFFBIG_CFLAGS
_CS_POSIX_V6_ILP32_OFFBIG_LDFLAGS
_CS_POSIX_V6_ILP32_OFFBIG_LIBS
_CS_POSIX_V6_LP64_OFF64_CFLAGS
_CS_POSIX_V6_LP64_OFF64_LDFLAGS
_CS_POSIX_V6_LP64_OFF64_LIBS
_CS_POSIX_V6_LPBIG_OFFBIG_CFLAGS
_CS_POSIX_V6_LPBIG_OFFBIG_LDFLAGS
_CS_POSIX_V6_LPBIG_OFFBIG_LIBS
_CS_POSIX_V6_WIDTH_RESTRICTED_ENVS

If len is not 0, and if name has a configuration-defined value, confstr() shall copy that value into the len-byte buffer pointed to by buf. If the string to be returned is longer than len bytes, including the terminating null, then confstr() shall truncate the string to len−1 bytes and null-terminate the result. The application can detect that the string was truncated by comparing the value returned by confstr() with len.

If len is 0 and buf is a null pointer, then confstr() shall still return the integer value as defined below, but shall not return a string. If len is 0 but buf is not a null pointer, the result is unspecified.
If the implementation supports the POSIX shell option, the string stored in \texttt{buf} after a call to:

\begin{verbatim}
confstr(_CS_PATH, buf, sizeof(buf))
\end{verbatim}

can be used as a value of the \texttt{PATH} environment variable that accesses all of the standard utilities of IEEE Std 1003.1-2001, if the return value is less than or equal to \texttt{sizeof(buf)}.

### RETURN VALUE

If \texttt{name} has a configuration-defined value, \texttt{confstr()} shall return the size of buffer that would be needed to hold the entire configuration-defined value including the terminating null. If this return value is greater than \texttt{len}, the string returned in \texttt{buf} is truncated.

If \texttt{name} is invalid, \texttt{confstr()} shall return 0 and set \texttt{errno} to indicate the error.

If \texttt{name} does not have a configuration-defined value, \texttt{confstr()} shall return 0 and leave \texttt{errno} unchanged.

### ERRORS

The \texttt{confstr()} function shall fail if:

\begin{verbatim}
[EINVAL] The value of the name argument is invalid.
\end{verbatim}

### EXAMPLES

None.

### APPLICATION USAGE

An application can distinguish between an invalid \texttt{name} parameter value and one that corresponds to a configurable variable that has no configuration-defined value by checking if \texttt{errno} is modified. This mirrors the behavior of \texttt{sysconf()}.

The original need for this function was to provide a way of finding the configuration-defined default value for the environment variable \texttt{PATH}. Since \texttt{PATH} can be modified by the user to include directories that could contain utilities replacing the standard utilities in the Shell and Utilities volume of IEEE Std 1003.1-2001, applications need a way to determine the system-supplied \texttt{PATH} environment variable value that contains the correct search path for the standard utilities.

An application could use:

\begin{verbatim}
confstr(name, (char *)NULL, (size_t)0)
\end{verbatim}

to find out how big a buffer is needed for the string value; use \texttt{malloc()} to allocate a buffer to hold the string; and call \texttt{confstr()} again to get the string. Alternately, it could allocate a fixed, static buffer that is big enough to hold most answers (perhaps 512 or 1024 bytes), but then use \texttt{malloc()} to allocate a larger buffer if it finds that this is too small.

### RATIONALE

Application developers can normally determine any configuration variable by means of reading from the stream opened by a call to:

\begin{verbatim}
popen("command -p getconf variable", "r");
\end{verbatim}

The \texttt{confstr()} function with a \texttt{name} argument of \_CS\_PATH returns a string that can be used as a \texttt{PATH} environment variable setting that will reference the standard shell and utilities as described in the Shell and Utilities volume of IEEE Std 1003.1-2001.

The \texttt{confstr()} function copies the returned string into a buffer supplied by the application instead of returning a pointer to a string. This allows a cleaner function in some implementations (such as those with lightweight threads) and resolves questions about when the application must copy the string returned.
FUTURE DIRECTIONS

None.

SEE ALSO

CHANGE HISTORY

Issue 5

A table indicating the permissible values of name is added to the DESCRIPTION. All those marked EX are new in this issue.

Issue 6

The Open Group Corrigendum U033/7 is applied. The return value for the case returning the size of the buffer now explicitly states that this includes the terminating null.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The DESCRIPTION is updated with new arguments which can be used to determine configuration strings for C compiler flags, linker/loader flags, and libraries for each different supported programming environment. This is a change to support data size neutrality.

The following changes were made to align with the IEEE P1003.1a draft standard:

- The DESCRIPTION is updated to include text describing how _CS_PATH can be used to obtain a PATH to access the standard utilities.

The macros associated with the c89 programming models are marked LEGACY and new equivalent macros associated with c99 are introduced.
NAME
conj, conjf, conjl — complex conjugate functions

SYNOPSIS
#include <complex.h>

double complex conj(double complex z);
float complex conjf(float complex z);
long double complex conjl(long double complex z);

DESCRIPTION
The functionality described on this reference page is aligned with the ISO C standard. Any
conflict between the requirements described here and the ISO C standard is unintentional. This

These functions shall compute the complex conjugate of z, by reversing the sign of its imaginary
part.

RETURN VALUE
These functions return the complex conjugate value.

ERRORS
No errors are defined.

CHANGE HISTORY
NAME
connect — connect a socket

SYNOPSIS
#include <sys/socket.h>

int connect(int socket, const struct sockaddr *address,
            socklen_t address_len);

DESCRIPTION
The connect() function shall attempt to make a connection on a socket. The function takes the
following arguments:

socket      Specifies the file descriptor associated with the socket.
address     Points to a sockaddr structure containing the peer address. The length and
            format of the address depend on the address family of the socket.
address_len Specifies the length of the sockaddr structure pointed to by the address
            argument.

If the socket has not already been bound to a local address, connect() shall bind it to an address
which, unless the socket’s address family is AF_UNIX, is an unused local address.

If the initiating socket is not connection-mode, then connect() shall set the socket’s peer address,
and no connection is made. For SOCK_DGRAM sockets, the peer address identifies where all
datagrams are sent on subsequent send() functions, and limits the remote sender for subsequent
recv() functions. If address is a null address for the protocol, the socket’s peer address shall be
reset.

If the initiating socket is connection-mode, then connect() shall attempt to establish a connection
to the address specified by the address argument. If the connection cannot be established
immediately and O_NONBLOCK is not set for the file descriptor for the socket, connect() shall
block for up to an unspecified timeout interval until the connection is established. If the timeout
interval expires before the connection is established, connect() shall fail and the connection
attempt shall be aborted. If connect() is interrupted by a signal that is caught while blocked
waiting to establish a connection, connect() shall fail and set errno to [EINTR], but the connection
request shall not be aborted, and the connection shall be established asynchronously.

If the connection cannot be established immediately and O_NONBLOCK is set for the file
descriptor for the socket, connect() shall fail and set errno to [EINPROGRESS], but the connection
request shall not be aborted, and the connection shall be established asynchronously.
Subsequent calls to connect() for the same socket, before the connection is established, shall fail
and set errno to [EAGAIN].

When the connection has been established asynchronously, select() and poll() shall indicate that
the file descriptor for the socket is ready for writing.

The socket in use may require the process to have appropriate privileges to use the connect() function.

RETURN VALUE
Upon successful completion, connect() shall return 0; otherwise, −1 shall be returned and errno
set to indicate the error.

ERRORS
The connect() function shall fail if:

[EADDRNOTAVAIL]
The specified address is not available from the local machine.
The specified address is not a valid address for the address family of the specified socket.

A connection request is already in progress for the specified socket.

The socket argument is not a valid file descriptor.

The target address was not listening for connections or refused the connection request.

O_NONBLOCK is set for the file descriptor for the socket and the connection cannot be immediately established; the connection shall be established asynchronously.

The attempt to establish a connection was interrupted by delivery of a signal that was caught; the connection shall be established asynchronously.

The specified socket is connection-mode and is already connected.

No route to the network is present.

The socket argument does not refer to a socket.

The specified address has a different type than the socket bound to the specified peer address.

The attempt to connect timed out before a connection was made.

If the address family of the socket is AF_UNIX, then connect() shall fail if:

An I/O error occurred while reading from or writing to the file system.

A loop exists in symbolic links encountered during resolution of the pathname in address.

A component of a pathname exceeded {NAME_MAX} characters, or an entire pathname exceeded {PATH_MAX} characters.

A component of the pathname does not name an existing file or the pathname is an empty string.

A component of the path prefix of the pathname in address is not a directory.

The connect() function may fail if:

Search permission is denied for a component of the path prefix; or write access to the named socket is denied.

Attempt to establish a connection that uses addresses that are already in use.

Remote host reset the connection request.

The destination host cannot be reached (probably because the host is down or a remote router cannot reach it).

The address_len argument is not a valid length for the address family; or invalid address family in the sockaddr structure.
connect()  

[ELOOP]  More than [SYMLOOP_MAX] symbolic links were encountered during resolution of the pathname in address.

[ENAMETOOLONG]  Pathname resolution of a symbolic link produced an intermediate result whose length exceeds [PATH_MAX].

[ENETDOWN]  The local network interface used to reach the destination is down.

[ENOBUFS]  No buffer space is available.

[EOPNOTSUPP]  The socket is listening and cannot be connected.

EXAMPLES
None.

APPLICATION USAGE
If connect() fails, the state of the socket is unspecified. Conforming applications should close the file descriptor and create a new socket before attempting to reconnect.

RATIONALE
None.

FUTURE DIRECTIONS
None.

SEE ALSO
accept(), bind(), close(), getsockname(), poll(), select(), send(), shutdown(), socket(), the Base Definitions volume of IEEE Std 1003.1-2001, <sys/socket.h>

CHANGE HISTORY
First released in Issue 6. Derived from the XNS, Issue 5.2 specification.

The wording of the mandatory [ELOOP] error condition is updated, and a second optional [ELOOP] error condition is added.
NAME
copysign, copysignf, copysignl — number manipulation function

SYNOPSIS
#include <math.h>
double copysign(double x, double y);
float copysignf(float x, float y);
long double copysignl(long double x, long double y);

DESCRIPTION
The functionality described on this reference page is aligned with the ISO C standard. Any
conflict between the requirements described here and the ISO C standard is unintentional. This
These functions shall produce a value with the magnitude of x and the sign of y. On
implementations that represent a signed zero but do not treat negative zero consistently in
arithmetic operations, these functions regard the sign of zero as positive.

RETURN VALUE
Upon successful completion, these functions shall return a value with the magnitude of x and
the sign of y.

ERRORS
No errors are defined.

EXAMPLES
None.

APPLICATION USAGE
None.

RATIONALE
None.

FUTURE DIRECTIONS
None.

SEE ALSO
signbit(), the Base Definitions volume of IEEE Std 1003.1-2001, <math.h>

CHANGE HISTORY
These functions shall compute the cosine of their argument \( x \), measured in radians.

An application wishing to check for error situations should set \( \text{errno} \) to zero and call \( \text{feclearexcept}(\text{FE_ALL_EXCEPT}) \) before calling these functions. On return, if \( \text{errno} \) is non-zero or \( \text{fetestexcept}(\text{FE_INVALID} \mid \text{FE_DIVBYZERO} \mid \text{FE_OVERFLOW} \mid \text{FE_UNDERFLOW}) \) is non-zero, an error has occurred.

**RETURN VALUE**

Upon successful completion, these functions shall return the cosine of \( x \).

If \( x \) is NaN, a NaN shall be returned.

If \( x \) is ±0, the value 1.0 shall be returned.

If \( x \) is ±\( \infty \), a domain error shall occur, and either a NaN (if supported), or an implementation-defined value shall be returned.

**ERRORS**

These functions shall fail if:

If the integer expression (\( \text{math_errhandling} \& \text{MATH_ERRNO} \)) is non-zero, then \( \text{errno} \) shall be set to [EDOM]. If the integer expression (\( \text{math_errhandling} \& \text{MATH_ERREXCEPT} \)) is non-zero, then the invalid floating-point exception shall be raised.

**EXAMPLES**

**Taking the Cosine of a 45-Degree Angle**

```c
#include <math.h>
...
double radians = 45 * M_PI / 180;
double result;
...
result = cos(radians);
```

**APPLICATION USAGE**

These functions may lose accuracy when their argument is near an odd multiple of \( \pi/2 \) or is far from 0.

On error, the expressions (\( \text{math_errhandling} \& \text{MATH_ERRNO} \)) and (\( \text{math_errhandling} \& \text{MATH_ERREXCEPT} \)) are independent of each other, but at least one of them must be non-zero.
RATIONALE
None.

FUTURE DIRECTIONS
None.

CHANGE HISTORY
First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 5
The DESCRIPTION is updated to indicate how an application should check for an error. This text was previously published in the APPLICATION USAGE section.

Issue 6
The cosf() and cosl() functions are added for alignment with the ISO/IEC 9899:1999 standard.
The DESCRIPTION, RETURN VALUE, ERRORS, and APPLICATION USAGE sections are revised to align with the ISO/IEC 9899:1999 standard.
NAME
cosh, coshf, coshl — hyperbolic cosine functions

SYNOPSIS
#include <math.h>

double cosh(double x);
float coshf(float x);
long double coshl(long double x);

DESCRIPTION
The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-2001 defers to the ISO C standard.

These functions shall compute the hyperbolic cosine of their argument \( x \).

An application wishing to check for error situations should set \( \text{errno} \) to zero and call \( \text{feclearexcept}(\text{FE_ALL_EXCEPT}) \) before calling these functions. On return, if \( \text{errno} \) is non-zero or \( \text{fetestexcept}(\text{FE_INVALID} | \text{FE_DIVBYZERO} | \text{FE_OVERFLOW} | \text{FE_UNDERFLOW}) \) is non-zero, an error has occurred.

RETURN VALUE
Upon successful completion, these functions shall return the hyperbolic cosine of \( x \).

If the correct value would cause overflow, a range error shall occur and \( \text{cosh()} \), \( \text{coshf()} \), and \( \text{coshl()} \) shall return the value of the macro \( \text{HUGE_VAL} \), \( \text{HUGE_VALF} \), and \( \text{HUGE_VALL} \), respectively.

MX
If \( x \) is NaN, a NaN shall be returned.

If \( x \) is \( \pm 0 \), the value 1.0 shall be returned.

If \( x \) is \( \pm \infty \), +\( \infty \) shall be returned.

ERRORS
These functions shall fail if:

Range Error
The result would cause an overflow.

If the integer expression (\( \text{math_errhandling} & \text{MATH_ERRNO} \)) is non-zero, then \( \text{errno} \) shall be set to [ERANGE]. If the integer expression (\( \text{math_errhandling} & \text{MATH_ERREXCEPT} \)) is non-zero, then the overflow floating-point exception shall be raised.

EXAMPLES
None.

APPLICATION USAGE
On error, the expressions (\( \text{math_errhandling} & \text{MATH_ERRNO} \)) and (\( \text{math_errhandling} & \text{MATH_ERREXCEPT} \)) are independent of each other, but at least one of them must be non-zero.

For IEEE Std 754-1985 \texttt{double}, \( 710.5 < |x| \) implies that \( \text{cosh}(x) \) has overflowed.

RATIONALE
None.

FUTURE DIRECTIONS
None.

CHANGE HISTORY

Issue 5
First released in Issue 1. Derived from Issue 1 of the SVID.

The DESCRIPTION is updated to indicate how an application should check for an error. This
text was previously published in the APPLICATION USAGE section.

Issue 6
The coshf() and coshl() functions are added for alignment with the ISO/IEC 9899:1999 standard.
The DESCRIPTION, RETURN VALUE, ERRORS, and APPLICATION USAGE sections are
revised to align with the ISO/IEC 9899:1999 standard.
NAME

cosl — cosine function

SYNOPSIS

#include <math.h>

long double cosl(long double x);

DESCRIPTION

Refer to cos().
NAME
    cpow, cpowf, cpowl — complex power functions

SYNOPSIS
    #include <complex.h>
    double complex cpow(double complex x, double complex y);
    float complex cpowf(float complex x, float complex y);
    long double complex cpowl(long double complex x,
    long double complex y);

DESCRIPTION
    The functionality described on this reference page is aligned with the ISO C standard. Any
    conflict between the requirements described here and the ISO C standard is unintentional. This

    These functions shall compute the complex power function \(x^y\), with a branch cut for the first
    parameter along the negative real axis.

RETURN VALUE
    These functions shall return the complex power function value.

ERRORS
    No errors are defined.

EXAMPLES
    None.

APPLICATION USAGE
    None.

RATIONALE
    None.

FUTURE DIRECTIONS
    None.

NAME
cproj, cprojf, cprojl — complex projection functions

SYNOPSIS
#include <complex.h>
double complex cproj(double complex z);
float complex cprojf(float complex z);
long double complex cprojl(long double complex z);

DESCRIPTION
The functionality described on this reference page is aligned with the ISO C standard. Any
conflict between the requirements described here and the ISO C standard is unintentional. This

These functions shall compute a projection of z onto the Riemann sphere: z projects to z, except
that all complex infinities (even those with one infinite part and one NaN part) project to
positive infinity on the real axis. If z has an infinite part, then cproj(z) shall be equivalent to:

INFINITY + I * copysign(0.0, cimag(z))

RETURN VALUE
These functions shall return the value of the projection onto the Riemann sphere.

ERRORS
No errors are defined.

EXAMPLES
None.

APPLICATION USAGE
None.

RATIONALE
Two topologies are commonly used in complex mathematics: the complex plane with its
continuum of infinities, and the Riemann sphere with its single infinity. The complex plane is
better suited for transcendental functions, the Riemann sphere for algebraic functions. The
complex types with their multiplicity of infinities provide a useful (though imperfect) model for
the complex plane. The cproj() function helps model the Riemann sphere by mapping all
infinities to one, and should be used just before any operation, especially comparisons, that
might give spurious results for any of the other infinities. Note that a complex value with one
infinite part and one NaN part is regarded as an infinity, not a NaN, because if one part is
infinite, the complex value is infinite independent of the value of the other part. For the same
reason, cabs() returns an infinity if its argument has an infinite part and a NaN part.

FUTURE DIRECTIONS
None.

CHANGE HISTORY
NAME
creat — create a new file or rewrite an existing one

SYNOPSIS
OH
#include <sys/stat.h>
#include <fcntl.h>
int creat(const char *path, mode_t mode);

DESCRIPTION
The function call:
creat(path, mode)
shall be equivalent to:
open(path, O_WRONLY|O_CREAT|O_TRUNC, mode)

RETURN VALUE
Refer to open().

ERRORS
Refer to open().

EXAMPLES
Creating a File
The following example creates the file /tmp/file with read and write permissions for the file
owner and read permission for group and others. The resulting file descriptor is assigned to the
fd variable.

#include <fcntl.h>
...
int fd;
mode_t mode = S_IRUSR | S_IWUSR | S_IRGRP | S_IROTH;
char *filename = "/tmp/file";
...
fd = creat(filename, mode);
...

APPLICATION USAGE
None.

RATIONALE
The creat() function is redundant. Its services are also provided by the open() function. It has
been included primarily for historical purposes since many existing applications depend on it. It
is best considered a part of the C binding rather than a function that should be provided in other
languages.

FUTURE DIRECTIONS
None.

SEE ALSO
open(), the Base Definitions volume of IEEE Std 1003.1-2001, <fcntl.h>, <sys/stat.h>,
<sys/types.h>
CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID.

In the SYNOPSIS, the optional include of the `<sys/types.h>` header is removed.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The requirement to include `<sys/types.h>` has been removed. Although `<sys/types.h>` was required for conforming implementations of previous POSIX specifications, it was not required for UNIX applications.
NAME

crypt — string encoding function (CRYPT)

SYNOPSIS

XSI
#include <unistd.h>

char *crypt(const char *key, const char *salt);

DESCRIPTION

The crypt() function is a string encoding function. The algorithm is implementation-defined.

The key argument points to a string to be encoded. The salt argument is a string chosen from the set:

abcdefghijklmnopqrstuvwxyz
ABCDEFGHIJKLMNOPQRSTUVWXYZ
0123456789./

The first two characters of this string may be used to perturb the encoding algorithm.

The return value of crypt() points to static data that is overwritten by each call.

The crypt() function need not be reentrant. A function that is not required to be reentrant is not required to be thread-safe.

RETURN VALUE

Upon successful completion, crypt() shall return a pointer to the encoded string. The first two characters of the returned value shall be those of the salt argument. Otherwise, it shall return a null pointer and set errno to indicate the error.

ERRORS

The crypt() function shall fail if:

[ENOSYS] The functionality is not supported on this implementation.

EXAMPLES

Encoding Passwords

The following example finds a user database entry matching a particular user name and changes the current password to a new password. The crypt() function generates an encoded version of each password. The first call to crypt() produces an encoded version of the old password; that encoded password is then compared to the password stored in the user database. The second call to crypt() encodes the new password before it is stored.

The putpwent() function, used in the following example, is not part of IEEE Std 1003.1-2001.

#include <unistd.h>
#include <pwd.h>
#include <string.h>
#include <stdio.h>
...
int valid_change;
int pfds; /* Integer for file descriptor returned by open(). */
FILE *fpfd; /* File pointer for use in putpwent(). */
struct passwd *p;
char user[100];
char oldpasswd[100];
char newpasswd[100];
```
7792    char savepasswd[100];
7793    ...
7794    valid_change = 0;
7795    while ((p = getpwent()) != NULL) {
7796        /* Change entry if found. */
7797        if (strcmp(p->pw_name, user) == 0) {
7798            if (strcmp(p->pw_passwd, crypt(oldpasswd, p->pw_passwd)) == 0) {
7799                strcpy(savepasswd, crypt(newpasswd, user));
7800                p->pw_passwd = savepasswd;
7801                valid_change = 1;
7802            } else {
7803                fprintf(stderr, "Old password is not valid\n");
7804            }
7805        } /* Put passwd entry into ptmp. */
7806        putpwent(p, fpfd);
7807    }

APPLICATION USAGE
7810    The values returned by this function need not be portable among XSI-conformant systems.

RATIONALE
7812    None.

NAME
ctermid — generate a pathname for the controlling terminal

SYNOPSIS

```c
#include <stdio.h>

char *ctermid(char *s);
```

DESCRIPTION

The `ctermid()` function shall generate a string that, when used as a pathname, refers to the
current controlling terminal for the current process. If `ctermid()` returns a pathname, access to the
file is not guaranteed.

If the application uses any of the `_POSIX_THREAD_SAFE_FUNCTIONS` or `_POSIX_THREADS`
functions, it shall ensure that the `ctermid()` function is called with a non-NULL parameter.

RETURN VALUE

If `s` is a null pointer, the string shall be generated in an area that may be static (and therefore may
be overwritten by each call), the address of which shall be returned. Otherwise, `s` is assumed to
point to a character array of at least `L_ctermid` bytes; the string is placed in this array and the
value of `s` shall be returned. The symbolic constant `L_ctermid` is defined in `<stdio.h>`, and shall
have a value greater than 0.

The `ctermid()` function shall return an empty string if the pathname that would refer to the
controlling terminal cannot be determined, or if the function is unsuccessful.

ERRORS

No errors are defined.

EXAMPLES

**Determining the Controlling Terminal for the Current Process**

The following example returns a pointer to a string that identifies the controlling terminal for the
current process. The pathname for the terminal is stored in the array pointed to by the `ptr`
argument, which has a size of `L_ctermid` bytes, as indicated by the `term` argument.

```c
#include <stdio.h>
...
char term[L_ctermid];
char *ptr;
ptr = ctermid(term);
```

APPLICATION USAGE

The difference between `ctermid()` and `ttyname()` is that `ttyname()` must be handed a file
descriptor and return a path of the terminal associated with that file descriptor, while `ctermid()`
returns a string (such as `"/dev/tty"`) that refers to the current controlling terminal if used as a
pathname.

RATIONALE

`L_ctermid` must be defined appropriately for a given implementation and must be greater than
zero so that array declarations using it are accepted by the compiler. The value includes the
terminating null byte.

Conforming applications that use threads cannot call `ctermid()` with NULL as the parameter if
either `_POSIX_THREAD_SAFE_FUNCTIONS` or `_POSIX_THREADS` is defined. If `s` is not
NULL, the `ctermid()` function generates a string that, when used as a pathname, refers to the
current controlling terminal for the current process. If \texttt{s} is NULL, the return value of \texttt{ctermid()} is undefined.

There is no additional burden on the programmer—changing to use a hypothetical thread-safe version of \texttt{ctermid()} along with allocating a buffer is more of a burden than merely allocating a buffer. Application code should not assume that the returned string is short, as some implementations have more than two pathname components before reaching a logical device name.

**FUTURE DIRECTIONS**

None.

**SEE ALSO**

\texttt{ttymame()}, the Base Definitions volume of IEEE Std 1003.1-2001, \texttt{<stdio.h>}

**CHANGE HISTORY**

First released in Issue 1. Derived from Issue 1 of the SVID.

**Issue 5**

The DESCRIPTION is updated for alignment with the POSIX Threads Extension.

**Issue 6**

The DESCRIPTION is updated to avoid use of the term “must” for application requirements.
NAME
ctime, ctime_r — convert a time value to a date and time string

SYNOPSIS
#include <time.h>
char *ctime(const time_t *clock);
TSF char *ctime_r(const time_t *clock, char *buf);

DESCRIPTION
CX For ctime(): The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-2001 defers to the ISO C standard.
The ctime() function shall convert the time pointed to by clock, representing time in seconds since the Epoch, to local time in the form of a string. It shall be equivalent to:
asctime(localtime(clock))

CX The asctime(), ctime(), gmtime(), and localtime() functions shall return values in one of two static objects: a broken-down time structure and an array of char. Execution of any of the functions may overwrite the information returned in either of these objects by any of the other functions.
The ctime() function need not be reentrant. A function that is not required to be reentrant is not required to be thread-safe.
TSF The ctime_r() function shall convert the calendar time pointed to by clock to local time in exactly the same form as ctime() and put the string into the array pointed to by buf (which shall be at least 26 bytes in size) and return buf.
Unlike ctime(), the thread-safe version ctime_r() is not required to set tzname.

RETURN VALUE
The ctime() function shall return the pointer returned by asctime() with that broken-down time as an argument.
TSF Upon successful completion, ctime_r() shall return a pointer to the string pointed to by buf. When an error is encountered, a null pointer shall be returned.

ERRORS
No errors are defined.

EXAMPLES
None.

APPLICATION USAGE
Values for the broken-down time structure can be obtained by calling gmtime() or localtime(). The ctime() function is included for compatibility with older implementations, and does not support localized date and time formats. Applications should use the strftime() function to achieve maximum portability.
The ctime_r() function is thread-safe and shall return values in a user-supplied buffer instead of possibly using a static data area that may be overwritten by each call.

RATIONALE
None.
FUTURE DIRECTIONS

None.

SEE ALSO

asctime(), clock(), difftime(), gmtime(), localtime(), mktime(), strftime(), strptime(), time(), utime(), the Base Definitions volume of IEEE Std 1003.1-2001, <time.h>

CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 5

Normative text previously in the APPLICATION USAGE section is moved to the DESCRIPTION.

The ctime_r() function is included for alignment with the POSIX Threads Extension.

A note indicating that the ctime() function need not be reentrant is added to the DESCRIPTION.

Issue 6

Extensions beyond the ISO C standard are marked.

In the DESCRIPTION, the note about reentrancy is expanded to cover thread-safety.

The APPLICATION USAGE section is updated to include a note on the thread-safe function and its avoidance of possibly using a static data area.
NAME
daylight — daylight savings time flag

SYNOPSIS
XSI
#include <time.h>
extern int daylight;

DESCRIPTION
Refer to tzset().
NAME

dbm_clearerr(), dbm_close, dbm_delete, dbm_error, dbm_fetch, dbm_firstkey, dbm_nextkey,
dbm_open, dbm_store — database functions

SYNOPSIS

#include <ndbm.h>

int dbm_clearerr(DBM *db);
void dbm_close(DBM *db);
int dbm_delete(DBM *db, datum key);
int dbm_error(DBM *db);
datum dbm_fetch(DBM *db, datum key);
datum dbm_firstkey(DBM *db);
datum dbm_nextkey(DBM *db);
DBM *dbm_open(const char *file, int open_flags, mode_t file_mode);
int dbm_store(DBM *db, datum key, datum content, int store_mode);

DESCRIPTION

These functions create, access, and modify a database.

A datum consists of at least two members, dptr and dsize. The dptr member points to an object
that is dsize bytes in length. Arbitrary binary data, as well as character strings, may be stored in
the object pointed to by dptr.

The database is stored in two files. One file is a directory containing a bitmap of keys and has
.dir as its suffix. The second file contains all data and has .pag as its suffix.

The dbm_open() function shall open a database. The file argument to the function is the
pathname of the database. The function opens two files named file.dir and file.pag. The
open_flags argument has the same meaning as the flags argument of open() except that a database
opened for write-only access opens the files for read and write access and the behavior of the
O_APPEND flag is unspecified. The file_mode argument has the same meaning as the third
argument of open().

The dbm_close() function shall close a database. The application shall ensure that argument db is
a pointer to a dbm structure that has been returned from a call to dbm_open().

These database functions shall support an internal block size large enough to support
key/content pairs of at least 1023 bytes.

The dbm_fetch() function shall read a record from a database. The argument db is a pointer to a
database structure that has been returned from a call to dbm_open(). The argument key is a
datum that has been initialized by the application to the value of the key that matches the key of
the record the program is fetching.

The dbm_store() function shall write a record to a database. The argument db is a pointer to a
database structure that has been returned from a call to dbm_open(). The argument key is a
datum that has been initialized by the application to the value of the key that identifies (for
subsequent reading, writing, or deleting) the record the application is writing. The argument
content is a datum that has been initialized by the application to the value of the record the
program is writing. The argument store_mode controls whether dbm_store() replaces any pre-
existing record that has the same key that is specified by the key argument. The application shall
set store_mode to either DBM_INSERT or DBM_REPLACE. If the database contains a record that
matches the key argument and store_mode is DBM_REPLACE, the existing record shall be
replaced with the new record. If the database contains a record that matches the key argument
and store_mode is DBM_INSERT, the existing record shall be left unchanged and the new record
ignored. If the database does not contain a record that matches the key argument and store_mode is either DBM_INSERT or DBM_REPLACE, the new record shall be inserted in the database.

If the sum of a key/content pair exceeds the internal block size, the result is unspecified. Moreover, the application shall ensure that all key/content pairs that hash together fit on a single block. The dbm_store() function shall return an error in the event that a disk block fills with inseparable data.

The dbm_delete() function shall delete a record and its key from the database. The argument db is a pointer to a database structure that has been returned from a call to dbm_open(). The argument key is a datum that has been initialized by the application to the value of the key that identifies the record the program is deleting.

The dbm_firstkey() function shall return the first key in the database. The argument db is a pointer to a database structure that has been returned from a call to dbm_open().

The dbm_nextkey() function shall return the next key in the database. The argument db is a pointer to a database structure that has been returned from a call to dbm_open(). The application shall ensure that the dbm_firstkey() function is called before calling dbm_nextkey(). Subsequent calls to dbm_nextkey() return the next key until all of the keys in the database have been returned.

The dbm_error() function shall return the error condition of the database. The argument db is a pointer to a database structure that has been returned from a call to dbm_open().

The dbm_clearerr() function shall clear the error condition of the database. The argument db is a pointer to a database structure that has been returned from a call to dbm_open().

The dptr pointers returned by these functions may point into static storage that may be changed by subsequent calls.

These functions need not be reentrant. A function that is not required to be reentrant is not required to be thread-safe.

RETURN VALUE

The dbm_store() and dbm_delete() functions shall return 0 when they succeed and a negative value when they fail.

The dbm_store() function shall return 1 if it is called with a flags value of DBM_INSERT and the function finds an existing record with the same key.

The dbm_error() function shall return 0 if the error condition is not set and return a non-zero value if the error condition is set.

The return value of dbm_clearerr() is unspecified.

The dbm_firstkey() and dbm_nextkey() functions shall return a key datum. When the end of the database is reached, the dptr member of the key is a null pointer. If an error is detected, the dptr member of the key shall be a null pointer and the error condition of the database shall be set.

The dbm_fetch() function shall return a content datum. If no record in the database matches the key or if an error condition has been detected in the database, the dptr member of the content shall be a null pointer.

The dbm_open() function shall return a pointer to a database structure. If an error is detected during the operation, dbm_open() shall return a (DBM *)0.
**dbm_clearerr()**

**System Interfaces**

**ERRORS**

No errors are defined.

**EXAMPLES**

None.

**APPLICATION USAGE**

The following code can be used to traverse the database:

```c
for(key = dbm_firstkey(db); key.dptr != NULL; key = dbm_nextkey(db))
```

The `dbm_*` functions provided in this library should not be confused in any way with those of a general-purpose database management system. These functions do not provide for multiple search keys per entry, they do not protect against multi-user access (in other words they do not lock records or files), and they do not provide the many other useful database functions that are found in more robust database management systems. Creating and updating databases by use of these functions is relatively slow because of data copies that occur upon hash collisions. These functions are useful for applications requiring fast lookup of relatively static information that is to be indexed by a single key.

Note that a strictly conforming application is extremely limited by these functions: since there is no way to determine that the keys in use do not all hash to the same value (although that would be rare), a strictly conforming application cannot be guaranteed that it can store more than one block’s worth of data in the database. As long as a key collision does not occur, additional data may be stored, but because there is no way to determine whether an error is due to a key collision or some other error condition (`dbm_error()` being effectively a Boolean), once an error is detected, the application is effectively limited to guessing what the error might be if it wishes to continue using these functions.

The `dbm_delete()` function need not physically reclaim file space, although it does make it available for reuse by the database.

After calling `dbm_store()` or `dbm_delete()` during a pass through the keys by `dbm_firstkey()` and `dbm_nextkey()`, the application should reset the database by calling `dbm_firstkey()` before again calling `dbm_nextkey()`. The contents of these files are unspecified and may not be portable.

**RATIONALE**

None.

**FUTURE DIRECTIONS**

None.

A note indicating that these functions need not be reentrant is added to the DESCRIPTION.
The DESCRIPTION is updated to avoid use of the term “must” for application requirements.
NAME
difftime — compute the difference between two calendar time values

SYNOPSIS
#include <time.h>

double difftime(time_t time1, time_t time0);

DESCRIPTION
The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-2001 defers to the ISO C standard.

The difftime() function shall compute the difference between two calendar times (as returned by time()): time1 – time0.

RETURN VALUE
The difftime() function shall return the difference expressed in seconds as a type double.

ERRORS
No errors are defined.

EXAMPLES
None.

APPLICATION USAGE
None.

RATIONALE
None.

FUTURE DIRECTIONS
None.

NAME
dirname — report the parent directory name of a file pathname

SYNOPSIS
XSI
#include <libgen.h>

char *dirname(char *path);

DESCRIPTION
The dirname() function shall take a pointer to a character string that contains a pathname, and
return a pointer to a string that is a pathname of the parent directory of that file. Trailing '/'
characters in the path are not counted as part of the path.

If path does not contain a '/', then dirname() shall return a pointer to the string ".". If path is a
null pointer or points to an empty string, dirname() shall return a pointer to the string ".".

The dirname() function need not be reentrant. A function that is not required to be reentrant is
not required to be thread-safe.

RETURN VALUE
The dirname() function shall return a pointer to a string that is the parent directory of path. If
path is a null pointer or points to an empty string, a pointer to a string "." is returned.

The dirname() function may modify the string pointed to by path, and may return a pointer to
static storage that may then be overwritten by subsequent calls to dirname().

ERRORS
No errors are defined.

EXAMPLES
The following code fragment reads a pathname, changes the current working directory to the
parent directory, and opens the file.

char path[PATH_MAX], *pathcopy;
int fd;
fgets(path, PATH_MAX, stdin);
pathcopy = strdup(path);
chdir(dirname(pathcopy));
fd = open(basename(path), O_RDONLY);

Sample Input and Output Strings for dirname()
In the following table, the input string is the value pointed to by path, and the output string is
the return value of the dirname() function.

<table>
<thead>
<tr>
<th>Input String</th>
<th>Output String</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;/usr/lib&quot;</td>
<td>&quot;/usr&quot;</td>
</tr>
<tr>
<td>&quot;/usr/&quot;</td>
<td>&quot;/&quot;</td>
</tr>
<tr>
<td>&quot;usr&quot;</td>
<td>&quot;.&quot;</td>
</tr>
<tr>
<td>&quot;/&quot;</td>
<td>&quot;.&quot;</td>
</tr>
<tr>
<td>&quot;.&quot;</td>
<td>&quot;.&quot;</td>
</tr>
<tr>
<td>&quot;..&quot;</td>
<td>&quot;.&quot;</td>
</tr>
</tbody>
</table>
Changing the Current Directory to the Parent Directory

The following program fragment reads a pathname, changes the current working directory to the parent directory, and opens the file.

```
#include <unistd.h>
#include <limits.h>
#include <stdio.h>
#include <fcntl.h>
#include <string.h>
#include <libgen.h>
...
char path[PATH_MAX], *pathcopy;
int fd;
...
fgets(path, PATH_MAX, stdin);
pathcopy = strdup(path);
chdir(dirname(pathcopy));
fd = open(basename(path), O_RDONLY);
```

APPLICATION USAGE
The `dirname()` and `basename()` functions together yield a complete pathname. The expression `dirname(path)` obtains the pathname of the directory where `basename(path)` is found.

Since the meaning of the leading "/" is implementation-defined, `dirname("//foo")` may return either "/" or '/' (but nothing else).

RATIONALE
None.

FUTURE DIRECTIONS
None.

Issue 5
Moved from X/Open UNIX extension to BASE.

Normative text previously in the APPLICATION USAGE section is moved to the DESCRIPTION.

A note indicating that this function need not be reentrant is added to the DESCRIPTION.
NAME

div — compute the quotient and remainder of an integer division

SYNOPSIS

#include <stdlib.h>

div_t div(int numer, int denom);

DESCRIPTION

The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-2001 defers to the ISO C standard.

The div() function shall compute the quotient and remainder of the division of the numerator numer by the denominator denom. If the division is inexact, the resulting quotient is the integer of lesser magnitude that is the nearest to the algebraic quotient. If the result cannot be represented, the behavior is undefined; otherwise, quot*denom+rem shall equal numer.

RETURN VALUE

The div() function shall return a structure of type div_t, comprising both the quotient and the remainder. The structure includes the following members, in any order:

int quot; /* quotient */
int rem; /* remainder */

ERRORS

No errors are defined.

EXAMPLES

None.

APPLICATION USAGE

None.

**NAME**

dlclose — close a *dlopen()* object

**SYNOPSIS**

```c
#include <dlfcn.h>

int dlclose(void *handle);
```

**DESCRIPTION**

The *dlclose()* function shall inform the system that the object referenced by a *handle* returned from a previous *dlopen()* invocation is no longer needed by the application.

The use of *dlclose()* reflects a statement of intent on the part of the process, but does not create any requirement upon the implementation, such as removal of the code or symbols referenced by *handle*. Once an object has been closed using *dlclose()* an application should assume that its symbols are no longer available to *dlsym()*.

All objects loaded automatically as a result of invoking *dlopen()* on the referenced object shall also be closed if this is the last reference to it.

Although a *dlclose()* operation is not required to remove structures from an address space, neither is an implementation prohibited from doing so. The only restriction on such a removal is that no object shall be removed to which references have been relocated, until or unless all such references are removed. For instance, an object that had been loaded with a *dlopen()* operation specifying the RTLD_GLOBAL flag might provide a target for dynamic relocations performed in the processing of other objects—in such environments, an application may assume that no relocation, once made, shall be undone or remade unless the object requiring the relocation has itself been removed.

**RETURN VALUE**

If the referenced object was successfully closed, *dlclose()* shall return 0. If the object could not be closed, or if *handle* does not refer to an open object, *dlclose()* shall return a non-zero value. More detailed diagnostic information shall be available through *dlerror()*.

**ERRORS**

No errors are defined.

**EXAMPLES**

The following example illustrates use of *dlopen()* and *dlclose()*:

```c
... /* Open a dynamic library and then close it ... */
#include <dlfcn.h>
void *mylib;
int eret;
mylib = dlopen("mylib.so", RTLD_LOCAL | RTLD_LAZY);
... eret = dlclose(mylib);
... 
```

**APPLICATION USAGE**

A conforming application should employ a *handle* returned from a *dlopen()* invocation only within a given scope bracketed by the *dlopen()* and *dlclose()* operations. Implementations are free to use reference counting or other techniques such that multiple calls to *dlopen()* referencing the same object may return the same object for *handle*. Implementations are also free to reuse a *handle*. For these reasons, the value of a *handle* must be treated as an opaque object by the application, used only in calls to *dlsym()* and *dlclose()*.
Rationale
None.

Future Directions
None.

dlerror(), dlopen(), dlsym(), the Base Definitions volume of IEEE Std 1003.1-2001, <dlfcn.h>

Change History
First released in Issue 5.

Issue 6
The DESCRIPTION is updated to say that the referenced object is closed “if this is the last reference to it”.

dlclose()
NAME
dlerror — get diagnostic information

SYNOPSIS
XSI
#include <dlfcn.h>

DESCRIPTION
The dlerror() function shall return a null-terminated character string (with no trailing <newline>)
that describes the last error that occurred during dynamic linking processing. If no dynamic
linking errors have occurred since the last invocation of dlerror(), dlerror() shall return NULL.
Thus, invoking dlerror() a second time, immediately following a prior invocation, shall result in
NULL being returned.
The dlerror() function need not be reentrant. A function that is not required to be reentrant is not
required to be thread-safe.

RETURN VALUE
If successful, dlerror() shall return a null-terminated character string; otherwise, NULL shall be
returned.

ERRORS
No errors are defined.

EXAMPLES
The following example prints out the last dynamic linking error:

#include <dlfcn.h>
char *errstr;
errstr = dlerror();
if (errstr != NULL)
printf ("A dynamic linking error occurred: (%s)
errstr); ...

APPLICATION USAGE
The messages returned by dlerror() may reside in a static buffer that is overwritten on each call
to dlerror(). Application code should not write to this buffer. Programs wishing to preserve an
error message should make their own copies of that message. Depending on the application
environment with respect to asynchronous execution events, such as signals or other
asynchronous computation sharing the address space, conforming applications should use a
critical section to retrieve the error pointer and buffer.

RATIONALE
None.

FUTURE DIRECTIONS
None.

Issue 6

In the DESCRIPTION the note about reentrancy and thread-safety is added.
NAME
dlopen — gain access to an executable object file

SYNOPSIS
#include <dlfcn.h>

void *dlopen(const char *file, int mode);

DESCRIPTION
The dlopen() function shall make an executable object file specified by file available to the calling
program. The class of files eligible for this operation and the manner of their construction are
implementation-defined, though typically such files are executable objects such as shared
libraries, relocatable files, or programs. Note that some implementations permit the construction
of dependencies between such objects that are embedded within files. In such cases, a dlopen()
operation shall load such dependencies in addition to the object referenced by file. Implementations may also impose specific constraints on the construction of programs that can employ dlopen() and its related services.

A successful dlopen() shall return a handle which the caller may use on subsequent calls to
dlsym() and dlclose(). The value of this handle should not be interpreted in any way by the caller.

The file argument is used to construct a pathname to the object file. If file contains a slash
character, the file argument is used as the pathname for the file. Otherwise, file is used in an
implementation-defined manner to yield a pathname.

If the value of file is 0, dlopen() shall provide a handle on a global symbol object. This object shall
provide access to the symbols from an ordered set of objects consisting of the original program
image file, together with any objects loaded at program start-up as specified by that process
image file (for example, shared libraries), and the set of objects loaded using a dlopen() operation
together with the RTLD_GLOBAL flag. As the latter set of objects can change during execution,
the set identified by handle can also change dynamically.

Only a single copy of an object file is brought into the address space, even if dlopen() is invoked
multiple times in reference to the file, and even if different pathnames are used to reference the
file.

The mode parameter describes how dlopen() shall operate upon file with respect to the processing
of relocations and the scope of visibility of the symbols provided within file. When an object is
brought into the address space of a process, it may contain references to symbols whose
addresses are not known until the object is loaded. These references shall be relocated before the
symbols can be accessed. The mode parameter governs when these relocations take place and
may have the following values:

RTLD_LAZY Relocations shall be performed at an implementation-defined time,
ranging from the time of the dlopen() call until the first reference to a
given symbol occurs. Specifying RTLD_LAZY should improve
performance on implementations supporting dynamic symbol binding as
a process may not reference all of the functions in any given object. And,
for systems supporting dynamic symbol resolution for normal process
execution, this behavior mimics the normal handling of process
execution.

RTLD_NOW All necessary relocations shall be performed when the object is first
loaded. This may waste some processing if relocations are performed for
functions that are never referenced. This behavior may be useful for
applications that need to know as soon as an object is loaded that all
symbols referenced during execution are available.

Any object loaded by dlopen() that requires relocations against global symbols can reference the symbols in the original process image file, any objects loaded at program start-up, from the object itself as well as any other object included in the same dlopen() invocation, and any objects that were loaded in any dlopen() invocation and which specified the RTLD_GLOBAL flag. To determine the scope of visibility for the symbols loaded with a dlopen() invocation, the mode parameter should be a bitwise-inclusive OR with one of the following values:

- **RTLD_GLOBAL** The object’s symbols shall be made available for the relocation processing of any other object. In addition, symbol lookup using dlopen(0, mode) and an associated dlsym() allows objects loaded with this mode to be searched.
- **RTLD_LOCAL** The object’s symbols shall not be made available for the relocation processing of any other object.

If neither RTLD_GLOBAL nor RTLD_LOCAL are specified, then an implementation-defined default behavior shall be applied.

If a file is specified in multiple dlopen() invocations, mode is interpreted at each invocation. Note, however, that once RTLD_NOW has been specified all relocations shall have been completed rendering further RTLD_NOW operations redundant and any further RTLD_LAZY operations irrelevant. Similarly, note that once RTLD_GLOBAL has been specified the object shall maintain the RTLD_GLOBAL status regardless of any previous or future specification of RTLD_LOCAL, as long as the object remains in the address space (see dlclose()).

Symbols introduced into a program through calls to dlopen() may be used in relocation activities. Symbols so introduced may duplicate symbols already defined by the program or previous dlopen() operations. To resolve the ambiguities such a situation might present, the resolution of a symbol reference to symbol definition is based on a symbol resolution order. Two such resolution orders are defined: load or dependency ordering. Load order establishes an ordering among symbol definitions, such that the definition first loaded (including definitions from the image file and any dependent objects loaded with it) has priority over objects added later (via dlopen()). Load ordering is used in relocation processing. Dependency ordering uses a breadth-first order starting with a given object, then all of its dependencies, then any dependents of those, iterating until all dependencies are satisfied. With the exception of the global symbol object obtained via a dlopen() operation on a file of 0, dependency ordering is used by the dlsym() function. Load ordering is used in dlsym() operations upon the global symbol object.

When an object is first made accessible via dlopen() it and its dependent objects are added in dependency order. Once all the objects are added, relocations are performed using load order. Note that if an object or its dependencies had been previously loaded, the load and dependency orders may yield different resolutions.

The symbols introduced by dlopen() operations and available through dlsym() are at a minimum those which are exported as symbols of global scope by the object. Typically such symbols shall be those that were specified in (for example) C source code as having extern linkage. The precise manner in which an implementation constructs the set of exported symbols for a dlopen() object is specified by that implementation.

**RETURN VALUE**

If file cannot be found, cannot be opened for reading, is not of an appropriate object format for processing by dlopen(), or if an error occurs during the process of loading file or relocating its symbolic references, dlopen() shall return NULL. More detailed diagnostic information shall be available through dlerror().

CHANGE HISTORY
First released in Issue 5.
NAME
dlsym — obtain the address of a symbol from a dlopen() object

SYNOPSIS
xsi

```c
#include <dlfcn.h>

void *dlsym(void *restrict handle, const char *restrict name);
```

DESCRIPTION
The dlsym() function shall obtain the address of a symbol defined within an object made accessible through a dlopen() call. The handle argument is the value returned from a call to dlopen() (and which has not since been released via a call to dlclose()), and name is the symbol’s name as a character string.

The dlsym() function shall search for the named symbol in all objects loaded automatically as a result of loading the object referenced by handle (see dlopen()). Load ordering is used in dlsym() operations upon the global symbol object. The symbol resolution algorithm used shall be dependency order as described in dlopen().

The RTLD_DEFAULT and RTLD_NEXT flags are reserved for future use.

RETURN VALUE
If handle does not refer to a valid object opened by dlopen(), or if the named symbol cannot be found within any of the objects associated with handle, dlsym() shall return NULL. More detailed diagnostic information shall be available through dlerror().

ERRORS
No errors are defined.

EXAMPLES
The following example shows how dlopen() and dlsym() can be used to access either function or data objects. For simplicity, error checking has been omitted.

```c
void *handle;
int *iptr, (*fptr)(int);
/* open the needed object */
handle = dlopen("/usr/home/me/libfoo.so", RTLD_LOCAL | RTLD_LAZY);
/* find the address of function and data objects */
*(void **)(&fptr) = dlsym(handle, "my_function"l);
iptr = (int *)dlsym(handle, "my_object");
/* invoke function, passing value of integer as a parameter */
(*fptr)(*iptr);
```

APPLICATION USAGE
Special purpose values for handle are reserved for future use. These values and their meanings are:

RTLD_DEFAULT The symbol lookup happens in the normal global scope; that is, a search for a symbol using this handle would find the same definition as a direct use of this symbol in the program code.

RTLD_NEXT Specifies the next object after this one that defines name. This one refers to the object containing the invocation of dlsym(). The next object is the one found upon the application of a load order symbol resolution algorithm (see dlopen()). The next object is either one of global scope (because it was introduced as part of the original process image or because it was added with
a dlopen() operation including the RTLD_GLOBAL flag), or is an object that
was included in the same dlopen() operation that loaded this one.

The RTLD_NEXT flag is useful to navigate an intentionally created hierarchy
of multiply-defined symbols created through interposition. For example, if a
program wished to create an implementation of malloc() that embedded some
statistics gathering about memory allocations, such an implementation could
use the real malloc() definition to perform the memory allocation—and itself
only embed the necessary logic to implement the statistics gathering function.

RATIONALE

The ISO C standard does not require that pointers to functions can be cast back and forth to
pointers to data. Indeed, the ISO C standard does not require that an object of type void * can
hold a pointer to a function. Implementations supporting the XSI extension, however, do require
that an object of type void * can hold a pointer to a function. The result of converting a pointer to
a function into a pointer to another data type (except void *) is still undefined, however. Note
that compilers conforming to the ISO C standard are required to generate a warning if a
conversion from a void * pointer to a function pointer is attempted as in:

fptr = (int (*)(int))dlsym(handle, "my_function");

Due to the problem noted here, a future version may either add a new function to return
function pointers, or the current interface may be deprecated in favor of two new functions: one
that returns data pointers and the other that returns function pointers.

NAME

drand48, erand48, jrand48, icong48, lrand48, mrand48, nrand48, seed48, srand48 — generate
uniformly distributed pseudo-random numbers

SYNOPSIS

XSI
#include <stdlib.h>

double drand48(void);
double erand48(unsigned short xsubi[3]);
long jrand48(unsigned short xsubi[3]);
void lcong48(unsigned short param[7]);
long lrand48(void);
long mrand48(void);
long nrand48(unsigned short xsubi[3]);
unsigned short *seed48(unsigned short seed16v[3]);
void srand48(long seedval);

DESCRIPTION

This family of functions shall generate pseudo-random numbers using a linear congruential
algorithm and 48-bit integer arithmetic.

The drand48() and erand48() functions shall return non-negative, double-precision, floating-
point values, uniformly distributed over the interval [0.0,1.0).

The lrand48() and nrand48() functions shall return non-negative, long integers, uniformly
distributed over the interval [0,2^{31}).

The mrand48() and jrand48() functions shall return signed long integers uniformly distributed
over the interval [−2^{31},2^{31}).

The srand48(), seed48(), and lcong48() functions are initialization entry points, one of which
should be invoked before either drand48(), lrand48(), or mrand48() is called. (Although it is not
recommended practice, constant default initializer values shall be supplied automatically if
drand48(), lrand48(), or mrand48() is called without a prior call to an initialization entry point.)
The erand48(), nrand48(), and jrand48() functions do not require an initialization entry point to
be called first.

All the routines work by generating a sequence of 48-bit integer values, X_i, according to the
linear congruential formula:

X_{i+1} = (aX_i + c) \mod m \quad n \geq 0

The parameter m = 2^{48}; hence 48-bit integer arithmetic is performed. Unless lcong48() is invoked,
the multiplier value a and the addend value c are given by:

a = 5DEECE66D_{16} = 273673163155_8

c = B_{16} = 13_8

The value returned by any of the drand48(), erand48(), jrand48(), lrand48(), mrand48(), or
nrand48() functions is computed by first generating the next 48-bit X_i in the sequence. Then the
appropriate number of bits, according to the type of data item to be returned, are copied from
the high-order (leftmost) bits of X_i and transformed into the returned value.

The drand48(), lrand48(), and mrand48() functions store the last 48-bit X_i generated in an
internal buffer; that is why the application shall ensure that these are initialized prior to being
invoked. The erand48(), nrand48(), and jrand48() functions require the calling program to
provide storage for the successive X_i values in the array specified as an argument when the
functions are invoked. That is why these routines do not have to be initialized; the calling
program merely has to place the desired initial value of \( X_i \) into the array and pass it as an
argument. By using different arguments, \( \text{erand48}() \), \( \text{nrand48}() \), and \( \text{jrand48}() \) allow separate
modules of a large program to generate several independent streams of pseudo-random numbers;
that is, the sequence of numbers in each stream shall not depend upon how many times the
routines are called to generate numbers for the other streams.

The initializer function \( \text{srand48}() \) sets the high-order 32 bits of \( X_i \) to the low-order 32 bits
contained in its argument. The low-order 16 bits of \( X_i \) are set to the arbitrary value \( 330E_{16} \).
The initializer function \( \text{seed48}() \) sets the value of \( X_i \) to the 48-bit value specified in the argument
array. The low-order 16 bits of \( X_i \) are set to the low-order 16 bits of \( \text{seed16v}[0] \). The mid-order 16
bits of \( X_i \) are set to the low-order 16 bits of \( \text{seed16v}[1] \). The high-order 16 bits of \( X_i \) are set to the
low-order 16 bits of \( \text{seed16v}[2] \). In addition, the previous value of \( X_i \) is copied into a 48-bit
internal buffer, used only by \( \text{seed48}() \), and a pointer to this buffer is the value returned by
\( \text{seed48}() \). This returned pointer, which can just be ignored if not needed, is useful if a program is
to be restarted from a given point at some future time—use the pointer to get at and store the
last \( X_i \) value, and then use this value to reinitialize via \( \text{seed48}() \) when the program is restarted.

The initializer function \( \text{lcong48}() \) allows the user to specify the initial \( X_i \), the multiplier value \( a \),
and the addend value \( c \). Argument array elements \( \text{param}[0-2] \) specify \( X_i \), \( \text{param}[3-5] \) specify the
multiplier \( a \), and \( \text{param}[6] \) specifies the 16-bit addend \( c \). After \( \text{lcong48}() \) is called, a subsequent
call to either \( \text{srand48}() \) or \( \text{seed48}() \) shall restore the standard multiplier and addend values, \( a \) and
\( c \), specified above.

The \( \text{drand48}() \), \( \text{lrand48}() \), and \( \text{mrand48}() \) functions need not be reentrant. A function that is not
required to be reentrant is not required to be thread-safe.

RETURN VALUE

NAME
dup, dup2 — duplicate an open file descriptor

SYNOPSIS
#include <unistd.h>
int dup(int fildes);
int dup2(int fildes, int fildes2);

DESCRIPTION
The dup() and dup2() functions provide an alternative interface to the service provided by
fcntl() using the F_DUPFD command. The call:
fid = dup(fildes);
shall be equivalent to:
fid = fcntl(fildes, F_DUPFD, 0);
The call:
fid = dup2(fildes, fildes2);
shall be equivalent to:
close(fildes2);
fid = fcntl(fildes, F_DUPFD, fildes2);
except for the following:
• If fildes2 is less than 0 or greater than or equal to {OPEN_MAX}, dup2() shall return –1 with
  errno set to [EBADF].
• If fildes is a valid file descriptor and is equal to fildes2, dup2() shall return fildes2 without
  closing it.
• If fildes is not a valid file descriptor, dup2() shall return –1 and shall not close fildes2.
• The value returned shall be equal to the value of fildes2 upon successful completion, or –1
  upon failure.

RETURN VALUE
Upon successful completion a non-negative integer, namely the file descriptor, shall be returned;
otherwise, –1 shall be returned and errno set to indicate the error.

ERRORS
The dup() function shall fail if:
[EBADF] The fildes argument is not a valid open file descriptor.
[EMFILE] The number of file descriptors in use by this process would exceed
{OPEN_MAX}.

The dup2() function shall fail if:
[EBADF] The fildes argument is not a valid open file descriptor or the argument fildes2 is
negative or greater than or equal to {OPEN_MAX}.
[EINTR] The dup2() function was interrupted by a signal.
**dup()**

**System Interfaces**

874 **EXAMPLES**

875 **Redirecting Standard Output to a File**

876 The following example closes standard output for the current processes, re-assigns standard output to go to the file referenced by `pfd`, and closes the original file descriptor to clean up.

877 ```
#include <unistd.h>
...
int pfd;
...
close(1);
dup(pfd);
```  

8788 close(pfd);
```
...
```

8796 **Redirecting Error Messages**

8797 The following example redirects messages from `stderr` to `stdout`.

8798 ```
#include <unistd.h>
...
```  

8799 ```
dup2(1, 2);
```  

8800 ```
...
```

8802 **APPLICATION USAGE**

8803 None.

8804 **RATIONALE**

8805 The `dup()` and `dup2()` functions are redundant. Their services are also provided by the `fcntl()` function. They have been included in this volume of IEEE Std 1003.1-2001 primarily for historical reasons, since many existing applications use them.

8806 While the brief code segment shown is very similar in behavior to `dup2()`, a conforming implementation based on other functions defined in this volume of IEEE Std 1003.1-2001 is significantly more complex. Least obvious is the possible effect of a signal-catching function that could be invoked between steps and allocate or deallocate file descriptors. This could be avoided by blocking signals.

8807 The `dup2()` function is not marked obsolescent because it presents a type-safe version of functionality provided in a type-unsafe version by `fcntl()`. It is used in the POSIX Ada binding.

8808 In the description of [EBADF], the case of `fildes` being out of range is covered by the given case of `fildes` not being valid. The descriptions for `fildes` and `fildes2` are different because the only kind of invalidity that is relevant for `fildes2` is whether it is out of range; that is, it does not matter whether `fildes2` refers to an open file when the `dup2()` call is made.

8809 **FUTURE DIRECTIONS**

8810 None.

First released in Issue 1. Derived from Issue 1 of the SVID.
NAME
ecvt, fcvt, gcvt — convert a floating-point number to a string (LEGACY)

SYNOPSIS
XSI
#include <stdlib.h>

char *ecvt(double value, int ndigit, int *restrict decpt,
           int *restrict sign);
char *fcvt(double value, int ndigit, int *restrict decpt,
           int *restrict sign);
char *gcvt(double value, int ndigit, char *buf);

DESCRIPTION
The ecvt(), fcvt(), and gcvt() functions shall convert floating-point numbers to null-terminated strings.

The ecvt() function shall convert value to a null-terminated string of ndigit digits (where ndigit is reduced to an unspecified limit determined by the precision of a double) and return a pointer to the string. The high-order digit shall be non-zero, unless the value is 0. The low-order digit shall be rounded in an implementation-defined manner. The position of the radix character relative to the beginning of the string shall be stored in the integer pointed to by decpt (negative means to the left of the returned digits). If value is zero, it is unspecified whether the integer pointed to by decpt would be 0 or 1. The radix character shall not be included in the returned string. If the sign of the result is negative, the integer pointed to by sign shall be non-zero; otherwise, it shall be 0.

If the converted value is out of range or is not representable, the contents of the returned string are unspecified.

The fcvt() function shall be equivalent to ecvt(), except that ndigit specifies the number of digits desired after the radix character. The total number of digits in the result string is restricted to an unspecified limit as determined by the precision of a double.

The gcvt() function shall convert value to a null-terminated string (similar to that of the %g conversion specification format of printf()) in the array pointed to by buf and shall return buf. It shall produce ndigit significant digits (limited to an unspecified value determined by the precision of a double) in the %e conversion specification format of printf() if possible, or the %e conversion specification format of printf() (scientific notation) otherwise. A minus sign shall be included in the returned string if value is less than 0. A radix character shall be included in the returned string if value is not a whole number. Trailing zeros shall be suppressed where value is not a whole number. The radix character is determined by the current locale. If setlocale() has not been called successfully, the default locale, POSIX, is used. The default locale specifies a period (‘.’) as the radix character. The LC_NUMERIC category determines the value of the radix character within the current locale.

These functions need not be reentrant. A function that is not required to be reentrant is not required to be thread-safe.

RETURN VALUE
The ecvt() and fcvt() functions shall return a pointer to a null-terminated string of digits.

The gcvt() function shall return buf.

The return values from ecvt() and fcvt() may point to static data which may be overwritten by subsequent calls to these functions.
ERRORS
No errors are defined.

EXAMPLES
None.

APPLICATION USAGE
The sprintf() function is preferred over this function.

RATIONALE
None.

FUTURE DIRECTIONS
These functions may be withdrawn in a future version.

SEE ALSO
printf(), setlocale(), the Base Definitions volume of IEEE Std 1003.1-2001, <stdlib.h>

CHANGE HISTORY
First released in Issue 4, Version 2.

Issue 5
Moved from X/OPEN UNIX extension to BASE.
Normative text previously in the APPLICATION USAGE section is moved to the DESCRIPTION.
A note indicating that these functions need not be reentrant is added to the DESCRIPTION.

Issue 6
In the DESCRIPTION, the note about reentrancy is expanded to cover thread-safety.
This function is marked LEGACY.
The restrict keyword is added to the ecvt() and fcvt() prototypes for alignment with the ISO/IEC 9899: 1999 standard.
The DESCRIPTION is updated to explicitly use “conversion specification” to describe %g, %f, and %e.
NAME
encrypt — encoding function (CRYPT)

SYNOPSIS
#include <unistd.h>
void encrypt(char block[64], int edflag);

DESCRIPTION
The encrypt() function shall provide access to an implementation-defined encoding algorithm.
The key generated by setkey() is used to encrypt the string block with encrypt().
The block argument to encrypt() shall be an array of length 64 bytes containing only the bytes
with values of 0 and 1. The array is modified in place to a similar array using the key set by
setkey(). If edflag is 0, the argument is encoded. If edflag is 1, the argument may be decoded (see
the APPLICATION USAGE section); if the argument is not decoded, errno shall be set to
[ENOSYS].

The encrypt() function shall not change the setting of errno if successful. An application wishing
to check for error situations should set errno to 0 before calling encrypt(). If errno is non-zero on
return, an error has occurred.

The encrypt() function need not be reentrant. A function that is not required to be reentrant is
not required to be thread-safe.

RETURN VALUE
The encrypt() function shall not return a value.

ERRORS
The encrypt() function shall fail if:
[ENOSYS] The functionality is not supported on this implementation.

EXAMPLES
None.

APPLICATION USAGE
Historical implementations of the encrypt() function used a rather primitive encoding algorithm.
In some environments, decoding might not be implemented. This is related to some Government
restrictions on encryption and decryption routines. Historical practice has been to ship a
different version of the encryption library without the decryption feature in the routines
supplied. Thus the exported version of encrypt() does encoding but not decoding.

RATIONALE
None.

FUTURE DIRECTIONS
None.

In the DESCRIPTION, the note about reentrancy is expanded to cover thread-safety.
NAME
endgrent, getgrent, setgrent — group database entry functions

SYNOPSIS
XSI
#include <grp.h>

void endgrent(void);
struct group *getgrent(void);
void setgrent(void);

DESCRIPTION
The getgrent() function shall return a pointer to a structure containing the broken-out fields of an
token in the group database. When first called, getgrent() shall return a pointer to a group
structure containing the first entry in the group database. Thereafter, it shall return a pointer to a
group structure containing the next group structure in the group database, so successive calls
may be used to search the entire database.

An implementation that provides extended security controls may impose further
implementation-defined restrictions on accessing the group database. In particular, the system
may deny the existence of some or all of the group database entries associated with groups other
than those groups associated with the caller and may omit users other than the caller from the
list of members of groups in database entries that are returned.

The setgrent() function shall rewind the group database to allow repeated searches.

The endgrent() function may be called to close the group database when processing is complete.

These functions need not be reentrant. A function that is not required to be reentrant is not
required to be thread-safe.

RETURN VALUE
When first called, getgrent() shall return a pointer to the first group structure in the group
database. Upon subsequent calls it shall return the next group structure in the group database.
The getgrent() function shall return a null pointer on end-of-file or an error and errno may be set
to indicate the error.

The return value may point to a static area which is overwritten by a subsequent call to
getgrgid(), getgrnam(), or getgrent().

ERRORS
The getgrent() function may fail if:

[EINTR] A signal was caught during the operation.
[EIO] An I/O error has occurred.
[EMFILE] [OPEN_MAX] file descriptors are currently open in the calling process.
[ENFILE] The maximum allowable number of files is currently open in the system.
EXAMPLES
None.

APPLICATION USAGE
These functions are provided due to their historical usage. Applications should avoid dependencies on fields in the group database, whether the database is a single file, or where in the file system name space the database resides. Applications should use `getgrnam()` and `getgrgid()` whenever possible because it avoids these dependencies.

RATIONALE
None.

FUTURE DIRECTIONS
None.

Issue 5
Moved from X/OPEN UNIX extension to BASE.

Issue 6
Normative text previously in the APPLICATION USAGE section is moved to the RETURN VALUE section.

A note indicating that these functions need not be reentrant is added to the DESCRIPTION.

Issue 6
In the DESCRIPTION, the note about reentrancy is expanded to cover thread-safety.
NAME
endhostent, gethostent, sethostent — network host database functions

SYNOPSIS
#include <netdb.h>

void endhostent(void);
struct hostent *gethostent(void);
void sethostent(int stayopen);

DESCRIPTION
These functions shall retrieve information about hosts. This information is considered to be
stored in a database that can be accessed sequentially or randomly. The implementation of this
database is unspecified.

Note: In many cases this database is implemented by the Domain Name System, as documented in
RFC 1034, RFC 1035, and RFC 1886.

The sethostent() function shall open a connection to the database and set the next entry for
retrieval to the first entry in the database. If the stayopen argument is non-zero, the connection
shall not be closed by a call to gethostent(), gethostbyname(), or gethostbyaddr(), and the
implementation may maintain an open file descriptor.

The gethostent() function shall read the next entry in the database, opening and closing a
connection to the database as necessary.

Entries shall be returned in hostent structures. Refer to gethostbyaddr() for a definition of the
hostent structure.

The endhostent() function shall close the connection to the database, releasing any open file
descriptor.

These functions need not be reentrant. A function that is not required to be reentrant is not
required to be thread-safe.

RETURN VALUE
Upon successful completion, the gethostent() function shall return a pointer to a hostent
structure if the requested entry was found, and a null pointer if the end of the database was
reached or the requested entry was not found.

ERRORS
No errors are defined for endhostent(), gethostent(), and sethostent().

EXAMPLES
None.

APPLICATION USAGE
The gethostent() function may return pointers to static data, which may be overwritten by
subsequent calls to any of these functions.

RATIONALE
None.

FUTURE DIRECTIONS
None.

endnetent()

NAME
endnetent, getnetbyaddr, getnetbyname, getnetent, setnetent — network database functions

SYNOPSIS
#include <netdb.h>

void endnetent(void);

struct netent *getnetbyaddr(uint32_t net, int type);

struct netent *getnetbyname(const char *name);

struct netent *getnetent(void);

void setnetent(int stayopen);

DESCRIPTION
These functions shall retrieve information about networks. This information is considered to be
stored in a database that can be accessed sequentially or randomly. The implementation of this
database is unspecified.

The setnetent() function shall open and rewind the database. If the stayopen argument is non-
zero, the connection to the net database shall not be closed after each call to getnetent() (either
directly, or indirectly through one of the other getnet*() functions), and the implementation may
maintain an open file descriptor to the database.

The getnetent() function shall read the next entry of the database, opening and closing a
connection to the database as necessary.

The getnetbyaddr() function shall search the database from the beginning, and find the first entry
for which the address family specified by type matches the n_addrtype member and the network
number net matches the n_net member, opening and closing a connection to the database as
necessary. The net argument shall be the network number in host byte order.

The getnetbyname() function shall search the database from the beginning and find the first entry
for which the network name specified by name matches the n_name member, opening and
closing a connection to the database as necessary.

The getnetbyaddr(), getnetbyname(), and getnetent() functions shall each return a pointer to a
netent structure, the members of which shall contain the fields of an entry in the network
database.

The endnetent() function shall close the database, releasing any open file descriptor.

These functions need not be reentrant. A function that is not required to be reentrant is not
required to be thread-safe.

RETURN VALUE
Upon successful completion, getnetbyaddr(), getnetbyname(), and getnetent() shall return a
pointer to a netent structure if the requested entry was found, and a null pointer if the end of the
database was reached or the requested entry was not found. Otherwise, a null pointer shall be
returned.

ERRORS
No errors are defined.
EXAMPLES
None.

APPLICATION USAGE
The getnetbyaddr(), getnetbyname(), and getnetent() functions may return pointers to static data, which may be overwritten by subsequent calls to any of these functions.

RATIONALE
None.

FUTURE DIRECTIONS

NAME

deprotoent, getprotobynumber, getprotobynumber, getprotoent, setprotoent — network protocol
database functions

SYNOPSIS

#include <netdb.h>

void endprotoent(void);
struct protoent *getprotobyname(const char *name);
struct protoent *getprotobynumber(int proto);
struct protoent *getprotoent(void);
void setprotoent(int stayopen);

DESCRIPTION

These functions shall retrieve information about protocols. This information is considered to be
stored in a database that can be accessed sequentially or randomly. The implementation of this
database is unspecified.

The setprotoent() function shall open a connection to the database, and set the next entry to the
first entry. If the stayopen argument is non-zero, the connection to the network protocol database
shall not be closed after each call to getprotoent() (either directly, or indirectly through one of the
other getproto*() functions), and the implementation may maintain an open file descriptor for
the database.

The getprotobyname() function shall search the database from the beginning and find the first
entry for which the protocol name specified by name matches the p_name member, opening and
closing a connection to the database as necessary.

The getprotobynumber() function shall search the database from the beginning and find the first
entry for which the protocol number specified by proto matches the p_proto member, opening
and closing a connection to the database as necessary.

The getprotoent() function shall read the next entry of the database, opening and closing a
connection to the database as necessary.

The getprotobyname(), getprotobynumber(), and getprotoent() functions shall each return a pointer
to a protoent structure, the members of which shall contain the fields of an entry in the network
protocol database.

The endprotoent() function shall close the connection to the database, releasing any open file
descrriptor.

These functions need not be reentrant. A function that is not required to be reentrant is not
required to be thread-safe.

RETURN VALUE

Upon successful completion, getprotobyname(), getprotobynumber(), and getprotoent() return a
pointer to a protoent structure if the requested entry was found, and a null pointer if the end of
the database was reached or the requested entry was not found. Otherwise, a null pointer is
returned.

ERRORS

No errors are defined.
EXAMPLES

None.

APPLICATION USAGE

The getprotobyname(), getprotobynumber(), and getprotoent() functions may return pointers to static data, which may be overwritten by subsequent calls to any of these functions.

RATIONALE

None.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 6. Derived from the XNS, Issue 5.2 specification.
endpwent()

NAME
endpwent, getpwent, setpwent — user database functions

SYNOPSIS
#include <pwd.h>

void endpwent(void);

struct passwd *getpwent(void);

void setpwent(void);

DESCRIPTION
These functions shall retrieve information about users. The getpwent() function shall return a pointer to a structure containing the broken-out fields of an entry in the user database. Each entry in the user database contains a passwd structure. When first called, getpwent() shall return a pointer to a passwd structure containing the first entry in the user database. Thereafter, it shall return a pointer to a passwd structure containing the next entry in the user database. Successive calls can be used to search the entire user database.

If an end-of-file or an error is encountered on reading, getpwent() shall return a null pointer.

An implementation that provides extended security controls may impose further implementation-defined restrictions on accessing the user database. In particular, the system may deny the existence of some or all of the user database entries associated with users other than the caller.

The setpwent() function effectively rewinds the user database to allow repeated searches.

The endpwent() function may be called to close the user database when processing is complete.

These functions need not be reentrant. A function that is not required to be reentrant is not required to be thread-safe.

RETURN VALUE
The getpwent() function shall return a null pointer on end-of-file or error.

ERRORS
The getpwent(), setpwent(), and endpwent() functions may fail if:

[EIO] An I/O error has occurred.

In addition, getpwent() and setpwent() may fail if:

[EMFILE] [OPEN_MAX] file descriptors are currently open in the calling process.

[ENFILE] The maximum allowable number of files is currently open in the system.

The return value may point to a static area which is overwritten by a subsequent call to getpwuid(), getpwnam(), or getpwent().
EXAMPLES

Searching the User Database

The following example uses the `getpwent()` function to get successive entries in the user database, returning a pointer to a `passwd` structure that contains information about each user. The call to `endpwent()` closes the user database and cleans up.

```
#include <pwd.h>
...
struct passwd *p;
...
while ((p = getpwent ()) != NULL) {
  ...  
}
endpwent();
...
```

APPLICATION USAGE

These functions are provided due to their historical usage. Applications should avoid dependencies on fields in the password database, whether the database is a single file, or where in the file system name space the database resides. Applications should use `getpwuid()` whenever possible because it avoids these dependencies.

RATIONALE
None.

FUTURE DIRECTIONS
None.

CHANGE HISTORY

First released in Issue 4, Version 2.

Issue 5
Moved from X/OPEN UNIX extension to BASE.

Normative text previously in the APPLICATION USAGE section is moved to the RETURN VALUE section.

A note indicating that these functions need not be reentrant is added to the DESCRIPTION.

Issue 6
In the DESCRIPTION, the note about reentrancy is expanded to cover thread-safety.
endservent

NAME
endservent, getservbyname, getservbyport, getservent, setservent — network services database functions

SYNOPSIS
#include <netdb.h>

void endservent(void);

struct servent *getservbyname(const char *name, const char *proto);

struct servent *getservbyport(int port, const char *proto);

struct servent *getservent(void);

void setservent(int stayopen);

DESCRIPTION
These functions shall retrieve information about network services. This information is considered to be stored in a database that can be accessed sequentially or randomly. The implementation of this database is unspecified.

The setservent() function shall open a connection to the database, and set the next entry to the first entry. If the stayopen argument is non-zero, the net database shall not be closed after each call to the getservent() function (either directly, or indirectly through one of the other getserv*() functions), and the implementation may maintain an open file descriptor for the database.

The getservent() function shall read the next entry of the database, opening and closing a connection to the database as necessary.

The getservbyname() function shall search the database from the beginning and find the first entry for which the service name specified by name matches the s_name member and the protocol name specified by proto matches the s_proto member, opening and closing a connection to the database as necessary. If proto is a null pointer, any value of the s_proto member shall be matched.

The getservbyport() function shall search the database from the beginning and find the first entry for which the port specified by port matches the s_port member and the protocol name specified by proto matches the s_proto member, opening and closing a connection to the database as necessary. If proto is a null pointer, any value of the s_proto member shall be matched. The port argument shall be in network byte order.

The getservbyname(), getservbyport(), and getservent() functions shall each return a pointer to a servent structure, the members of which shall contain the fields of an entry in the network services database.

The endservent() function shall close the database, releasing any open file descriptor.

These functions need not be reentrant. A function that is not required to be reentrant is not required to be thread-safe.

RETURN VALUE
Upon successful completion, getservbyname(), getservbyport(), and getservent() return a pointer to a servent structure if the requested entry was found, and a null pointer if the end of the database was reached or the requested entry was not found. Otherwise, a null pointer is returned.

ERRORS
No errors are defined.
EXAMPLES
None.

APPLICATION USAGE
The port argument of getservbyport() need not be compatible with the port values of all address families.

The getservbyname(), getservbyport(), and getservent() functions may return pointers to static data, which may be overwritten by subsequent calls to any of these functions.

RATIONALE
None.

FUTURE DIRECTIONS
None.

CHANGE HISTORY
First released in Issue 6. Derived from the XNS, Issue 5.2 specification.
NAME
endutxent, getutxent, getutxid, getutxline, pututxline, setutxent — user accounting database functions

SYNOPSIS
#include <utmpx.h>

void endutxent(void);
struct utmpx *getutxent(void);
struct utmpx *getutxid(const struct utmpx *id);
struct utmpx *getutxline(const struct utmpx *line);
struct utmpx *pututxline(const struct utmpx *utmpx);
void setutxent(void);

DESCRIPTION
These functions shall provide access to the user accounting database.

The getutxent() function shall read the next entry from the user accounting database. If the database is not already open, it shall open it. If it reaches the end of the database, it shall fail.

The getutxid() function shall search forward from the current point in the database. If the ut_type value of the utmpx structure pointed to by id is BOOT_TIME, OLD_TIME, or NEW_TIME, then it shall stop when it finds an entry with a matching ut_type value. If the ut_type value is INIT_PROCESS, LOGIN_PROCESS, USER_PROCESS, or DEAD_PROCESS, then it shall stop when it finds an entry whose type is one of these four and whose ut_id member matches the ut_id member of the utmpx structure pointed to by id. If the end of the database is reached without a match, getutxid() shall fail.

The getutxline() function shall search forward from the current point in the database until it finds an entry of the type LOGIN_PROCESS or USER_PROCESS which also has a ut_line value matching that in the utmpx structure pointed to by line. If the end of the database is reached without a match, getutxline() shall fail.

The getutxid() or getutxline() function may cache data. For this reason, to use getutxline() to search for multiple occurrences, the application shall zero out the static data after each success, or getutxline() may return a pointer to the same utmpx structure.

There is one exception to the rule about clearing the structure before further reads are done. The implicit read done by pututxline() (if it finds that it is not already at the correct place in the user accounting database) shall not modify the static structure returned by getutxent(), getutxid(), or getutxline(), if the application has modified this structure and passed the pointer back to pututxline().

For all entries that match a request, the ut_type member indicates the type of the entry. Other members of the entry shall contain meaningful data based on the value of the ut_type member as follows:
### System Interfaces

#### endutxent()

<table>
<thead>
<tr>
<th>ut_type Member</th>
<th>Other Members with Meaningful Data</th>
</tr>
</thead>
<tbody>
<tr>
<td>EMPTY</td>
<td>No others</td>
</tr>
<tr>
<td>BOOT_TIME</td>
<td>\textit{ut_tv}</td>
</tr>
<tr>
<td>OLD_TIME</td>
<td>\textit{ut_tv}</td>
</tr>
<tr>
<td>NEW_TIME</td>
<td>\textit{ut_tv}</td>
</tr>
<tr>
<td>USER_PROCESS</td>
<td>\textit{ut_id}, \textit{ut_user} (login name of the user), \textit{ut_line}, \textit{ut_pid}, \textit{ut_tv}</td>
</tr>
<tr>
<td>INIT_PROCESS</td>
<td>\textit{ut_id}, \textit{ut_pid}, \textit{ut_tv}</td>
</tr>
<tr>
<td>LOGIN_PROCESS</td>
<td>\textit{ut_id}, \textit{ut_user} (implementation-defined name of the login process), \textit{ut_pid}, \textit{ut_tv}</td>
</tr>
<tr>
<td>DEAD_PROCESS</td>
<td>\textit{ut_id}, \textit{ut_pid}, \textit{ut_tv}</td>
</tr>
</tbody>
</table>

An implementation that provides extended security controls may impose implementation-defined restrictions on accessing the user accounting database. In particular, the system may deny the existence of some or all of the user accounting database entries associated with users other than the caller.

If the process has appropriate privileges, the \textit{pututxline()} function shall write out the structure into the user accounting database. It shall use \textit{getutxid()} to search for a record that satisfies the request. If this search succeeds, then the entry shall be replaced. Otherwise, a new entry shall be made at the end of the user accounting database.

The \textit{endutxent()} function shall close the user accounting database.

The \textit{setutxent()} function shall reset the input to the beginning of the database. This should be done before each search for a new entry if it is desired that the entire database be examined.

These functions need not be reentrant. A function that is not required to be reentrant is not required to be thread-safe.

#### RETURN VALUE

Upon successful completion, \textit{getutxent()}, \textit{getutxid()}, and \textit{getutxline()} shall return a pointer to a \texttt{utmpx} structure containing a copy of the requested entry in the user accounting database. Otherwise, a null pointer shall be returned.

The return value may point to a static area which is overwritten by a subsequent call to \textit{getutxid()} or \textit{getutxline()}.

Upon successful completion, \textit{pututxline()} shall return a pointer to a \texttt{utmpx} structure containing a copy of the entry added to the user accounting database. Otherwise, a null pointer shall be returned.

The \textit{endutxent()} and \textit{setutxent()} functions shall not return a value.

#### ERRORS

No errors are defined for the \textit{endutxent()}, \textit{getutxent()}, \textit{getutxid()}, \textit{getutxline()}, and \textit{setutxent()} functions.

The \textit{pututxline()} function may fail if:

[EPERM] The process does not have appropriate privileges.

long double erfl(long double x);

DESCRIPTION
The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-2001 defers to the ISO C standard.

These functions shall compute the error function of their argument \( x \), defined as:

\[
\frac{2}{\sqrt{\pi}} \int_0^x e^{-t^2} dt
\]

An application wishing to check for error situations should set \( \text{errno} \) to zero and call \( \text{feclearexcept}(\text{FE_ALL_EXCEPT}) \) before calling these functions. On return, if \( \text{errno} \) is non-zero or \( \text{fetestexcept}(\text{FE_INVALID} | \text{FE_DIVBYZERO} | \text{FE_OVERFLOW} | \text{FE_UNDERFLOW}) \) is non-zero, an error has occurred.

RETURN VALUE
Upon successful completion, these functions shall return the value of the error function.

If \( x \) is NaN, a NaN shall be returned.
If \( x \) is ±0, ±0 shall be returned.
If \( x \) is ±Inf, ±1 shall be returned.
If \( x \) is subnormal, a range error may occur, and \( 2 * x / \sqrt{\pi} \) should be returned.

ERRORS
These functions may fail if:

Range Error The result underflows.

If the integer expression (\( \text{math_errno} \) & MATH_ERRNO) is non-zero, then \( \text{errno} \) shall be set to [ERANGE]. If the integer expression (\( \text{math_errno} \) & MATH_ERREXCEPT) is non-zero, then the underflow floating-point exception shall be raised.

EXAMPLES
None.

APPLICATION USAGE
Underflow occurs when \( |x| < \text{DBL_MIN} * (\sqrt{\pi}/2) \).
On error, the expressions (\( \text{math_errno} \) & MATH_ERRNO) and (\( \text{math_errno} \) & MATH_ERREXCEPT) are independent of each other, but at least one of them must be non-zero.

RATIONALE
None.
FUTURE DIRECTIONS

None.

SEE ALSO

erfc(), feclearexcept(), fetestexcept(), isnan(), the Base Definitions volume of IEEE Std 1003.1-2001, Section 4.18, Treatment of Error Conditions for Mathematical Functions, <math.h>

CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 5

The DESCRIPTION is updated to indicate how an application should check for an error. This text was previously published in the APPLICATION USAGE section.

Issue 6

The erf() function is no longer marked as an extension.

The erfc() function is split out onto its own reference page.

The erf() and erfl() functions are added for alignment with the ISO/IEC 9899:1999 standard.

The DESCRIPTION, RETURN VALUE, ERRORS, and APPLICATION USAGE sections are revised to align with the ISO/IEC 9899:1999 standard.

NAME
erfc, erfcf, erfcl — complementary error functions

SYNOPSIS
#include <math.h>

double erfc(double x);
float erfcf(float x);
long double erfcl(long double x);

DESCRIPTION
The functionality described on this reference page is aligned with the ISO C standard. Any
conflict between the requirements described here and the ISO C standard is unintentional. This

These functions shall compute the complementary error function 1.0 - erf(x).

An application wishing to check for error situations should set errno to zero and call
feclearexcept(FE_ALL_EXCEPT) before calling these functions. On return, if errno is non-zero or
fetestexcept(FE_INVALID | FE_DIVBYZERO | FE_OVERFLOW | FE_UNDERFLOW) is non-zero, an error has occurred.

RETURN VALUE
Upon successful completion, these functions shall return the value of the complementary error
function.

If the correct value would cause underflow and is not representable, a range error may occur
and either 0.0 (if representable), or an implementation-defined value shall be returned.

Mx
If x is NaN, a NaN shall be returned.
If x is ±0, +1 shall be returned.
If x is −Inf, +2 shall be returned.
If x is +Inf, +0 shall be returned.

If the correct value would cause underflow and is representable, a range error may occur and the
 correct value shall be returned.

ERRORS
These functions may fail if:

Range Error The result underflows.

If the integer expression (math_errno & MATH_ERRNO) is non-zero,
then errno shall be set to [ERANGE]. If the integer expression
(math_errno & MATH_ERREXCEPT) is non-zero, then the underflow
floating-point exception shall be raised.

EXAMPLES
None.

APPLICATION USAGE
The erfc() function is provided because of the extreme loss of relative accuracy if erf(x) is called
for large x and the result subtracted from 1.0.

Note for IEEE Std 754-1985 double, 26.55 < x implies erfc(x) has underflowed.

On error, the expressions (math_errno & MATH_ERRNO) and (math_errno &
MATH_ERREXCEPT) are independent of each other, but at least one of them must be non-zero.
erfc()

RATIONALE
None.

FUTURE DIRECTIONS
None.

NAME
erff, erfl — error functions

SYNOPSIS
#include <math.h>

float erff(float x);
long double erfl(long double x);

DESCRIPTION
Refer to erf().
NAME
errno — error return value

SYNOPSIS
#include <errno.h>

DESCRIPTION
The lvalue errno is used by many functions to return error values.

Many functions provide an error number in errno, which has type int and is defined in
<errno.h>. The value of errno shall be defined only after a call to a function for which it is
explicitly stated to be set and until it is changed by the next function call or if the application
assigns it a value. The value of errno should only be examined when it is indicated to be valid by
a function's return value. Applications shall obtain the definition of errno by the inclusion of
<errno.h>. No function in this volume of IEEE Std 1003.1-2001 shall set errno to 0.

It is unspecified whether errno is a macro or an identifier declared with external linkage. If a
macro definition is suppressed in order to access an actual object, or a program defines an
identifier with the name errno, the behavior is undefined.

The symbolic values stored in errno are documented in the ERRORS sections on all relevant
pages.

RETURN VALUE
None.

ERRORS
None.

EXAMPLES
None.

APPLICATION USAGE
Previously both POSIX and X/Open documents were more restrictive than the ISO C standard
in that they required errno to be defined as an external variable, whereas the ISO C standard
required only that errno be defined as a modifiable lvalue with type int.

An application that needs to examine the value of errno to determine the error should set it to 0
before a function call, then inspect it before a subsequent function call.

RATIONALE
None.

FUTURE DIRECTIONS
None.

CHANGE HISTORY
First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 5
The following sentence is deleted from the DESCRIPTION: ‘The value of errno is 0 at program
start-up, but is never set to 0 by any XSI function’. The DESCRIPTION also no longer states that
conforming implementations may support the declaration:
extern int errno;
9554 Issue 6
9555 Obsolescent text regarding defining `errno` as:
9556 extern int errno
9557 is removed.
9558 Text regarding no function setting `errno` to zero to indicate an error is changed to no function
9559 shall set `errno` to zero. This is for alignment with the ISO/IEC 9899:1999 standard.
The exec family of functions shall replace the current process image with a new process image. The new image shall be constructed from a regular, executable file called the new process image file. There shall be no return from a successful exec, because the calling process image is overlaid by the new process image.

When a C-language program is executed as a result of this call, it shall be entered as a C-language function call as follows:

```
int main (int argc, char *argv[]);
```

where `argc` is the argument count and `argv` is an array of character pointers to the arguments themselves. In addition, the following variable:

```
extern char **environ;
```

is initialized as a pointer to an array of character pointers to the environment strings. The `argv` and `environ` arrays are each terminated by a null pointer. The null pointer terminating the `argv` array is not counted in `argc`.

Conforming multi-threaded applications shall not use the `environ` variable to access or modify any environment variable while any other thread is concurrently modifying any environment variable. A call to any function dependent on any environment variable shall be considered a use of the `environ` variable to access that environment variable.

The arguments specified by a program with one of the exec functions shall be passed on to the new process image in the corresponding `main()` arguments.

The argument `path` points to a pathname that identifies the new process image file.

The argument `file` is used to construct a pathname that identifies the new process image file. If the `file` argument contains a slash character, the `file` argument shall be used as the pathname for this file. Otherwise, the path prefix for this file is obtained by a search of the directories passed as the environment variable `PATH` (see the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 8, Environment Variables). If this environment variable is not present, the results of the search are implementation-defined.

There are two distinct ways in which the contents of the process image file may cause the execution to fail, distinguished by the setting of `errno` to either [ENOEXEC] or [EINVAL] (see the ERRORS section). In the cases where the other members of the exec family of functions would fail and set `errno` to [ENOEXEC], the `execlp()` and `execvp()` functions shall execute a command interpreter and the environment of the executed command shall be as if the process invoked the `sh` utility using `execl()` as follows:
exec(<shell path>, arg0, file, arg1, ..., (char *)0);

where <shell path> is an unspecified pathname for the sh utility, file is the process image file, and for execvp(), where arg0, arg1, and so on correspond to the values passed to execvp() in argv[0], argv[1], and so on.

The arguments represented by arg0,... are pointers to null-terminated character strings. These strings shall constitute the argument list available to the new process image. The list is terminated by a null pointer. The argument arg0 should point to a filename that is associated with the process being started by one of the exec functions.

The argument argv is an array of character pointers to null-terminated strings. The application shall ensure that the last member of this array is a null pointer. These strings shall constitute the argument list available to the new process image. The value in argv[0] should point to a filename that is associated with the process being started by one of the exec functions.

The argument envp is an array of character pointers to null-terminated strings. These strings shall constitute the environment for the new process image. The envp array is terminated by a null pointer.

For those forms not containing an envp pointer (execl(), execv(), execvp(), and execvp()), the environment for the new process image shall be taken from the external variable environ in the calling process.

The number of bytes available for the new process' combined argument and environment lists is {ARG_MAX}. It is implementation-defined whether null terminators, pointers, and/or any alignment bytes are included in this total.

File descriptors open in the calling process image shall remain open in the new process image, except for those whose close-on-exec flag FD_CLOEXEC is set. For those file descriptors that remain open, all attributes of the open file description remain unchanged. For any file descriptor that is closed for this reason, file locks are removed as a result of the close as described in close(). Locks that are not removed by closing of file descriptors remain unchanged.

If file descriptors 0, 1, and 2 would otherwise be closed after a successful call to one of the exec family of functions, and the new process image file has the set-user-ID or set-group-ID file mode bits set, and the ST_NOSUID bit is not set for the file system containing the new process image file, implementations may open an unspecified file for each of these file descriptors in the new process image.

Directory streams open in the calling process image shall be closed in the new process image.

The state of the floating-point environment in the new process image shall be set to the default.

The state of conversion descriptors and message catalog descriptors in the new process image is undefined. For the new process image, the equivalent of:

```
setlocale(LC_ALL, "C")
```

shall be executed at start-up.

Signals set to the default action (SIG_DFL) in the calling process image shall be set to the default action in the new process image. Except for SIGCHLD, signals set to be ignored (SIG_IGN) by the calling process image shall be set to be ignored by the new process image. Signals set to be caught by the calling process image shall be set to the default action in the new process image (see <signal.h>). If the SIGCHLD signal is set to be ignored by the calling process image, it is unspecified whether the SIGCHLD signal is set to be ignored or to the default action in the new process image. After a successful call to any of the exec functions, alternate signal stacks are not preserved and the SA_ONSTACK flag shall be cleared for all signals.
After a successful call to any of the exec functions, any functions previously registered by atexit() are no longer registered.

If the ST_NOSUID bit is set for the file system containing the new process image file, then the effective user ID, effective group ID, saved set-user-ID, and saved set-group-ID are unchanged in the new process image. Otherwise, if the set-user-ID mode bit of the new process image file is set, the effective user ID of the new process image shall be set to the user ID of the new process image file. Similarly, if the set-group-ID mode bit of the new process image file is set, the effective group ID of the new process image shall be set to the group ID of the new process image file. The real user ID, real group ID, and supplementary group IDs of the new process image shall remain the same as those of the calling process image. The effective user ID and effective group ID of the new process image shall be saved (as the saved set-user-ID and the saved set-group-ID) for use by setuid().

Any shared memory segments attached to the calling process image shall not be attached to the new process image.

Any named semaphores open in the calling process shall be closed as if by appropriate calls to sem_close().

Any blocks of typed memory that were mapped in the calling process are unmapped, as if munmap() was implicitly called to unmap them.

Memory locks established by the calling process via calls to mlockall() or mlock() shall be removed. If locked pages in the address space of the calling process are also mapped into the address spaces of other processes and are locked by those processes, the locks established by the other processes shall be unaffected by the call by this process to the exec function. If the exec function fails, the effect on memory locks is unspecified.

Memory mappings created in the process are unmapped before the address space is rebuilt for the new process image.

For the SCHED_FIFO and SCHED_RR scheduling policies, the policy and priority settings shall not be changed by a call to an exec function. For other scheduling policies, the policy and priority settings on exec are implementation-defined.

Per-process timers created by the calling process shall be deleted before replacing the current process image with the new process image.

All open message queue descriptors in the calling process shall be closed, as described in mq_close().

Any outstanding asynchronous I/O operations may be canceled. Those asynchronous I/O operations that are not canceled shall complete as if the exec function had not yet occurred, but any associated signal notifications shall be suppressed. It is unspecified whether the exec function itself blocks awaiting such I/O completion. In no event, however, shall the new process image created by the exec function be affected by the presence of outstanding asynchronous I/O operations at the time the exec function is called. Whether any I/O is canceled, and which I/O may be canceled upon exec, is implementation-defined.

The new process image shall inherit the CPU-time clock of the calling process image. This inheritance means that the process CPU-time clock of the process being exec-ed shall not be reinitialized or altered as a result of the exec function other than to reflect the time spent by the process executing the exec function itself.

The initial value of the CPU-time clock of the initial thread of the new process image shall be set to zero.
If the calling process is being traced, the new process image shall continue to be traced into the same trace stream as the original process image, but the new process image shall not inherit the mapping of trace event names to trace event type identifiers that was defined by calls to the `posix_trace_eventid_open()` or the `posix_trace_trid_eventid_open()` functions in the calling process image.

If the calling process is a trace controller process, any trace streams that were created by the calling process shall be shut down as described in the `posix_trace_shutdown()` function.

The new process shall inherit at least the following attributes from the calling process image:

- Nice value (see `nice()`)
- `semadj` values (see `semop()`)
- Process ID
- Parent process ID
- Process group ID
- Session membership
- Real user ID
- Real group ID
- Supplementary group IDs
- Time left until an alarm clock signal (see `alarm()`)
- Current working directory
- Root directory
- File mode creation mask (see `umask()`)
- File size limit (see `ulimit()`)
- Process signal mask (see `sigprocmask()`)
- Pending signal (see `sigpending()`)
- `tms_utime`, `tms_stime`, `tms_cutime`, and `tms_cstime` (see `times()`)
- Resource limits
- Controlling terminal
- Interval timers

All other process attributes defined in this volume of IEEE Std 1003.1-2001 shall be the same in the new and old process images. The inheritance of process attributes not defined by this volume of IEEE Std 1003.1-2001 is implementation-defined.

A call to any `exec` function from a process with more than one thread shall result in all threads being terminated and the new executable image being loaded and executed. No destructor functions shall be called.

Upon successful completion, the `exec` functions shall mark for update the `st_atime` field of the file. If an `exec` function failed but was able to locate the process image file, whether the `st_atime` field is marked for update is unspecified. Should the `exec` function succeed, the process image file shall be considered to have been opened with `open()`. The corresponding `close()` shall be considered to occur at a time after this open, but before process termination or successful completion of a subsequent call to one of the `exec` functions, `posix_spawn()`, or `posix_spawnp()`.
The `argv[]` and `envp[]` arrays of pointers and the strings to which those arrays point shall not be modified by a call to one of the `exec` functions, except as a consequence of replacing the process image.

The saved resource limits in the new process image are set to be a copy of the process’ corresponding hard and soft limits.

**RETURN VALUE**

If one of the `exec` functions returns to the calling process image, an error has occurred; the return value shall be −1, and `errno` shall be set to indicate the error.

**ERRORS**

The `exec` functions shall fail if:

- **[E2BIG]** The number of bytes used by the new process image’s argument list and environment list is greater than the system-imposed limit of `{ARG_MAX}` bytes.
- **[EACCES]** Search permission is denied for a directory listed in the new process image file’s path prefix, or the new process image file denies execution permission, or the new process image file is not a regular file and the implementation does not support execution of files of its type.
- **[EINVAL]** The new process image file has the appropriate permission and has a recognized executable binary format, but the system does not support execution of a file with this format.
- **[ELOOP]** A loop exists in symbolic links encountered during resolution of the path or file argument.
- **[ENAMETOOLONG]** The length of the path or file arguments exceeds `{PATH_MAX}` or a pathname component is longer than `{NAME_MAX}`.
- **[ENOENT]** A component of path or file does not name an existing file or path or file is an empty string.
- **[ENOTDIR]** A component of the new process image file’s path prefix is not a directory.

The `exec` functions, except for `excep()` and `execvp()`, shall fail if:

- **[ENOEXEC]** The new process image file has the appropriate access permission but has an unrecognized format.

The `exec` functions may fail if:

- **[ELOOP]** More than `{SYMLOOP_MAX}` symbolic links were encountered during resolution of the path or file argument.
- **[ENAMETOOLONG]** As a result of encountering a symbolic link in resolution of the path argument, the length of the substituted pathname string exceeded `{PATH_MAX}`.
- **[ENOMEM]** The new process image requires more memory than is allowed by the hardware or system-imposed memory management constraints.
- **[ETXTBSY]** The new process image file is a pure procedure (shared text) file that is currently open for writing by some process.
EXAMPLES

Using execl()

The following example executes the \texttt{ls} command, specifying the pathname of the executable (/bin/ls) and using arguments supplied directly to the command to produce single-column output.

```
#include <unistd.h>
int ret;
... 
ret = execl ("/bin/ls", "ls", "-l", (char *)0);
```

Using execl()

The following example is similar to Using execl(). In addition, it specifies the environment for the new process image using the \textit{env} argument.

```
#include <unistd.h>
int ret;
char *env[] = { "HOME=/usr/home", "LOGNAME=home", (char *)0 };
... 
ret = execl ("/bin/ls", "ls", "-l", (char *)0, env);
```

Using execlp()

The following example searches for the location of the \texttt{ls} command among the directories specified by the \textit{PATH} environment variable.

```
#include <unistd.h>
int ret;
... 
ret = execlp ("ls", "ls", "-l", (char *)0);
```

Using execv()

The following example passes arguments to the \texttt{ls} command in the \textit{cmd} array.

```
#include <unistd.h>
int ret;
char *cmd[] = { "ls", "-l", (char *)0 };
... 
ret = execv ("/bin/ls", cmd);
```
Using execve()

The following example passes arguments to the `ls` command in the `cmd` array, and specifies the environment for the new process image using the `env` argument.

```c
#include <unistd.h>

int ret;
char *cmd[] = { "ls", "-l", (char *)0 };
char *env[] = { "HOME=/usr/home", "LOGNAME=home", (char *)0 };
...
ret = execve ("/bin/ls", cmd, env);
```

Using execvp()

The following example searches for the location of the `ls` command among the directories specified by the `PATH` environment variable, and passes arguments to the `ls` command in the `cmd` array.

```c
#include <unistd.h>

int ret;
char *cmd[] = { "ls", "-l", (char *)0 };
...
ret = execvp ("ls", cmd);
```

APPLICATION USAGE

As the state of conversion descriptors and message catalog descriptors in the new process image is undefined, conforming applications should not rely on their use and should close them prior to calling one of the `exec` functions.

Applications that require other than the default POSIX locale should call `setlocale()` with the appropriate parameters to establish the locale of the new process.

The `environ` array should not be accessed directly by the application.

Applications should not depend on file descriptors 0, 1, and 2 being closed after an `exec`. A future version may allow these file descriptors to be automatically opened for any process.

RATIONALE

Early proposals required that the value of `argc` passed to `main()` be ‘one or greater’. This was driven by the same requirement in drafts of the ISO C standard. In fact, historical implementations have passed a value of zero when no arguments are supplied to the caller of the `exec` functions. This requirement was removed from the ISO C standard and subsequently removed from this volume of IEEE Std 1003.1-2001 as well. The wording, in particular the use of the word `should`, requires a Strictly Conforming POSIX Application to pass at least one argument to the `exec` function, thus guaranteeing that `argc` be one or greater when invoked by such an application. In fact, this is good practice, since many existing applications reference `argv[0]` without first checking the value of `argc`.

The requirement on a Strictly Conforming POSIX Application also states that the value passed as the first argument be a filename associated with the process being started. Although some existing applications pass a pathname rather than a filename in some circumstances, a filename is more generally useful, since the common usage of `argv[0]` is in printing diagnostics. In some cases the filename passed is not the actual filename of the file; for example, many implementations of the `login` utility use a convention of prefixing a hyphen (‘−’) to the actual filename, which indicates to the command interpreter being invoked that it is a “login shell”.

Historically there have been two ways that implementations can exec shell scripts.

One common historical implementation is that the `exec()`, `execv()` and `execve()` functions return an [ENOEXEC] error for any file not recognizable as executable, including a shell script. When the `execl()` and `execvp()` functions encounter such a file, they assume the file to be a shell script and invoke a known command interpreter to interpret such files. This is now required by IEEE Std 1003.1-2001. These implementations of `execvp()` and `execl()` only give the [ENOEXEC] error in the rare case of a problem with the command interpreter's executable file. Because of these implementations, the [ENOEXEC] error is not mentioned for `execlp()` or `execvp()`, although implementations can still give it.

Another way that some historical implementations handle shell scripts is by recognizing the first two bytes of the file as the character string "#!" and using the remainder of the first line of the file as the name of the command interpreter to execute.

One potential source of confusion noted by the standard developers is over how the contents of a process image file affect the behavior of the exec family of functions. The following is a description of the actions taken:

1. If the process image file is a valid executable (in a format that is executable and valid and having appropriate permission) for this system, then the system executes the file.

2. If the process image file has appropriate permission and is in a format that is executable but not valid for this system (such as a recognized binary for another architecture), then this is an error and `errno` is set to [EINVAL] (see later RATIONALE on [EINVAL]).

3. If the process image file has appropriate permission but is not otherwise recognized:
   a. If this is a call to `execlp()` or `execvp()`, then they invoke a command interpreter assuming that the process image file is a shell script.
   b. If this is not a call to `execlp()` or `execvp()`, then an error occurs and `errno` is set to [ENOEXEC].

Applications that do not require to access their arguments may use the form:

```c
main(void)
```

as specified in the ISO C standard. However, the implementation will always provide the two arguments `argc` and `argv`, even if they are not used.

Some implementations provide a third argument to `main()` called `envp`. This is defined as a pointer to the environment. The ISO C standard specifies invoking `main()` with two arguments, so implementations must support applications written this way. Since this volume of IEEE Std 1003.1-2001 defines the global variable `environ`, which is also provided by historical implementations and can be used anywhere that `envp` could be used, there is no functional need for the `envp` argument. Applications should use the `getenv()` function rather than accessing the environment directly via either `envp` or `environ`. Implementations are required to support the two-argument calling sequence, but this does not prohibit an implementation from supporting `envp` as an optional third argument.

This volume of IEEE Std 1003.1-2001 specifies that signals set to `SIG_IGN` remain set to `SIG_IGN`, and that the process signal mask be unchanged across an exec. This is consistent with historical implementations, and it permits some useful functionality, such as the `nohup` command. However, it should be noted that many existing applications wrongly assume that they start with certain signals set to the default action and/or unblocked. In particular, applications written with a simpler signal model that does not include blocking of signals, such as the one in the ISO C standard, may not behave properly if invoked with some signals blocked.

Therefore, it is best not to block or ignore signals across execs without explicit reason to do so,
and especially not to block signals across execs of arbitrary (not closely co-operating) programs.

The exec functions always save the value of the effective user ID and effective group ID of the process at the completion of the exec, whether or not the set-user-ID or the set-group-ID bit of the process image file is set.

The statement about argv[] and envp[] being constants is included to make explicit to future writers of language bindings that these objects are completely constant. Due to a limitation of the ISO C standard, it is not possible to state that idea in standard C. Specifying two levels of const-qualification for the argv[] and envp[] parameters for the exec functions may seem to be the natural choice, given that these functions do not modify either the array of pointers or the characters to which the function points, but this would disallow existing correct code. Instead, only the array of pointers is noted as constant. The table of assignment compatibility for dst=src derived from the ISO C standard summarizes the compatibility:

<table>
<thead>
<tr>
<th>src:</th>
<th>char *[]</th>
<th>const char *[]</th>
<th>char *const[]</th>
<th>const char *const[]</th>
</tr>
</thead>
<tbody>
<tr>
<td>dst:</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>char *[]</td>
<td>VALID</td>
<td>—</td>
<td>VALID</td>
<td>—</td>
</tr>
<tr>
<td>const char *[]</td>
<td>—</td>
<td>VALID</td>
<td>—</td>
<td>VALID</td>
</tr>
<tr>
<td>char * const[]</td>
<td>—</td>
<td>—</td>
<td>VALID</td>
<td>—</td>
</tr>
<tr>
<td>const char *const[]</td>
<td>—</td>
<td>—</td>
<td>—</td>
<td>VALID</td>
</tr>
</tbody>
</table>

Since all existing code has a source type matching the first row, the column that gives the most valid combinations is the third column. The only other possibility is the fourth column, but using it would require a cast on the argv or envp arguments. It is unfortunate that the fourth column cannot be used, because the declaration a non-expert would naturally use would be that in the second row.

The ISO C standard and this volume of IEEE Std 1003.1-2001 do not conflict on the use of environ, but some historical implementations of environ may cause a conflict. As long as environ is treated in the same way as an entry point (for example, fork()), it conforms to both standards. A library can contain fork(), but if there is a user-provided fork(), that fork() is given precedence and no problem ensues. The situation is similar for environ: the definition in this volume of IEEE Std 1003.1-2001 is to be used if there is no user-provided environ to take precedence. At least three implementations are known to exist that solve this problem.

[E2BIG] The limit [ARG_MAX] applies not just to the size of the argument list, but to the sum of that and the size of the environment list.

[EFAULT] Some historical systems return [EFAULT] rather than [ENOEXEC] when the new process image file is corrupted. They are non-conforming.

[EINVAL] This error condition was added to IEEE Std 1003.1-2001 to allow an implementation to detect executable files generated for different architectures, and indicate this situation to the application. Historical implementations of shells, execvp(), and execlp() that encounter an [ENOEXEC] error will execute a shell on the assumption that the file is a shell script. This will not produce the desired effect when the file is a valid executable for a different architecture. An implementation may now choose to avoid this problem by returning [EINVAL] when a valid executable for a different architecture is encountered. Some historical implementations return [EINVAL] to indicate that the path argument contains a character with the high order bit set. The standard developers chose to deviate from historical practice for the following reasons:
1. The new utilization of [EINVAL] will provide some measure of utility to the user community.

2. Historical use of [EINVAL] is not acceptable in an internationalized operating environment.

[ENAMETOOLONG] Since the file pathname may be constructed by taking elements in the PATH variable and putting them together with the filename, the [ENAMETOOLONG] error condition could also be reached this way.

[ETXTBSY] System V returns this error when the executable file is currently open for writing by some process. This volume of IEEE Std 1003.1-2001 neither requires nor prohibits this behavior.

Other systems (such as System V) may return [EINTR] from exec. This is not addressed by this volume of IEEE Std 1003.1-2001, but implementations may have a window between the call to exec and the time that a signal could cause one of the exec calls to return with [EINTR].

An explicit statement regarding the floating-point environment (as defined in the <fenv.h> header) was added to make it clear that the floating-point environment is set to its default when a call to one of the exec functions succeeds. The requirements for inheritance or setting to the default for other process and thread start-up functions is covered by more generic statements in their descriptions and can be summarized as follows:

- **posix_spawn()** Set to default.
- **fork()** Inherit.
- **pthread_create()** Inherit.

**FUTURE DIRECTIONS**

None.

**CHANGE HISTORY**

First released in Issue 1. Derived from Issue 1 of the SVID.

**Issue 5**

The DESCRIPTION is updated for alignment with the POSIX Realtime Extension and the POSIX Threads Extension.

Large File Summit extensions are added.

**Issue 6**

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- In the DESCRIPTION, behavior is defined for when the process image file is not a valid executable.

- In this issue, _POSIX_SAVED_IDS is mandated, thus the effective user ID and effective group ID of the new process image shall be saved (as the saved set-user-ID and the saved set-group-ID) for use by the setuid() function.
• The [ELOOP] mandatory error condition is added.

• A second [ENAMETOOLONG] is added as an optional error condition.

• The [ETXTBSY] optional error condition is added.

The following changes were made to align with the IEEE P1003.1a draft standard:

• The [EINVAL] mandatory error condition is added.

• The [ELOOP] optional error condition is added.

The description of CPU-time clock semantics is added for alignment with IEEE Std 1003.1d-1999.

The DESCRIPTION is updated for alignment with IEEE Std 1003.1j-2000 by adding semantics for typed memory.

The DESCRIPTION is updated to avoid use of the term “must” for application requirements.

The description of tracing semantics is added for alignment with IEEE Std 1003.1q-2000.

IEEE PASC Interpretation 1003.1 #132 is applied.

The DESCRIPTION is updated to make it explicit that the floating-point environment in the new process image is set to the default.

The DESCRIPTION and RATIONALE are updated to include clarifications of how the contents of a process image file affect the behavior of the exec functions.

IEEE Std 1003.1-2001/Cor 1-2002, item XSH/TC1/D6/15 is applied, adding a new paragraph to the DESCRIPTION and text to the end of the APPLICATION USAGE section. This change addresses a security concern, where implementations may want to reopen file descriptors 0, 1, and 2 for programs with the set-user-id or set-group-id file mode bits calling the exec family of functions.
NAME
exit, _Exit, _exit — terminate a process

SYNOPSIS
#include <stdlib.h>
void exit(int status);
void _Exit(int status);

#include <unistd.h>
void _exit(int status);

DESCRIPTION
For exit() and _Exit(): The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-2001 defers to the ISO C standard.
The value of status may be 0, EXIT_SUCCESS, EXIT_FAILURE, or any other value, though only the least significant 8 bits (that is, status & 0377) shall be available to a waiting parent process.
The exit() function shall first call all functions registered by atexit(), in the reverse order of their registration, except that a function is called after any previously registered functions that had already been called at the time it was registered. Each function is called as many times as it was registered. If, during the call to any such function, a call to the longjmp() function is made that would terminate the call to the registered function, the behavior is undefined.
If a function registered by a call to atexit() fails to return, the remaining registered functions shall not be called and the rest of the exit() processing shall not be completed. If exit() is called more than once, the behavior is undefined.
The exit() function shall then flush all open streams with unwritten buffered data, close all open streams, and remove all files created by tmpfile(). Finally, control shall be terminated with the consequences described below.

The _Exit() and _exit() functions shall be functionally equivalent.
The _Exit() and _exit() functions shall not call functions registered with atexit() nor any registered signal handlers. Whether open streams are flushed or closed, or temporary files are removed is implementation-defined. Finally, the calling process is terminated with the consequences described below.
These functions shall terminate the calling process with the following consequences:

Note: These consequences are all extensions to the ISO C standard and are not further CX shaded. However, XSI extensions are shaded.

- All of the file descriptors, directory streams, conversion descriptors, and message catalog descriptors open in the calling process shall be closed.
- If the parent process of the calling process is executing a wait() or waitpid(), and has neither set its SA_NOCLDWAIT flag nor set SIGCHLD to SIG_IGN, it shall be notified of the calling process’ termination and the low-order eight bits (that is, bits 0377) of status shall be made available to it. If the parent is not waiting, the child’s status shall be made available to it when the parent subsequently executes wait() or waitpid().
The semantics of the waitid() function shall be equivalent to wait().
- If the parent process of the calling process is not executing a wait() or waitpid(), and has neither set its SA_NOCLDWAIT flag nor set SIGCHLD to SIG_IGN, the calling process shall be transformed into a zombie process. A zombie process is an inactive process and it shall be
The semantics of the `waitid()` function shall be equivalent to `wait()`.

- Termination of a process does not directly terminate its children. The sending of a SIGHUP signal as described below indirectly terminates children in some circumstances.

- Either:

  If the implementation supports the SIGCHLD signal, a SIGCHLD shall be sent to the parent process.

  Or:

  If the parent process has set its SA_NOCLDWAIT flag, or set SIGCHLD to SIG_IGN, the status shall be discarded, and the lifetime of the calling process shall end immediately. If SA_NOCLDWAIT is set, it is implementation-defined whether a SIGCHLD signal is sent to the parent process.

- The parent process ID of all of the calling process’ existing child processes and zombie processes shall be set to the process ID of an implementation-defined system process. That is, these processes shall be inherited by a special system process.

- Each attached shared-memory segment is detached and the value of `shm_nattch` (see `shmget()`) in the data structure associated with its shared memory ID shall be decremented by 1.

- For each semaphore for which the calling process has set a `semadj` value (see `semop()`), that value shall be added to the `semval` of the specified semaphore.

- If the process is a controlling process, the SIGHUP signal shall be sent to each process in the foreground process group of the controlling terminal belonging to the calling process.

- If the process is a controlling process, the controlling terminal associated with the session shall be disassociated from the session, allowing it to be acquired by a new controlling process.

- If the exit of the process causes a process group to become orphaned, and if any member of the newly-orphaned process group is stopped, then a SIGHUP signal followed by a SIGCONT signal shall be sent to each process in the newly-orphaned process group.

- All open named semaphores in the calling process shall be closed as if by appropriate calls to `sem_close()`.

- Any memory locks established by the process via calls to `mlockall()` or `mlock()` shall be removed. If locked pages in the address space of the calling process are also mapped into the address spaces of other processes and are locked by those processes, the locks established by the other processes shall be unaffected by the call by this process to `_Exit()` or `_exit()`.

- Memory mappings that were created in the process shall be unmapped before the process is destroyed.

- Any blocks of typed memory that were mapped in the calling process shall be unmapped, as if `munmap()` was implicitly called to unmap them.

- All open message queue descriptors in the calling process shall be closed as if by appropriate calls to `mq_close()`.

- Any outstanding cancelable asynchronous I/O operations may be canceled. Those asynchronous I/O operations that are not canceled shall complete as if the `_Exit()` or `_exit()` operation had not yet occurred, but any associated signal notifications shall be suppressed.
The _Exit() or _exit() operation may block awaiting such I/O completion. Whether any I/O is canceled, and which I/O may be canceled upon _Exit() or _exit(), is implementation-defined.

- Threads terminated by a call to _Exit() or _exit() shall not invoke their cancellation cleanup handlers or per-thread data destructors.
- If the calling process is a trace controller process, any trace streams that were created by the calling process shall be shut down as described by the posix_trace_shutdown() function, and any process’ mapping of trace event names to trace event type identifiers built for these trace streams may be deallocated.

**RETURN VALUE**

These functions do not return.

**ERRORS**

No errors are defined.

**EXAMPLES**

None.

**APPLICATION USAGE**

Normally applications should use exit() rather than _Exit() or _exit().

**RATIONALE**

**Process Termination**

Early proposals drew a distinction between normal and abnormal process termination. Abnormal termination was caused only by certain signals and resulted in implementation-defined “actions”, as discussed below. Subsequent proposals distinguished three types of termination: normal termination (as in the current specification), simple abnormal termination, and abnormal termination with actions. Again the distinction between the two types of abnormal termination was that they were caused by different signals and that implementation-defined actions would result in the latter case. Given that these actions were completely implementation-defined, the early proposals were only saying when the actions could occur and how their occurrence could be detected, but not what they were. This was of little or no use to conforming applications, and thus the distinction is not made in this volume of IEEE Std 1003.1-2001.

The implementation-defined actions usually include, in most historical implementations, the creation of a file named core in the current working directory of the process. This file contains an image of the memory of the process, together with descriptive information about the process, perhaps sufficient to reconstruct the state of the process at the receipt of the signal.

There is a potential security problem in creating a core file if the process was set-user-ID and the current user is not the owner of the program, if the process was set-group-ID and none of the user’s groups match the group of the program, or if the user does not have permission to write in the current directory. In this situation, an implementation either should not create a core file or should make it unreadable by the user.

Despite the silence of this volume of IEEE Std 1003.1-2001 on this feature, applications are advised not to create files named core because of potential conflicts in many implementations. Some implementations use a name other than core for the file; for example, by appending the process ID to the filename.
Terminating a Process

It is important that the consequences of process termination as described occur regardless of whether the process called _exit() (perhaps indirectly through exit()) or instead was terminated due to a signal or for some other reason. Note that in the specific case of exit() this means that the status argument to exit() is treated in the same way as the status argument to _exit().

A language other than C may have other termination primitives than the C-language exit() function, and programs written in such a language should use its native termination primitives, but those should have as part of their function the behavior of _exit() as described. Implementations in languages other than C are outside the scope of this version of this volume of IEEE Std 1003.1-2001, however.

As required by the ISO C standard, using return from main() has the same behavior (other than with respect to language scope issues) as calling exit() with the returned value. Reaching the end of the main() function has the same behavior as calling exit(0).

A value of zero (or EXIT_SUCCESS, which is required to be zero) for the argument status conventionally indicates successful termination. This corresponds to the specification for exit() in the ISO C standard. The convention is followed by utilities such as make and various shells, which interpret a zero status from a child process as success. For this reason, applications should not call exit(0) or _exit(0) when they terminate unsuccessfully; for example, in signal-catching functions.

Historically, the implementation-defined process that inherits children whose parents have terminated without waiting on them is called init and has a process ID of 1.

The sending of a SIGHUP to the foreground process group when a controlling process terminates corresponds to somewhat different historical implementations. In System V, the kernel sends a SIGHUP on termination of (essentially) a controlling process. In 4.2 BSD, the kernel does not send SIGHUP in a case like this, but the termination of a controlling process is usually noticed by a system daemon, which arranges to send a SIGHUP to the foreground process group with the vhangup() function. However, in 4.2 BSD, due to the behavior of the shells that support job control, the controlling process is usually a shell with no other processes in its process group. Thus, a change to make _exit() behave this way in such systems should not cause problems with existing applications.

The termination of a process may cause a process group to become orphaned in either of two ways. The connection of a process group to its parent(s) outside of the group depends on both the parents and their children. Thus, a process group may be orphaned by the termination of the last connecting parent process outside of the group or by the termination of the last direct descendant of the parent process(es). In either case, if the termination of a process causes a process group to become orphaned, processes within the group are disconnected from their job control shell, which no longer has any information on the existence of the process group. Stopped processes within the group would languish forever. In order to avoid this problem, newly orphaned process groups that contain stopped processes are sent a SIGHUP signal and a SIGCONT signal to indicate that they have been disconnected from their session. The SIGHUP signal causes the process group members to terminate unless they are catching or ignoring SIGHUP. Under most circumstances, all of the members of the process group are stopped if any of them are stopped.

The action of sending a SIGHUP and a SIGCONT signal to members of a newly orphaned process group is similar to the action of 4.2 BSD, which sends SIGHUP and SIGCONT to each stopped child of an exiting process. If such children exit in response to the SIGHUP, any additional descendants receive similar treatment at that time. In this volume of IEEE Std 1003.1-2001, the signals are sent to the entire process group at the same time. Also, in
this volume of IEEE Std 1003.1-2001, but not in 4.2 BSD, stopped processes may be orphaned, but
may be members of a process group that is not orphaned; therefore, the action taken at _exit() 
must consider processes other than child processes.

It is possible for a process group to be orphaned by a call to setpgid() or setsid(), as well as by
process termination. This volume of IEEE Std 1003.1-2001 does not require sending SIGHUP and
SIGCONT in those cases, because, unlike process termination, those cases are not caused
accidentally by applications that are unaware of job control. An implementation can choose to
send SIGHUP and SIGCONT in those cases as an extension; such an extension must be
documented as required in <signal.h>.

The ISO/IEC 9899: 1999 standard adds the _Exit() function that results in immediate program
termination without triggering signals or atexit()-registered functions. In IEEE Std 1003.1-2001,  
this is equivalent to the _exit() function.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 5

The DESCRIPTION is updated for alignment with the POSIX Realtime Extension and the POSIX
Threads Extension.

Interactions with the SA_NOCLDWAIT flag and SIGCHLD signal are further clarified.

The values of status from exit() are better described.

Issue 6

Extensions beyond the ISO C standard are marked.

The DESCRIPTION is updated for alignment with IEEE Std 1003.1j-2000 by adding semantics for
typed memory.

The following changes are made for alignment with the ISO/IEC 9899: 1999 standard:

• The _Exit() function is included.

• The DESCRIPTION is updated.

The description of tracing semantics is added for alignment with IEEE Std 1003.1q-2000.

References to the wait3() function are removed.

IEEE Std 1003.1-2001/Cor 1-2002, item XSH/TC1/D6/16 is applied, correcting grammar in the |
**NAME**
exp, expf, expl — exponential function

**SYNOPSIS**
```
#include <math.h>

double exp(double x);
float expf(float x);
long double expl(long double x);
```

**DESCRIPTION**
The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-2001 defers to the ISO C standard.

These functions shall compute the base-e exponential of \(x\).

An application wishing to check for error situations should set \(errno\) to zero and call `feclearexcept(FE_ALL_EXCEPT)` before calling these functions. On return, if \(errno\) is non-zero or `fetestexcept(FE_INVALID | FE_DIVBYZERO | FE_OVERFLOW | FE_UNDERFLOW)` is non-zero, an error has occurred.

**RETURN VALUE**
Upon successful completion, these functions shall return the exponential value of \(x\).

If the correct value would cause overflow, a range error shall occur and `exp()` , `expf()` , and `expl()` shall return the value of the macro `HUGE_VAL`, `HUGE_VALF`, and `HUGE_VALL`, respectively.

If the correct value would cause underflow, and is not representable, a range error may occur, and either \(0.0\) (if supported), or an implementation-defined value shall be returned.

If \(x\) is NaN, a NaN shall be returned.

If \(x\) is \(\pm0\), 1 shall be returned.

If \(x\) is \(-\infty\), \(+0\) shall be returned.

If \(x\) is \(+\infty\), \(x\) shall be returned.

If the correct value would cause underflow, and is representable, a range error may occur and the correct value shall be returned.

**ERRORS**
These functions shall fail if:

**Range Error** The result overflows.

If the integer expression (math_errno & MATH_ERRNO) is non-zero, then \(errno\) shall be set to [ERANGE]. If the integer expression (math_errno & MATH_ERREXCEPT) is non-zero, then the overflow floating-point exception shall be raised.

These functions may fail if:

**Range Error** The result underflows.

If the integer expression (math_errno & MATH_ERRNO) is non-zero, then \(errno\) shall be set to [ERANGE]. If the integer expression (math_errno & MATH_ERREXCEPT) is non-zero, then the underflow floating-point exception shall be raised.
**EXAMPLES**
None.

**APPLICATION USAGE**
Note that for IEEE Std 754-1985 double, 709.8 < x implies \( \exp(x) \) has overflowed. The value \( x < -708.4 \) implies \( \exp(x) \) has underflowed.

On error, the expressions (math_errhandling & MATH_ERRNO) and (math_errhandling & MATH_ERREXCEPT) are independent of each other, but at least one of them must be non-zero.

**RATIONALE**
None.

**FUTURE DIRECTIONS**
None.

**CHANGE HISTORY**
First released in Issue 1. Derived from Issue 1 of the SVID.

**Issue 5**
The DESCRIPTION is updated to indicate how an application should check for an error. This text was previously published in the APPLICATION USAGE section.

**Issue 6**
The \( \expf() \) and \( \expl() \) functions are added for alignment with the ISO/IEC 9899:1999 standard.

The DESCRIPTION, RETURN VALUE, ERRORS, and APPLICATION USAGE sections are revised to align with the ISO/IEC 9899:1999 standard.

exp2()  

NAME
exp2, exp2f, exp2l — exponential base 2 functions

SYNOPSIS
#include <math.h>

double exp2(double x);
float exp2f(float x);
long double exp2l(long double x);

DESCRIPTION
The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-2001 defers to the ISO C standard.

These functions shall compute the base-2 exponential of x.

An application wishing to check for error situations should set errno to zero and call
fleckarexcept(FE_ALL_EXCEPT) before calling these functions. On return, if errno is non-zero or
fetestexcept(FE_INVALID | FE_DIVBYZERO | FE_OVERFLOW | FE_UNDERFLOW) is non-zero, an error has occurred.

RETURN VALUE
Upon successful completion, these functions shall return 2^x.

If the correct value would cause overflow, a range error shall occur and exp2 (), exp2f (), and
exp2l () shall return the value of the macro HUGE_VAL, HUGE_VALF, and HUGE_VALL,
respectively.

If the correct value would cause underflow, and is not representable, a range error may occur, and either 0.0 (if supported), or an implementation-defined value shall be returned.

If x is NaN, a NaN shall be returned.
If x is ±0, 1 shall be returned.
If x is −Inf, +0 shall be returned.
If x is +Inf, x shall be returned.

If the correct value would cause underflow, and is representable, a range error may occur and the correct value shall be returned.

ERRORS
These functions shall fail if:

Range Error The result overflows.

If the integer expression (math_errnohandling & MATH_ERRNO) is non-zero,
then errno shall be set to [ERANGE]. If the integer expression
(math_errnohandling & MATH_ERREXCEPT) is non-zero, then the overflow
floating-point exception shall be raised.

These functions may fail if:

Range Error The result underflows.

If the integer expression (math_errnohandling & MATH_ERRNO) is non-zero,
then errno shall be set to [ERANGE]. If the integer expression
(math_errnohandling & MATH_ERREXCEPT) is non-zero, then the underflow
floating-point exception shall be raised.
EXAMPLES
None.

APPLICATION USAGE
For IEEE Std 754-1985 double, 1024 <= x implies exp2(x) has overflowed. The value x<−1022 implies exp(x) has underflowed.

On error, the expressions (math_errhandling & MATH_ERRNO) and (math_errhandling & MATH_ERREXCEPT) are independent of each other, but at least one of them must be non-zero.

RATIONALE
None.

FUTURE DIRECTIONS
None.

expm1() © 2001-2003, IEEE and The Open Group. All rights reserved.

NAME
expm1, expm1f, expm1l — compute exponential functions

SYNOPSIS
#include <math.h>

double expm1(double x);
float expm1f(float x);
long double expm1l(long double x);

DESCRIPTION
The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-2001 defers to the ISO C standard.

These functions shall compute \( e^x - 1.0 \).

An application wishing to check for error situations should set \( \text{errno} \) to zero and call \( \text{feclearexcept} \) \( \text{FE_ALL_EXCEPT} \) before calling these functions. On return, if \( \text{errno} \) is non-zero or \( \text{fetestexcept} \) \( \text{FE_INVALID} | \text{FE_DIVBYZERO} | \text{FE_OVERFLOW} | \text{FE_UNDERFLOW} \) is non-zero, an error has occurred.

RETURN VALUE
Upon successful completion, these functions return \( e^x - 1.0 \).

If the correct value would cause overflow, a range error shall occur and \( \text{expm1}() \), \( \text{expm1f}() \), and \( \text{expm1l}() \) shall return the value of the macro HUGE_VAL, HUGE_VALF, and HUGE_VALL, respectively.

If \( x \) is NaN, a NaN shall be returned.

If \( x \) is \( \pm 0 \), \( \pm 0 \) shall be returned.

If \( x \) is \( -\infty \), \( -1 \) shall be returned.

If \( x \) is \( +\infty \), \( x \) shall be returned.

If \( x \) is subnormal, a range error may occur and \( x \) should be returned.

ERRORS
These functions shall fail if:

Range Error The result overflows.

If the integer expression \( \text{math_errhandling} & \text{MATH_ERRNO} \) is non-zero, then \( \text{errno} \) shall be set to \( \text{[ERANGE]} \). If the integer expression \( \text{math_errhandling} & \text{MATH_ERREXCEPT} \) is non-zero, then the overflow floating-point exception shall be raised.

These functions may fail if:

Range Error The value of \( x \) is subnormal.

If the integer expression \( \text{math_errhandling} & \text{MATH_ERRNO} \) is non-zero, then \( \text{errno} \) shall be set to \( \text{[ERANGE]} \). If the integer expression \( \text{math_errhandling} & \text{MATH_ERREXCEPT} \) is non-zero, then the underflow floating-point exception shall be raised.
EXAMPLES
None.

APPLICATION USAGE
The value of \texttt{expm1}(x) may be more accurate than \texttt{exp}(x)-1.0 for small values of \(x\).

The \texttt{expm1()} and \texttt{log1p()} functions are useful for financial calculations of \(((1+x)^n-1)/x\), namely:

\[
\texttt{expm1}(n \times \texttt{log1p}(x))/x
\]
when \(x\) is very small (for example, when calculating small daily interest rates). These functions also simplify writing accurate inverse hyperbolic functions.

For IEEE Std 754-1985 \texttt{double}, \(709.8 < x\) implies \texttt{expm1}(x) has overflowed.

On error, the expressions (math_errhandling & MATH_ERRNO) and (math_errhandling & MATH_ERREXCEPT) are independent of each other, but at least one of them must be non-zero.

RATIONALE
None.

FUTURE DIRECTIONS
None.

CHANGE HISTORY
First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 5
The DESCRIPTION is updated to indicate how an application should check for an error. This
text was previously published in the APPLICATION USAGE section.

Issue 6
The fabsf() and fabsl() functions are added for alignment with the ISO/IEC 9899: 1999 standard.
The DESCRIPTION, RETURN VALUE, ERRORS, and APPLICATION USAGE sections are
revised to align with the ISO/IEC 9899: 1999 standard.
NAME
fattach — attach a STREAMS-based file descriptor to a file in the file system name space
(STREAMS)

SYNOPSIS
XSR
#include <stropts.h>
int fattach(int fildes, const char *path);

DESCRIPTION
The fattach() function shall attach a STREAMS-based file descriptor to a file, effectively
associating a pathname with fildes. The application shall ensure that the fildes argument is a
valid open file descriptor associated with a STREAMS file. The path argument points to a
pathname of an existing file. The application shall have the appropriate privileges or be the
owner of the file named by path and have write permission. A successful call to fattach() shall
cause all pathnames that name the file named by path to name the STREAMS file associated with
fildes, until the STREAMS file is detached from the file. A STREAMS file can be attached to more
than one file and can have several pathnames associated with it.

The attributes of the named STREAMS file shall be initialized as follows: the permissions, user
ID, group ID, and times are set to those of the file named by path, the number of links is set to 1,
and the size and device identifier are set to those of the STREAMS file associated with fildes. If
any attributes of the named STREAMS file are subsequently changed (for example, by chmod()),
neither the attributes of the underlying file nor the attributes of the STREAMS file to which fildes
refers shall be affected.

File descriptors referring to the underlying file, opened prior to an fattach() call, shall continue to
refer to the underlying file.

RETURN VALUE
Upon successful completion, fattach() shall return 0. Otherwise, −1 shall be returned and errno
set to indicate the error.

ERRORS
The fattach() function shall fail if:

[EACCES] Search permission is denied for a component of the path prefix, or the process
is the owner of path but does not have write permissions on the file named by
path.

[EBADF] The fildes argument is not a valid open file descriptor.

[EBUSY] The file named by path is currently a mount point or has a STREAMS file
attached to it.

[ELOOP] A loop exists in symbolic links encountered during resolution of the path
argument.

[ENAMETOOLONG] The size of path exceeds [PATH_MAX] or a component of path is longer than
[NAME_MAX].

[ENOENT] A component of path does not name an existing file or path is an empty string.

[ENOTDIR] A component of the path prefix is not a directory.

[EPERM] The effective user ID of the process is not the owner of the file named by path
and the process does not have appropriate privilege.
The `fattach()` function may fail if:

- `[EINVAL]` The `fildes` argument does not refer to a STREAMS file.
- `[ELOOP]` More than [SYMLOOP_MAX] symbolic links were encountered during resolution of the `path` argument.
- `[ENAMETOOLONG]` Pathname resolution of a symbolic link produced an intermediate result whose length exceeds [PATH_MAX].
- `[EXDEV]` A link to a file on another file system was attempted.

**EXAMPLES**

**Attaching a File Descriptor to a File**

In the following example, `fd` refers to an open STREAMS file. The call to `fattach()` associates this STREAM with the file `/tmp/named-STREAM`, such that any future calls to open `/tmp/named-STREAM`, prior to breaking the attachment via a call to `fdetach()`, will instead create a new file handle referring to the STREAMS file associated with `fd`.

```c
#include <stropts.h>
...
int fd;
char *filename = "/tmp/named-STREAM";
int ret;
ret = fattach(fd, filename);
```

**APPLICATION USAGE**

The `fattach()` function behaves similarly to the traditional `mount()` function in the way a file is temporarily replaced by the root directory of the mounted file system. In the case of `fattach()`, the replaced file need not be a directory and the replacing file is a STREAMS file.

**RATIONALE**

The file attributes of a file which has been the subject of an `fattach()` call are specifically set because of an artefact of the original implementation. The internal mechanism was the same as for the `mount()` function. Since `mount()` is typically only applied to directories, the effects when applied to a regular file are a little surprising, especially as regards the link count which rigidly remains one, even if there were several links originally and despite the fact that all original links refer to the STREAM as long as the `fattach()` remains in effect.

**FUTURE DIRECTIONS**

None.

**SEE ALSO**

`fdetach()`, `isastream()`, the Base Definitions volume of IEEE Std 1003.1-2001, `<stropts.h>`

**CHANGE HISTORY**

First released in Issue 4, Version 2.

**Issue 5**

Moved from X/OPEN UNIX extension to BASE.

The [EXDEV] error is added to the list of optional errors in the ERRORS section.
Issue 6

This function is marked as part of the XSI STREAMS Option Group.

The DESCRIPTION is updated to avoid use of the term “must” for application requirements.

The wording of the mandatory [ELOOP] error condition is updated, and a second optional [ELOOP] error condition is added.
NAME
fchdir — change working directory

SYNOPSIS
#include <unistd.h>
int fchdir(int fildes);

DESCRIPTION
The fchdir() function shall be equivalent to chdir() except that the directory that is to be the new current working directory is specified by the file descriptor fildes.

A conforming application can obtain a file descriptor for a file of type directory using open(), provided that the file status flags and access modes do not contain O_WRONLY or O_RDWR.

RETURN VALUE
Upon successful completion, fchdir() shall return 0. Otherwise, it shall return −1 and set errno to indicate the error. On failure the current working directory shall remain unchanged.

ERRORS
The fchdir() function shall fail if:

- [EACCES] Search permission is denied for the directory referenced by fildes.
- [EBADF] The fildes argument is not an open file descriptor.
- [ENOTDIR] The open file descriptor fildes does not refer to a directory.
- [EINTR] A signal was caught during the execution of fchdir().
- [EIO] An I/O error occurred while reading from or writing to the file system.

CHANGE HISTORY
First released in Issue 4, Version 2.

Issue 5
Moved from X/OPEN UNIX extension to BASE.
NAME
fchmod — change mode of a file

SYNOPSIS
#include <sys/stat.h>
int fchmod(int fildes, mode_t mode);

DESCRIPTION
The fchmod() function shall be equivalent to chmod() except that the file whose permissions are
changed is specified by the file descriptor fildes.

SHM
If fildes references a shared memory object, the fchmod() function need only affect the S_IRUSR,
S_IWUSR, S_IRGRP, S_IWGRP, S_IROTH, and S_IWOTH file permission bits.

TYM
If fildes references a typed memory object, the behavior of fchmod() is unspecified.

XSR
If fildes refers to a STREAM (which is fattach()-ed into the file system name space) the call
returns successfully, doing nothing.

RETURN VALUE
Upon successful completion, fchmod() shall return 0. Otherwise, it shall return −1 and set errno to
indicate the error.

ERRORS
The fchmod() function shall fail if:

[EBADF] The fildes argument is not an open file descriptor.
[EPERM] The effective user ID does not match the owner of the file and the process
does not have appropriate privilege.
[EROFS] The file referred to by fildes resides on a read-only file system.

XSI
[EINTR] The fchmod() function was interrupted by a signal.
[EINVAL] The value of the mode argument is invalid.
[EINVAL] The fildes argument refers to a pipe and the implementation disallows
execution of fchmod() on a pipe.

EXAMPLES
Changing the Current Permissions for a File
The following example shows how to change the permissions for a file named /home/cnd/mod1
so that the owner and group have read/write/execute permissions, but the world only has
read/write permissions.

#include <sys/stat.h>
#include <fcntl.h>
mode_t mode;
int fildes;
... fildes = open("/home/cnd/mod1", O_RDWR);
fchmod(fildes, S_IRWXU | S_IRWXG | S_IROTH | S_IWOTH);
**APPLICATION USAGE**

None.

**RATIONALE**

None.

**FUTURE DIRECTIONS**

None.

**CHANGE HISTORY**

First released in Issue 4, Version 2.

**Issue 5**

Moved from X/OPEN UNIX extension to BASE and aligned with `fchmod()` in the POSIX Realtime Extension. Specifically, the second paragraph of the DESCRIPTION is added and a second instance of `[EINVAL]` is defined in the list of optional errors.

**Issue 6**

The DESCRIPTION is updated for alignment with IEEE Std 1003.1j-2000 by stating that `fchmod()` behavior is unspecified for typed memory objects.
**NAME**

fchown — change owner and group of a file

**SYNOPSIS**

```c
#include <unistd.h>
int fchown(int fildes, uid_t owner, gid_t group);
```

**DESCRIPTION**

The `fchown()` function shall be equivalent to `chown()` except that the file whose owner and group are changed is specified by the file descriptor `fildes`.

**RETURN VALUE**

Upon successful completion, `fchown()` shall return 0. Otherwise, it shall return −1 and set `errno` to indicate the error.

**ERRORS**

The `fchown()` function shall fail if:

- **[EBADF]** The `fildes` argument is not an open file descriptor.
- **[EPERM]** The effective user ID does not match the owner of the file or the process does not have appropriate privilege and `_POSIX_CHOWN_RESTRICTED` indicates that such privilege is required.
- **[EROFS]** The file referred to by `fildes` resides on a read-only file system.
- **[EINVAL]** The owner or group ID is not a value supported by the implementation. The `fildes` argument refers to a pipe or socket or an `fattach()`-ed STREAM and the implementation disallows execution of `fchown()` on a pipe.
- **[EIO]** A physical I/O error has occurred.
- **[EINTR]** The `fchown()` function was interrupted by a signal which was caught.

**EXAMPLES**

**Changing the Current Owner of a File**

The following example shows how to change the owner of a file named `/home/cnd/mod1` to “jones” and the group to “cnd”.

The numeric value for the user ID is obtained by extracting the user ID from the user database entry associated with “jones”. Similarly, the numeric value for the group ID is obtained by extracting the group ID from the group database entry associated with “cnd”. This example assumes the calling program has appropriate privileges.

```c
#include <sys/types.h>
#include <unistd.h>
#include <fcntl.h>
#include <pwd.h>
#include <grp.h>

struct passwd *pwd;
struct group *grp;
int fildes;
...

fildes = open("/home/cnd/mod1", O_RDWR);
pwd = getpwnam("jones");
```
fchown()

grp = getgrnam("cnd");
fchown(fildes, pwd->pw_uid, grp->gr_gid);

APPLICATION USAGE
None.

RATIONALE
None.

FUTURE DIRECTIONS
None.

SEE ALSO
chown(), the Base Definitions volume of IEEE Std 1003.1-2001, <unistd.h>

CHANGE HISTORY
First released in Issue 4, Version 2.
Moved from X/OPEN UNIX extension to BASE.
The following changes were made to align with the IEEE P1003.1a draft standard:
Clarification is added that a call to fchown() may not be allowed on a pipe.
The fchown() function is defined as mandatory.
**NAME**

fclose — close a stream

**SYNOPSIS**

```c
#include <stdio.h>

int fclose(FILE *stream);
```

**DESCRIPTION**

The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-2001 defers to the ISO C standard.

The `fclose()` function shall cause the stream pointed to by `stream` to be flushed and the associated file to be closed. Any untranslated buffered data for the stream shall be written to the file; any unread buffered data shall be discarded. Whether or not the call succeeds, the stream shall be disassociated from the file and any buffer set by the `setbuf()` or `setvbuf()` function shall be disassociated from the stream. If the associated buffer was automatically allocated, it shall be deallocated.

The `fclose()` function shall mark for update the `st_ctime` and `st_mtime` fields of the underlying file, if the stream was writable, and if buffered data remains that has not yet been written to the file.

The `fclose()` function shall perform the equivalent of a `close()` on the file descriptor that is associated with the stream pointed to by `stream`.

After the call to `fclose()`, any use of `stream` results in undefined behavior.

**RETURN VALUE**

Upon successful completion, `fclose()` shall return 0; otherwise, it shall return EOF and set `errno` to indicate the error.

**ERRORS**

The `fclose()` function shall fail if:

- **[EAGAIN]** The O_NONBLOCK flag is set for the file descriptor underlying `stream` and the process would be delayed in the write operation.
- **[EBADF]** The file descriptor underlying `stream` is not valid.
- **[EFBIG]** An attempt was made to write a file that exceeds the maximum file size.
- **[EIO]** The process is a member of a background process group attempting to write to its controlling terminal, TOSTOP is set, the process is neither ignoring nor blocking SIGTTOU, and the process group of the process is orphaned. This error may also be returned under implementation-defined conditions.
- **[ENOSPC]** There was no free space remaining on the device containing the file.
- **[EPipe]** An attempt is made to write to a pipe or FIFO that is not open for reading by any process. A SIGPIPE signal shall also be sent to the thread.

The `fclose()` function may fail if:

- **[ENXIO]** A request was made of a nonexistent device, or the request was outside the capabilities of the device.
**fclose()**

**EXAMPLES**
None.

**APPLICATION USAGE**
None.

**RATIONALE**
None.

**FUTURE DIRECTIONS**
None.

**SEE ALSO**
`close()`, `fopen()`, `getrlimit()`, `ulimit()`, the Base Definitions volume of IEEE Std 1003.1-2001, `<stdio.h>`

**CHANGE HISTORY**
First released in Issue 1. Derived from Issue 1 of the SVID.

**Issue 5**
Large File Summit extensions are added.

**Issue 6**
Extensions beyond the ISO C standard are marked.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The `EFBIG` error is added as part of the large file support extensions.
- The `ENXIO` optional error condition is added.

The DESCRIPTION is updated to note that the stream and any buffer are disassociated whether or not the call succeeds. This is for alignment with the ISO/IEC 9899:1999 standard.
NAME
fcntl — file control

SYNOPSIS
#include <unistd.h>
#include <fcntl.h>
int fcntl(int fildes, int cmd, ...);

DESCRIPTION
The fcntl() function shall perform the operations described below on open files. The fildes argument is a file descriptor.

The available values for cmd are defined in <fcntl.h> and are as follows:

F_DUPFD Return a new file descriptor which shall be the lowest numbered available (that is, not already open) file descriptor greater than or equal to the third argument, arg, taken as an integer of type int. The new file descriptor shall refer to the same open file description as the original file descriptor, and shall share any locks. The FD_CLOEXEC flag associated with the new file descriptor shall be cleared to keep the file open across calls to one of the exec functions.

F_GETFD Get the file descriptor flags defined in <fcntl.h> that are associated with the file descriptor fildes. File descriptor flags are associated with a single file descriptor and do not affect other file descriptors that refer to the same file.

F_SETFD Set the file descriptor flags defined in <fcntl.h>, that are associated with fildes, to the third argument, arg, taken as type int. If the FD_CLOEXEC flag in the third argument is 0, the file shall remain open across the exec functions; otherwise, the file shall be closed upon successful execution of one of the exec functions.

F_GETFL Get the file status flags and file access modes, defined in <fcntl.h>, for the file description associated with fildes. The file access modes can be extracted from the return value using the mask O_ACCMODE, which is defined in <fcntl.h>. File status flags and file access modes are associated with the file description and do not affect other file descriptors that refer to the same file with different open file descriptions.

F_SETFL Set the file status flags, defined in <fcntl.h>, for the file description associated with fildes from the corresponding bits in the third argument, arg, taken as type int. Bits corresponding to the file access mode and the file creation flags, as defined in <fcntl.h>, that are set in arg shall be ignored. If any bits in arg other than those mentioned here are changed by the application, the result is unspecified.

F_GETOWN If fildes refers to a socket, get the process or process group ID specified to receive SIGURG signals when out-of-band data is available. Positive values indicate a process ID; negative values, other than −1, indicate a process group ID. If fildes does not refer to a socket, the results are unspecified.

F_SETOWN If fildes refers to a socket, set the process or process group ID specified to receive SIGURG signals when out-of-band data is available, using the value of the third argument, arg, taken as type int. Positive values indicate a process ID; negative values, other than −1, indicate a process group ID. If fildes does not refer to a socket, the results are unspecified.
The following values for cmd are available for advisory record locking. Record locking shall be supported for regular files, and may be supported for other files.

**F_GETLK** Get the first lock which blocks the lock description pointed to by the third argument, `arg`, taken as a pointer to type `struct flock`, defined in `<fcntl.h>`. The information retrieved shall overwrite the information passed to `fcntl()` in the structure `flock`. If no lock is found that would prevent this lock from being created, then the structure shall be left unchanged except for the lock type which shall be set to F_UNLCK.

**F_SETLK** Set or clear a file segment lock according to the lock description pointed to by the third argument, `arg`, taken as a pointer to type `struct flock`, defined in `<fcntl.h>`. `F_SETLK` can establish shared (or read) locks (F_RDLCK) or exclusive (or write) locks (F_WRLCK), as well as to remove either type of lock (F_UNLCK). `F_RDLCK`, `F_WRLCK`, and `F_UNLCK` are defined in `<fcntl.h>`. If a shared or exclusive lock cannot be set, `fcntl()` shall return immediately with a return value of −1.

**F_SETLKW** This command shall be equivalent to `F_SETLK` except that if a shared or exclusive lock is blocked by other locks, the thread shall wait until the request can be satisfied. If a signal that is to be caught is received while `fcntl()` is waiting for a region, `fcntl()` shall be interrupted. Upon return from the signal handler, `fcntl()` shall return −1 with `errno` set to [EINTR], and the lock operation shall not be done.

Additional implementation-defined values for `cmd` may be defined in `<fcntl.h>`. Their names shall start with F_.

When a shared lock is set on a segment of a file, other processes shall be able to set shared locks on that segment or a portion of it. A shared lock prevents any other process from setting an exclusive lock on any portion of the protected area. A request for a shared lock shall fail if the file descriptor was not opened with read access.

An exclusive lock shall prevent any other process from setting a shared lock or an exclusive lock on any portion of the protected area. A request for an exclusive lock shall fail if the file descriptor was not opened with write access.

The structure `flock` describes the type (l_type), starting offset (l_whence), relative offset (l_start), size (l_len), and process ID (l_pid) of the segment of the file to be affected.

The value of `l_whence` is SEEK_SET, SEEK_CUR, or SEEK_END, to indicate that the relative offset `l_start` bytes shall be measured from the start of the file, current position, or end of the file, respectively. The value of `l_len` is the number of consecutive bytes to be locked. The value of `l_len` may be negative (where the definition of `off_t` permits negative values of `l_len`). The `l_pid` field is only used with `F_GETLK` to return the process ID of the process holding a blocking lock. After a successful `F_GETLK` request, when a blocking lock is found, the values returned in the `flock` structure shall be as follows:

- `l_type`: Type of blocking lock found.
- `l_whence`: SEEK_SET.
- `l_start`: Start of the blocking lock.
- `l_len`: Length of the blocking lock.
- `l_pid`: Process ID of the process that holds the blocking lock.
If the command is F_SETLKW and the process must wait for another process to release a lock, then the range of bytes to be locked shall be determined before the `fcntl()` function blocks. If the file size or file descriptor seek offset change while `fcntl()` is blocked, this shall not affect the range of bytes locked.

If \( l_{\text{len}} \) is positive, the area affected shall start at \( l_{\text{start}} \) and end at \( l_{\text{start}}+l_{\text{len}}-1 \). If \( l_{\text{len}} \) is negative, the area affected shall start at \( l_{\text{start}}+l_{\text{len}} \) and end at \( l_{\text{start}}-1 \). Locks may start and extend beyond the current end of a file, but shall not extend before the beginning of the file. A lock shall be set to extend to the largest possible value of the file offset for that file by setting \( l_{\text{len}} \) to 0. If such a lock also has \( l_{\text{start}} \) set to 0 and \( l_{\text{whence}} \) is set to SEEK_SET, the whole file shall be locked.

There shall be at most one type of lock set for each byte in the file. Before a successful return from an F_SETLK or an F_SETLKW request when the calling process has previously existing locks on bytes in the region specified by the request, the previous lock type for each byte in the specified region shall be replaced by the new lock type. As specified above under the descriptions of shared locks and exclusive locks, an F_SETLK or an F_SETLKW request (respectively) shall fail or block when another process has existing locks on bytes in the specified region and the type of any of those locks conflicts with the type specified in the request.

All locks associated with a file for a given process shall be removed when a file descriptor for that file is closed by that process or the process holding that file descriptor terminates. Locks are not inherited by a child process.

A potential for deadlock occurs if a process controlling a locked region is put to sleep by attempting to lock another process’ locked region. If the system detects that sleeping until a locked region is unlocked would cause a deadlock, `fcntl()` shall fail with an [EDEADLK] error.

An unlock (F_UNLCK) request in which \( l_{\text{len}} \) is non-zero and the offset of the last byte of the requested segment is the maximum value for an object of type \( \text{off}_t \), when the process has an existing lock in which \( l_{\text{len}} \) is 0 and which includes the last byte of the requested segment, shall be treated as a request to unlock from the start of the requested segment with an \( l_{\text{len}} \) equal to 0. Otherwise, an unlock (F_UNLCK) request shall attempt to unlock only the requested segment.

When the file descriptor \( fildes \) refers to a shared memory object, the behavior of `fcntl()` shall be the same as for a regular file except the effect of the following values for the argument \( cmd \) shall be unspecified: F_SETFL, F_GETLK, F_SETLK, and F_SETLKW.

If \( fildes \) refers to a typed memory object, the result of the `fcntl()` function is unspecified.

**RETURN VALUE**

Upon successful completion, the value returned shall depend on \( cmd \) as follows:

- **F_DUPFD** A new file descriptor.
- **F_GETFD** Value of flags defined in `<fcntl.h>`. The return value shall not be negative.
- **F_SETFD** Value other than \(-1\).
- **F_GETFL** Value of file status flags and access modes. The return value is not negative.
- **F_SETFL** Value other than \(-1\).
- **F_GETLK** Value other than \(-1\).
- **F_SETLK** Value other than \(-1\).
- **F_SETLKW** Value other than \(-1\).
- **F_GETOWN** Value of the socket owner process or process group; this will not be \(-1\).
F_SETOWN  Value other than \(-1\).
Otherwise, \(-1\) shall be returned and \(errno\) set to indicate the error.

**ERRORS**

The \(fcntl()\) function shall fail if:

- \([EACCES]\) or \([EAGAIN]\)
  - The \(cmd\) argument is \(F\_SETLK\); the type of lock \((l\_type)\) is a shared \((F\_RDLCK)\)
    or exclusive \((F\_WRLCK)\) lock and the segment of a file to be locked is already
    exclusive-locked by another process, or the type is an exclusive lock and some
    portion of the segment of a file to be locked is already shared-locked or
    exclusive-locked by another process.

- \([EBADF]\)
  - The \(fildes\) argument is not a valid open file descriptor, or the argument \(cmd\) is
    \(F\_SETLK\) or \(F\_SETLKW\), the type of lock, \(l\_type\), is a shared lock \((F\_RDLCK)\),
    and \(fildes\) is not a valid file descriptor open for reading, or the type of lock,
    \(l\_type\), is an exclusive lock \((F\_WRLCK)\), and \(fildes\) is not a valid file descriptor
    open for writing.

- \([EINTR]\)
  - The \(cmd\) argument is \(F\_SETLKW\) and the function was interrupted by a signal.

- \([EINVAL]\)
  - The \(cmd\) argument is invalid, or the \(cmd\) argument is \(F\_DUPFD\) and \(arg\) is
    negative or greater than or equal to \(\{OPEN\_MAX\}\), or the \(cmd\) argument is
    \(F\_GETLK\), \(F\_SETLK\), or \(F\_SETLKW\) and the data pointed to by \(arg\) is not valid,
    or \(fildes\) refers to a file that does not support locking.

- \([EMFILE]\)
  - The argument \(cmd\) is \(F\_DUPFD\) and \(\{OPEN\_MAX\}\) file descriptors are
    currently open in the calling process, or no file descriptors greater than or
    equal to \(arg\) are available.

- \([ENOLCK]\)
  - The argument \(cmd\) is \(F\_SETLK\) or \(F\_SETLKW\) and satisfying the lock or unlock
    request would result in the number of locked regions in the system exceeding
    a system-imposed limit.

- \([EOVERFLOW]\)
  - One of the values to be returned cannot be represented correctly.

- \([EOVERFLOW]\)
  - The \(cmd\) argument is \(F\_GETLK\), \(F\_SETLK\), or \(F\_SETLKW\) and the smallest or,
    if \(l\_len\) is non-zero, the largest offset of any byte in the requested segment
    cannot be represented correctly in an object of type \(off\_t\).

- The \(fcntl()\) function may fail if:

- \([EDEADLK]\)
  - The \(cmd\) argument is \(F\_SETLKW\), the lock is blocked by a lock from another
    process, and putting the calling process to sleep to wait for that lock to
    become free would cause a deadlock.

**EXAMPLES**

None.

**APPLICATION USAGE**

None.

**RATIONALE**

The ellipsis in the SYNOPSIS is the syntax specified by the ISO C standard for a variable number
of arguments. It is used because System V uses pointers for the implementation of file locking
functions.

The \(arg\) values to \(F\_GETFD\), \(F\_SETFD\), \(F\_GETFL\), and \(F\_SETFL\) all represent flag values to allow
for future growth. Applications using these functions should do a read-modify-write operation
on them, rather than assuming that only the values defined by this volume of IEEE Std 1003.1-2001 are valid. It is a common error to forget this, particularly in the case of F_SETFD.

This volume of IEEE Std 1003.1-2001 permits concurrent read and write access to file data using the `fcntl()` function; this is a change from the 1984 /usr/group standard and early proposals. Without concurrency controls, this feature may not be fully utilized without occasional loss of data.

Data losses occur in several ways. One case occurs when several processes try to update the same record, without sequencing controls; several updates may occur in parallel and the last writer ‘wins’. Another case is a bit-tree or other internal list-based database that is undergoing reorganization. Without exclusive use to the tree segment by the updating process, other reading processes chance getting lost in the database when the index blocks are split, condensed, inserted, or deleted. While `fcntl()` is useful for many applications, it is not intended to be overly general and does not handle the bit-tree example well.

This facility is only required for regular files because it is not appropriate for many devices such as terminals and network connections.

Since `fcntl()` works with “any file descriptor associated with that file, however it is obtained”, the file descriptor may have been inherited through a `fork()` or `exec` operation and thus may affect a file that another process also has open.

The use of the open file description to identify what to lock requires extra calls and presents problems if several processes are sharing an open file description, but there are too many implementations of the existing mechanism for this volume of IEEE Std 1003.1-2001 to use different specifications.

Another consequence of this model is that closing any file descriptor for a given file (whether or not it is the same open file description that created the lock) causes the locks on that file to be relinquished for that process. Equivalently, any close for any file/process pair relinquishes the locks owned on that file for that process. But note that while an open file description may be shared through `fork()`, locks are not inherited through `fork()`. Yet locks may be inherited through one of the `exec` functions.

The identification of a machine in a network environment is outside the scope of this volume of IEEE Std 1003.1-2001. Thus, an `l_sysid` member, such as found in System V, is not included in the locking structure.

Changing of lock types can result in a previously locked region being split into smaller regions.

Mandatory locking was a major feature of the 1984 /usr/group standard.

For advisory file record locking to be effective, all processes that have access to a file must cooperate and use the advisory mechanism before doing I/O on the file. Enforcement-mode record locking is important when it cannot be assumed that all processes are cooperating. For example, if one user uses an editor to update a file at the same time that a second user executes another process that updates the same file and if only one of the two processes is using advisory locking, the processes are not cooperating. Enforcement-mode record locking would protect against accidental collisions.

Secondly, advisory record locking requires a process using locking to bracket each I/O operation with lock (or test) and unlock operations. With enforcement-mode file and record locking, a process can lock the file once and unlock when all I/O operations have been completed. Enforcement-mode record locking provides a base that can be enhanced; for example, with sharable locks. That is, the mechanism could be enhanced to allow a process to lock a file so other processes could read it, but none of them could write it.
Mandatory locks were omitted for several reasons:

1. Mandatory lock setting was done by multiplexing the set-group-ID bit in most implementations; this was confusing, at best.

2. The relationship to file truncation as supported in 4.2 BSD was not well specified.

3. Any publicly readable file could be locked by anyone. Many historical implementations keep the password database in a publicly readable file. A malicious user could thus prohibit logins. Another possibility would be to hold open a long-distance telephone line.

4. Some demand-paged historical implementations offer memory mapped files, and enforcement cannot be done on that type of file.

Since sleeping on a region is interrupted with any signal, \texttt{alarm()} may be used to provide a timeout facility in applications requiring it. This is useful in deadlock detection. Since implementation of full deadlock detection is not always feasible, the \texttt{[EDEADLK]} error was made optional.

\textbf{FUTURE DIRECTIONS}

None.

\textbf{SEE ALSO}

\texttt{alarm()}, \texttt{close()}, \texttt{exec()}, \texttt{open()}, \texttt{sigaction()}, the Base Definitions volume of IEEE Std 1003.1-2001, <fcntl.h>, <signal.h>, <unistd.h>

\textbf{CHANGE HISTORY}

First released in Issue 1. Derived from Issue 1 of the SVID.

\textbf{Issue 5}

The DESCRIPTION is updated for alignment with the POSIX Realtime Extension and the POSIX Threads Extension.

Large File Summit extensions are added.

\textbf{Issue 6}

In the SYNOPSIS, the optional include of the \texttt{<sys/types.h>} header is removed.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The requirement to include \texttt{<sys/types.h>} has been removed. Although \texttt{<sys/types.h>} was required for conforming implementations of previous POSIX specifications, it was not required for UNIX applications.

- In the DESCRIPTION, sentences describing behavior when \texttt{l_len} is negative are now mandated, and the description of unlock (F_UNLOCK) when \texttt{l_len} is non-negative is mandated.

- In the ERRORS section, the \texttt{[EINVAL]} error condition has the case mandated when the \texttt{cmd} is invalid, and two \texttt{[EOVERFLOW]} error conditions are added.

The F_GETOWN and F_SETOWN values are added for sockets.

The following changes were made to align with the IEEE P1003.1a draft standard:

- Clarification is added that the extent of the bytes locked is determined prior to the blocking action.

The DESCRIPTION is updated for alignment with IEEE Std 1003.1j-2000 by specifying that \texttt{fcntl()} results are unspecified for typed memory objects.
The DESCRIPTION is updated to avoid use of the term “must” for application requirements.
NAME

fcvt — convert a floating-point number to a string (LEGACY)

SYNOPSIS

```c
#include <stdlib.h>

char *fcvt(double value, int ndigit, int *restrict decpt,
            int *restrict sign);
```

DESCRIPTION

Refer to `ecvt()`.
NAME
fdatasync — synchronize the data of a file (REALTIME)

SYNOPSIS
#include <unistd.h>
int fdatasync(int fildes);

DESCRIPTION
The fdatasync() function shall force all currently queued I/O operations associated with the file indicated by file descriptor fildes to the synchronized I/O completion state.

The functionality shall be equivalent to fsync() with the symbol _POSIX_SYNCHRONIZED_IO defined, with the exception that all I/O operations shall be completed as defined for synchronized I/O data integrity completion.

RETURN VALUE
If successful, the fdatasync() function shall return the value 0; otherwise, the function shall return the value -1 and set errno to indicate the error. If the fdatasync() function fails, outstanding I/O operations are not guaranteed to have been completed.

ERRORS
The fdatasync() function shall fail if:

[EBADF] The fildes argument is not a valid file descriptor open for writing.

 EINVAL] This implementation does not support synchronized I/O for this file.

In the event that any of the queued I/O operations fail, fdatasync() shall return the error conditions defined for read() and write().

EXAMPLES
None.

APPLICATION USAGE
None.

RATIONALE
None.

FUTURE DIRECTIONS
None.

SEE ALSO
aio_fsync(), fcntl(), fsync(), open(), read(), write(), the Base Definitions volume of IEEE Std 1003.1-2001, <unistd.h>

CHANGE HISTORY
First released in Issue 5. Included for alignment with the POSIX Realtime Extension.

Issue 6
The [ENOSYS] error condition has been removed as stubs need not be provided if an implementation does not support the Synchronized Input and Output option.
The fdatasync() function is marked as part of the Synchronized Input and Output option.
NAME
fdetach — detach a name from a STREAMS-based file descriptor (STREAMS)

SYNOPSIS
#include <stropts.h>

int fdetach(const char *path);

DESCRIPTION
The fdetach() function shall detach a STREAMS-based file from the file to which it was attached
by a previous call to fattach(). The path argument points to the pathname of the attached
STREAMS file. The process shall have appropriate privileges or be the owner of the file. A
successful call to fdetach() shall cause all pathnames that named the attached STREAMS file to
again name the file to which the STREAMS file was attached. All subsequent operations on path
shall operate on the underlying file and not on the STREAMS file.

All open file descriptions established while the STREAMS file was attached to the file referenced
by path shall still refer to the STREAMS file after the fdetach() has taken effect.

If there are no open file descriptors or other references to the STREAMS file, then a successful
call to fdetach() shall be equivalent to performing the last close() on the attached file.

RETURN VALUE
Upon successful completion, fdetach() shall return 0; otherwise, it shall return −1 and set errno to
indicate the error.

ERRORS
The fdetach() function shall fail if:

[EACCES] Search permission is denied on a component of the path prefix.
[EINVAL] The path argument names a file that is not currently attached.
[ELOOP] A loop exists in symbolic links encountered during resolution of the path argument.

[ENAMETOOLONG] The size of a pathname exceeds {PATH_MAX} or a pathname component is
longer than {NAME_MAX}.

[ENOENT] A component of path does not name an existing file or path is an empty string.
[ENOTDIR] A component of the path prefix is not a directory.
[EPERM] The effective user ID is not the owner of path and the process does not have
appropriate privileges.

The fdetach() function may fail if:

[ELOOP] More than {SYMLOOP_MAX} symbolic links were encountered during
resolution of the path argument.

[ENAMETOOLONG] Pathname resolution of a symbolic link produced an intermediate result
whose length exceeds {PATH_MAX}.
Detaching a File

The following example detaches the STREAMS-based file /tmp/named-STREAM from the file to which it was attached by a previous, successful call to fattach(). Subsequent calls to open this file refer to the underlying file, not to the STREAMS file.

```c
#include <stropts.h>
...
char *filename = "/tmp/named-STREAM";
int ret;
ret = fdetach(filename);
```

APPLICATION USAGE
None.

RATIONALE
None.

FUTURE DIRECTIONS
None.

fattach(), the Base Definitions volume of IEEE Std 1003.1-2001, <stropts.h>

CHANGE HISTORY
First released in Issue 4, Version 2.

Issue 5
Moved from X/OPEN UNIX extension to BASE.

Issue 6
The DESCRIPTION is updated to avoid use of the term “must” for application requirements.

The wording of the mandatory [ELOOP] error condition is updated, and a second optional [ELOOP] error condition is added.
**SYNOPSIS**

```c
#include <math.h>

double fdim(double x, double y);
float fdimf(float x, float y);
long double fdiml(long double x, long double y);
```

**DESCRIPTION**

The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-2001 defers to the ISO C standard.

These functions shall determine the positive difference between their arguments. If \( x \) is greater than \( y \), \( x - y \) is returned. If \( x \) is less than or equal to \( y \), +0 is returned.

An application wishing to check for error situations should set \( \text{errno} \) to zero and call \( \text{fctclearexcept}(\text{FE_ALL_EXCEPT}) \) before calling these functions. On return, if \( \text{errno} \) is non-zero or \( \text{fcttestexcept}(\text{FE_INVALID | FE_DIVBYZERO | FE_OVERFLOW | FE_UNDERFLOW}) \) is non-zero, an error has occurred.

**RETURN VALUE**

Upon successful completion, these functions shall return the positive difference value. If \( x - y \) is positive and overflows, a range error shall occur and \( \text{fdim}(), \text{fdimf}(), \) and \( \text{fdiml}() \) shall return the value of the macro \( \text{HUGE_VAL}, \text{HUGE_VALF}, \) and \( \text{HUGE_VALL} \), respectively.

If \( x - y \) is positive and underflows, a range error may occur, and either \( (x - y) \) (if representable), or 0.0 (if supported), or an implementation-defined value shall be returned.

**ERRORS**

The \( \text{fdim}() \) function shall fail if:

**Range Error**

- The result overflows.
- If the integer expression \((\text{math_errhandling} & \text{MATH_ERRNO})\) is non-zero, then \( \text{errno} \) shall be set to \([\text{ERANGE}]\). If the integer expression \((\text{math_errhandling} & \text{MATH_ERREXCEPT})\) is non-zero, then the overflow floating-point exception shall be raised.

The \( \text{fdim}() \) function may fail if:

**Range Error**

- The result underflows.
- If the integer expression \((\text{math_errhandling} & \text{MATH_ERRNO})\) is non-zero, then \( \text{errno} \) shall be set to \([\text{ERANGE}]\). If the integer expression \((\text{math_errhandling} & \text{MATH_ERREXCEPT})\) is non-zero, then the underflow floating-point exception shall be raised.
**EXAMPLES**
None.

**APPLICATION USAGE**
On implementations supporting IEEE Std 754-1985, $x-y$ cannot underflow, and hence the 0.0 return value is shaded as an extension for implementations supporting the XSI extension rather than an MX extension.

On error, the expressions (math_errnohandling & MATH_ERRNO) and (math_errnohandling & MATH_ERREXCEPT) are independent of each other, but at least one of them must be non-zero.

**RATIONALE**
None.

**FUTURE DIRECTIONS**
None.

**SEE ALSO**

**CHANGE HISTORY**
NAME
fdopen — associate a stream with a file descriptor

SYNOPSIS
CX

```c
#include <stdio.h>

FILE *fdopen(int fildes, const char *mode);
```

DESCRIPTION
The `fdopen()` function shall associate a stream with a file descriptor.

The `mode` argument is a character string having one of the following values:

- `r` or `rb`     Open a file for reading.
- `w` or `wb`     Open a file for writing.
- `a` or `ab`     Open a file for writing at end-of-file.
- `r+` or `rb+` or `r+b` Open a file for update (reading and writing).
- `w+` or `wb+` or `w+b` Open a file for update (reading and writing).
- `a+` or `ab+` or `a+b` Open a file for update (reading and writing) at end-of-file.

The meaning of these flags is exactly as specified in `fopen()`, except that modes beginning with `w` shall not cause truncation of the file.

Additional values for the `mode` argument may be supported by an implementation.

The application shall ensure that the mode of the stream as expressed by the `mode` argument is allowed by the file access mode of the open file description to which `fildes` refers. The file position indicator associated with the new stream is set to the position indicated by the file offset associated with the file descriptor.

The error and end-of-file indicators for the stream shall be cleared. The `fdopen()` function may cause the `st_atime` field of the underlying file to be marked for update.

If `fildes` refers to a shared memory object, the result of the `fdopen()` function is unspecified.

If `fildes` refers to a typed memory object, the result of the `fdopen()` function is unspecified.

The `fdopen()` function shall preserve the offset maximum previously set for the open file description corresponding to `fildes`.

RETURN VALUE
Upon successful completion, `fdopen()` shall return a pointer to a stream; otherwise, a null pointer shall be returned and `errno` set to indicate the error.

ERRORS
The `fdopen()` function may fail if:

- `[EBADF]`     The `fildes` argument is not a valid file descriptor.
- `[EINVAL]`    The `mode` argument is not a valid mode.
- `[EMFILE]`   (FOPEN_MAX) streams are currently open in the calling process.
- `[EMFILE]`   (STREAM_MAX) streams are currently open in the calling process.
- `[ENOMEM]`   Insufficient space to allocate a buffer.
EXAMPLES

None.

APPLICATION USAGE

File descriptors are obtained from calls like open(), dup(), creat(), or pipe(), which open files but do not return streams.

RATIONALE

The file descriptor may have been obtained from open(), creat(), pipe(), dup(), or fcntl(); inherited through fork() or exec; or perhaps obtained by implementation-defined means, such as the 4.3 BSD socket() call.

The meanings of the mode arguments of fdopen() and fopen() differ. With fdopen(), open for write (w or w+) does not truncate, and append (a or a+) cannot create for writing. The mode argument formats that include a b are allowed for consistency with the ISO C standard function fopen(). The b has no effect on the resulting stream. Although not explicitly required by this volume of IEEE Std 1003.1-2001, a good implementation of append (a) mode would cause the O_APPEND flag to be set.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 5

The DESCRIPTION is updated for alignment with the POSIX Realtime Extension.

Large File Summit extensions are added.

Issue 6

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

• In the DESCRIPTION, the use and setting of the mode argument are changed to include binary streams.

• In the DESCRIPTION, text is added for large file support to indicate setting of the offset maximum in the open file description.

• All errors identified in the ERRORS section are added.

• In the DESCRIPTION, text is added that the fdopen() function may cause st_atime to be updated.

The following changes were made to align with the IEEE P1003.1a draft standard:

• Clarification is added that it is the responsibility of the application to ensure that the mode is compatible with the open file descriptor.

• The DESCRIPTION is updated for alignment with IEEE Std 1003.1j-2000 by specifying that fdopen() results are unspecified for typed memory objects.
fecleralercept() — clear floating-point exception

#include <fenv.h>

int fecleralercept(int excepts);

The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-2001 defers to the ISO C standard.

The fecleralercept() function shall attempt to clear the supported floating-point exceptions represented by excepts.

If the argument is zero or if all the specified exceptions were successfully cleared, fecleralercept() shall return zero. Otherwise, it shall return a non-zero value.

No errors are defined.

NAME
fegetenv, fesetenv — get and set current floating-point environment

SYNOPSIS
#include <fenv.h>
int fegetenv(fenv_t *envp);
int fesetenv(const fenv_t *envp);

DESCRIPTION
The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-2001 defers to the ISO C standard.

The fegetenv() function shall attempt to store the current floating-point environment in the object pointed to by envp.

The fesetenv() function shall attempt to establish the floating-point environment represented by the object pointed to by envp. The argument envp shall point to an object set by a call to fegetenv() or feholdexcept(), or equal a floating-point environment macro. The fesetenv() function does not raise floating-point exceptions, but only installs the state of the floating-point status flags represented through its argument.

RETURN VALUE
If the representation was successfully stored, fegetenv() shall return zero. Otherwise, it shall return a non-zero value. If the environment was successfully established, fesetenv() shall return zero. Otherwise, it shall return a non-zero value.

ERRORS
No errors are defined.

CHANGE HISTORY
### NAME
fegetround, fesetround — get and set current rounding direction

### SYNOPSIS
```
#include <fenv.h>

int fegetround(void);
int fesetround(int round);
```

### DESCRIPTION
The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-2001 defers to the ISO C standard.

The `fegetround()` function shall get the current rounding direction.

The `fesetround()` function shall establish the rounding direction represented by its argument `round`. If the argument is not equal to the value of a rounding direction macro, the rounding direction is not changed.

### RETURN VALUE
The `fegetround()` function shall return the value of the rounding direction macro representing the current rounding direction or a negative value if there is no such rounding direction macro or the current rounding direction is not determinable.

The `fesetround()` function shall return a zero value if and only if the requested rounding direction was established.

### ERRORS
No errors are defined.

### EXAMPLES
The following example saves, sets, and restores the rounding direction, reporting an error and aborting if setting the rounding direction fails:
```
#include <fenv.h>
#include <assert.h>
void f(int round_dir)
{
    #pragma STDC FENV_ACCESS ON
    int save_round;
    int setround_ok;
    save_round = fegetround();
    setround_ok = fesetround(round_dir);
    assert(setround_ok == 0);
    /* ... */
    fesetround(save_round);
    /* ... */
}
```

### APPLICATION USAGE
None.

### RATIONALE
None.
fegetround()

CHANGE HISTORY
NAME
feholdexcept — save current floating-point environment

SYNOPSIS
#include <fenv.h>
int feholdexcept(fenv_t *envp);

DESCRIPTION
The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-2001 defers to the ISO C standard.

The feholdexcept() function shall save the current floating-point environment in the object pointed to by envp, clear the floating-point status flags, and then install a non-stop (continue on floating-point exceptions) mode, if available, for all floating-point exceptions.

RETURN VALUE
The feholdexcept() function shall return zero if and only if non-stop floating-point exception handling was successfully installed.

ERRORS
No errors are defined.

EXAMPLES
None.

APPLICATION USAGE
None.

RATIONALE
The feholdexcept() function should be effective on typical IEC 60559:1989 standard implementations which have the default non-stop mode and at least one other mode for trap handling or aborting. If the implementation provides only the non-stop mode, then installing the non-stop mode is trivial.

FUTURE DIRECTIONS
None.

NAME
feraiseexcept — raise floating-point exception

SYNOPSIS
#include <fenv.h>
int feraiseexcept(int excepts);

DESCRIPTION
The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-2001 defers to the ISO C standard.

The feraiseexcept() function shall attempt to raise the supported floating-point exceptions represented by the argument excepts. The order in which these floating-point exceptions are raised is unspecified. Whether the feraiseexcept() function additionally raises the inexact floating-point exception whenever it raises the overflow or underflow floating-point exception is implementation-defined.

RETURN VALUE
If the argument is zero or if all the specified exceptions were successfully raised, feraiseexcept() shall return zero. Otherwise, it shall return a non-zero value.

ERRORS
No errors are defined.

EXAMPLES
None.

APPLICATION USAGE
The effect is intended to be similar to that of floating-point exceptions raised by arithmetic operations. Hence, enabled traps for floating-point exceptions raised by this function are taken.

RATIONALE
Raising overflow or underflow is allowed to also raise inexact because on some architectures the only practical way to raise an exception is to execute an instruction that has the exception as a side effect. The function is not restricted to accept only valid coincident expressions for atomic operations, so the function can be used to raise exceptions accrued over several operations.

FUTURE DIRECTIONS
None.

DESCRIPTION

CX

The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-2001 defers to the ISO C standard.

The feupdateenv() function shall attempt to save the currently raised floating-point exceptions in its automatic storage, attempt to install the floating-point environment represented by the object pointed to by envp, and then attempt to raise the saved floating-point exceptions. The argument envp shall point to an object set by a call to feholdexcept() or fegetenv(), or equal a floating-point environment macro.

RETURN VALUE

The feupdateenv() function shall return a zero value if and only if all the required actions were successfully carried out.

ERRORS

No errors are defined.

EXAMPLES

The following example shows sample code to hide spurious underflow floating-point exceptions:

```c
#include <fenv.h>
double f(double x)
{
    #pragma STDC FENV_ACCESS ON
    double result;
    fenv_t save_env;
    feholdexcept(&save_env);
    // compute result
    if (/* test spurious underflow */) feclearexcept(FE_UNDERFLOW);
    feupdateenv(&save_env);
    return result;
}
```

APPLICATION USAGE

None.

RATIONALE

None.

FUTURE DIRECTIONS

None.

SEE ALSO

NAME
fflush — flush a stream

SYNOPSIS
#include <stdio.h>

int fflush(FILE *stream);

DESCRIPTION
The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-2001 defers to the ISO C standard.

If `stream` points to an output stream or an update stream in which the most recent operation was not input, `fflush()` shall cause any unwritten data for that stream to be written to the file, and the `st_ctime` and `st_mtime` fields of the underlying file shall be marked for update.

If `stream` is a null pointer, `fflush()` shall perform this flushing action on all streams for which the behavior is defined above.

RETURN VALUE
Upon successful completion, `fflush()` shall return 0; otherwise, it shall set the error indicator for the stream, return EOF, and set `errno` to indicate the error.

ERRORS
The `fflush()` function shall fail if:

- [EAGAIN] The O_NONBLOCK flag is set for the file descriptor underlying `stream` and the process would be delayed in the write operation.
- [EBADF] The file descriptor underlying `stream` is not valid.
- [EFBIG] An attempt was made to write a file that exceeds the maximum file size.
- [EFBIG] An attempt was made to write a file that exceeds the process’ file size limit.
- [EFBIG] The file is a regular file and an attempt was made to write at or beyond the offset maximum associated with the corresponding stream.
- [EINTR] The `fflush()` function was interrupted by a signal.
- [EIO] The process is a member of a background process group attempting to write to its controlling terminal, TOSTOP is set, the process is neither ignoring nor blocking SIGTTOU, and the process group of the process is orphaned. This error may also be returned under implementation-defined conditions.
- [ENOSPC] There was no free space remaining on the device containing the file.
- [EPipe] An attempt is made to write to a pipe or FIFO that is not open for reading by any process. A SIGPIPE signal shall also be sent to the thread.
- [ENXIO] The `fflush()` function may fail if:
- [ENXIO] A request was made of a nonexistent device, or the request was outside the capabilities of the device.
EXAMPLES

Sending Prompts to Standard Output

The following example uses printf() calls to print a series of prompts for information the user must enter from standard input. The fflush() calls force the output to standard output. The fflush() function is used because standard output is usually buffered and the prompt may not immediately be printed on the output or terminal. The gets() calls read strings from standard input and place the results in variables, for use later in the program.

```c
#include <stdio.h>
...
char user[100];
char oldpasswd[100];
char newpasswd[100];
...
printf("User name: ");
fflush(stdout);
gets(user);
printf("Old password: ");
fflush(stdout);
gets(oldpasswd);
printf("New password: ");
fflush(stdout);
gets(newpasswd);
...
```

APPLICATION USAGE

None.

RATIONALE

Data buffered by the system may make determining the validity of the position of the current file descriptor impractical. Thus, enforcing the repositioning of the file descriptor after fflush() on streams open for read() is not mandated by IEEE Std 1003.1-2001.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 5

Large File Summit extensions are added.

Issue 6

Extensions beyond the ISO C standard are marked.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The [EFBIG] error is added as part of the large file support extensions.
- The [ENXIO] optional error condition is added.
The RETURN VALUE section is updated to note that the error indicator shall be set for the stream. This is for alignment with the ISO/IEC 9899:1999 standard.
NAME
ffs — find first set bit

SYNOPSIS
XSI
#include <strings.h>

int ffs(int i);

DESCRIPTION
The ffs() function shall find the first bit set (beginning with the least significant bit) in i, and return the index of that bit. Bits are numbered starting at one (the least significant bit).

RETURN VALUE
The ffs() function shall return the index of the first bit set. If i is 0, then ffs() shall return 0.

ERRORS
No errors are defined.

EXAMPLES

CHANGE HISTORY
First released in Issue 4, Version 2.

Issue 5
Moved from X/OPEN UNIX extension to BASE.
NAME
fgetc — get a byte from a stream

SYNOPSIS
#include <stdio.h>

int fgetc(FILE *stream);

DESCRIPTION
The functionality described on this reference page is aligned with the ISO C standard. Any
conflict between the requirements described here and the ISO C standard is unintentional. This

If the end-of-file indicator for the input stream pointed to by stream is not set and a next byte is
present, the fgetc() function shall obtain the next byte as an unsigned char converted to an int,
from the input stream pointed to by stream, and advance the associated file position indicator for
the stream (if defined). Since fgetc() operates on bytes, reading a character consisting of multiple
bytes (or “a multi-byte character”) may require multiple calls to fgetc().

The fgetc() function may mark the st_atime field of the file associated with stream for update. The
st_atime field shall be marked for update by the first successful execution of fgetc(), fgets(),
getwc(), fgetws(), fread(), fscanf(), getc(), getchar(), gets(), or scanf() using stream that returns
data not supplied by a prior call to ungetc() or ungetwc().

RETURN VALUE
Upon successful completion, fgetc() shall return the next byte from the input stream pointed to
by stream. If the end-of-file indicator for the stream is set, or if the stream is at end-of-file, the
end-of-file indicator for the stream shall be set and fgetc() shall return EOF. If a read error occurs,
the error indicator for the stream shall be set, fgetc() shall return EOF, and shall set errno to
indicate the error.

ERRORS
The fgetc() function shall fail if data needs to be read and:

[EAGAIN] The O_NONBLOCK flag is set for the file descriptor underlying stream and the
process would be delayed in the fgetc() operation.

[EBADF] The file descriptor underlying stream is not a valid file descriptor open for
reading.

[EINTR] The read operation was terminated due to the receipt of a signal, and no data
was transferred.

[EIO] A physical I/O error has occurred, or the process is in a background process
group attempting to read from its controlling terminal, and either the process
is ignoring or blocking the SIGTTIN signal or the process group is orphaned.
This error may also be generated for implementation-defined reasons.

[EOVERFLOW] The file is a regular file and an attempt was made to read at or beyond the
offset maximum associated with the corresponding stream.

The fgetc() function may fail if:

[ENOMEM] Insufficient storage space is available.

[ENXIO] A request was made of a nonexistent device, or the request was outside the
capabilities of the device.
EXAMPLES
None.

APPLICATION USAGE
If the integer value returned by \texttt{fgetc()} is stored into a variable of type \texttt{char} and then compared against the integer constant EOF, the comparison may never succeed, because sign-extension of a variable of type \texttt{char} on widening to integer is implementation-defined.

The \texttt{ferror()} or \texttt{feof()} functions must be used to distinguish between an error condition and an end-of-file condition.

RATIONALE
None.

FUTURE DIRECTIONS
None.

SEE ALSO
\texttt{feof()}, \texttt{ferror()}, \texttt{fopen()}, \texttt{getchar()}, \texttt{getc()}, the Base Definitions volume of IEEE Std 1003.1-2001, <stdio.h>

CHANGE HISTORY
First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 6
Large File Summit extensions are added.

Issue 6
Extensions beyond the ISO C standard are marked.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

• The [EIO] and [EOVERFLOW] mandatory error conditions are added.
• The [ENOMEM] and [ENXIO] optional error conditions are added.

The following changes are made for alignment with the ISO/IEC 9899:1999 standard:

• The DESCRIPTION is updated to clarify the behavior when the end-of-file indicator for the input stream is not set.
• The RETURN VALUE section is updated to note that the error indicator shall be set for the stream.
NAME
fgetpos — get current file position information

SYNOPSIS
#include <stdio.h>

int fgetpos(FILE *restrict stream, fpos_t *restrict pos);

DESCRIPTION
The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-2001 defers to the ISO C standard.

The fgetpos() function shall store the current values of the parse state (if any) and file position indicator for the stream pointed to by stream in the object pointed to by pos. The value stored contains unspecified information usable by fsetpos() for repositioning the stream to its position at the time of the call to fgetpos().

RETURN VALUE
Upon successful completion, fgetpos() shall return 0; otherwise, it shall return a non-zero value and set errno to indicate the error.

ERRORS
The fgetpos() function shall fail if:

- [EOVERFLOW] The current value of the file position cannot be represented correctly in an object of type fpos_t.
- [EBADF] The file descriptor underlying stream is not valid.
- [ESPIPE] The file descriptor underlying stream is associated with a pipe, FIFO, or socket.

EXAMPLES
None.

APPLICATION USAGE
None.

RATIONALE
None.

FUTURE DIRECTIONS
None.

CHANGE HISTORY
First released in Issue 4. Derived from the ISO C standard.

Issue 5
Large File Summit extensions are added.

Issue 6
Extensions beyond the ISO C standard are marked.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:
• The [EBADF] and [ESPIPE] optional error conditions are added.

An additional [ESPIPE] error condition is added for sockets.

The prototype for `fgetpos()` is changed for alignment with the ISO/IEC 9899: 1999 standard.
NAME
fgets — get a string from a stream

SYNOPSIS
#include <stdio.h>
char *fgets(char *restrict s, int n, FILE *restrict stream);

DESCRIPTION
CX The functionality described on this reference page is aligned with the ISO C standard. Any
collision between the requirements described here and the ISO C standard is unintentional. This

CX The fgets() function shall read bytes from stream into the array pointed to by s, until n–1 bytes
are read, or a <newline> is read and transferred to s, or an end-of-file condition is encountered.
The string is then terminated with a null byte.

CX The fgets() function may mark the st_atime field of the file associated with stream for update. The
st_atime field shall be marked for update by the first successful execution of fgetc(), fgets(),
fgetwc(), fgetws(), fread(), fscanf(), getc(), getchar(), gets(), or scanf() using stream that returns
data not supplied by a prior call to ungetc() or ungetwc().

RETURN VALUE
Upon successful completion, fgets() shall return s. If the stream is at end-of-file, the end-of-file
indicator for the stream shall be set and fgets() shall return a null pointer. If a read error occurs,
CX the error indicator for the stream shall be set, fgets() shall return a null pointer, and shall set
errno to indicate the error.

ERRORS
Refer to fgetc().

EXAMPLES
Reading Input
The following example uses fgets() to read each line of input. {LINE_MAX}, which defines the
maximum size of the input line, is defined in the <limits.h> header.

#include <stdio.h>
...
char line[LINE_MAX];
...
while (fgets(line, LINE_MAX, fp) != NULL) {
  ...
}

APPLICATION USAGE
None.

Extensions beyond the ISO C standard are marked.

The prototype for `fgets()` is changed for alignment with the ISO/IEC 9899:1999 standard.
NAME
fgetwc — get a wide-character code from a stream

SYNOPSIS
#include <stdio.h>
#include <wchar.h>
wint_t fgetwc(FILE *stream);

DESCRIPTION
The functionality described on this reference page is aligned with the ISO C standard. Any
conflict between the requirements described here and the ISO C standard is unintentional. This
The fgetwc( ) function shall obtain the next character (if present) from the input stream pointed to
by stream, convert that to the corresponding wide-character code, and advance the associated
file position indicator for the stream (if defined).
If an error occurs, the resulting value of the file position indicator for the stream is unspecified.
The fgetwc() function may mark the st_atime field of the file associated with stream for update.
The st_atime field shall be marked for update by the first successful execution of fgetc(), fgets(),
fgetwc(), fgets(), fread(), fscanf(), getc(), getchar(), gets(), or scanf() using stream that returns
data not supplied by a prior call to ungetc() or ungetwc().

RETURN VALUE
Upon successful completion, the fgetwc() function shall return the wide-character code of the
character read from the input stream pointed to by stream converted to a type wint_t. If the
stream is at end-of-file, the end-of-file indicator for the stream shall be set and fgetwc() shall
return WEOF. If a read error occurs, the error indicator for the stream shall be set, fgetwc() shall
return WEOF, and shall set errno to indicate the error. If an encoding error occurs, the error
indicator for the stream shall be set, fgetwc() shall return WEOF, and shall set errno to indicate
the error.

ERRORS
The fgetwc() function shall fail if data needs to be read and:

[EAGAIN] The O_NONBLOCK flag is set for the file descriptor underlying stream and the
process would be delayed in the fgetwc() operation.
[EBADF] The file descriptor underlying stream is not a valid file descriptor open for
reading.
[EILSEQ] The data obtained from the input stream does not form a valid character.
[EINTR] The read operation was terminated due to the receipt of a signal, and no data
was transferred.
[EIO] A physical I/O error has occurred, or the process is in a background process
group attempting to read from its controlling terminal, and either the process
is ignoring or blocking the SIGTTIN signal or the process group is orphaned.
This error may also be generated for implementation-defined reasons.
[EOVERFLOW] The file is a regular file and an attempt was made to read at or beyond the
offset maximum associated with the corresponding stream.
The fgetwc() function may fail if:
[ENOMEM] Insufficient storage space is available.
fgetwc()

A request was made of a nonexistent device, or the request was outside the capabilities of the device.

EXAMPLES
None.

APPLICATION USAGE
The ferror() or feof() functions must be used to distinguish between an error condition and an end-of-file condition.

RATIONALE
None.

FUTURE DIRECTIONS
None.

CHANGE HISTORY
First released in Issue 4. Derived from the MSE working draft.

Issue 5
The Optional Header (OH) marking is removed from <stdio.h>.
Large File Summit extensions are added.

Issue 6
Extensions beyond the ISO C standard are marked.
The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:
• The [EIO] and [EOVERFLOW] mandatory error conditions are added.
• The [ENOMEM] and [ENXIO] optional error conditions are added.
NAME
fgetws — get a wide-character string from a stream

SYNOPSIS
#include <stdio.h>
#include <wchar.h>
wchar_t *fgetws(wchar_t *restrict ws, int n, 
    FILE *restrict stream);

DESCRIPTION
CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-2001 defers to the ISO C standard.

The fgetws() function shall read characters from the stream, convert these to the corresponding wide-character codes, place them in the wchar_t array pointed to by ws, until n−1 characters are read, or a <newline> is read, converted, and transferred to ws, or an end-of-file condition is encountered. The wide-character string, ws, shall then be terminated with a null wide-character code.

If an error occurs, the resulting value of the file position indicator for the stream is unspecified.

CX The fgetws() function may mark the st_atime field of the file associated with stream for update. The st_atime field shall be marked for update by the first successful execution of fgetc(), fgets(), fgetwc(), fgetws(), fread(), fscanf(), getc(), getchar(), gets(), or scanf() using stream that returns data not supplied by a prior call to ungetc() or ungetwc().

RETURN VALUE
Upon successful completion, fgetws() shall return ws. If the stream is at end-of-file, the end-of-file indicator for the stream shall be set and fgetws() shall return a null pointer. If a read error occurs, the error indicator for the stream shall be set, fgetws() shall return a null pointer, and shall set errno to indicate the error.

ERRORS
Refer to fgetwc().

EXAMPLES
None.

APPLICATION USAGE
None.

RATIONALE
None.

FUTURE DIRECTIONS
None.

First released in Issue 4. Derived from the MSE working draft.

Issue 5
The Optional Header (OH) marking is removed from <stdio.h>. 

Extensions beyond the ISO C standard are marked.

The prototype for `fgetws()` is changed for alignment with the ISO/IEC 9899:1999 standard.
NAME
fileno — map a stream pointer to a file descriptor

SYNOPSIS
CX
#include <stdio.h>

int fileno(FILE *stream);

DESCRIPTION
The fileno() function shall return the integer file descriptor associated with the stream pointed to
by stream.

RETURN VALUE
Upon successful completion, fileno() shall return the integer value of the file descriptor
associated with stream. Otherwise, the value −1 shall be returned and errno set to indicate the
error.

ERRORS
The fileno() function may fail if:

[EBADF] The stream argument is not a valid stream.

EXAMPLES
None.

APPLICATION USAGE
None.

RATIONALE
Without some specification of which file descriptors are associated with these streams, it is
impossible for an application to set up the streams for another application it starts with fork() and exec. In particular, it would not be possible to write a portable version of the sh command
interpreter (although there may be other constraints that would prevent that portability).

FUTURE DIRECTIONS
None.

SEE ALSO

IEEE Std 1003.1-2001, <stdio.h>

CHANGE HISTORY
First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 6
The following new requirements on POSIX implementations derive from alignment with the
Single UNIX Specification:

• The [EBADF] optional error condition is added.
NAME
flockfile, ftrylockfile, funlockfile — stdio locking functions

SYNOPSIS
#include <stdio.h>

void flockfile(FILE *file);
int ftrylockfile(FILE *file);
void funlockfile(FILE *file);

DESCRIPTION
These functions shall provide for explicit application-level locking of stdio (FILE *) objects.
These functions can be used by a thread to delineate a sequence of I/O statements that are
executed as a unit.

The flockfile() function shall acquire for a thread ownership of a (FILE *) object.
The ftrylockfile() function shall acquire for a thread ownership of a (FILE *) object if the object is
available; ftrylockfile() is a non-blocking version of flockfile().
The funlockfile() function shall relinquish the ownership granted to the thread. The behavior is
undefined if a thread other than the current owner calls the funlockfile() function.

The functions shall behave as if there is a lock count associated with each (FILE *) object. This
count is implicitly initialized to zero when the (FILE *) object is created. The (FILE *) object is
unlocked when the count is zero. When the count is positive, a single thread owns the (FILE *)
object. When the flockfile() function is called, if the count is zero or if the count is positive and
the caller owns the (FILE *) object, the count shall be incremented. Otherwise, the calling thread
shall be suspended, waiting for the count to return to zero. Each call to funlockfile() shall
decrement the count. This allows matching calls to flockfile() (or successful calls to ftrylockfile())
and funlockfile() to be nested.

All functions that reference (FILE *) objects shall behave as if they use flockfile() and funlockfile()
internally to obtain ownership of these (FILE *) objects.

RETURN VALUE
None for flockfile() and funlockfile().
The ftrylockfile() function shall return zero for success and non-zero to indicate that the lock
cannot be acquired.

ERRORS
No errors are defined.

EXAMPLES
None.

APPLICATION USAGE
Applications using these functions may be subject to priority inversion, as discussed in the Base

RATIONALE
The flockfile() and funlockfile() functions provide an orthogonal mutual-exclusion lock for each
FILE. The ftrylockfile() function provides a non-blocking attempt to acquire a file lock,
 analogous to pthread_mutex_trylock().

These locks behave as if they are the same as those used internally by stdio for thread-safety.
This both provides thread-safety of these functions without requiring a second level of internal
locking and allows functions in stdio to be implemented in terms of other stdio functions.
Application writers and implementors should be aware that there are potential deadlock problems on `FILE` objects. For example, the line-buffered flushing semantics of `stdio` (requested via `(_IOLBF)`) require that certain input operations sometimes cause the buffered contents of implementation-defined line-buffered output streams to be flushed. If two threads each hold the lock on the other’s `FILE`, deadlock ensues. This type of deadlock can be avoided by acquiring `FILE` locks in a consistent order. In particular, the line-buffered output stream deadlock can typically be avoided by acquiring locks on input streams before locks on output streams if a thread would be acquiring both.

In summary, threads sharing `stdio` streams with other threads can use `flockfile()` and `funlockfile()` to cause sequences of I/O performed by a single thread to be kept bundled. The only case where the use of `flockfile()` and `funlockfile()` is required is to provide a scope protecting uses of the `*_unlocked()` functions/macros. This moves the cost/performance tradeoff to the optimal point.

**FUTURE DIRECTIONS**

None.

`getc_unlocked()`, `putc_unlocked()`, the Base Definitions volume of IEEE Std 1003.1-2001, `<stdio.h>`

**CHANGE HISTORY**

First released in Issue 5. Included for alignment with the POSIX Threads Extension.

**Issue 6**

These functions are marked as part of the Thread-Safe Functions option.
NAME
floor, floorf, floorl — floor function

SYNOPSIS
#include <math.h>
double floor(double x);
float floorf(float x);
long double floorl(long double x);

DESCRIPTION
The functionality described on this reference page is aligned with the ISO C standard. Any
conflict between the requirements described here and the ISO C standard is unintentional. This

These functions shall compute the largest integral value not greater than x.

An application wishing to check for error situations should set errno to zero and call
fceuarexcept(FE_ALL_EXCEPT) before calling these functions. On return, if errno is non-zero or
fetestexcept(FE_INVALID | FE_DIVBYZERO | FE_OVERFLOW | FE_UNDERFLOW) is non-zero, an error has occurred.

RETURN VALUE
Upon successful completion, these functions shall return the largest integral value not greater
than x, expressed as a double, float, or long double, as appropriate for the return type of the
function.

If x is NaN, a NaN shall be returned.
If x is ±0 or ±Inf, x shall be returned.

XSI If the correct value would cause overflow, a range error shall occur and floor(), floorf(), and
floorl() shall return the value of the macro −HUGE_VAL, −HUGE_VALF, and −HUGE_VALL,
respectively.

ERRORS
These functions shall fail if:

XSI Range Error The result would cause an overflow.
If the integer expression (math_errhandling & MATH_ERRNO) is non-zero,
then errno shall be set to [ERANGE]. If the integer expression
(math_errhandling & MATH_ERREXCEPT) is non-zero, then the overflow
floating-point exception shall be raised.

EXAMPLES
None.

APPLICATION USAGE
The integral value returned by these functions might not be expressible as an int or long. The
return value should be tested before assigning it to an integer type to avoid the undefined results
of an integer overflow.

The floor() function can only overflow when the floating-point representation has
DBL_MANT_DIG > DBL_MAX_EXP.
On error, the expressions (math_errhandling & MATH_ERRNO) and (math_errhandling &
MATH_ERREXCEPT) are independent of each other, but at least one of them must be non-zero.
floor()

RATIONALE
None.

FUTURE DIRECTIONS
None.

CHANGE HISTORY
First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 5
The DESCRIPTION is updated to indicate how an application should check for an error. This text was previously published in the APPLICATION USAGE section.

Issue 6
The floor() and floorl() functions are added for alignment with the ISO/IEC 9899:1999 standard.
The DESCRIPTION, RETURN VALUE, ERRORS, and APPLICATION USAGE sections are revised to align with the ISO/IEC 9899:1999 standard.
NAME
fma, fmaf, fmal — floating-point multiply-add

SYNOPSIS
#include <math.h>

double fma(double x, double y, double z);
float fmaf(float x, float y, float z);
long double fmal(long double x, long double y, long double z);

DESCRIPTION
The functionality described on this reference page is aligned with the ISO C standard. Any
conflict between the requirements described here and the ISO C standard is unintentional. This

These functions shall compute \((x \times y) + z\), rounded as one ternary operation: they shall compute
the value (as if) to infinite precision and round once to the result format, according to the
rounding mode characterized by the value of FLT_ROUNDS.

An application wishing to check for error situations should set \(errno\) to zero and call
\(feclearexcept(FE_ALL_EXCEPT)\) before calling these functions. On return, if \(errno\) is non-zero or
\(fetestexcept(FE_INVALID | FE_DIVBYZERO | FE_OVERFLOW | FE_UNDERFLOW)\) is non-
zero, an error has occurred.

RETURN VALUE
Upon successful completion, these functions shall return \((x \times y) + z\), rounded as one ternary
operation.

If \(x\) or \(y\) are NaN, a NaN shall be returned.

If \(x\) multiplied by \(y\) is an exact infinity and \(z\) is also an infinity but with the opposite sign, a
domain error shall occur, and either a NaN (if supported), or an implementation-defined value
shall be returned.

If one of \(x\) and \(y\) is infinite, the other is zero, and \(z\) is not a NaN, a domain error shall occur, and
either a NaN (if supported), or an implementation-defined value shall be returned.

If one of \(x\) and \(y\) is infinite, the other is zero, and \(z\) is a NaN, a NaN shall be returned and a
domain error may occur.

If \(x \times y\) is not 0*Inf nor Inf*0 and \(z\) is a NaN, a NaN shall be returned.

ERRORS
These functions shall fail if:

Domain Error The value of \(x \times y + z\) is invalid, or the value \(x \times y\) is invalid and \(z\) is not a NaN.

If the integer expression (\(\text{math_errhandling} \& \text{MATH_ERRNO}\)) is non-zero,
then \(errno\) shall be set to [EDOM]. If the integer expression (\(\text{math_errhandling}
\& \text{MATH_ERREXCEPT}\)) is non-zero, then the invalid floating-point exception
shall be raised.

Range Error The result overflows.

If the integer expression (\(\text{math_errhandling} \& \text{MATH_ERRNO}\)) is non-zero,
then \(errno\) shall be set to [ERANGE]. If the integer expression
\(\text{math_errhandling} \& \text{MATH_ERREXCEPT}\) is non-zero, then the overflow
floating-point exception shall be raised.
These functions may fail if:

**Domain Error**  The value \( x \cdot y \) is invalid and \( z \) is a NaN.

If the integer expression (math_errhandling & MATH_ERRNO) is non-zero, then \( errno \) shall be set to [EDOM]. If the integer expression (math_errhandling & MATH_ERREXCEPT) is non-zero, then the invalid floating-point exception shall be raised.

**Range Error**  The result underflows.

If the integer expression (math_errhandling & MATH_ERRNO) is non-zero, then \( errno \) shall be set to [ERANGE]. If the integer expression (math_errhandling & MATH_ERREXCEPT) is non-zero, then the underflow floating-point exception shall be raised.

**EXAMPLES**  None.

**APPLICATION USAGE**  On error, the expressions (math_errhandling & MATH_ERRNO) and (math_errhandling & MATH_ERREXCEPT) are independent of each other, but at least one of them must be non-zero.

**RATIONALE**  In many cases, clever use of floating (fused) multiply-add leads to much improved code; but its unexpected use by the compiler can undermine carefully written code. The FP_CONTRACT macro can be used to disallow use of floating multiply-add; and the \( \text{fma()} \) function guarantees its use where desired. Many current machines provide hardware floating multiply-add instructions; software implementation can be used for others.

**FUTURE DIRECTIONS**  None.

**SEE ALSO**  \( \text{feclearexcept()} \), \( \text{fetestexcept()} \), the Base Definitions volume of IEEE Std 1003.1-2001, Section 4.18, Treatment of Error Conditions for Mathematical Functions, \( \text{<math.h>} \)

fmax(), fmaxf(), fmaxl — determine maximum numeric value of two floating-point numbers

#include <math.h>

double fmax(double x, double y);
float fmaxf(float x, float y);
long double fmaxl(long double x, long double y);

The functionality described on this reference page is aligned with the ISO C standard. Any
conflict between the requirements described here and the ISO C standard is unintentional. This

These functions shall determine the maximum numeric value of their arguments. NaN
arguments shall be treated as missing data: if one argument is a NaN and the other numeric,
then these functions shall choose the numeric value.

Upon successful completion, these functions shall return the maximum numeric value of their
arguments.

If just one argument is a NaN, the other argument shall be returned.

If $x$ and $y$ are NaN, a NaN shall be returned.

No errors are defined.

CHANGE HISTORY
NAME
fmod, fmodf, fmodl — floating-point remainder value function

SYNOPSIS

#include <math.h>

double fmod(double x, double y);
float fmodf(float x, float y);
long double fmodl(long double x, long double y);

DESCRIPTION

The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-2001 defers to the ISO C standard.

These functions shall return the floating-point remainder of the division of \( x \) by \( y \).

An application wishing to check for error situations should set \( \text{errno} \) to zero and call \text{feclearexcept}(\text{FE_ALL_EXCEPT}) before calling these functions. On return, if \( \text{errno} \) is non-zero or \text{fetestexcept}(\text{FE_INVALID} | \text{FE_DIVBYZERO} | \text{FE_OVERFLOW} | \text{FE_UNDERFLOW}) is non-zero, an error has occurred.

RETURN VALUE

These functions shall return the value \( x - i \ast y \), for some integer \( i \) such that, if \( y \) is non-zero, the result has the same sign as \( x \) and magnitude less than the magnitude of \( y \).

If the correct value would cause underflow, and is not representable, a range error may occur, and either 0.0 (if supported), or an implementation-defined value shall be returned.

If \( x \) or \( y \) is NaN, a NaN shall be returned.

If \( y \) is zero, a domain error shall occur, and either a NaN (if supported), or an implementation-defined value shall be returned.

If \( x \) is infinite, a domain error shall occur, and either a NaN (if supported), or an implementation-defined value shall be returned.

If \( x \) is \( \pm 0 \) and \( y \) is not zero, \( \pm 0 \) shall be returned.

If \( x \) is not infinite and \( y \) is \( \pm \text{Inf} \), \( x \) shall be returned.

If the correct value would cause underflow, and is representable, a range error may occur and the correct value shall be returned.

ERRORS

These functions shall fail if:

Domain Error  The \( x \) argument is infinite or \( y \) is zero.

If the integer expression (\text{math_errhandling} & \text{MATH_ERRNO}) is non-zero, then \( \text{errno} \) shall be set to [EDOM]. If the integer expression (\text{math_errhandling} & \text{MATH_ERREXCEPT}) is non-zero, then the invalid floating-point exception shall be raised.

These functions may fail if:

Range Error  The result underflows.

If the integer expression (\text{math_errhandling} & \text{MATH_ERRNO}) is non-zero, then \( \text{errno} \) shall be set to [ERANGE]. If the integer expression (\text{math_errhandling} & \text{MATH_ERREXCEPT}) is non-zero, then the underflow floating-point exception shall be raised.
fmod()

EXAMPLES
None.

APPLICATION USAGE
On error, the expressions (math_errhandling & MATH_ERRNO) and (math_errhandling & MATH_ERREXCEPT) are independent of each other, but at least one of them must be non-zero.

RATIONALE

CHANGE HISTORY
First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 5
The DESCRIPTION is updated to indicate how an application should check for an error. This text was previously published in the APPLICATION USAGE section.

Issue 6
The behavior for when the y argument is zero is now defined.
The fmodf() and fmodl() functions are added for alignment with the ISO/IEC 9899:1999 standard.
The DESCRIPTION, RETURN VALUE, ERRORS, and APPLICATION USAGE sections are revised to align with the ISO/IEC 9899:1999 standard.
**NAME**
fmtmsg — display a message in the specified format on standard error and/or a system console

**SYNOPSIS**

```
#include <fmtmsg.h>

int fmtmsg(long classification, const char *label, int severity,
           const char *text, const char *action, const char *tag);
```

**DESCRIPTION**
The `fmtmsg()` function shall display messages in a specified format instead of the traditional `printf()` function.

Based on a message's classification component, `fmtmsg()` shall write a formatted message either to standard error, to the console, or to both.

A formatted message consists of up to five components as defined below. The component `classification` is not part of a message displayed to the user, but defines the source of the message and directs the display of the formatted message.

- **classification**: Contains the sum of identifying values constructed from the constants defined below. Any one identifier from a subclass may be used in combination with a single identifier from a different subclass. Two or more identifiers from the same subclass should not be used together, with the exception of identifiers from the display subclass. (Both display subclass identifiers may be used so that messages can be displayed to both standard error and the system console.)

  - **Major Classifications**: Identifies the source of the condition. Identifiers are: MM_HARD (hardware), MM_SOFT (software), and MM_FIRM (firmware).
  - **Message Source Subclassifications**: Identifies the type of software in which the problem is detected. Identifiers are: MM_APPL (application), MM_UTIL (utility), and MM_OPSYS (operating system).
  - **Display Subclassifications**: Indicates where the message is to be displayed. Identifiers are: MM_PRINT to display the message on the standard error stream, MM_CONSOLE to display the message on the system console. One or both identifiers may be used.
  - **Status Subclassifications**: Indicates whether the application can recover from the condition. Identifiers are: MM_RECOVER (recoverable) and MM_NRECOV (non-recoverable).
  - An additional identifier, MM_NULLMC, indicates that no classification component is supplied for the message.

- **label**: Identifies the source of the message. The format is two fields separated by a colon. The first field is up to 10 bytes, the second is up to 14 bytes.

- **severity**: Indicates the seriousness of the condition. Identifiers for the levels of severity are:
fmtmsg()  System Interfaces

12464 MM_HALT Indicates that the application has encountered a severe fault
12465 and is halting. Produces the string "HALT".
12466 MM_ERROR Indicates that the application has detected a fault. Produces
12467 the string "ERROR".
12468 MM_WARNING Indicates a condition that is out of the ordinary, that might
12469 be a problem, and should be watched. Produces the string
12470 "WARNING".
12471 MM_INFO Provides information about a condition that is not in error.
12472 Produces the string "INFO".
12473 MM_NOSEV Indicates that no severity level is supplied for the message.
12474 text Describes the error condition that produced the message. The character string
12475 is not limited to a specific size. If the character string is empty, then the text
12476 produced is unspecified.
12477 action Describes the first step to be taken in the error-recovery process. The fmtmsg() function precedes the action string with the prefix: "TO FIX: ". The action
12478 string is not limited to a specific size.
12480 tag An identifier that references on-line documentation for the message. Suggested usage is that tag includes the label and a unique identifying number.
12481 A sample tag is "XSI:cat:146".
12482
12483 The MSGVERB environment variable (for message verbosity) shall determine for fmtmsg() which message components it is to select when writing messages to standard error. The value of
12484 MSGVERB shall be a colon-separated list of optional keywords. Valid keywords are: label, severity, text, action, and tag. If MSGVERB contains a keyword for a component and the
12485 component’s value is not the component’s null value, fmtmsg() shall include that component in
12486 the message when writing the message to standard error. If MSGVERB does not include a
12487 keyword for a message component, that component shall not be included in the display of the
12488 message. The keywords may appear in any order. If MSGVERB is not defined, if its value is the
12489 null string, if its value is not of the correct format, or if it contains keywords other than the valid
12490 ones listed above, fmtmsg() shall select all components.
12491
12493 MSGVERB shall determine which components are selected for display to standard error. All message components shall be included in console messages.

12496 RETURN VALUE
12497 The fmtmsg() function shall return one of the following values:
12498 MM_OK The function succeeded.
12499 MM_NOTOK The function failed completely.
12500 MM_NOMSG The function was unable to generate a message on standard error, but otherwise succeeded.
12501 MM_NOCON The function was unable to generate a console message, but otherwise succeeded.

12503 ERRORS
12504 None.
EXAMPLES

1. The following example of `fmtmsg()`:

```
fmtmsg(MM_PRINT, "XSI:cat", MM_ERROR, "illegal option",
      "refer to cat in user’s reference manual", "XSI:cat:001")
```

produces a complete message in the specified message format:

```
XSI:cat: ERROR: illegal option
TO FIX: refer to cat in user’s reference manual XSI:cat:001
```

2. When the environment variable `MSGVERB` is set as follows:

```
MSGVERB=severity:text:action
```

and Example 1 is used, `fmtmsg()` produces:

```
ERROR: illegal option
TO FIX: refer to cat in user’s reference manual
```

APPLICATION USAGE

One or more message components may be systematically omitted from messages generated by
an application by using the null value of the argument for that component.

RATIONALE

None.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 4, Version 2.

Issue 5

Moved from X/OPEN UNIX extension to BASE.
NAME
fnmatch — match a filename or a pathname

SYNOPSIS
#include <fnmatch.h>

int fnmatch(const char *pattern, const char *string, int flags);

DESCRIPTION
The fnmatch() function shall match patterns as described in the Shell and Utilities volume of
IEEE Std 1003.1-2001, Section 2.13.1, Patterns Matching a Single Character, and Section 2.13.2,
Patterns Matching Multiple Characters. It checks the string specified by the string argument to
see if it matches the pattern specified by the pattern argument.

The flags argument shall modify the interpretation of pattern and string. It is the bitwise-inclusive
OR of zero or more of the flags defined in <fnmatch.h>. If the FNM_PATHNAME flag is set in
flags, then a slash character ('/') in string shall be explicitly matched by a slash in pattern; it shall
not be matched by either the asterisk or question-mark special characters, nor by a bracket
expression. If the FNM_PATHNAME flag is not set, the slash character shall be treated as an
ordinary character.

If FNM_NOESCAPE is not set in flags, a backslash character ('\') in pattern followed by any
other character shall match that second character in string. In particular, "\" shall match a
backslash in string. If FNM_NOESCAPE is set, a backslash character shall be treated as an
ordinary character.

If FNM_PERIOD is set in flags, then a leading period ('.') in string shall match a period in
pattern; as described by rule 2 in the Shell and Utilities volume of IEEE Std 1003.1-2001, Section
2.13.3, Patterns Used for Filename Expansion where the location of ‘‘leading’’ is indicated by the
value of FNM_PATHNAME:

• If FNM_PATHNAME is set, a period is ‘‘leading’’ if it is the first character in string or if it
  immediately follows a slash.

• If FNM_PATHNAME is not set, a period is ‘‘leading’’ only if it is the first character of string.

If FNM_PERIOD is not set, then no special restrictions are placed on matching a period.

RETURN VALUE
If string matches the pattern specified by pattern, then fnmatch() shall return 0. If there is no
match, fnmatch() shall return FNM_NOMATCH, which is defined in <fnmatch.h>. If an error
occurs, fnmatch() shall return another non-zero value.

ERRORS
No errors are defined.

EXAMPLES
None.

APPLICATION USAGE
The fnmatch() function has two major uses. It could be used by an application or utility that
needs to read a directory and apply a pattern against each entry. The find utility is an example of
this. It can also be used by the pax utility to process its pattern operands, or by applications that
need to match strings in a similar manner.

The name fnmatch() is intended to imply filename match, rather than pathname match. The default
action of this function is to match filenames, rather than pathnames, since it gives no special
significance to the slash character. With the FNM_PATHNAME flag, fnmatch() does match
pathnames, but without tilde expansion, parameter expansion, or special treatment for a period
at the beginning of a filename.

**RATIONALE**
This function replaced the REG_FILENAME flag of `regcomp()` in early proposals of this volume of IEEE Std 1003.1-2001. It provides virtually the same functionality as the `regcomp()` and `regexec()` functions using the REG_FILENAME and REG_FSLASH flags (the REG_FSLASH flag was proposed for `regcomp()`), and would have had the opposite effect from FNM_PATHNAME), but with a simpler function and less system overhead.

**FUTURE DIRECTIONS**
None.

**SEE ALSO**
`glob()`, `wordexp()`, the Base Definitions volume of IEEE Std 1003.1-2001, `<fnmatch.h>`, the Shell and Utilities volume of IEEE Std 1003.1-2001

**CHANGE HISTORY**

Issue 5
Moved from POSIX2 C-language Binding to BASE.
NAME
fopen — open a stream

SYNOPSIS
#include <stdio.h>

FILE *fopen(const char *restrict filename, const char *restrict mode);

DESCRIPTION
The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-2001 defers to the ISO C standard.

The fopen() function shall open the file whose pathname is the string pointed to by filename, and associates a stream with it.

The mode argument points to a string. If the string is one of the following, the file shall be opened in the indicated mode. Otherwise, the behavior is undefined.

r or rb  Open file for reading.
w or wb  Truncate to zero length or create file for writing.
a or ab  Append; open or create file for writing at end-of-file.
r+ or rb+ or r+b  Open file for update (reading and writing).
w+ or wb+ or w+b  Truncate to zero length or create file for update.
a+ or ab+ or a+b  Append; open or create file for update, writing at end-of-file.

The character 'b' shall have no effect, but is allowed for ISO C standard conformance. Opening a file with read mode (r as the first character in the mode argument) shall fail if the file does not exist or cannot be read.

Opening a file with append mode (a as the first character in the mode argument) shall cause all subsequent writes to the file to be forced to the then current end-of-file, regardless of intervening calls to fseek().

When a file is opened with update mode ('+' as the second or third character in the mode argument), both input and output may be performed on the associated stream. However, the application shall ensure that output is not directly followed by input without an intervening call to fflush() or to a file positioning function (fseek(), fsetpos(), or rewind()), and input is not directly followed by output without an intervening call to a file positioning function, unless the input operation encounters end-of-file.

When opened, a stream is fully buffered if and only if it can be determined not to refer to an interactive device. The error and end-of-file indicators for the stream shall be cleared.

If mode is w, wb, a, ab, w+, wb+, w+b, a+, ab+, or a+b, and the file did not previously exist, upon successful completion, the fopen() function shall mark for update the st_atime, st_ctime, and st_mtime fields of the file and the st_ctime and st_mtime fields of the parent directory.

If mode is w, wb, w+, wb+, or w+b, and the file did previously exist, upon successful completion, fopen() shall mark for update the st_ctime and st_mtime fields of the file. The fopen() function shall allocate a file descriptor as open() does.

After a successful call to the fopen() function, the orientation of the stream shall be cleared, the encoding rule shall be cleared, and the associated mbstate_t object shall be set to describe an initial conversion state.
The largest value that can be represented correctly in an object of type `off_t` shall be established as the offset maximum in the open file description.

**RETURN VALUE**

Upon successful completion, `fopen()` shall return a pointer to the object controlling the stream. Otherwise, a null pointer shall be returned, and `errno` shall be set to indicate the error.

**ERRORS**

The `fopen()` function shall fail if:

- **[EACCES]** Search permission is denied on a component of the path prefix, or the file exists and the permissions specified by `mode` are denied, or the file does not exist and write permission is denied for the parent directory of the file to be created.

- **[EINTR]** A signal was caught during `fopen()`.

- **[EISDIR]** The named file is a directory and `mode` requires write access.

- **[ELOOP]** A loop exists in symbolic links encountered during resolution of the `path` argument.

- **[EMFILE]** [OPEN_MAX] file descriptors are currently open in the calling process.

- **[ENAMETOOLONG]**
  
  The length of the `filename` argument exceeds [PATH_MAX] or a pathname component is longer than [NAME_MAX].

- **[ENFILE]** The maximum allowable number of files is currently open in the system.

- **[ENOENT]** A component of `filename` does not name an existing file or `filename` is an empty string.

- **[ENOSPC]** The directory or file system that would contain the new file cannot be expanded, the file does not exist, and the file was to be created.

- **[ENOTDIR]** A component of the path prefix is not a directory.

- **[ENXIO]** The named file is a character special or block special file, and the device associated with this special file does not exist.

- **[EOVERFLOW]** The named file is a regular file and the size of the file cannot be represented correctly in an object of type `off_t`.

- **[EROFS]** The named file resides on a read-only file system and `mode` requires write access.

The `fopen()` function may fail if:

- **[EINVAL]** The value of the `mode` argument is not valid.

- **[ELOOP]** More than [SYMLOOP_MAX] symbolic links were encountered during resolution of the `path` argument.

- **[EMFILE]** [FOPEN_MAX] streams are currently open in the calling process.

- **[EMFILE]** [STREAM_MAX] streams are currently open in the calling process.

- **[ENAMETOOLONG]**
  
  Pathname resolution of a symbolic link produced an intermediate result whose length exceeds [PATH_MAX].
EXAMPLES

Opening a File

The following example tries to open the file named file for reading. The \texttt{fopen()} function returns a file pointer that is used in subsequent \texttt{fgets()} and \texttt{fclose()} calls. If the program cannot open the file, it just ignores it.

\begin{verbatim}
#include <stdio.h>
...
FILE *fp;
...
void rgrep(const char *file)
{
  ...
  if ((fp = fopen(file, "r")) == NULL)
    return;
  ...
}
\end{verbatim}

APPLICATION USAGE

None.

RATIONALE

None.

FUTURE DIRECTIONS

None.

SEE ALSO

\texttt{fclose()}, \texttt{fdopen()}, \texttt{freopen()}, the Base Definitions volume of IEEE Std 1003.1-2001, \texttt{<stdio.h>}

CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 5

Large File Summit extensions are added.

Issue 6

Extensions beyond the ISO C standard are marked.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- In the DESCRIPTION, text is added to indicate setting of the offset maximum in the open file description. This change is to support large files.
- In the ERRORS section, the [EOVERFLOW] condition is added. This change is to support large files.
- The [ELOOP] mandatory error condition is added.
- The [EINVAL], [EMFILE], [ENAMETOOLONG], [ENOMEM], and [ETXTBSY] optional error conditions are added.
The DESCRIPTION is updated to avoid use of the term “must” for application requirements.

The following changes are made for alignment with the ISO/IEC 9899:1999 standard:

- The prototype for `fopen()` is updated.
- The DESCRIPTION is updated to note that if the argument `mode` points to a string other than those listed, then the behavior is undefined.
- The wording of the mandatory [ELOOP] error condition is updated, and a second optional [ELOOP] error condition is added.
NAME
fork — create a new process

SYNOPSIS
#include <unistd.h>

pid_t fork(void);

DESCRIPTION
The fork() function shall create a new process. The new process (child process) shall be an exact
copy of the calling process (parent process) except as detailed below:

• The child process shall have a unique process ID.
• The child process ID also shall not match any active process group ID.
• The child process shall have a different parent process ID, which shall be the process ID of
  the calling process.
• The child process shall have its own copy of the parent’s file descriptors. Each of the child’s
  file descriptors shall refer to the same open file description with the corresponding file
  descriptor of the parent.
• The child process shall have its own copy of the parent’s open directory streams. Each open
  directory stream in the child process may share directory stream positioning with the
  corresponding directory stream of the parent.
• The child process shall have its own copy of the parent’s message catalog descriptors.

XSI
• All semadj values shall be cleared.

XSI
• File locks set by the parent process shall not be inherited by the child process.
• The set of signals pending for the child process shall be initialized to the empty set.
• Interval timers shall be reset in the child process.
• Any semaphores that are open in the parent process shall also be open in the child process.
• The child process shall not inherit any address space memory locks established by the parent
  process via calls to mlockall() or mlock().

MF | SHM
• Memory mappings created in the parent shall be retained in the child process.
• MAP_PRIVATE mappings inherited from the parent shall also be MAP_PRIVATE mappings
  in the child, and any modifications to the data in these mappings made by the parent prior to
  calling fork() shall be visible to the child. Any modifications to the data in MAP_PRIVATE
  mappings made by the parent after fork() returns shall be visible only to the parent.
  Modifications to the data in MAP_PRIVATE mappings made by the child shall be visible only
  to the child.

PS
• For the SCHED_FIFO and SCHED_RR scheduling policies, the child process shall inherit the
  policy and priority settings of the parent process during a fork() function. For other
  scheduling policies, the policy and priority settings on fork() are implementation-defined.

TMR
• Per-process timers created by the parent shall not be inherited by the child process.

MSG
• The child process shall have its own copy of the message queue descriptors of the parent.
  Each of the message descriptors of the child shall refer to the same open message queue
description as the corresponding message descriptor of the parent.

• No asynchronous input or asynchronous output operations shall be inherited by the child process.

• A process shall be created with a single thread. If a multi-threaded process calls `fork()`, the new process shall contain a replica of the calling thread and its entire address space, possibly including the states of mutexes and other resources. Consequently, to avoid errors, the child process may only execute async-signal-safe operations until such time as one of the `exec` functions is called. Fork handlers may be established by means of the `pthread_atfork()` function in order to maintain application invariants across `fork()` calls.

When the application calls `fork()` from a signal handler and any of the fork handlers registered by `pthread_atfork()` calls a function that is not async-signal-safe, the behavior is undefined.

• If the Trace option and the Trace Inherit option are both supported:
  - If the calling process was being traced in a trace stream that had its inheritance policy set to POSIX_TRACE_INHERITED, the child process shall be traced into that trace stream, and the child process shall inherit the parent’s mapping of trace event names to trace event type identifiers. If the trace stream in which the calling process was being traced had its inheritance policy set to POSIX_TRACE_CLOSE_FOR_CHILD, the child process shall not be traced into that trace stream. The inheritance policy is set by a call to the `posix_trace_attr_setinherited()` function.

• If the Trace option is supported, but the Trace Inherit option is not supported:
  - The child process shall not be traced into any of the trace streams of its parent process.

• If the Trace option is supported, the child process of a trace controller process shall not control the trace streams controlled by its parent process.

• The initial value of the CPU-time clock of the child process shall be set to zero.

• The initial value of the CPU-time clock of the single thread of the child process shall be set to zero.

All other process characteristics defined by IEEE Std 1003.1-2001 shall be the same in the parent and child processes. The inheritance of process characteristics not defined by IEEE Std 1003.1-2001 is unspecified by IEEE Std 1003.1-2001.

After `fork()`, both the parent and the child processes shall be capable of executing independently before either one terminates.

Upon successful completion, `fork()` shall return 0 to the child process and shall return the process ID of the child process to the parent process. Both processes shall continue to execute from the `fork()` function. Otherwise, −1 shall be returned to the parent process, no child process shall be created, and `errno` shall be set to indicate the error.

The `fork()` function shall fail if:

[EAGAIN] The system lacked the necessary resources to create another process, or the system-imposed limit on the total number of processes under execution system-wide or by a single user [CHILD_MAX] would be exceeded.
The `fork()` function may fail if:

- `[ENOMEM]` Insufficient storage space is available.

**EXAMPLES**

None.

**APPLICATION USAGE**

None.

**RATIONALE**

Many historical implementations have timing windows where a signal sent to a process group (for example, an interactive SIGINT) just prior to or during execution of `fork()` is delivered to the parent following the `fork()` but not to the child because the `fork()` code clears the child’s set of pending signals. This volume of IEEE Std 1003.1-2001 does not require, or even permit, this behavior. However, it is pragmatic to expect that problems of this nature may continue to exist in implementations that appear to conform to this volume of IEEE Std 1003.1-2001 and pass available verification suites. This behavior is only a consequence of the implementation failing to make the interval between signal generation and delivery totally invisible. From the application’s perspective, a `fork()` call should appear atomic. A signal that is generated prior to the `fork()` should be delivered prior to the `fork()`. A signal sent to the process group after the `fork()` should be delivered to both parent and child. The implementation may actually initialize internal data structures corresponding to the child’s set of pending signals to include signals sent to the process group during the `fork()`. Since the `fork()` call can be considered as atomic from the application’s perspective, the set would be initialized as empty and such signals would have arrived after the `fork()`; see also `<signal.h>`.

One approach that has been suggested to address the problem of signal inheritance across `fork()` is to add an `[EINTR]` error, which would be returned when a signal is detected during the call. While this is preferable to losing signals, it was not considered an optimal solution. Although it is not recommended for this purpose, such an error would be an allowable extension for an implementation.

The `[ENOMEM]` error value is reserved for those implementations that detect and distinguish such a condition. This condition occurs when an implementation detects that there is not enough memory to create the process. This is intended to be returned when `[EAGAIN]` is inappropriate because there can never be enough memory (either primary or secondary storage) to perform the operation. Since `fork()` duplicates an existing process, this must be a condition where there is sufficient memory for one such process, but not for two. Many historical implementations actually return `[ENOMEM]` due to temporary lack of memory, a case that is not generally distinct from `[EAGAIN]` from the perspective of a conforming application.

Part of the reason for including the optional error `[ENOMEM]` is because the SVID specifies it and it should be reserved for the error condition specified there. The condition is not applicable on many implementations.

IEEE Std 1003.1-1988 neglected to require concurrent execution of the parent and child of `fork()`. A system that single-threads processes was clearly not intended and is considered an unacceptable “toy implementation” of this volume of IEEE Std 1003.1-2001. The only objection anticipated to the phrase “executing independently” is testability, but this assertion should be testable. Such tests require that both the parent and child can block on a detectable action of the other, such as a write to a pipe or a signal. An interactive exchange of such actions should be possible for the system to conform to the intent of this volume of IEEE Std 1003.1-2001.

The `[EAGAIN]` error exists to warn applications that such a condition might occur. Whether it occurs or not is not in any practical sense under the control of the application because the condition is usually a consequence of the user’s use of the system, not of the application’s code.
Thus, no application can or should rely upon its occurrence under any circumstances, nor should the exact semantics of what concept of “user” is used be of concern to the application writer. Validation writers should be cognizant of this limitation.

There are two reasons why POSIX programmers call `fork()`. One reason is to create a new thread of control within the same program (which was originally only possible in POSIX by creating a new process); the other is to create a new process running a different program. In the latter case, the call to `fork()` is soon followed by a call to one of the `exec` functions.

The general problem with making `fork()` work in a multi-threaded world is what to do with all of the threads. There are two alternatives. One is to copy all of the threads into the new process. This causes the programmer or implementation to deal with threads that are suspended on system calls or that might be about to execute system calls that should not be executed in the new process. The other alternative is to copy only the thread that calls `fork()`. This creates the difficulty that the state of process-local resources is usually held in process memory. If a thread that is not calling `fork()` holds a resource, that resource is never released in the child process because the thread whose job it is to release the resource does not exist in the child process.

When a programmer is writing a multi-threaded program, the first described use of `fork()`, creating new threads in the same program, is provided by the `pthread_create()` function. The `fork()` function is thus used only to run new programs, and the effects of calling functions that require certain resources between the call to `fork()` and the call to an `exec` function are undefined.

The addition of the `forkall()` function to the standard was considered and rejected. The `forkall()` function lets all the threads in the parent be duplicated in the child. This essentially duplicates the state of the parent in the child. This allows threads in the child to continue processing and allows locks and the state to be preserved without explicit `pthread_atfork()` code. The calling process has to ensure that the threads processing state that is shared between the parent and child (that is, file descriptors or MAP_SHARED memory) behaves properly after `forkall()`.

For example, if a thread is reading a file descriptor in the parent when `forkall()` is called, then two threads (one in the parent and one in the child) are reading the file descriptor after the `forkall()`. If this is not desired behavior, the parent process has to synchronize with such threads before calling `forkall()`.

While the `fork()` function is async-signal-safe, there is no way for an implementation to determine whether the fork handlers established by `pthread_atfork()` are async-signal-safe. The fork handlers may attempt to execute portions of the implementation that are not async-signal-safe, such as those that are protected by mutexes, leading to a deadlock condition. It is therefore undefined for the fork handlers to execute functions that are not async-signal-safe when `fork()` is called from a signal handler.

When `forkall()` is called, threads, other than the calling thread, that are in functions that can return with an [EINTR] error may have those functions return [EINTR] if the implementation cannot ensure that the function behaves correctly in the parent and child. In particular, `pthread_cond_wait()` and `pthread_cond_timedwait()` need to return in order to ensure that the condition has not changed. These functions can be awakened by a spurious condition wakeup rather than returning [EINTR].

**FUTURE DIRECTIONS**

None.

fork()

CHANGE HISTORY
First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 5
The DESCRIPTION is changed for alignment with the POSIX Realtime Extension and the POSIX Threads Extension.

Issue 6
The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The requirement to include <sys/types.h> has been removed. Although <sys/types.h> was required for conforming implementations of previous POSIX specifications, it was not required for UNIX applications.

The following changes were made to align with the IEEE P1003.1a draft standard:

- The effect of fork() on a pending alarm call in the child process is clarified.

The description of CPU-time clock semantics is added for alignment with IEEE Std 1003.1d-1999.

The description of tracing semantics is added for alignment with IEEE Std 1003.1q-2000.

IEEE Std 1003.1-2001/Cor 1-2002, item XSH/TC1/D6/17 is applied, adding text to the DESCRIPTION and RATIONALE relating to fork handlers registered by the pthread_atfork() function and async-signal safety.
NAME

fpathconf, pathconf — get configurable pathname variables

SYNOPSIS

#include <unistd.h>

long fpathconf(int fildes, int name);
l long pathconf(const char *path, int name);

DESCRIPTION

The fpathconf() and pathconf() functions shall determine the current value of a configurable limit
or option (variable) that is associated with a file or directory.

For pathconf(), the path argument points to the pathname of a file or directory.

For fpathconf(), the fildes argument is an open file descriptor.

The name argument represents the variable to be queried relative to that file or directory.

Implementations shall support all of the variables listed in the following table and may support
others. The variables in the following table come from <limits.h> or <unistd.h> and the
symbolic constants, defined in <unistd.h>, are the corresponding values used for name.

Requirements

1. If path or fildes refers to a directory, the value returned shall apply to the directory itself.
2. If path or fildes does not refer to a terminal file, it is unspecified whether an implementation
   supports an association of the variable name with the specified file.
3. If path or fildes refers to a directory, the value returned shall apply to filenames within the
directory.
4. If path or fildes does not refer to a directory, it is unspecified whether an implementation
   supports an association of the variable name with the specified file.
5. If path or fildes refers to a directory, the value returned shall be the maximum length of a relative pathname when the specified directory is the working directory.

6. If path refers to a FIFO, or fildes refers to a pipe or FIFO, the value returned shall apply to the referenced object. If path or fildes refers to a directory, the value returned shall apply to any FIFO that exists or can be created within the directory. If path or fildes refers to any other type of file, it is unspecified whether an implementation supports an association of the variable name with the specified file.

7. If path or fildes refers to a directory, the value returned shall apply to any files, other than directories, that exist or can be created within the directory.

8. If path or fildes refers to a directory, it is unspecified whether an implementation supports an association of the variable name with the specified file.

9. If path or fildes refers to a directory, the value returned shall be the maximum length of the string that a symbolic link in that directory can contain.

RETURN VALUE
If name is an invalid value, both pathconf() and fpathconf() shall return −1 and set errno to indicate the error.

If the variable corresponding to name has no limit for the path or file descriptor, both pathconf() and fpathconf() shall return −1 without changing errno. If the implementation needs to use path to determine the value of name and the implementation does not support the association of name with the file specified by path, or if the process did not have appropriate privileges to query the file specified by path, or path does not exist, pathconf() shall return −1 and set errno to indicate the error.

If the implementation needs to use fildes to determine the value of name and the implementation does not support the association of name with the file specified by fildes, or if fildes is an invalid file descriptor, fpathconf() shall return −1 and set errno to indicate the error.

Otherwise, pathconf() or fpathconf() shall return the current variable value for the file or directory without changing errno. The value returned shall not be more restrictive than the corresponding value available to the application when it was compiled with the implementation’s <limits.h> or <unistd.h>.

ERRORS
The pathconf() function shall fail if:

- [EINVAL] The value of name is not valid.
- [ELOOP] A loop exists in symbolic links encountered during resolution of the path argument.

The pathconf() function may fail if:

- [EACCES] Search permission is denied for a component of the path prefix.
- [EINVAL] The implementation does not support an association of the variable name with the specified file.
- [ELOOP] More than [SYMLOOP_MAX] symbolic links were encountered during resolution of the path argument.
- [ENAMETOOLONG] The length of the path argument exceeds [PATH_MAX] or a pathname component is longer than [NAME_MAX].
fpathconf(

[ENAMETOOLONG] As a result of encountering a symbolic link in resolution of the path argument, the length of the substituted pathname string exceeded \{PATH_MAX\}.

[ENOENT] A component of path does not name an existing file or path is an empty string.

[ENOTDIR] A component of the path prefix is not a directory.

The fpathconf() function shall fail if:

[EINVAL] The value of name is not valid.

The fpathconf() function may fail if:

[EBADF] The fildes argument is not a valid file descriptor.

[EINVAL] The implementation does not support an association of the variable name with the specified file.

EXAMPLES None.

APPLICATION USAGE None.

RATIONALE The pathconf() function was proposed immediately after the sysconf() function when it was realized that some configurable values may differ across file system, directory, or device boundaries.

For example, \{NAME_MAX\} frequently changes between System V and BSD-based file systems; System V uses a maximum of 14, BSD 255. On an implementation that provides both types of file systems, an application would be forced to limit all pathname components to 14 bytes, as this would be the value specified in <limits.h> on such a system.

Therefore, various useful values can be queried on any pathname or file descriptor, assuming that the appropriate permissions are in place.

The value returned for the variable \{PATH_MAX\} indicates the longest relative pathname that could be given if the specified directory is the process' current working directory. A process may not always be able to generate a name that long and use it if a subdirectory in the pathname crosses into a more restrictive file system.

The value returned for the variable _POSIX_CHOWN_RESTRICTED also applies to directories that do not have file systems mounted on them. The value may change when crossing a mount point, so applications that need to know should check for each directory. (An even easier check is to try the chown() function and look for an error in case it happens.)

Unlike the values returned by sysconf(), the pathname-oriented variables are potentially more volatile and are not guaranteed to remain constant throughout the process' lifetime. For example, in between two calls to pathconf(), the file system in question may have been unmounted and remounted with different characteristics.

Also note that most of the errors are optional. If one of the variables always has the same value on an implementation, the implementation need not look at path or fildes to return that value and is, therefore, not required to detect any of the errors except the meaning of [EINVAL] that indicates that the value of name is not valid for that variable.

If the value of any of the limits is unspecified (logically infinite), they will not be defined in <limits.h> and the pathconf() and fpathconf() functions return -1 without changing errno. This can be distinguished from the case of giving an unrecognized name argument because errno is set
to [EINVAL] in this case.

Since −1 is a valid return value for the pathconf() and fpathconf() functions, applications should set errno to zero before calling them and check errno only if the return value is −1.

For the case of {SYMLINK_MAX}, since both pathconf() and open() follow symbolic links, there is no way that path or fildes could refer to a symbolic link.

FUTURE DIRECTIONS
None.

CHANGE HISTORY
First released in Issue 3. Included for alignment with the POSIX.1-1988 standard.

Issue 5
The DESCRIPTION is updated for alignment with the POSIX Realtime Extension.

Large File Summit extensions are added.

Issue 6
The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

• The DESCRIPTION is updated to include {FILESIZEBITS},
• The [ELOOP] mandatory error condition is added.
• A second [ENAMETOOLONG] is added as an optional error condition.

The following changes were made to align with the IEEE P1003.1a draft standard:

• The _PC_SYMLINK_MAX entry is added to the table in the DESCRIPTION.

The following pathconf() variables and their associated names are added for alignment with IEEE Std 1003.1d-1999:

[POSIX_ALLOC_SIZE_MIN]
[POSIX_REC_INCR_XFER_SIZE]
[POSIX_REC_MAX_XFER_SIZE]
[POSIX_REC_MIN_XFER_SIZE]
[POSIX_REC_XFER_ALIGN]

IEEE Std 1003.1-2001/Cor 1-2002, item XSH/TC1/D6/18 is applied, changing the fourth paragraph of the DESCRIPTION and removing shading and margin markers from the table. This change is needed since implementations are required to support all of these symbols.
NAME
fpclassify — classify real floating type

SYNOPSIS
#include <math.h>
int fpclassify(real-floating x);

DESCRIPTION
CX
The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-2001 defers to the ISO C standard.

The fpclassify() macro shall classify its argument value as NaN, infinite, normal, subnormal, zero, or into another implementation-defined category. First, an argument represented in a format wider than its semantic type is converted to its semantic type. Then classification is based on the type of the argument.

RETURN VALUE
The fpclassify() macro shall return the value of the number classification macro appropriate to the value of its argument.

ERRORS
No errors are defined.

EXAMPLES
None.

APPLICATION USAGE
None.

RATIONALE
None.

FUTURE DIRECTIONS

CHANGE HISTORY
NAME
fprintf, printf, snprintf, sprintf — print formatted output

SYNOPSIS
#include <stdio.h>

int fprintf(FILE *restrict stream, const char *restrict format, ...);
int printf(const char *restrict format, ...);
int snprintf(char *restrict s, size_t n, const char *restrict format, ...);
int sprintf(char *restrict s, const char *restrict format, ...);

DESCRIPTION
The functionality described on this reference page is aligned with the ISO C standard. Any
conflict between the requirements described here and the ISO C standard is unintentional. This

The fprintf() function shall place output on the named output stream. The printf() function shall
place output on the standard output stream stdout. The sprintf() function shall place output
followed by the null byte, '\0', in consecutive bytes starting at *s; it is the user's responsibility
to ensure that enough space is available.

The snprintf() function shall be equivalent to sprintf(), with the addition of the n argument
which states the size of the buffer referred to by s. If n is zero, nothing shall be written and s may
be a null pointer. Otherwise, output bytes beyond the n-1st shall be discarded instead of being
written to the array, and a null byte is written at the end of the bytes actually written into the
array.

If copying takes place between objects that overlap as a result of a call to sprintf() or snprintf(),
the results are undefined.

Each of these functions converts, formats, and prints its arguments under control of the format.
The format is a character string, beginning and ending in its initial shift state, if any. The format is
composed of zero or more directives: ordinary characters, which are simply copied to the output
stream, and conversion specifications, each of which shall result in the fetching of zero or more
arguments. The results are undefined if there are insufficient arguments for the format. If the
format is exhausted while arguments remain, the excess arguments shall be evaluated but are
otherwise ignored.

Conversions can be applied to the n-th argument after the format in the argument list, rather than
to the next unused argument. In this case, the conversion specifier character % (see below) is
replaced by the sequence "%n$", where n is a decimal integer in the range [1, {NL_ARGMAX}],
giving the position of the argument in the argument list. This feature provides for the definition
of format strings that select arguments in an order appropriate to specific languages (see the
EXAMPLES section).

The format can contain either numbered argument conversion specifications (that is, "%n$" and
"*n$"), or unnumbered argument conversion specifications (that is, % and *), but not both. The
only exception to this is that % can be mixed with the "%n$" form. The results of mixing
numbered and unnumbered argument specifications in a format string are undefined. When
numbered argument specifications are used, specifying the N-th argument requires that all the
leading arguments, from the first to the (N-1)th, are specified in the format string.

In format strings containing the "%n$" form of conversion specification, numbered arguments
in the argument list can be referenced from the format string as many times as required.

In format strings containing the % form of conversion specification, each conversion specification
uses the first unused argument in the argument list.
All forms of the `fprintf()` functions allow for the insertion of a language-dependent radix character in the output string. The radix character is defined in the program’s locale (category `LC_NUMERIC`). In the POSIX locale, or in a locale where the radix character is not defined, the radix character shall default to a period ('.').

Each conversion specification is introduced by the '%' character or by the character sequence "%n$", after which the following appear in sequence:

- Zero or more flags (in any order), which modify the meaning of the conversion specification.
- An optional minimum field width. If the converted value has fewer bytes than the field width, it shall be padded with spaces by default on the left; it shall be padded on the right if the left-adjustment flag ('-'), described below, is given to the field width. The field width takes the form of an asterisk ('*'), described below, or a decimal integer.
- An optional precision that gives the minimum number of digits to appear for the d, i, o, u, x, and X conversion specifiers; the number of digits to appear after the radix character for the a, A, e, E, f, and F conversion specifiers; the maximum number of significant digits for the g and G conversion specifiers; or the maximum number of bytes to be printed from a string in the s and S conversion specifiers. The precision takes the form of a period ('.') followed either by an asterisk ('*'), described below, or an optional decimal digit string, where a null digit string is treated as zero. If a precision appears with any other conversion specifier, the behavior is undefined.
- An optional length modifier that specifies the size of the argument.
- A conversion specifier character that indicates the type of conversion to be applied.

A field width, or precision, or both, may be indicated by an asterisk ('*'). In this case an argument of type `int` supplies the field width or precision. Applications shall ensure that arguments specifying field width, or precision, or both appear in that order before the argument, if any, to be converted. A negative field width is taken as a '−' flag followed by a positive field width. A negative precision is taken as if the precision were omitted. In format strings containing the "%n$" form of a conversion specification, a field width or precision may be indicated by the sequence "*m$", where m is a decimal integer in the range [1,NL_ARGMAX] giving the position in the argument list (after the format argument) of an integer argument containing the field width or precision, for example:

```c
printf("%1$d:%2$.*3$d:%4$.*3$d\n", hour, min, precision, sec);
```

The flag characters and their meanings are:

- `'` The integer portion of the result of a decimal conversion (%i, %d, %u, %f, %F, %g, or %G) shall be formatted with thousands' grouping characters. For other conversions the behavior is undefined.
- `-` The result of the conversion shall be left-justified within the field. The conversion is right-justified if this flag is not specified.
- `+` The result of a signed conversion shall always begin with a sign ('+' or '−'). The conversion shall begin with a sign only when a negative value is converted if this flag is not specified.
- `<space>` If the first character of a signed conversion is not a sign or if a signed conversion results in no characters, a <space> shall be prefixed to the result. This means that if the <space> and '+' flags both appear, the <space> flag shall be ignored.
- `#` Specifies that the value is to be converted to an alternative form. For o conversion, it increases the precision (if necessary) to force the first digit of the result to be zero. For x
or X conversion specifiers, a non-zero result shall have 0x (or 0X) prefixed to it. For a, A, 
e, E, F, g, and G conversion specifiers, the result shall always contain a radix 
character, even if no digits follow the radix character. Without this flag, a radix 
character appears in the result of these conversions only if a digit follows it. For g and G 
conversion specifiers, trailing zeros shall not be removed from the result as they 
normally are. For other conversion specifiers, the behavior is undefined.

For d, i, o, u, x, X, a, A, e, E, F, P, g, and G conversion specifiers, leading zeros 
(following any indication of sign or base) are used to pad to the field width; no space 
padding is performed. If the ‘0’ and ‘−’ flags both appear, the ‘0’ flag is ignored. For 
d, i, o, u, x, and X conversion specifiers, if a precision is specified, the ‘0’ flag is 
ignored. If the ‘0’ and ‘+’ flags both appear, the grouping characters are inserted 
before zero padding. For other conversions, the behavior is undefined.

The length modifiers and their meanings are:

- hh: Specifies that a following d, i, o, u, x, or X conversion specifier applies to a signed char 
or unsigned char argument (the argument will have been promoted according to the 
integer promotions, but its value shall be converted to signed char or unsigned char 
before printing); or that a following n conversion specifier applies to a pointer to a 
signed char argument.

- h: Specifies that a following d, i, o, u, x, or X conversion specifier applies to a short or 
unsigned short argument (the argument will have been promoted according to the 
integer promotions, but its value shall be converted to short or unsigned short before 
printing); or that a following n conversion specifier applies to a pointer to a short 
argument.

- l (ell): Specifies that a following d, i, o, u, x, or X conversion specifier applies to a long or 
unsigned long argument; that a following n conversion specifier applies to a pointer to 
a long argument; that a following c conversion specifier applies to a wint_t argument; 
that a following s conversion specifier applies to a pointer to a wchar_t argument; or 
has no effect on a following a, A, e, E, f, F, g, or G conversion specifier.

- ll (ell-ell): Specifies that a following d, i, o, u, x, or X conversion specifier applies to a long long or 
unsigned long long argument; or that a following n conversion specifier applies to a 
pointer to a long long argument.

- j: Specifies that a following d, i, o, u, x, or X conversion specifier applies to an intmax_t 
or uintmax_t argument; or that a following n conversion specifier applies to a pointer 
to an intmax_t argument.

- z: Specifies that a following d, i, o, u, x, or X conversion specifier applies to a size_t or the 
corresponding signed integer type argument; or that a following n conversion specifier 
applies to a pointer to a signed integer type corresponding to a size_t argument.

- t: Specifies that a following d, i, o, u, x, or X conversion specifier applies to a ptrdiff_t or 
the corresponding unsigned type argument; or that a following n conversion specifier 
applies to a pointer to a ptrdiff_t argument.

- L: Specifies that a following a, A, e, E, f, F, g, or G conversion specifier applies to a long 
double argument.

If a length modifier appears with any conversion specifier other than as specified above, the 
behavior is undefined.
The conversion specifiers and their meanings are:

- **d, i**  The `int` argument shall be converted to a signed decimal in the style "[-] ddd\(d\). The precision specifies the minimum number of digits to appear; if the value being converted can be represented in fewer digits, it shall be expanded with leading zeros. The default precision is 1. The result of converting zero with an explicit precision of zero shall be no characters.

- **o**  The `unsigned` argument shall be converted to unsigned octal format in the style "dddd\(d\). The precision specifies the minimum number of digits to appear; if the value being converted can be represented in fewer digits, it shall be expanded with leading zeros. The default precision is 1. The result of converting zero with an explicit precision of zero shall be no characters.

- **u**  The `unsigned` argument shall be converted to unsigned decimal format in the style "dddd\(d\). The precision specifies the minimum number of digits to appear; if the value being converted can be represented in fewer digits, it shall be expanded with leading zeros. The default precision is 1. The result of converting zero with an explicit precision of zero shall be no characters.

- **x**  The `unsigned` argument shall be converted to unsigned hexadecimal format in the style "dddd\(d\); the letters "abcde\(f\) are used. The precision specifies the minimum number of digits to appear; if the value being converted can be represented in fewer digits, it shall be expanded with leading zeros. The default precision is 1. The result of converting zero with an explicit precision of zero shall be no characters.

- **X**  Equivalent to the x conversion specifier, except that letters "ABCDEF\(i\) are used instead of "abcde\(f\".

- **f, F**  The `double` argument shall be converted to decimal notation in the style "[-] ddd.ddd\(d\), where there is one digit before the radix character (which is non-zero if the argument is non-zero) and the number of digits after it is equal to the precision specification. If the precision is missing, it shall be taken as 6; if the precision is explicitly zero and no '#' flag is present, no radix character shall appear. If a radix character appears, at least one digit appears before it. The low-order digit shall be rounded in an implementation-defined manner.

  A `double` argument representing an infinity shall be converted in one of the styles "[-] inf\(n\) or "[-] infinity\(n\)", which style is implementation-defined. A `double` argument representing a NaN shall be converted in one of the styles "[-] nan\(n\- char-sequence\)" or "[-] nan\(n\)"; which style, and the meaning of any n-char-sequence, is implementation-defined. The F conversion specifier produces "INF\(n\), "INFINITY\(n\), or "NAN\(n\) instead of "inf\(n\), "infinity\(n\), or "nan\(n\), respectively.

- **e, E**  The `double` argument shall be converted in the style "[-] d. ddeedd\(d\), where there is one digit before the radix character (which is non-zero if the argument is non-zero) and the number of digits after it is equal to the precision; if the precision is missing, it shall be taken as 6; if the precision is zero and no '#' flag is present, no radix character shall appear. The low-order digit shall be rounded in an implementation-defined manner.

  The E conversion specifier shall produce a number with 'E' instead of 'e' introducing the exponent. The exponent shall always contain at least two digits. If the value is zero, the exponent shall be zero.

  A `double` argument representing an infinity or NaN shall be converted in the style of an f or F conversion specifier.

- **g, G**  The `double` argument shall be converted in the style f or e (or in the style F or E in the case of a G conversion specifier), with the precision specifying the number of significant digits to appear.
digits. If an explicit precision is zero, it shall be taken as 1. The style used depends on
the value converted; style e (or E) shall be used only if the exponent resulting from
such a conversion is less than −4 or greater than or equal to the precision. Trailing zeros
shall be removed from the fractional portion of the result; a radix character shall appear
only if it is followed by a digit or a ‘#’ flag is present.

A **double** argument representing an infinity or NaN shall be converted in the style of
an f or F conversion specifier.

A **double** argument representing a floating-point number shall be converted in the
style "[-]*0xh.hhhhp±d", where there is one hexadecimal digit (which shall be non-
zero if the argument is a normalized floating-point number and is otherwise
unspecified) before the decimal-point character and the number of hexadecimal digits
after it is equal to the precision; if the precision is missing and FLT_RADIX is a power
of 2, then the precision shall be sufficient for an exact representation of the value; if the
precision is missing and FLT_RADIX is not a power of 2, then the precision shall be
sufficient to distinguish values of type **double**, except that trailing zeros may be
omitted; if the precision is zero and the ‘#’ flag is not specified, no decimal-point
character shall appear. The letters "abcdef" shall be used for a conversion and the
letters "ABCDEF" for A conversion. The A conversion specifier produces a number with
‘X’ and ‘P’ instead of ‘x’ and ‘p’. The exponent shall always contain at least one
digit, and only as many more digits as necessary to represent the decimal exponent of
2. If the value is zero, the exponent shall be zero.

A **double** argument representing an infinity or NaN shall be converted in the style of
an f or F conversion specifier.

The **int** argument shall be converted to an **unsigned char**, and the resulting byte shall
be written.

If an l (ell) qualifier is present, the **wint_t** argument shall be converted as if by an ls
conversion specification with no precision and an argument that points to a two-
element array of type **wchar_t**, the first element of which contains the **wint_t** argument
to the ls conversion specification and the second element contains a null wide
character.

The argument shall be a pointer to an array of **char**. Bytes from the array shall be
written up to (but not including) any terminating null byte. If the precision is specified,
no more than that many bytes shall be written. If the precision is not specified or is
greater than the size of the array, the application shall ensure that the array contains a
null byte.

If an l (ell) qualifier is present, the argument shall be a pointer to an array of type
**wchar_t**. Wide characters from the array shall be converted to characters (each as if by
a call to the **wcrtomb()** function, with the conversion state described by an **mbstate_t**
object initialized to zero before the first wide character is converted) up to and
including a terminating null wide character. The resulting characters shall be written
up to (but not including) the terminating null character (byte). If no precision is
specified, the application shall ensure that the array contains a null wide character. If a
precision is specified, no more than that many characters (bytes) shall be written
(including shift sequences, if any), and the array shall contain a null wide character if,
to equal the character sequence length given by the precision, the function would need
to access a wide character one past the end of the array. In no case shall a partial
character be written.
The argument shall be a pointer to `void`. The value of the pointer is converted to a sequence of printable characters, in an implementation-defined manner.

The argument shall be a pointer to an integer into which is written the number of bytes written to the output so far by this call to one of the `fprintf()` functions. No argument is converted.

C  Equivalent to `lc`.

S  Equivalent to `ls`.

Print a `'%'` character; no argument is converted. The complete conversion specification shall be `%%`.

If a conversion specification does not match one of the above forms, the behavior is undefined. If any argument is not the correct type for the corresponding conversion specification, the behavior is undefined.

In no case shall a nonexistent or small field width cause truncation of a field; if the result of a conversion is wider than the field width, the field shall be expanded to contain the conversion result. Characters generated by `fprintf()` and `printf()` are printed as if `fputc()` had been called.

For the `a` and `A` conversion specifiers, if FLT_RADIX is a power of 2, the value shall be correctly rounded to a hexadecimal floating number with the given precision.

For `a` and `A` conversions, if FLT_RADIX is not a power of 2 and the result is not exactly representable in the given precision, the result should be one of the two adjacent numbers in hexadecimal floating style with the given precision, with the extra stipulation that the error should have a correct sign for the current rounding direction.

For the `e`, `E`, `f`, `g`, and `G` conversion specifiers, if the number of significant decimal digits is at most DECIMAL_DIG, then the result should be correctly rounded. If the number of significant decimal digits is more than DECIMAL_DIG but the source value is exactly representable with DECIMAL_DIG digits, then the result should be an exact representation with trailing zeros.

Otherwise, the source value is bounded by two adjacent decimal strings $L < U$, both having DECIMAL_DIG significant digits; the value of the resultant decimal string $D$ should satisfy $L \leq D \leq U$, with the extra stipulation that the error should have a correct sign for the current rounding direction.

The `st_cTime` and `st_mtime` fields of the file shall be marked for update between the call to a successful execution of `fprintf()` or `printf()` and the next successful completion of a call to `fflush()` or `fclose()` on the same stream or a call to `exit()` or `abort()`.

Upon successful completion, the `fprintf()` and `printf()` functions shall return the number of bytes transmitted.

Upon successful completion, the `sprintf()` function shall return the number of bytes written to `s`, excluding the terminating null byte.

Upon successful completion, the `snprintf()` function shall return the number of bytes that would be written to `s` had `n` been sufficiently large excluding the terminating null byte.

If an output error was encountered, these functions shall return a negative value.

If the value of `n` is zero on a call to `snprintf()`, nothing shall be written, the number of bytes that would have been written had `n` been sufficiently large excluding the terminating null shall be returned, and `s` may be a null pointer.
For the conditions under which `fprintf()` and `printf()` fail and may fail, refer to `fputc()` or `fputwc()`.

In addition, all forms of `fprintf()` may fail if:

- **[EILSEQ]** A wide-character code that does not correspond to a valid character has been detected.
- **[EINVAL]** There are insufficient arguments.

The `printf()` and `fprintf()` functions may fail if:

- **[ENOMEM]** Insufficient storage space is available.

The `snprintf()` function shall fail if:

- **[EOVERFLOW]** The value of `n` is greater than `INT_MAX` or the number of bytes needed to hold the output excluding the terminating null is greater than `INT_MAX`.

### EXAMPLES

#### Printing Language-Independent Date and Time

The following statement can be used to print date and time using a language-independent format:

```c
printf(format, weekday, month, day, hour, min);
```

For American usage, `format` could be a pointer to the following string:

```c
"%s, %s %d, %d:%.2d
"
```

This example would produce the following message:

**Sunday, July 3, 10:02**

For German usage, `format` could be a pointer to the following string:

```c
"%1$s, %3$d. %2$s, %4$d:%5$.2d
"
```

This definition of `format` would produce the following message:

**Sonntag, 3. Juli, 10:02**

#### Printing File Information

The following example prints information about the type, permissions, and number of links of a specific file in a directory.

The first two calls to `printf()` use data decoded from a previous `stat()` call. The user-defined `strperm()` function shall return a string similar to the one at the beginning of the output for the following command:

```bash
ls -l
```

The next call to `printf()` outputs the owner’s name if it is found using `getpwuid()`; the `getpwuid()` function shall return a `passwd` structure from which the name of the user is extracted. If the user name is not found, the program instead prints out the numeric value of the user ID.

The next call prints out the group name if it is found using `getgrgid()`; `getgrgid()` is very similar to `getpwuid()` except that it shall return group information based on the group number. Once again, if the group is not found, the program prints the numeric value of the group for the entry.
The final call to `printf()` prints the size of the file.

```c
#include <stdio.h>
#include <sys/types.h>
#include <pwd.h>
#include <grp.h>

char *strperm (mode_t);
...
struct stat statbuf;
struct passwd *pwd;
struct group *grp;
...
printf("%10.10s", strperm (statbuf.st_mode));
printf("%4d", statbuf.st_nlink);
if ((pwd = getpwuid(statbuf.st_uid)) != NULL)
    printf(" %−8.8s", pwd->pw_name);
else
    printf(" %−8ld", (long) statbuf.st_uid);
if ((grp = getgrgid(statbuf.st_gid)) != NULL)
    printf(" %−8.8s", grp->gr_name);
else
    printf(" %−8ld", (long) statbuf.st_gid);
printf("%9jd", (intmax_t) statbuf.st_size);
...
```

**Printing a Localized Date String**

The following example gets a localized date string. The `nl_langinfo()` function shall return the localized date string, which specifies the order and layout of the date. The `strftime()` function takes this information and, using the `tm` structure for values, places the date and time information into `datestring`. The `printf()` function then outputs `datestring` and the name of the entry.

```c
#include <stdio.h>
#include <time.h>
#include <langinfo.h>
...
struct dirent *dp;
struct tm *tm;
char datestring[256];
...
strftime(datestring, sizeof(datestring), nl_langinfo (D_T_FMT), tm);
printf(" %s %s
", datestring, dp->d_name);
...
```
Printing Error Information

The following example uses `fprintf()` to write error information to standard error.

In the first group of calls, the program tries to open the password lock file named `LOCKFILE`. If the file already exists, this is an error, as indicated by the `O_EXCL` flag on the `open()` function. If the call fails, the program assumes that someone else is updating the password file, and the program exits.

The next group of calls saves a new password file as the current password file by creating a link between `LOCKFILE` and the new password file `PASSWDFILE`.

```c
#include <sys/types.h>
#include <sys/stat.h>
#include <fcntl.h>
#include <stdio.h>
#include <stdlib.h>
#include <unistd.h>
#include <string.h>
#include <errno.h>
#define LOCKFILE "/etc/ptmp"
#define PASSWDFILE "/etc/passwd"
...
int pfd;
...
if ((pfd = open(LOCKFILE, O_WRONLY | O_CREAT | O_EXCL, 
    S_IRUSR | S_IWUSR | S_IRGRP | S_IROTH)) == -1)
{
    fprintf(stderr, "Cannot open /etc/ptmp. Try again later.\n");
    exit(1);
}
...
if (link(LOCKFILE,PASSWDFILE) == -1) {
    fprintf(stderr, "Link error: %s\n", strerror(errno));
    exit(1);
}
...
```

Printing Usage Information

The following example checks to make sure the program has the necessary arguments, and uses `fprintf()` to print usage information if the expected number of arguments is not present.

```c
#include <stdio.h>
#include <stdlib.h>
...
char *Options = "hdbtl";
...
if (argc < 2) {
    fprintf(stderr, "Usage: %s -%s <file\n", argv[0], Options); exit(1);
}
```
Formatting a Decimal String

The following example prints a key and data pair on stdout. Note use of the ‘*’ (asterisk) in the format string; this ensures the correct number of decimal places for the element based on the number of elements requested.

```c
#include <stdio.h>
...
long i;
char *keystr;
int elementlen, len;
...
while (len < elementlen) {
  ...
  printf("%s Element%0*1d\n", keystr, elementlen, i);
  ...
}
```

Creating a Filename

The following example creates a filename using information from a previous getpwnam() function that returned the HOME directory of the user.

```c
#include <stdio.h>
#include <sys/types.h>
#include <unistd.h>
...
char filename[PATH_MAX+1];
struct passwd *pw;
...
sprintf(filename, "%s/%d.out", pw->pw_dir, getpid());
```

Reporting an Event

The following example loops until an event has timed out. The pause() function waits forever unless it receives a signal. The fprintf() statement should never occur due to the possible return values of pause().

```c
#include <stdio.h>
#include <unistd.h>
#include <string.h>
#include <errno.h>
...
while (!event_complete) {
  ...
  if (pause() != -1 || errno != EINTR)
    fprintf(stderr, "pause: unknown error: %s\n", strerror(errno));
}
```
Printing Monetary Information

The following example uses `strfmon()` to convert a number and store it as a formatted monetary string named `convbuf`. If the first number is printed, the program prints the format and the description; otherwise, it just prints the number.

```c
#include <monetary.h>
#include <stdio.h>

... 
struct tblfmt {
    char *format;
    char *description;
}

struct tblfmt table[] = {
    { "%n", "default formatting" },
    { "%11n", "right align within an 11 character field" },
    { "%#5n", "aligned columns for values up to 99999" },
    { "%=*#5n", "specify a fill character" },
    { "=%0#5n", "fill characters do not use grouping" },
    { "%=5.0n", "round off to whole units" },
    { "%=5.4n", "increase the precision" },
    { "%(#5n", "use an alternative pos/neg style" },
    { "%!(#5n", "disable the currency symbol" },
    { "%\n", "disable the grouping separator" },
    { "%\n", "round off to whole units" },
    { "%\n", "use an alternative pos/neg style" },
    { "%\n", "disable the currency symbol" },
};

... 
float input[3];
int i, j;
char convbuf[100];

... 
strfmon(convbuf, sizeof(convbuf), table[i].format, input[j]);

if (j == 0) {
    printf("%s\n", table[i].description);
}
else {
    printf("%s\n", convbuf);
}
... 
```

Printing Wide Characters

The following example prints a series of wide characters. Suppose that "L'@'" expands to three bytes:

```c
wchar_t wz [3] = L"@@";  // Zero-terminated
wchar_t wn [3] = L"@@@";  // Unterminated

fprintf (stdout,"%ls", wz);  // Outputs 6 bytes
fprintf (stdout,"%ls", wn);  // Undefined because wn has no terminator
fprintf (stdout,"%ls", wz);  // Outputs 3 bytes
fprintf (stdout,"%ls", wn);  // Outputs 3 bytes; no terminator needed
fprintf (stdout,"%ls", wz);  // Outputs 6 bytes
```
fprintf( )

13600  fprintf (stdout,"%9ls", wn); // Outputs 9 bytes; no terminator needed
13601  fprintf (stdout,"%10ls", wz); // Outputs 6 bytes
13602  fprintf (stdout,"%10ls", wn); // Undefined because wn has no terminator
13603  In the last line of the example, after processing three characters, nine bytes have been output.
13604  The fourth character must then be examined to determine whether it converts to one byte or
13605  more. If it converts to more than one byte, the output is only nine bytes. Since there is no fourth
13606  character in the array, the behavior is undefined.
13607
APPLICATION USAGE
13608  If the application calling fprintf() has any objects of type wint_t or wchar_t, it must also include
13609  the <wchar.h> header to have these objects defined.
13610
RATIONALE
13611  None.

13617
CHANGE HISTORY
13618  First released in Issue 1. Derived from Issue 1 of the SVID.
13619
Issue 5
13620  Aligned with ISO/IEC 9899:1990/Amendment 1:1995 (E). Specifically, the l (ell) qualifier can
13621  now be used with c and s conversion specifiers.
13622  The snprintf() function is new in Issue 5.
13623
Issue 6
13624  Extensions beyond the ISO C standard are marked.
13625  The DESCRIPTION is updated to avoid use of the term “must” for application requirements.
13626  The following changes are made for alignment with the ISO/IEC 9899:1999 standard:
13627  • The prototypes for fprintf(), printf(), snprintf(), and sprintf() are updated, and the XSI
13628  shading is removed from snprintf().
13629  • The description of snprintf() is aligned with the ISO C standard. Note that this supersedes
13630  the snprintf() description in The Open Group Base Resolution bwg98-006, which changed the
13631  behavior from Issue 5.
13632  • The DESCRIPTION is updated.
13633  The DESCRIPTION is updated to use the terms “conversion specifier” and “conversion
13634  specification” consistently.
13636  An example of printing wide characters is added.
NAME
fputc — put a byte on a stream

SYNOPSIS
#include <stdio.h>
int fputc(int c, FILE *stream);

DESCRIPTION
The functionality described on this reference page is aligned with the ISO C standard. Any
conflict between the requirements described here and the ISO C standard is unintentional. This
The fputc() function shall write the byte specified by c (converted to an unsigned char) to the
output stream pointed to by stream, at the position indicated by the associated file-position
indicator for the stream (if defined), and shall advance the indicator appropriately. If the file
cannot support positioning requests, or if the stream was opened with append mode, the byte
shall be appended to the output stream.
The st_ctime and st_mtime fields of the file shall be marked for update between the successful
execution of fputc() and the next successful completion of a call to fflush() or fclose() on the same
stream or a call to exit() or abort().

RETURN VALUE
Upon successful completion, fputc() shall return the value it has written. Otherwise, it shall
return EOF, the error indicator for the stream shall be set, and errno shall be set to indicate the
error.

ERRORS
The fputc() function shall fail if either the stream is unbuffered or the stream’s buffer needs to be
flushed, and:

[EAGAIN] The O_NONBLOCK flag is set for the file descriptor underlying stream and the
process would be delayed in the write operation.
[EBADF] The file descriptor underlying stream is not a valid file descriptor open for
writing.
[EFBIG] An attempt was made to write to a file that exceeds the maximum file size.
[EFBIG] An attempt was made to write to a file that exceeds the process’ file size limit.
[EFBIG] The file is a regular file and an attempt was made to write at or beyond the
offset maximum.
[EINTR] The write operation was terminated due to the receipt of a signal, and no data
was transferred.
[EIO] A physical I/O error has occurred, or the process is a member of a
background process group attempting to write to its controlling terminal,
TOSTOP is set, the process is neither ignoring nor blocking SIGTTOU, and the
process group of the process is orphaned. This error may also be returned
under implementation-defined conditions.
[ENOSPC] There was no free space remaining on the device containing the file.
[EPipe] An attempt is made to write to a pipe or FIFO that is not open for reading by
any process. A SIGPIPE signal shall also be sent to the thread.
The `fputc()` function may fail if:

- [ENOMEM] Insufficient storage space is available.
- [ENXIO] A request was made of a nonexistent device, or the request was outside the capabilities of the device.

**Applications Usage**
None.

**Rationale**
None.

**Future Directions**
None.

**See Also**
- `ferror()`, `fopen()`, `getrlimit()`, `putc()`, `puts()`, `setbuf()`, `ulimit()`, the Base Definitions volume of IEEE Std 1003.1-2001, `<stdio.h>`

**Change History**
First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 5
Large File Summit extensions are added.

Issue 6
Extensions beyond the ISO C standard are marked.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:
- The [EIO] and [EFBIG] mandatory error conditions are added.
- The [ENOMEM] and [ENXIO] optional error conditions are added.
NAME
fputs — put a string on a stream

SYNOPSIS
#include <stdio.h>

int fputs(const char *restrict s, FILE *restrict stream);

DESCRIPTION
The functionality described on this reference page is aligned with the ISO C standard. Any
conflict between the requirements described here and the ISO C standard is unintentional. This

The fputs() function shall write the null-terminated string pointed to by s to the stream pointed
to by stream. The terminating null byte shall not be written.

The st_ctime and st_mtime fields of the file shall be marked for update between the successful
execution of fputs() and the next successful completion of a call to fflush() or fclose() on the same
stream or a call to exit() or abort().

RETURN VALUE
Upon successful completion, fputs() shall return a non-negative number. Otherwise, it shall
return EOF, set an error indicator for the stream, and set errno to indicate the error.

ERRORS
Refer to fputc().

EXAMPLES

Printing to Standard Output

The following example gets the current time, converts it to a string using localtime() and
asctime(), and prints it to standard output using fputs(). It then prints the number of minutes to
an event for which it is waiting.

#include <time.h>
#include <stdio.h>
...
time_t now;
int minutes_to_event;
...
time(&now);
printf("The time is ");
fputs(asctime(localtime(&now)), stdout);
printf("There are still %d minutes to the event.\n",
minutes_to_event);
...

APPLICATION USAGE
The puts() function appends a <newline> while fputs() does not.

RATIONALE
None.

FUTURE DIRECTIONS
None.

fopen(), putc(), puts(), the Base Definitions volume of IEEE Std 1003.1-2001, <stdio.h>

CHANGE HISTORY
First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 6
Extensions beyond the ISO C standard are marked.

The fputs() prototype is updated for alignment with the ISO/IEC 9899:1999 standard.
NAME
fputwc — put a wide-character code on a stream

SYNOPSIS
#include <stdio.h>
#include <wchar.h>

wint_t fputwc(wchar_t wc, FILE *stream);

DESCRIPTION
The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-2001 defers to the ISO C standard.

The fputwc() function shall write the character corresponding to the wide-character code wc to the output stream pointed to by stream, at the position indicated by the associated file-position indicator for the stream (if defined), and advances the indicator appropriately. If the file cannot support positioning requests, or if the stream was opened with append mode, the character is appended to the output stream. If an error occurs while writing the character, the shift state of the output file is left in an undefined state.

CX The st_ctime and st_mtime fields of the file shall be marked for update between the successful execution of fputwc() and the next successful completion of a call to fflush() or fclose() on the same stream or a call to exit() or abort().

RETURN VALUE
Upon successful completion, fputwc() shall return wc. Otherwise, it shall return WEOF, the error indicator for the stream shall be set, and errno shall be set to indicate the error.

ERRORS
The fputwc() function shall fail if either the stream is unbuffered or data in the stream’s buffer needs to be written, and:

CX [EAGAIN] The O_NONBLOCK flag is set for the file descriptor underlying stream and the process would be delayed in the write operation.

CX [EBADF] The file descriptor underlying stream is not a valid file descriptor open for writing.

CX [EFBIG] An attempt was made to write to a file that exceeds the maximum file size or the process’ file size limit.

CX [EFBIG] The file is a regular file and an attempt was made to write at or beyond the offset maximum associated with the corresponding stream.

CX [EILSEQ] The wide-character code wc does not correspond to a valid character.

CX [EINTR] The write operation was terminated due to the receipt of a signal, and no data was transferred.

CX [EIO] A physical I/O error has occurred, or the process is a member of a background process group attempting to write to its controlling terminal, TOSTOP is set, the process is neither ignoring nor blocking SIGTTOU, and the process group of the process is orphaned. This error may also be returned under implementation-defined conditions.

CX [ENOSPC] There was no free space remaining on the device containing the file.

CX [EPipe] An attempt is made to write to a pipe or FIFO that is not open for reading by any process. A SIGPIPE signal shall also be sent to the thread.
The \fputwc\( )\ function may fail if:

- [ENOMEM] Insufficient storage space is available.
- [ENXIO] A request was made of a nonexistent device, or the request was outside the capabilities of the device.

**EXAMPLES**

**APPLICATION USAGE**

None.

**RATIONALE**

None.

**FUTURE DIRECTIONS**

None.

**SEE ALSO**

\ferror\( )\, \fopen\( )\, \setbuf\( )\, \ulimit\( )\), the Base Definitions volume of IEEE Std 1003.1-2001, <stdio.h>, <wchar.h>

**CHANGE HISTORY**

First released in Issue 4. Derived from the MSE working draft.

**Issue 5**

Aligned with ISO/IEC 9899:1990/Amendment 1:1995 (E). Specifically, the type of argument \(wc\) is changed from \wint_t\ to \wchar_t\.

The Optional Header (OH) marking is removed from <stdio.h>.

Large File Summit extensions are added.

**Issue 6**

Extensions beyond the ISO C standard are marked.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The [EFBIG] and [EIO] mandatory error conditions are added.
- The [ENOMEM] and [ENXIO] optional error conditions are added.
**NAME**

fputws — put a wide-character string on a stream

**SYNOPSIS**

```c
#include <stdio.h>
#include <wchar.h>
int fputws(const wchar_t *restrict ws, FILE *restrict stream);
```

**DESCRIPTION**

The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-2001 defers to the ISO C standard.

The `fputws()` function shall write a character string corresponding to the (null-terminated) wide-character string pointed to by `ws` to the stream pointed to by `stream`. No character corresponding to the terminating null wide-character code shall be written.

The `st_atime` and `st_mtime` fields of the file shall be marked for update between the successful execution of `fputws()` and the next successful completion of a call to `fflush()` or `fclose()` on the same stream or a call to `exit()` or `abort()`.

**RETURN VALUE**

Upon successful completion, `fputws()` shall return a non-negative number. Otherwise, it shall return −1, set an error indicator for the stream, and set `errno` to indicate the error.

**ERRORS**

Refer to `fputc()`.

**EXAMPLES**

None.

**APPLICATION USAGE**

The `fputws()` function does not append a `<newline>`.

**RATIONALE**

None.

**FUTURE DIRECTIONS**

None.

**SEE ALSO**

`fopen()`, the Base Definitions volume of IEEE Std 1003.1-2001, `<stdio.h>`, `<wchar.h>`

**CHANGE HISTORY**

First released in Issue 4. Derived from the MSE working draft.

**Issue 5**

The Optional Header (OH) marking is removed from `<stdio.h>`.

**Issue 6**

Extensions beyond the ISO C standard are marked.

The `fputws()` prototype is updated for alignment with the ISO/IEC 9899:1999 standard.
NAME
fread — binary input

SYNOPSIS
#include <stdio.h>

size_t fread(void *restrict ptr, size_t size, size_t nitems,
FILE *restrict stream);

DESCRIPTION
The functionality described on this reference page is aligned with the ISO C standard. Any
conflict between the requirements described here and the ISO C standard is unintentional. This

The fread() function shall read into the array pointed to by ptr up to nitems elements whose size
is specified by size in bytes, from the stream pointed to by stream. For each object, size calls shall
be made to the fgetc() function and the results stored, in the order read, in an array of unsigned
char exactly overlaying the object. The file position indicator for the stream (if defined) shall be
advanced by the number of bytes successfully read. If an error occurs, the resulting value of the
file position indicator for the stream is unspecified. If a partial element is read, its value is
unspecified.

The fread() function may mark the st_atime field of the file associated with stream for update. The
st_atime field shall be marked for update by the first successful execution of fgetc(), fgets(),
getwc(), getws(), fread(), fscanf(), getc(), getchar(), gets(), or scanf() using stream that returns
data not supplied by a prior call to ungetc() or ungetwc().

RETURN VALUE
Upon successful completion, fread() shall return the number of elements successfully read which
is less than nitems only if a read error or end-of-file is encountered. If size or nitems is 0, fread()
shall return 0 and the contents of the array and the state of the stream remain unchanged.
Otherwise, if a read error occurs, the error indicator for the stream shall be set, and errno shall be
set to indicate the error.

ERRORS
Refer to fgetc().

EXAMPLES
Reading from a Stream
The following example reads a single element from the fp stream into the array pointed to by buf.

#include <stdio.h>
...
size_t bytes_read;
char buf[100];
FILE *fp;
...
bytes_read = fread(buf, sizeof(buf), 1, fp);
...

APPLICATION USAGE
The ferror() or feof() functions must be used to distinguish between an error condition and an
end-of-file condition.

Because of possible differences in element length and byte ordering, files written using fwrite() are application-dependent, and possibly cannot be read using fread() by a different application.
or by the same application on a different processor.

**RATIONALE**
None.

**FUTURE DIRECTIONS**
None.

**SEE ALSO**
feof(), ferror(), fgetc(), fopen(), gets(), scanf(), the Base Definitions volume of IEEE Std 1003.1-2001, `<stdio.h>`

**CHANGE HISTORY**
First released in Issue 1. Derived from Issue 1 of the SVID.

**Issue 6**
Extensions beyond the ISO C standard are marked.

The following changes are made for alignment with the ISO/IEC 9899: 1999 standard:

- The `fread()` prototype is updated.
- The `fread()` prototype is updated to describe how the bytes from a call to `fgetc()` are stored.
name
free — free allocated memory

synopsis
#include <stdlib.h>

void free(void *ptr);

description
The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-2001 defers to the ISO C standard.

The free() function shall cause the space pointed to by ptr to be deallocated; that is, made available for further allocation. If ptr is a null pointer, no action shall occur. Otherwise, if the argument does not match a pointer earlier returned by the calloc(), malloc(), posix_memalign(), realloc(), or strdup() function, or if the space has been deallocated by a call to free() or realloc(), the behavior is undefined.

Any use of a pointer that refers to freed space results in undefined behavior.

return value
The free() function shall not return a value.

errors
No errors are defined.

descision
There is now no requirement for the implementation to support the inclusion of <malloc.h>.

rationale
None.

future directions
None.

change history
First released in Issue 1. Derived from Issue 1 of the SVID.

issue 6
Reference to the valloc() function is removed.
NAME
freeaddrinfo, getaddrinfo — get address information

SYNOPSIS
#include <sys/socket.h>
#include <netdb.h>

void freeaddrinfo(struct addrinfo *ai);
int getaddrinfo(const char *restrict nodename,
const char *restrict servname,
const struct addrinfo *restrict hints,
struct addrinfo **restrict res);

DESCRIPTION
The freeaddrinfo() function shall free one or more addrinfo structures returned by getaddrinfo(), along with any additional storage associated with those structures. If the ai_next field of the structure is not null, the entire list of structures shall be freed. The freeaddrinfo() function shall support the freeing of arbitrary sublists of an addrinfo list originally returned by getaddrinfo().

The getaddrinfo() function shall translate the name of a service location (for example, a host name) and/or a service name and shall return a set of socket addresses and associated information to be used in creating a socket with which to address the specified service.

Note: In many cases it is implemented by the Domain Name System, as documented in RFC 1034, RFC 1035, and RFC 1886.

The freeaddrinfo() and getaddrinfo() functions shall be thread-safe.

The nodename and servname arguments are either null pointers or pointers to null-terminated strings. One or both of these two arguments shall be supplied by the application as a non-null pointer.

The format of a valid name depends on the address family or families. If a specific family is not given and the name could be interpreted as valid within multiple supported families, the implementation shall attempt to resolve the name in all supported families and, in absence of errors, one or more results shall be returned.

If the nodename argument is not null, it can be a descriptive name or can be an address string. If the specified address family is AF_INET, AF_INET6, or AF_UNSPEC, valid descriptive names include host names. If the specified address family is AF_INET or AF_UNSPEC, address strings using Internet standard dot notation as specified in inet_addr() are valid.

If the specified address family is AF_INET6 or AF_UNSPEC, standard IPv6 text forms described in inet_ntop() are valid.

If the specified address family is AF_INET6 or AF_UNSPEC, standard IPv6 text forms described in inet_ntop() are valid.

If the nodename is not null, the requested service location is named by nodename; otherwise, the requested service location is local to the caller.

If servname is null, the call shall return network-level addresses for the specified nodename. If servname is not null, it is a null-terminated character string identifying the requested service. This can be either a descriptive name or a numeric representation suitable for use with the address family or families. If the specified address family is AF_INET, AF_INET6, or AF_UNSPEC, the service can be specified as a string specifying a decimal port number.

If the hints argument is not null, it refers to a structure containing input values that may direct the operation by providing options and by limiting the returned information to a specific socket type, address family, and/or protocol. In this hints structure every member other than ai_flags, ai_family, ai_socktype, and ai_protocol shall be set to zero or a null pointer. A value of AF_UNSPEC for ai_family means that the caller shall accept any address family. A value of zero
for ai_socktype means that the caller shall accept any socket type. A value of zero for ai_protocol means that the caller shall accept any protocol. If hints is a null pointer, the behavior shall be as if it referred to a structure containing the value zero for the ai_flags, ai_socktype, and ai_protocol fields, and AF_UNSPEC for the ai_family field.

The ai_flags field to which the hints parameter points shall be set to zero or be the bitwise-inclusive OR of one or more of the values AI_PASSIVE, AI_CANONNAME, AI_NUMERICHOST, AI_NUMERICSERV, AI_V4MAPPED, AI_ALL, and AI_ADDRCONFIG.

If the AI_PASSIVE flag is specified, the returned address information shall be suitable for use in binding a socket for accepting incoming connections for the specified service. In this case, if the nodename argument is null, then the IP address portion of the socket address structure shall be set to INADDR_ANY for an IPv4 address or IN6ADDR_ANY_INIT for an IPv6 address. If the AI_PASSIVE flag is not specified, the returned address information shall be suitable for a call to connect() (for a connection-mode protocol) or for a call to connect(), sendto(), or sendmsg() (for a connectionless protocol). In this case, if the nodename argument is null, then the IP address portion of the socket address structure shall be set to the loopback address. The AI_PASSIVE flag shall be ignored if the nodename argument is not null.

If the AI_CANONNAME flag is specified and the nodename argument is not null, the function shall attempt to determine the canonical name corresponding to nodename (for example, if nodename is an alias or shorthand notation for a complete name).

Note: Since different implementations use different conceptual models, the terms “canonical name” and “alias” cannot be precisely defined for the general case. However, Domain Name System implementations are expected to interpret them as they are used in RFC 1034.

A numeric host address string is not a “name”, and thus does not have a “canonical name” form; no address to host name translation is performed. See below for handling of the case where a canonical name cannot be obtained.

If the AI_NUMERICHOST flag is specified, then a non-null nodename string supplied shall be a numeric host address string. Otherwise, an [EAI_NONAME] error is returned. This flag shall prevent any type of name resolution service (for example, the DNS) from being invoked.

If the AI_NUMERICSERV flag is specified, then a non-null servname string supplied shall be a numeric port string. Otherwise, an [EAI_NONAME] error shall be returned. This flag shall prevent any type of name resolution service (for example, NIS+) from being invoked.

IPv6
If the AI_V4MAPPED flag is specified along with an ai_family of AF_INET6, then getaddrinfo() shall return IPv4-mapped IPv6 addresses on finding no matching IPv6 addresses (ai_addrlen shall be 16). The AI_V4MAPPED flag shall be ignored unless ai_family equals AF_INET6. If the AI_ALL flag is used with the AI_V4MAPPED flag, then getaddrinfo() shall return all matching IPv6 and IPv4 addresses. The AI_ALL flag without the AI_V4MAPPED flag is ignored.

If the AI_ADDRCONFIG flag is specified, IPv4 addresses shall be returned only if an IPv4 address is configured on the local system, and IPv6 addresses shall be returned only if an IPv6 address is configured on the local system.

The ai_socktype field to which argument hints points specifies the socket type for the service, as defined in socket(). If a specific socket type is not given (for example, a value of zero) and the service name could be interpreted as valid with multiple supported socket types, the implementation shall attempt to resolve the service name for all supported socket types and, in the absence of errors, all possible results shall be returned. A non-zero socket type value shall limit the returned information to values with the specified socket type.

If the ai_family field to which hints points has the value AF_UNSPEC, addresses shall be returned for use with any address family that can be used with the specified nodename and/or servname. Otherwise, addresses shall be returned for use only with the specified address family.
If `ai_family` is not AF_UNSPEC and `ai_protocol` is not zero, then addresses are returned for use only with the specified address family and protocol; the value of `ai_protocol` shall be interpreted as in a call to the `socket()` function with the corresponding values of `ai_family` and `ai_protocol`.

**RETURN VALUE**

A zero return value for `getaddrinfo()` indicates successful completion; a non-zero return value indicates failure. The possible values for the failures are listed in the ERRORS section.

Upon successful return of `getaddrinfo()`, the location to which `res` points shall refer to a linked list of `addrinfo` structures, each of which shall specify a socket address and information for use in creating a socket with which to use that socket address. The list shall include at least one `addrinfo` structure. The `ai_next` field of each structure contains a pointer to the next structure on the list, or a null pointer if it is the last structure on the list. Each structure on the list shall include values for use with a call to the `socket()` function, and a socket address for use with the `connect()` function or, if the AI_PASSIVE flag was specified, for use with the `bind()` function. The fields `ai_family`, `ai_socktype`, and `ai_protocol` shall be usable as the arguments to the `socket()` function to create a socket suitable for use with the returned address. The fields `ai_addr` and `ai_addrlen` are usable as the arguments to the `connect()` or `bind()` functions with such a socket, according to the AI_PASSIVE flag.

If `nodename` is not null, and if requested by the AI_CANONNAME flag, the `ai_canonname` field of the first returned `addrinfo` structure shall point to a null-terminated string containing the canonical name corresponding to the input `nodename`; if the canonical name is not available, then `ai_canonname` shall refer to the `nodename` argument or a string with the same contents. The contents of the `ai_flags` field of the returned structures are undefined.

All fields in socket address structures returned by `getaddrinfo()` that are not filled in through an explicit argument (for example, `sin6_flowinfo`) shall be set to zero.

**Note:** This makes it easier to compare socket address structures.

**ERRORS**

The `getaddrinfo()` function shall fail and return the corresponding value if:

- [EAI_AGAIN] The name could not be resolved at this time. Future attempts may succeed.
- [EAI_BADFLAGS] The `flags` parameter had an invalid value.
- [EAI_FAIL] A non-recoverable error occurred when attempting to resolve the name.
- [EAI_FAMILY] The address family was not recognized.
- [EAI_MEMORY] There was a memory allocation failure when trying to allocate storage for the return value.
- [EAI_NONAME] The name does not resolve for the supplied parameters.
- [EAI_SERVICE] Neither `nodename` nor `servname` were supplied. At least one of these shall be supplied.
- [EAI_SOCKETTYPE] The service passed was not recognized for the specified socket type.
- [EAI_SYSTEM] A system error occurred; the error code can be found in `errno`.
- [EAI_OVERFLOW] An argument buffer overflowed.
EXAMPLES
None.

APPLICATION USAGE
If the caller handles only TCP and not UDP, for example, then the ai_protocol member of the hints structure should be set to IPPROTO_TCP when getaddrinfo() is called.

If the caller handles only IPv4 and not IPv6, then the ai_family member of the hints structure should be set to AF_INET when getaddrinfo() is called.

The term “canonical name” is misleading; it is taken from the Domain Name System (RFC 2181).

It should be noted that the canonical name is a result of alias processing, and not necessarily a unique attribute of a host, address, or set of addresses. See RFC 2181 for more discussion of this in the Domain Name System context.

RATIONALE
None.

FUTURE DIRECTIONS
None.

SEE ALSO
connect(), gai_strerror(), gethostbyaddr(), getnameinfo(), getservbyname(), socket(), the Base Definitions volume of IEEE Std 1003.1-2001, <netdb.h>, <sys/socket.h>

CHANGE HISTORY
First released in Issue 6. Derived from the XNS, Issue 5.2 specification.

The restrict keyword is added to the getaddrinfo() prototype for alignment with the ISO/IEC 9899:1999 standard.

IEEE Std 1003.1-2001/Cor 1-2002, item XSH/TC1/D6/19 is applied, adding three notes to the DESCRIPTION and adding text to the APPLICATION USAGE related to the term “canonical name”. A reference to RFC 2181 is also added to the Informative References.

IEEE Std 1003.1-2001/Cor 1-2002, item XSH/TC1/D6/20 is applied, making changes for alignment with IPv6. These include the following:

• Adding AI_V4MAPPED, AI_ALL, and AI_ADDRCONFIG to the allowed values for the ai_flags field

• Adding a description of AI_ADDRCONFIG

• Adding a description of the consequences of ignoring the AI_PASSIVE flag.
freopen()

NAME
freopen — open a stream

SYNOPSIS
#include <stdio.h>

FILE *freopen(const char *restrict filename, const char *restrict mode,
              FILE *restrict stream);

DESCRIPTION
The functionality described on this reference page is aligned with the ISO C standard. Any
conflict between the requirements described here and the ISO C standard is unintentional. This

The freopen() function shall first attempt to flush the stream and close any file descriptor
associated with stream. Failure to flush or close the file descriptor successfully shall be ignored.
The error and end-of-file indicators for the stream shall be cleared.

The freopen() function shall open the file whose pathname is the string pointed to by filename and
associate the stream pointed to by stream with it. The mode argument shall be used just as in
fopen().

The original stream shall be closed regardless of whether the subsequent open succeeds.

If filename is a null pointer, the freopen() function shall attempt to change the mode of the stream
to that specified by mode, as if the name of the file currently associated with the stream had been
used. It is implementation-defined which changes of mode are permitted (if any), and under
what circumstances.

After a successful call to the freopen() function, the orientation of the stream shall be cleared, the
encoding rule shall be cleared, and the associated mbstate_t object shall be set to describe an
initial conversion state.

The largest value that can be represented correctly in an object of type off_t shall be established
as the offset maximum in the open file description.

RETURN VALUE
Upon successful completion, freopen() shall return the value of stream. Otherwise, a null pointer
shall be returned, and errno shall be set to indicate the error.

ERRORS
The freopen() function shall fail if:

[EACCES] Search permission is denied on a component of the path prefix, or the file
exists and the permissions specified by mode are denied, or the file does not
exist and write permission is denied for the parent directory of the file to be
created.

[EINTR] A signal was caught during freopen().

[EISDIR] The named file is a directory and mode requires write access.

[ELoop] A loop exists in symbolic links encountered during resolution of the path
argument.

[EMFILE] [OPEN_MAX] file descriptors are currently open in the calling process.

[ENAMETOOLONG] The length of the filename argument exceeds [PATH_MAX] or a pathname
component is longer than [NAME_MAX].
freopen() function may fail if:

- **[EINVAL]** The value of the `mode` argument is not valid.
- **[ENOENT]** A component of `filename` does not name an existing file or `filename` is an empty string.
- **[ENOSPC]** The directory or file system that would contain the new file cannot be expanded, the file does not exist, and it was to be created.
- **[ENOTDIR]** A component of the path prefix is not a directory.
- **[ENXIO]** The named file is a character special or block special file, and the device associated with this special file does not exist.
- **[EOVERFLOW]** The named file is a regular file and the size of the file cannot be represented correctly in an object of type `off_t`.
- **[EROSFS]** The named file resides on a read-only file system and `mode` requires write access.
- **[ENFILE]** The maximum allowable number of files is currently open in the system.
- **[ENOENT]** A component of `filename` does not name an existing file or `filename` is an empty string.
- **[ENOMEM]** Insufficient storage space is available.
- **[ENXIO]** A request was made of a nonexistent device, or the request was outside the capabilities of the device.
- **[ENAMETOOLONG]** Pathname resolution of a symbolic link produced an intermediate result whose length exceeds `{PATH_MAX}`.
- **[ETXTBSY]** The file is a pure procedure (shared text) file that is being executed and `mode` requires write access.
- **[ELOOP]** More than `{SYMLOOP_MAX}` symbolic links were encountered during resolution of the `path` argument.
- **[ENOTDIR]** A component of the path prefix is not a directory.
- **[ENOENT]** A component of `filename` does not name an existing file or `filename` is an empty string.
- **[ENOSPC]** The directory or file system that would contain the new file cannot be expanded, the file does not exist, and it was to be created.
- **[ENOTDIR]** A component of the path prefix is not a directory.
- **[ENXIO]** The named file is a character special or block special file, and the device associated with this special file does not exist.
- **[EOVERFLOW]** The named file is a regular file and the size of the file cannot be represented correctly in an object of type `off_t`.
- **[EROSFS]** The named file resides on a read-only file system and `mode` requires write access.
- **[ENFILE]** The maximum allowable number of files is currently open in the system.

**EXAMPLES**

**Directing Standard Output to a File**

The following example logs all standard output to the `/tmp/logfile` file.

```
#include <stdio.h>
...
FILE *fp;
...
fp = freopen ("/tmp/logfile", "a+", stdout);
...
```

**APPLICATION USAGE**

The `freopen()` function is typically used to attach the preopened streams associated with `stdin`, `stdout`, and `stderr` to other files.

**RATIONALE**

None.
FUTURE DIRECTIONS
None.

SEE ALSO
fclose(), fopen(), fdopen(), mbsinit(), the Base Definitions volume of IEEE Std 1003.1-2001, <stdio.h>

CHANGE HISTORY
First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 5
The DESCRIPTION is updated to indicate that the orientation of the stream is cleared and the conversion state of the stream is set to an initial conversion state by a successful call to the freopen() function.
Large File Summit extensions are added.

Issue 6
Extensions beyond the ISO C standard are marked.
The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:
- In the DESCRIPTION, text is added to indicate setting of the offset maximum in the open file description. This change is to support large files.
- In the ERRORS section, the [EOVERFLOW] condition is added. This change is to support large files.
- The [ELOOP] mandatory error condition is added.
- A second [ENAMETOOLONG] is added as an optional error condition.
- The [EINVAL], [ENOMEM], [ENXIO], and [ETXTBSY] optional error conditions are added.
The following changes are made for alignment with the ISO/IEC 9899:1999 standard:
- The freopen() prototype is updated.
- The DESCRIPTION is updated.
The wording of the mandatory [ELOOP] error condition is updated, and a second optional [ELOOP] error condition is added.
The DESCRIPTION is updated regarding failure to close, changing the “file” to “file descriptor”.

NAME
frexp, frexpf, frexpl — extract mantissa and exponent from a double precision number

SYNOPSIS
#include <math.h>

double frexp(double num, int *exp);
float frexpf(float num, int *exp);
long double frexpl(long double num, int *exp);

DESCRIPTION
The functionality described on this reference page is aligned with the ISO C standard. Any
conflict between the requirements described here and the ISO C standard is unintentional. This
These functions shall break a floating-point number num into a normalized fraction and an
integral power of 2. The integer exponent shall be stored in the int object pointed to by exp.

RETURN VALUE
For finite arguments, these functions shall return the value x, such that x has a magnitude in the
interval \([\frac{1}{2},1)\) or 0, and num equals x times 2 raised to the power *exp.

If num is NaN, a NaN shall be returned, and the value of *exp is unspecified.
If num is ±0, ±0 shall be returned, and the value of *exp shall be 0.
If num is ±Inf, num shall be returned, and the value of *exp is unspecified.

ERRORS
No errors are defined.

EXAMPLES
None.

APPLICATION USAGE
None.

RATIONALE
None.

FUTURE DIRECTIONS

The DESCRIPTION is updated to indicate how an application should check for an error. This
text was previously published in the APPLICATION USAGE section.

Issue 6
The frexpf() and frexpl() functions are added for alignment with the ISO/IEC 9899:1999
standard.
The DESCRIPTION, RETURN VALUE, ERRORS, and APPLICATION USAGE sections are revised to align with the ISO/IEC 9899:1999 standard.

NAME
fscanf, scanf, sscanf — convert formatted input

SYNOPSIS
#include <stdio.h>

int fscanf(FILE *restrict stream, const char *restrict format, ...);
int scanf(const char *restrict format, ...);
int sscanf(const char *restrict s, const char *restrict format, ...);

DESCRIPTION
The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-2001 defers to the ISO C standard.

The fscanf() function shall read from the named input stream. The scanf() function shall read from the standard input stream stdin. The sscanf() function shall read from the string s. Each function reads bytes, interprets them according to a format, and stores the results in its arguments. Each expects, as arguments, a control string format described below, and a set of pointer arguments indicating where the converted input should be stored. The result is undefined if there are insufficient arguments for the format. If the format is exhausted while arguments remain, the excess arguments shall be evaluated but otherwise ignored.

Conversions can be applied to the n-th argument after the format in the argument list, rather than to the next unused argument. In this case, the conversion specifier character % (see below) is replaced by the sequence "%)n$", where n is a decimal integer in the range [1,NL_ARGMAX]. This feature provides for the definition of format strings that select arguments in an order appropriate to specific languages. In format strings containing the "%)n$" form of conversion specifications, it is unspecified whether numbered arguments in the argument list can be referenced from the format string more than once.

The format can contain either form of a conversion specification—that is, % or "%)n$"—but the two forms cannot be mixed within a single format string. The only exception to this is that % or \* can be mixed with the "%)n$" form. When numbered argument specifications are used, specifying the Nth argument requires that all the leading arguments, from the first to the (N-1)th, are pointers.

The fscanf() function in all its forms shall allow detection of a language-dependent radix character in the input string. The radix character is defined in the program's locale (category LC_NUMERIC). In the POSIX locale, or in a locale where the radix character is not defined, the radix character shall default to a period ('.').

The format is a character string, beginning and ending in its initial shift state, if any, composed of zero or more directives. Each directive is composed of one of the following: one or more white-space characters (<space>s, <tab>s, <newline>s, <vertical-tab>s, or <form-feed>s); an ordinary character (neither '\%' nor a white-space character); or a conversion specification. Each conversion specification is introduced by the character '\%' or the character sequence "%)n$", after which the following appear in sequence:

- An optional assignment-suppressing character '\*'.
- An optional non-zero decimal integer that specifies the maximum field width.
- An option length modifier that specifies the size of the receiving object.
- A conversion specifier character that specifies the type of conversion to be applied. The valid conversion specifiers are described below.
The `fscanf()` functions shall execute each directive of the format in turn. If a directive fails, as
detailed below, the function shall return. Failures are described as input failures (due to the
unavailability of input bytes) or matching failures (due to inappropriate input).

A directive composed of one or more white-space characters shall be executed by reading input
until no more valid input can be read, or up to the first byte which is not a white-space character,
which remains unread.

A directive that is an ordinary character shall be executed as follows: the next byte shall be read
from the input and compared with the byte that comprises the directive; if the comparison
shows that they are not equivalent, the directive shall fail, and the differing and subsequent
bytes shall remain unread. Similarly, if end-of-file, an encoding error, or a read error prevents a
counted failure, unless assignment suppression was
character from being read, the directive shall fail.

A directive that is a conversion specification defines a set of matching input sequences, as
described below for each conversion character. A conversion specification shall be executed in
the following steps.

Input white-space characters (as specified by `isspace`()) shall be skipped, unless the conversion
specification includes a `, c, C, or n conversion specifier.

An item shall be read from the input, unless the conversion specification includes an n
conversion specifier. An input item shall be defined as the longest sequence of input bytes (up to
any specified maximum field width, which may be measured in characters or bytes dependent
on the conversion specifier) which is an initial subsequence of a matching sequence. The first
byte, if any, after the input item shall remain unread. If the length of the input item is 0, the
execution of the conversion specification shall fail; this condition is a matching failure, unless
end-of-file, an encoding error, or a read error prevented input from the stream, in which case it is
an input failure.

Except in the case of a `%` conversion specifier, the input item (or, in the case of a `%n` conversion
specification, the count of input bytes) shall be converted to a type appropriate to the conversion
character. If the input item is not a matching sequence, the execution of the conversion
specification fails; this condition is a matching failure. Unless assignment suppression was
indicated by a `'*'`, the result of the conversion shall be placed in the object pointed to by the
first argument following the `format` argument that has not already received a conversion result if
the conversion specification is introduced by `%`, or in the nth argument if introduced by the
character sequence `"%n$"`. If this object does not have an appropriate type, or if the result of the
conversion cannot be represented in the space provided, the behavior is undefined.

The length modifiers and their meanings are:

- `hh` Specifies that a following `d`, `i`, `o`, `u`, `x`, or `n` conversion specifier applies to an
  argument with type pointer to `signed char` or `unsigned char`.
- `h` Specifies that a following `d`, `i`, `o`, `u`, `x`, or `n` conversion specifier applies to an
  argument with type pointer to `short` or `unsigned short`.
- `l` (ell) Specifies that a following `d`, `i`, `o`, `u`, `x`, or `n` conversion specifier applies to an
  argument with type pointer to `long` or `unsigned long`; that a following `a`, `A`, `e`, `E`, `f`, `F`, `g`,
  or `G` conversion specifier applies to an argument with type pointer to `double`; or that a
  following `c`, `s`, or `l` conversion specifier applies to an argument with type pointer to `wchar_t`.
- `ll` (ell-ell) Specifies that a following `d`, `i`, `o`, `u`, `x`, or `n` conversion specifier applies to an
  argument with type pointer to `long long` or `unsigned long long`.

The system interfaces...
fscanf()

j  Specifies that a following d, i, o, u, x, or n conversion specifier applies to an argument with type pointer to intmax_t or uintmax_t.

z  Specifies that a following d, i, o, u, x, or n conversion specifier applies to an argument with type pointer to size_t or the corresponding signed integer type.

t  Specifies that a following d, i, o, u, x, or n conversion specifier applies to an argument with type pointer to ptrdiff_t or the corresponding unsigned type.

L  Specifies that a following a, A, e, E, f, F, g, or G conversion specifier applies to an argument with type pointer to long double.

If a length modifier appears with any conversion specifier other than as specified above, the behavior is undefined.

The following conversion specifiers are valid:

d  Matches an optionally signed decimal integer, whose format is the same as expected for the subject sequence of strtol() with the value 10 for the base argument. In the absence of a size modifier, the application shall ensure that the corresponding argument is a pointer to int.

i  Matches an optionally signed integer, whose format is the same as expected for the subject sequence of strtol() with 0 for the base argument. In the absence of a size modifier, the application shall ensure that the corresponding argument is a pointer to int.

o  Matches an optionally signed octal integer, whose format is the same as expected for the subject sequence of strtoul() with the value 8 for the base argument. In the absence of a size modifier, the application shall ensure that the corresponding argument is a pointer to unsigned.

u  Matches an optionally signed decimal integer, whose format is the same as expected for the subject sequence of strtoul() with the value 10 for the base argument. In the absence of a size modifier, the application shall ensure that the corresponding argument is a pointer to unsigned.

x  Matches an optionally signed hexadecimal integer, whose format is the same as expected for the subject sequence of strtoul() with the value 16 for the base argument. In the absence of a size modifier, the application shall ensure that the corresponding argument is a pointer to unsigned.

a, e, f, g  Matches an optionally signed floating-point number, infinity, or NaN, whose format is the same as expected for the subject sequence of strtod(). In the absence of a size modifier, the application shall ensure that the corresponding argument is a pointer to float.

If the fprintf() family of functions generates character string representations for infinity and NaN (a symbolic entity encoded in floating-point format) to support IEEE Std 754-1985, the fscanf() family of functions shall recognize them as input.

s  Matches a sequence of bytes that are not white-space characters. The application shall ensure that the corresponding argument is a pointer to the initial byte of an array of char, signed char, or unsigned char large enough to accept the sequence and a terminating null character code, which shall be added automatically.

If an l (ell) qualifier is present, the input is a sequence of characters that begins in the initial shift state. Each character shall be converted to a wide character as if by a call to...
the \texttt{mbtowc()} function, with the conversion state described by an \texttt{mbstate_t} object initialized to zero before the first character is converted. The application shall ensure that the corresponding argument is a pointer to an array of \texttt{wchar_t} large enough to accept the sequence and the terminating null wide character, which shall be added automatically.

Matches a non-empty sequence of bytes from a set of expected bytes (the \texttt{scanset}). The normal skip over white-space characters shall be suppressed in this case. The application shall ensure that the corresponding argument is a pointer to the initial byte of an array of \texttt{char}, \texttt{signed char}, or \texttt{unsigned char} large enough to accept the sequence and a terminating null byte, which shall be added automatically.

If an \texttt{ell} (ell) qualifier is present, the input is a sequence of characters that begins in the initial shift state. Each character in the sequence shall be converted to a wide character as if by a call to the \texttt{mbtowc()} function, with the conversion state described by an \texttt{mbstate_t} object initialized to zero before the first character is converted. The application shall ensure that the corresponding argument is a pointer to an array of \texttt{wchar_t} large enough to accept the sequence and the terminating null wide character, which shall be added automatically.

The conversion specification includes all subsequent bytes in the \texttt{format} string up to and including the matching right square bracket (\texttt{'}\lceil\texttt{'}). The bytes between the square brackets (the \texttt{scanset}) comprise the scanset, unless the byte after the left square bracket is a circumflex (\texttt{'}\lceil\texttt{'}\rangle), in which case the scanset contains all bytes that do not appear in the scanlist between the circumflex and the right square bracket. If the conversion specification begins with \texttt{"[\[]}" or \texttt{"[\^\[]"}, the right square bracket is included in the scanlist and the next right square bracket is the matching right square bracket that ends the conversion specification; otherwise, the first right square bracket is the one that ends the conversion specification. If a \texttt{'}\lceil\texttt{'}\rangle is in the scanlist and is not the first character, nor the second where the first character is a \texttt{'}\lceil\texttt{'}\rangle, nor the last character, the behavior is implementation-defined.

Matches a sequence of bytes of the number specified by the field width (1 if no field width is present in the conversion specification). The application shall ensure that the corresponding argument is a pointer to the initial byte of an array of \texttt{char}, \texttt{signed char}, or \texttt{unsigned char} large enough to accept the sequence. No null byte is added. The normal skip over white-space characters shall be suppressed in this case.

If an \texttt{ell} (ell) qualifier is present, the input shall be a sequence of characters that begins in the initial shift state. Each character in the sequence is converted to a wide character as if by a call to the \texttt{mbtowc()} function, with the conversion state described by an \texttt{mbstate_t} object initialized to zero before the first character is converted. The application shall ensure that the corresponding argument is a pointer to an array of \texttt{wchar_t} large enough to accept the resulting sequence of wide characters. No null wide character is added.

Matches an implementation-defined set of sequences, which shall be the same as the set of sequences that is produced by the \texttt{\$p} conversion specification of the corresponding \texttt{fprintf()} functions. The application shall ensure that the corresponding argument is a pointer to a pointer to \texttt{void}. The interpretation of the input item is implementation-defined. If the input item is a value converted earlier during the same program execution, the pointer that results shall compare equal to that value; otherwise, the behavior of the \texttt{\$p} conversion specification is undefined.

No input is consumed. The application shall ensure that the corresponding argument is a pointer to the integer into which shall be written the number of bytes read from the
input so far by this call to the `fscanf()` functions. Execution of a `%n` conversion specification shall not increment the assignment count returned at the completion of execution of the function. No argument shall be converted, but one shall be consumed. If the conversion specification includes an assignment-suppressing character or a field width, the behavior is undefined.

| XSI | Equivalent to `lc`. |
| XSI | Equivalent to `ls`. |

If a conversion specification is invalid, the behavior is undefined.

The conversion specifiers `A`, `E`, `F`, `G`, and `X` are also valid and shall be equivalent to `a`, `e`, `f`, `g`, and `x`, respectively.

If end-of-file is encountered during input, conversion shall be terminated. If end-of-file occurs before any bytes matching the current conversion specification (except for `%n`) have been read (other than leading white-space characters, where permitted), execution of the current conversion specification shall terminate with an input failure. Otherwise, unless execution of the current conversion specification is terminated with a matching failure, execution of the following conversion specification (if any) shall be terminated with an input failure.

Reaching the end of the string in `sscanf()` shall be equivalent to encountering end-of-file for `fscanf()`.

If conversion terminates on a conflicting input, the offending input is left unread in the input. Any trailing white space (including <newline>s) shall be left unread unless matched by a conversion specification. The success of literal matches and suppressed assignments is only directly determinable via the `%n` conversion specification.

The `fscanf()` and `scanf()` functions may mark the `st_atime` field of the file associated with `stream` for update. The `st_atime` field shall be marked for update by the first successful execution of `fgetc()`, `fgets()`, `fread()`, `getc()`, `getchar()`, `gets()`, `fscanf()`, or `fscanf()` using `stream` that returns data not supplied by a prior call to `ungetc()`.

Upon successful completion, these functions shall return the number of successfully matched and assigned input items; this number can be zero in the event of an early matching failure. If the input ends before the first matching failure or conversion, EOF shall be returned. If a read error occurs, the error indicator for the stream is set, EOF shall be returned, and `errno` shall be set to indicate the error.

For the conditions under which the `fscanf()` functions fail and may fail, refer to `fgetc()` or `fgetwc()`.

In addition, `fscanf()` may fail if:

- `[EILSEQ]` Input byte sequence does not form a valid character.
- `[EINVAL]` There are insufficient arguments.
EXAMPLES

The call:

```c
int i, n; float x; char name[50];
n = scanf("%d%f%s", &i, &x, name);
```

with the input line:

```text
25 54.32E-1 Hamster
```

assigns to `n` the value 3, to `i` the value 25, to `x` the value 5.432, and `name` contains the string "Hamster".

The call:

```c
int i; float x; char name[50];
(void) scanf("%2d%f%*d %[0123456789]", &i, &x, name);
```

with input:

```text
56789 0123 56a72
```

assigns 56 to `i`, 789.0 to `x`, skips 0123, and places the string "56\0" in `name`. The next call to `getchar()` shall return the character ’a’.

Reading Data into an Array

The following call uses `fscanf()` to read three floating-point numbers from standard input into the input array.

```c
float input[3]; fscanf (stdin, "%f %f %f", input, input+1, input+2);
```

APPLICATION USAGE

If the application calling `fscanf()` has any objects of type `wint_t` or `wchar_t`, it must also include the `<wchar.h>` header to have these objects defined.

RATIONALE

This function is aligned with the ISO/IEC 9899:1999 standard, and in doing so a few “obvious” things were not included. Specifically, the set of characters allowed in a scanset is limited to single-byte characters. In other similar places, multi-byte characters have been permitted, but for alignment with the ISO/IEC 9899:1999 standard, it has not been done here. Applications needing this could use the corresponding wide-character functions to achieve the desired results.

FUTURE DIRECTIONS

None.

`getc()`, `printf()`, `setlocale()`, `strtod()`, `strtol()`, `strtoul()`, `wcrtomb()`, the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 7, Locale, `<langinfo.h>`, `<stdio.h>`, `<wchar.h>`

CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 5

Aligned with ISO/IEC 9899:1990/Amendment 1:1995 (E). Specifically, the `l` (ell) qualifier is now defined for the `c`, `s`, and `l` conversion specifiers.

The DESCRIPTION is updated to indicate that if infinity and NaN can be generated by the `fprintf()` family of functions, then they are recognized by the `fscanf()` family.
The Open Group Corrigenda U021/7 and U028/10 are applied. These correct several occurrences of “characters” in the text which have been replaced with the term “bytes”.

The DESCRIPTION is updated to avoid use of the term “must” for application requirements.

The following changes are made for alignment with the ISO/IEC 9899:1999 standard:

• The prototypes for `fscanf()`, `scanf()`, and `sscanf()` are updated.

• The DESCRIPTION is updated.

• The `hh`, `ll`, `j`, `t`, and `z` length modifiers are added.

• The `a`, `A`, and `F` conversion characters are added.

The DESCRIPTION is updated to use the terms “conversion specifier” and “conversion specification” consistently.
NAME
fseek, fseeko — reposition a file-position indicator in a stream

SYNOPSIS
#include <stdio.h>

int fseek(FILE *stream, long offset, int whence);

int fseeko(FILE *stream, off_t offset, int whence);

DESCRIPTION
The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-2001 defers to the ISO C standard.

The fseek() function shall set the file-position indicator for the stream pointed to by stream. If a read or write error occurs, the error indicator for the stream shall be set and fseek() fails.

The new position, measured in bytes from the beginning of the file, shall be obtained by adding offset to the position specified by whence. The specified point is the beginning of the file for SEEK_SET, the current value of the file-position indicator for SEEK_CUR, or end-of-file for SEEK_END.

If the stream is to be used with wide-character input/output functions, the application shall ensure that offset is either 0 or a value returned by an earlier call to ftell() on the same stream and whence is SEEK_SET.

A successful call to fseek() shall clear the end-of-file indicator for the stream and undo any effects of ungetc() and ungetwc() on the same stream. After an fseek() call, the next operation on an update stream may be either input or output.

If the most recent operation, other than ftell(), on a given stream is fflush(), the file offset in the underlying open file description shall be adjusted to reflect the location specified by fseek().

The fseek() function shall allow the file-position indicator to be set beyond the end of existing data in the file. If data is later written at this point, subsequent reads of data in the gap shall return bytes with the value 0 until data is actually written into the gap.

The behavior of fseek() on devices which are incapable of seeking is implementation-defined. The value of the file offset associated with such a device is undefined.

If the stream is writable and buffered data had not been written to the underlying file, fseek() shall cause the unwritten data to be written to the file and shall mark the st_ctime and st_mtime fields of the file for update.

In a locale with state-dependent encoding, whether fseek() restores the stream’s shift state is implementation-defined.

The fseeko() function shall be equivalent to the fseek() function except that the offset argument is of type off_t.

RETURN VALUE
The fseek() and fseeko() functions shall return 0 if they succeed.

Otherwise, they shall return −1 and set errno to indicate the error.

ERRORS
The fseek() and fseeko() functions shall fail if, either the stream is unbuffered or the stream’s buffer needed to be flushed, and the call to fseek() or fseeko() causes an underlying lseek() or write() to be invoked, and:

442 System Interfaces, Issue 6 — Copyright © 2001-2003, IEEE and The Open Group. All rights reserved.
The O_NONBLOCK flag is set for the file descriptor and the process would be delayed in the write operation.

The file descriptor underlying the stream file is not open for writing or the stream's buffer needed to be flushed and the file is not open.

An attempt was made to write a file that exceeds the maximum file size.

An attempt was made to write a file that exceeds the process' file size limit.

The file is a regular file and an attempt was made to write at or beyond the offset maximum associated with the corresponding stream.

The write operation was terminated due to the receipt of a signal, and no data was transferred.

The whence argument is invalid. The resulting file-position indicator would be set to a negative value.

A physical I/O error has occurred, or the process is a member of a background process group attempting to perform a write() to its controlling terminal, TOSTOP is set, the process is neither ignoring nor blocking SIGTTOU, and the process group of the process is orphaned. This error may also be returned under implementation-defined conditions.

There was no free space remaining on the device containing the file.

A request was made of a nonexistent device, or the request was outside the capabilities of the device.

For fseek(), the resulting file offset would be a value which cannot be represented correctly in an object of type long.

For fseeko(), the resulting file offset would be a value which cannot be represented correctly in an object of type off_t.

An attempt was made to write to a pipe or FIFO that is not open for reading by any process; a SIGPIPE signal shall also be sent to the thread.

The file descriptor underlying stream is associated with a pipe or FIFO.

First released in Issue 1. Derived from Issue 1 of the SVID.
Issue 5
Normative text previously in the APPLICATION USAGE section is moved to the DESCRIPTION.
Large File Summit extensions are added.

Issue 6
Extensions beyond the ISO C standard are marked.
The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:
- The fseeko() function is added.
- The [EFBIG], [EOVERFLOW], and [ENXIO] mandatory error conditions are added.

The following change is incorporated for alignment with the FIPS requirements:
- The [EINTR] error is no longer an indication that the implementation does not report partial transfers.

The DESCRIPTION is updated to avoid use of the term “must” for application requirements.
The DESCRIPTION is updated to explicitly state that fseek() sets the file-position indicator, and then on error the error indicator is set and fseek() fails. This is for alignment with the ISO/IEC 9899:1999 standard.
NAME
fsetpos — set current file position

SYNOPSIS
#include <stdio.h>

int fsetpos(FILE *stream, const fpos_t *pos);

DESCRIPTION
The functionality described on this reference page is aligned with the ISO C standard. Any
conflict between the requirements described here and the ISO C standard is unintentional. This

The fsetpos() function shall set the file position and state indicators for the stream pointed to by
stream according to the value of the object pointed to by pos, which the application shall ensure
is a value obtained from an earlier call to fgetpos() on the same stream. If a read or write error
occurs, the error indicator for the stream shall be set and fsetpos() fails.

A successful call to the fsetpos() function shall clear the end-of-file indicator for the stream and
undo any effects of ungetc() on the same stream. After an fsetpos() call, the next operation on an
update stream may be either input or output.

The behavior of fsetpos() on devices which are incapable of seeking is implementation-defined.
The value of the file offset associated with such a device is undefined.

RETURN VALUE
The fsetpos() function shall return 0 if it succeeds; otherwise, it shall return a non-zero value and
set errno to indicate the error.

ERRORS
The fsetpos() function shall fail if, either the stream is unbuffered or the stream’s buffer needed to
be flushed, and the call to fsetpos() causes an underlying lseek() or write() to be invoked, and:

[EAGAIN] The O_NONBLOCK flag is set for the file descriptor and the process would be
delayed in the write operation.

[EBADF] The file descriptor underlying the stream file is not open for writing or the
stream’s buffer needed to be flushed and the file is not open.

[EFBIG] An attempt was made to write a file that exceeds the maximum file size.

[EBUSY] An attempt was made to write a file that exceeds the process’ file size limit.

[EFBIG] The file is a regular file and an attempt was made to write at or beyond the
offset maximum associated with the corresponding stream.

[EINTR] The write operation was terminated due to the receipt of a signal, and no data
was transferred.

[EIO] A physical I/O error has occurred, or the process is a member of a
background process group attempting to perform a writet() to its controlling
terminal, TOSTOP is set, the process is neither ignoring nor blocking
SIGTTOU, and the process group of the process is orphaned. This error may
also be returned under implementation-defined conditions.

[ENOSPC] There was no free space remaining on the device containing the file.

[ENXIO] A request was made of a nonexistent device, or the request was outside the
capabilities of the device.
The file descriptor underlying stream is associated with a pipe or FIFO.

An attempt was made to write to a pipe or FIFO that is not open for reading by any process; a SIGPIPE signal shall also be sent to the thread.

CHANGE HISTORY
First released in Issue 4. Derived from the ISO C standard.

Issue 6
Extensions beyond the ISO C standard are marked.

An additional [ESPIPE] error condition is added for sockets.

The DESCRIPTION is updated to avoid use of the term “must” for application requirements.

The DESCRIPTION is updated to clarify that the error indicator is set for the stream on a read or write error. This is for alignment with the ISO/IEC 9899:1999 standard.

NAME
fstat — get file status

SYNOPSIS
#include <sys/stat.h>

int fstat(int fildes, struct stat *buf);

DESCRIPTION
The fstat() function shall obtain information about an open file associated with the file
descriptor fildes, and shall write it to the area pointed to by buf.

If fildes references a shared memory object, the implementation shall update in the stat structure
pointed to by the buf argument only the st_uid, st_gid, st_size, and st_mode fields, and only the
S_IRUSR, S_IWUSR, S_IRGRP, S_IWGRP, S_IROTH, and S_IWOTH file permission bits need be
valid. The implementation may update other fields and flags.

If fildes references a typed memory object, the implementation shall update in the stat structure
pointed to by the buf argument only the st_uid, st_gid, st_size, and st_mode fields, and only the
S_IRUSR, S_IWUSR, S_IRGRP, S_IWGRP, S_IROTH, and S_IWOTH file permission bits need be
valid. The implementation may update other fields and flags.

The buf argument is a pointer to a stat structure, as defined in <sys/stat.h>, into which
information is placed concerning the file.

The structure members st_mode, st_ino, st_dev, st_uid, st_gid, st_atime, st_ctime, and st_mtime
shall have meaningful values for all other file types defined in this volume of
IEEE Std 1003.1-2001. The value of the member st_nlink shall be set to the number of links to the
file.

An implementation that provides additional or alternative file access control mechanisms may,
under implementation-defined conditions, cause fstat() to fail.

The fstat() function shall update any time-related fields as described in the Base Definitions
volume of IEEE Std 1003.1-2001, Section 4.7, File Times Update, before writing into the stat
structure.

RETURN VALUE
Upon successful completion, 0 shall be returned. Otherwise, −1 shall be returned and errno set to
indicate the error.

ERRORS
The fstat() function shall fail if:

[EBADF] The fildes argument is not a valid file descriptor.

[EIO] An I/O error occurred while reading from the file system.

[ENOTTY] The file size in bytes or the number of blocks allocated to the file or the file
serial number cannot be represented correctly in the structure pointed to by
buf.

The fstat() function may fail if:

[EOVERFLOW] One of the values is too large to store into the structure pointed to by the buf
argument.
EXAMPLES

Obtaining File Status Information

The following example shows how to obtain file status information for a file named /home/cnd/mod1. The structure variable buffer is defined for the stat structure. The /home/cnd/mod1 file is opened with read/write privileges and is passed to the open file descriptor fildes.

```c
#include <sys/types.h>
#include <sys/stat.h>
#include <fcntl.h>

struct stat buffer;
int status;
...
fildes = open("/home/cnd/mod1", O_RDWR);
status = fstat(fildes, &buffer);
```

APPLICATION USAGE
None.

RATIONALE
None.

FUTURE DIRECTIONS
None.

SEE ALSO
lstat(), stat(), the Base Definitions volume of IEEE Std 1003.1-2001, <sys/stat.h>, <sys/types.h>

CHANGE HISTORY
First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 5
The DESCRIPTION is updated for alignment with the POSIX Realtime Extension.

Issue 6
In the SYNOPSIS, the optional include of the <sys/types.h> header is removed.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:
- The requirement to include <sys/types.h> has been removed. Although <sys/types.h> was required for conforming implementations of previous POSIX specifications, it was not required for UNIX applications.
- The [EIO] mandatory error condition is added.
- The [EOVERFLOW] mandatory error condition is added. This change is to support large files.
- The [EOVERFLOW] optional error condition is added.

The DESCRIPTION is updated for alignment with IEEE Std 1003.1j-2000 by specifying that shared memory object semantics apply to typed memory objects.
# System Interfaces

## NAME
fstatvfs, statvfs — get file system information

## SYNOPSIS

```c
#include <sys/statvfs.h>

int fstatvfs(int fildes, struct statvfs *buf);
int statvfs(const char *restrict path, struct statvfs *restrict buf);
```

## DESCRIPTION

The `fstatvfs()` function shall obtain information about the file system containing the file referenced by `fildes`.

The `statvfs()` function shall obtain information about the file system containing the file named by `path`.

For both functions, the `buf` argument is a pointer to a `statvfs` structure that shall be filled. Read, write, or execute permission of the named file is not required.

The following flags can be returned in the `f_flag` member:

- **ST_RDONLY** Read-only file system.
- **ST_NOSUID** Setuid/setgid bits ignored by `exec`.

It is unspecified whether all members of the `statvfs` structure have meaningful values on all file systems.

## RETURN VALUE

Upon successful completion, `statvfs()` shall return 0. Otherwise, it shall return -1 and set `errno` to indicate the error.

## ERRORS

The `fstatvfs()` and `statvfs()` functions shall fail if:

- **[EIO]** An I/O error occurred while reading the file system.
- **[EINTR]** A signal was caught during execution of the function.
- **[EOVERFLOW]** One of the values to be returned cannot be represented correctly in the structure pointed to by `buf`.

The `fstatvfs()` function shall fail if:

- **[EBADF]** The `fildes` argument is not an open file descriptor.

The `statvfs()` function shall fail if:

- **[EACCES]** Search permission is denied on a component of the path prefix.
- **[ELOOP]** A loop exists in symbolic links encountered during resolution of the `path` argument.

- **[ENAMETOOLONG]** The length of a pathname exceeds `PATH_MAX` or a pathname component is longer than `NAME_MAX`.
- **[ENOENT]** A component of `path` does not name an existing file or `path` is an empty string.
- **[ENOTDIR]** A component of the path prefix of `path` is not a directory.
The `statvfs()` function may fail if:

- [ELOOP] More than `SYMLOOP_MAX` symbolic links were encountered during resolution of the `path` argument.
- [ENAMETOOLONG] Pathname resolution of a symbolic link produced an intermediate result whose length exceeds `PATH_MAX`.

### EXAMPLES

#### Obtaining File System Information Using `fstatvfs()`

The following example shows how to obtain file system information for the file system upon which the file named `/home/cnd/mod1` resides, using the `fstatvfs()` function. The `/home/cnd/mod1` file is opened with read/write privileges and the open file descriptor is passed to the `fstatvfs()` function.

```c
#include <statvfs.h>
#include <fcntl.h>

struct statvfs buffer;
int status;
...
fd = open("/home/cnd/mod1", O_RDWR);
status = fstatvfs(fd, &buffer);
```

#### Obtaining File System Information Using `statvfs()`

The following example shows how to obtain file system information for the file system upon which the file named `/home/cnd/mod1` resides, using the `statvfs()` function.

```c
#include <statvfs.h>

struct statvfs buffer;
int status;
...
status = statvfs("/home/cnd/mod1", &buffer);
```

Moved from X/OPEN UNIX extension to BASE.

Large File Summit extensions are added.
The DESCRIPTION is updated to avoid use of the term “must” for application requirements.

The restrict keyword is added to the statvfs() prototype for alignment with the ISO/IEC 9899:1999 standard.

The wording of the mandatory [ELOOP] error condition is updated, and a second optional [ELOOP] error condition is added.
NAME
fsync — synchronize changes to a file

SYNOPSIS
#include <unistd.h>

int fsync(int fildes);

DESCRIPTION
The fsync() function shall request that all data for the open file descriptor named by fildes is to be
transferred to the storage device associated with the file described by fildes in an
implementation-defined manner. The fsync() function shall not return until the system has
completed that action or until an error is detected.

SIO
If _POSIX_SYNCHRONIZED_IO is defined, the fsync() function shall force all currently queued
I/O operations associated with the file indicated by file descriptor fildes to the synchronized I/O
completion state. All I/O operations shall be completed as defined for synchronized I/O file
integrity completion.

RETURN VALUE
Upon successful completion, fsync() shall return 0. Otherwise, −1 shall be returned and errno set
to indicate the error. If the fsync() function fails, outstanding I/O operations are not guaranteed
to have been completed.

ERRORS
The fsync() function shall fail if:
[EBADF] The fildes argument is not a valid descriptor.
[EINTR] The fsync() function was interrupted by a signal.
[EINVAL] The fildes argument does not refer to a file on which this operation is possible.
[EIO] An I/O error occurred while reading from or writing to the file system.

In the event that any of the queued I/O operations fail, fsync() shall return the error conditions
defined for read() and write().

EXAMPLES
None.

APPLICATION USAGE
The fsync() function should be used by programs which require modifications to a file to be
completed before continuing; for example, a program which contains a simple transaction
facility might use it to ensure that all modifications to a file or files caused by a transaction are
recorded.

RATIONALE
The fsync() function is intended to force a physical write of data from the buffer cache, and to
assure that after a system crash or other failure that all data up to the time of the fsync() call is
recorded on the disk. Since the concepts of “buffer cache”, “system crash”, “physical write”, and
“non-volatile storage” are not defined here, the wording has to be more abstract.

If _POSIX_SYNCHRONIZED_IO is not defined, the wording relies heavily on the conformance
document to tell the user what can be expected from the system. It is explicitly intended that a
null implementation is permitted. This could be valid in the case where the system cannot assure
non-volatile storage under any circumstances or when the system is highly fault-tolerant and the
functionality is not required. In the middle ground between these extremes, fsync() might or
might not actually cause data to be written where it is safe from a power failure. The
conformance document should identify at least that one configuration exists (and how to obtain
that configuration) where this can be assured for at least some files that the user can select to use
for critical data. It is not intended that an exhaustive list is required, but rather sufficient
information is provided so that if critical data needs to be saved, the user can determine how the
system is to be configured to allow the data to be written to non-volatile storage.

It is reasonable to assert that the key aspects of *fsync()* are unreasonable to test in a test suite.
That does not make the function any less valuable, just more difficult to test. A formal
conformance test should probably force a system crash (power shutdown) during the test for
this condition, but it needs to be done in such a way that automated testing does not require this
to be done except when a formal record of the results is being made. It would also not be
unreasonable to omit testing for *fsync()*, allowing it to be treated as a quality-of-implementation
issue.

**FUTURE DIRECTIONS**

None.

**SEE ALSO**

*sync()*, the Base Definitions volume of IEEE Std 1003.1-2001, `<unistd.h>`

**CHANGE HISTORY**

First released in Issue 3.

**Issue 5**

Aligned with *fsync()* in the POSIX Realtime Extension. Specifically, the DESCRIPTION and
RETURN VALUE sections are much expanded, and the ERRORS section is updated to indicate
that *fsync()* can return the error conditions defined for *read()* and *write()*.

**Issue 6**

This function is marked as part of the File Synchronization option.

The following new requirements on POSIX implementations derive from alignment with the
Single UNIX Specification:

- The [EINVAL] and [EIO] mandatory error conditions are added.
NAME
ftell, ftello — return a file offset in a stream

SYNOPSIS
#include <stdio.h>

long ftell(FILE *stream);
off_t ftello(FILE *stream);

DESCRIPTION
The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-2001 defers to the ISO C standard.

The ftell() function shall obtain the current value of the file-position indicator for the stream pointed to by stream.

The ftello() function shall be equivalent to ftell(), except that the return value is of type off_t.

RETURN VALUE
Upon successful completion, ftell() and ftello() shall return the current value of the file-position indicator for the stream measured in bytes from the beginning of the file.
Otherwise, ftell() and ftello() shall return −1, cast to long and off_t respectively, and set errno to indicate the error.

ERRORS
The ftell() and ftello() functions shall fail if:

- [EBADF] The file descriptor underlying stream is not an open file descriptor.
- [EOVERFLOW] For ftell(), the current file offset cannot be represented correctly in an object of type long.
- [EOVERFLOW] For ftello(), the current file offset cannot be represented correctly in an object of type off_t.
- [ESPIPE] The file descriptor underlying stream is associated with a pipe or FIFO.
- The ftell() function may fail if:
  - [ESPIPE] The file descriptor underlying stream is associated with a socket.

EXAMPLES
None.

APPLICATION USAGE
None.

RATIONALE
None.

FUTURE DIRECTIONS
None.

CHANGE HISTORY
First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 5
Large File Summit extensions are added.

Issue 6
Extensions beyond the ISO C standard are marked.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The ftello() function is added.
- The [EOVERFLOW] error conditions are added.
- An additional [ESPIPE] error condition is added for sockets.
NAME
ftime — get date and time (LEGACY)

SYNOPSIS
#include <sys/timeb.h>
int ftime(struct timeb *tp);

DESCRIPTION
The ftime() function shall set the time and millitm members of the timeb structure pointed to by tp to contain the seconds and milliseconds portions, respectively, of the current time in seconds since the Epoch. The contents of the timezone and dstflag members of tp after a call to ftime() are unspecified.

The system clock need not have millisecond granularity. Depending on any granularity (particularly a granularity of one) renders code non-portable.

RETURN VALUE
Upon successful completion, the ftime() function shall return 0; otherwise, −1 shall be returned.

ERRORS
No errors are defined.

EXAMPLES
Getting the Current Time and Date
The following example shows how to get the current system time values using the ftime() function. The timeb structure pointed to by tp is filled with the current system time values for time and millitm.
#include <sys/timeb.h>
struct timeb tp;
int status;
...
status = ftime(&tp);

APPLICATION USAGE
For applications portability, the time() function should be used to determine the current time instead of ftime(). Realtime applications should use clock_gettime() to determine the current time instead of ftime().

RATIONALE
None.

FUTURE DIRECTIONS
This function may be withdrawn in a future version.

SEE ALSO
clock_getres(), ctime(), gettimeofday(), time(), the Base Definitions volume of IEEE Std 1003.1-2001, <sys/timeb.h>

CHANGE HISTORY
First released in Issue 4, Version 2.
**Issue 5**

Moved from X/OPEN UNIX extension to BASE.

Normative text previously in the APPLICATION USAGE section is moved to the DESCRIPTION.

**Issue 6**

This function is marked LEGACY.

The DESCRIPTION is updated to refer to “seconds since the Epoch” rather than “seconds since 00:00:00 UTC (Coordinated Universal Time), January 1 1970” for consistency with other time functions.
NAME
ftok — generate an IPC key

SYNOPSIS
#include <sys/ipc.h>
key_t ftok(const char *path, int id);

DESCRIPTION
The ftok() function shall return a key based on path and id that is usable in subsequent calls to
msgget(), semget(), and shmget(). The application shall ensure that the path argument is the
pathname of an existing file that the process is able to stat().

The ftok() function shall return the same key value for all paths that name the same file, when
called with the same id value, and return different key values when called with different id
values or with paths that name different files existing on the same file system at the same time. It
is unspecified whether ftok() shall return the same key value when called again after the file
named by path is removed and recreated with the same name.

Only the low-order 8-bits of id are significant. The behavior of ftok() is unspecified if these bits
are 0.

RETURN VALUE
Upon successful completion, ftok() shall return a key. Otherwise, ftok() shall return (key_t)−1
and set errno to indicate the error.

ERRORS
The ftok() function shall fail if:

[EACCES] Search permission is denied for a component of the path prefix.

[ELOOP] A loop exists in symbolic links encountered during resolution of the path
argument.

[ENAMETOOLONG] The length of the path argument exceeds {PATH_MAX} or a pathname
component is longer than {NAME_MAX}.

[ENOENT] A component of path does not name an existing file or path is an empty string.

[ENOTDIR] A component of the path prefix is not a directory.

The ftok() function may fail if:

[ELOOP] More than {SYMLOOP_MAX} symbolic links were encountered during
resolution of the path argument.

[ENAMETOOLONG] Pathname resolution of a symbolic link produced an intermediate result
whose length exceeds {PATH_MAX}.
EXAMPLES

Getting an IPC Key

The following example gets a unique key that can be used by the IPC functions semget(), msgget(), and shmget(). The key returned by ftok() for this example is based on the ID value \textit{S} and the pathname /tmp.

```c
#include <sys/ipc.h>
...
key_t key;
char *path = "/tmp";
int id = 'S';
key = ftok(path, id);
```

Saving an IPC Key

The following example gets a unique key based on the pathname /tmp and the ID value \textit{a}. It also assigns the value of the resulting key to the \textit{semkey} variable so that it will be available to a later call to semget(), msgget(), or shmget().

```c
#include <sys/ipc.h>
...
key_t semkey;
if ((semkey = ftok("/tmp", 'a')) == (key_t) -1) {
    perror("IPC error: ftok"); exit(1);
}
```

APPLICATION USAGE

For maximum portability, \textit{id} should be a single-byte character.

RATIONALE

None.

FUTURE DIRECTIONS

None.

msgget(), semget(), shmget(), the Base Definitions volume of IEEE Std 1003.1-2001, <sys/ipc.h>

CHANGE HISTORY

First released in Issue 4, Version 2.

Issue 5

Moved from X/OPEN UNIX extension to BASE.

Issue 6

The DESCRIPTION is updated to avoid use of the term “must” for application requirements.

The wording of the mandatory [ELOOP] error condition is updated, and a second optional [ELOOP] error condition is added.
ftruncate()  System Interfaces

NAME
ftruncate — truncate a file to a specified length

SYNOPSIS
#include <unistd.h>
int ftruncate(int fildes, off_t length);

DESCRIPTION
If fildes is not a valid file descriptor open for writing, the ftruncate() function shall fail.
If fildes refers to a regular file, the ftruncate() function shall cause the size of the file to be
 truncated to length. If the size of the file previously exceeded length, the extra data shall no
longer be available to reads on the file. If the file previously was smaller than this size, ftruncate() shall either increase the size of the file or fail. XSI-conformant systems shall increase
the size of the file. If the file size is increased, the extended area shall appear as if it were zero-
filled. The value of the seek pointer shall not be modified by a call to ftruncate().
Upon successful completion, if fildes refers to a regular file, the ftruncate() function shall mark
for update the st_ctime and st_mtime fields of the file and the S_ISUID and S_ISGID bits of the file
mode may be cleared. If the ftruncate() function is unsuccessful, the file is unaffected.
If the request would cause the file size to exceed the soft file size limit for the process, the
request shall fail and the implementation shall generate the SIGXFSZ signal for the thread.
If fildes refers to a directory, ftruncate() shall fail.
If fildes refers to any other file type, except a shared memory object, the result is unspecified.
If fildes refers to a shared memory object, ftruncate() shall set the size of the shared memory
object to length.
If the effect of ftruncate() is to decrease the size of a shared memory object or memory mapped
file and whole pages beyond the new end were previously mapped, then the whole pages
beyond the new end shall be discarded.
If the Memory Protection option is supported, references to discarded pages shall result in the
generation of a SIGBUS signal; otherwise, the result of such references is undefined.
If the effect of ftruncate() is to increase the size of a shared memory object, it is unspecified
whether the contents of any mapped pages between the old end-of-file and the new are flushed
to the underlying object.
RETURN VALUE
Upon successful completion, ftruncate() shall return 0; otherwise, −1 shall be returned and errno
set to indicate the error.

ERRORS
The ftruncate() function shall fail if:

[EINTR] A signal was caught during execution.

[EINVAL] The length argument was less than 0.

[EFBIG] or [EINVAL]
The length argument was greater than the maximum file size.

[XSI][EFBIG] The file is a regular file and length is greater than the offset maximum
established in the open file description associated with fildes.

[EINVAL] An I/O error occurred while reading from or writing to a file system.
ftruncate()

[EBADF] or [EINVAL]
The fildes argument is not a file descriptor open for writing.

EINVAL]
The fildes argument references a file that was opened without write permission.

EROFS]
The named file resides on a read-only file system.

EXAMPLES
None.

APPLICATION USAGE
None.

RATIONALE
The ftruncate() function is part of IEEE Std 1003.1-2001 as it was deemed to be more useful than truncate(). The truncate() function is provided as an XSI extension.

FUTURE DIRECTIONS
None.

SEE ALSO
open(), truncate(), the Base Definitions volume of IEEE Std 1003.1-2001, <unistd.h>

CHANGE HISTORY
First released in Issue 4, Version 2.

Issue 5
Moved from X/OPEN UNIX extension to BASE and aligned with ftruncate() in the POSIX Realtime Extension. Specifically, the DESCRIPTION is extensively reworded and [EROFS] is added to the list of mandatory errors that can be returned by ftruncate(). Large File Summit extensions are added.

Issue 6
The truncate() function is split out into a separate reference page.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The DESCRIPTION is changed to indicate that if the file size is changed, and if the file is a regular file, the S_ISUID and S_ISGID bits in the file mode may be cleared.

The following changes were made to align with the IEEE P1003.1a draft standard:

- The DESCRIPTION text is updated.

XSI-conformant systems are required to increase the size of the file if the file was previously smaller than the size requested.
NAME
ftrylockfile — stdio locking functions

SYNOPSIS
TSF
#include <stdio.h>

int ftrylockfile(FILE *file);

DESCRIPTION
Refer to flockfile().
NAME

ftw — traverse (walk) a file tree

SYNOPSIS

#include <ftw.h>

int ftw(const char *path, int (*fn)(const char *,
    const struct stat *ptr, int flag), int ndirs);

DESCRIPTION

The ftw() function shall recursively descend the directory hierarchy rooted in path. For each
object in the hierarchy, ftw() shall call the function pointed to by fn, passing it a pointer to a
null-terminated character string containing the name of the object, a pointer to a stat structure
containing information about the object, and an integer. Possible values of the integer, defined
in the <ftw.h> header, are:

FTW_D For a directory.

FTW_DNR For a directory that cannot be read.

FTW_F For a file.

FTW_SL For a symbolic link (but see also FTW_NS below).

FTW_NS For an object other than a symbolic link on which stat() could not successfully be
executed. If the object is a symbolic link and stat() failed, it is unspecified whether
ftw() passes FTW_SL or FTW_NS to the user-supplied function.

If the integer is FTW_DNR, descendants of that directory shall not be processed. If the integer is
FTW_NS, the stat structure contains undefined values. An example of an object that would
cause FTW_NS to be passed to the function pointed to by fn would be a file in a directory with
read but without execute (search) permission.

The ftw() function shall visit a directory before visiting any of its descendants.

The ftw() function shall use at most one file descriptor for each level in the tree.

The argument ndirs should be in the range [1,OPEN_MAX].

The tree traversal shall continue until either the tree is exhausted, an invocation of fn returns a
non-zero value, or some error, other than [EACCES], is detected within ftw().

The ndirs argument shall specify the maximum number of directory streams or file descriptors
or both available for use by ftw() while traversing the tree. When ftw() returns it shall close any
directory streams and file descriptors it uses not counting any opened by the application-
supplied fn function.

The results are unspecified if the application-supplied fn function does not preserve the current
working directory.

The ftw() function need not be reentrant. A function that is not required to be reentrant is not
required to be thread-safe.

RETURN VALUE

If the tree is exhausted, ftw() shall return 0. If the function pointed to by fn returns a non-zero
value, ftw() shall stop its tree traversal and return whatever value was returned by the function
pointed to by fn. If ftw() detects an error, it shall return −1 and set errno to indicate the error.

If ftw() encounters an error other than [EACCES] (see FTW_DNR and FTW_NS above), it shall
return −1 and set errno to indicate the error. The external variable errno may contain any error
The `ftw()` function shall fail if:

- **[EACCES]** Search permission is denied for any component of `path` or read permission is denied for `path`.
- **[ELOOP]** A loop exists in symbolic links encountered during resolution of the `path` argument.
- **[ENAMETOOLONG]** The length of the `path` argument exceeds `[PATH_MAX]` or a pathname component is longer than `[NAME_MAX]`.
- **[ENOENT]** A component of `path` does not name an existing file or `path` is an empty string.
- **[ENOTDIR]** A component of `path` is not a directory.
- **[EIO]** A field in the `stat` structure cannot be represented correctly in the current programming environment for one or more files found in the file hierarchy.

The `ftw()` function may fail if:

- **[EINVAL]** The value of the `ndirs` argument is invalid.
- **[ELOOP]** More than `[SYMLOOP_MAX]` symbolic links were encountered during resolution of the `path` argument.
- **[ENAMETOOLONG]** Pathname resolution of a symbolic link produced an intermediate result whose length exceeds `[PATH_MAX]`.

In addition, if the function pointed to by `fn` encounters system errors, `errno` may be set accordingly.

### EXAMPLES

#### Walking a Directory Structure

The following example walks the current directory structure, calling the `fn` function for every directory entry, using at most 10 file descriptors:

```c
#include <ftw.h>
...
if (ftw(".", fn, 10) != 0) {
    perror("ftw"); exit(2);
}
```

### APPLICATION USAGE

The `ftw()` function may allocate dynamic storage during its operation. If `ftw()` is forcibly terminated, such as by `longjmp()` or `siglongjmp()` being executed by the function pointed to by `fn` or an interrupt routine, `ftw()` does not have a chance to free that storage, so it remains permanently allocated. A safe way to handle interrupts is to store the fact that an interrupt has occurred, and arrange to have the function pointed to by `fn` return a non-zero value at its next invocation.
RATIONALE
None.

FUTURE DIRECTIONS
None.

CHANGE HISTORY
First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 5
UX codings in the DESCRIPTION, RETURN VALUE, and ERRORS sections are changed to EX.

Issue 6
The ERRORS section is updated as follows:

- The wording of the mandatory [ELOOP] error condition is updated.
- A second optional [ELOOP] error condition is added.
- The [EOVERFLOW] mandatory error condition is added.

Text is added to the DESCRIPTION to say that the ftw() function need not be reentrant and that the results are unspecified if the application-supplied fn function does not preserve the current working directory.
funlockfile() — stdio locking functions

### Synopsis

```c
#include <stdio.h>

void funlockfile(FILE *file);
```

### Description

Refer to `flockfile()`.
NAME
fwide — set stream orientation

SYNOPSIS
#include <stdio.h>
#include <wchar.h>
int fwide(FILE *stream, int mode);

DESCRIPTION
The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-2001 defers to the ISO C standard.

The fwide() function shall determine the orientation of the stream pointed to by stream. If mode is greater than zero, the function first attempts to make the stream wide-oriented. If mode is less than zero, the function first attempts to make the stream byte-oriented. Otherwise, mode is zero and the function does not alter the orientation of the stream.

If the orientation of the stream has already been determined, fwide() shall not change it.

Since no return value is reserved to indicate an error, an application wishing to check for error situations should set errno to 0, then call fwide(), then check errno, and if it is non-zero, assume an error has occurred.

RETURN VALUE
The fwide() function shall return a value greater than zero if, after the call, the stream has wide-orientation, a value less than zero if the stream has byte-orientation, or zero if the stream has no orientation.

ERRORS
The fwide() function may fail if:

[EBADF] The stream argument is not a valid stream.

EXAMPLES
None.

APPLICATION USAGE
A call to fwide() with mode set to zero can be used to determine the current orientation of a stream.

RATIONALE
None.

FUTURE DIRECTIONS
None.

The Base Definitions volume of IEEE Std 1003.1-2001, <wchar.h>

CHANGE HISTORY

Issue 6
Extensions beyond the ISO C standard are marked.
**NAME**
fwprintf, swprintf, wprintf — print formatted wide-character output

**SYNOPSIS**
```
#include <stdio.h>
#include <wchar.h>

int fwprintf(FILE *restrict stream, const wchar_t *restrict format, ...);
int swprintf(wchar_t *restrict ws, size_t n, const wchar_t *restrict format, ...);
int wprintf(const wchar_t *restrict format, ...);
```

**DESCRIPTION**
The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-2001 defers to the ISO C standard.

The `fwprintf()` function shall place output on the named output `stream`. The `wprintf()` function shall place output on the standard output stream `stdout`. The `swprintf()` function shall place output followed by the null wide character in consecutive wide characters starting at `ws`; no more than `n` wide characters shall be written, including a terminating null wide character, which is always added (unless `n` is zero).

Each of these functions shall convert, format, and print its arguments under control of the `format` wide-character string. The `format` is composed of zero or more directives: ordinary wide-characters, which are simply copied to the output stream, and conversion specifications, each of which results in the fetching of zero or more arguments. The results are undefined if there are insufficient arguments for the `format`. If the `format` is exhausted while arguments remain, the excess arguments are evaluated but are otherwise ignored.

Conversions can be applied to the `n`th argument after the `format` in the argument list, rather than to the next unused argument. In this case, the conversion specifier wide character `%` (see below) is replaced by the sequence `%n$`, where `n` is a decimal integer in the range [1,NL_ARGMAX], giving the position of the argument in the argument list. This feature provides for the definition of `format` wide-character strings that select arguments in an order appropriate to specific languages (see the EXAMPLES section).

The `format` can contain either numbered argument specifications (that is, `%n$` and `*m$`), or unnumbered argument conversion specifications (that is, `%` and `*`), but not both. The only exception to this is that `%` can be mixed with the `%n$` form. The results of mixing numbered and unnumbered argument specifications in a `format` wide-character string are undefined. When numbered argument specifications are used, specifying the `N`th argument requires that all the leading arguments, from the first to the `(N-1)`th, are specified in the `format` wide-character string.

In `format` wide-character strings containing the `%n$` form of conversion specification, numbered arguments in the argument list can be referenced from the `format` wide-character string as many times as required.

In `format` wide-character strings containing the `%` form of conversion specification, each argument in the argument list shall be used exactly once.

All forms of the `fwprintf()` function allow for the insertion of a locale-dependent radix character in the output string, output as a wide-character value. The radix character is defined in the program’s locale (category `LC_NUMERIC`). In the POSIX locale, or in a locale where the radix character is not defined, the radix character shall default to a period (‘.’).

Each conversion specification is introduced by the ‘`%`’ wide character or by the wide-character sequence `"%n$"`, after which the following appear in sequence:
• Zero or more flags (in any order), which modify the meaning of the conversion specification.

• An optional minimum field width. If the converted value has fewer wide characters than the field width, it shall be padded with spaces by default on the left; it shall be padded on the right, if the left-adjustment flag ('-'), described below, is given to the field width. The field width takes the form of an asterisk ('**'), described below, or a decimal integer.

• An optional precision that gives the minimum number of digits to appear for the d, i, o, u, x, and X conversion specifiers; the number of digits to appear after the radix character for the a, A, e, E, f, and F conversion specifiers; the maximum number of significant digits for the g and G conversion specifiers; or the maximum number of wide characters to be printed from a string in the s conversion specifiers. The precision takes the form of a period ('.') followed either by an asterisk ('**'), described below, or an optional decimal digit string, where a null digit string is treated as 0. If a precision appears with any other conversion wide character, the behavior is undefined.

• An optional length modifier that specifies the size of the argument.

A field width, or precision, or both, may be indicated by an asterisk ('**'). In this case an argument of type int supplies the field width or precision. Applications shall ensure that arguments specifying field width, or precision, or both appear in that order before the argument, if any, to be converted. A negative field width is taken as a '-' flag followed by a positive field width. A negative precision is taken as if the precision were omitted. In format wide-character strings containing the "%%%" form of a conversion specification, a field width or precision may be indicated by the sequence "*m%", where m is a decimal integer in the range [1, NL_ARGMAX] giving the position in the argument list (after the format argument) of an integer argument containing the field width or precision, for example:

wprintf(L"%1$d:%2$.*3$d:%4$.*3$d
", hour, min, precision, sec);

The flag wide characters and their meanings are:

• The integer portion of the result of a decimal conversion (%i, %d, %u, %f, %F, %g, or %G) shall be formatted with thousands' grouping wide characters. For other conversions, the behavior is undefined. The numeric grouping wide character is used.

• The result of the conversion shall be left-justified within the field. The conversion shall be right-justified if this flag is not specified.

• The result of a signed conversion shall always begin with a sign ('+' or '-'). The conversion shall begin with a sign only when a negative value is converted if this flag is not specified.

• If the first wide character of a signed conversion is not a sign, or if a signed conversion results in no wide characters, a <space> shall be prefixed to the result. This means that if the <space> and '+' flags both appear, the <space> flag shall be ignored.

• Specifies that the value is to be converted to an alternative form. For o conversion, it increases the precision (if necessary) to force the first digit of the result to be 0. For x or X conversion specifiers, a non-zero result shall have 0x (or 0X) prefixed to it. For a, A, e, E, f, F, g, and G conversion specifiers, the result shall always contain a radix character, even if no digits follow it. Without this flag, a radix character appears in the result of these conversions only if a digit follows it. For g and G conversion specifiers, trailing zeros shall not be removed from the result as they normally are. For other conversion specifiers, the behavior is undefined.
For `d`, `i`, `o`, `u`, `x`, `X`, `a`, `A`, `e`, `E`, `f`, `F`, `g`, and `G` conversion specifiers, leading zeros (following any indication of sign or base) are used to pad to the field width; no space padding is performed. If the ‘`0’` and ‘`−’` flags both appear, the ‘`0’` flag shall be ignored. For `d`, `i`, `o`, `u`, `x`, and `X` conversion specifiers, if a precision is specified, the ‘`0’` flag shall be ignored. If the ‘`0’` and ‘`‘` flags both appear, the grouping wide characters are inserted before zero padding. For other conversions, the behavior is undefined.

The length modifiers and their meanings are:

- `hh` Specifies that a following `d`, `i`, `o`, `u`, `x`, or `X` conversion specifier applies to a `signed char` or `unsigned char` argument (the argument will have been promoted according to the integer promotions, but its value shall be converted to `signed char` or `unsigned char` before printing); or that a following `n` conversion specifier applies to a pointer to a `signed char` argument.

- `h` Specifies that a following `d`, `i`, `o`, `u`, `x`, or `X` conversion specifier applies to a `short` or `unsigned short` argument (the argument will have been promoted according to the integer promotions, but its value shall be converted to `short` or `unsigned short` before printing); or that a following `n` conversion specifier applies to a pointer to a `short` argument.

- `l` (ell) Specifies that a following `d`, `i`, `o`, `u`, `x`, or `X` conversion specifier applies to a `long` or `unsigned long` argument; that a following `n` conversion specifier applies to a pointer to a `long` argument; that a following `c` conversion specifier applies to a `wint_t` argument; that a following `s` conversion specifier applies to a pointer to a `wchar_t` argument; or has no effect on a following `a`, `A`, `e`, `E`, `f`, `F`, `g`, or `G` conversion specifier.

- `ll` (ell-ell) Specifies that a following `d`, `i`, `o`, `u`, `x`, or `X` conversion specifier applies to a `long long` or `unsigned long long` argument; or that a following `n` conversion specifier applies to a pointer to a `long long` argument.

- `j` Specifies that a following `d`, `i`, `o`, `u`, `x`, or `X` conversion specifier applies to an `intmax_t` or `uintmax_t` argument; or that a following `n` conversion specifier applies to a pointer to an `intmax_t` argument.

- `z` Specifies that a following `d`, `i`, `o`, `u`, `x`, or `X` conversion specifier applies to a `size_t` or the corresponding signed integer type argument; or that a following `n` conversion specifier applies to a pointer to a signed integer type corresponding to a `size_t` argument.

- `t` Specifies that a following `d`, `i`, `o`, `u`, `x`, or `X` conversion specifier applies to a `ptrdiff_t` or the corresponding `unsigned` type argument; or that a following `n` conversion specifier applies to a pointer to a `ptrdiff_t` argument.

- `L` Specifies that a following `a`, `A`, `e`, `E`, `f`, `F`, `g`, or `G` conversion specifier applies to a `long double` argument.

If a length modifier appears with any conversion specifier other than as specified above, the behavior is undefined.

The conversion specifiers and their meanings are:

- `d`, `i` The `int` argument shall be converted to a signed decimal in the style "[−]`ddd`d". The precision specifies the minimum number of digits to appear; if the value being converted can be represented in fewer digits, it shall be expanded with leading zeros. The default precision shall be 1. The result of converting zero with an explicit precision of zero shall be no wide characters.
The unsigned argument shall be converted to unsigned octal format in the style "ddddd", The precision specifies the minimum number of digits to appear; if the value being converted can be represented in fewer digits, it shall be expanded with leading zeros. The default precision shall be 1. The result of converting zero with an explicit precision of zero shall be no wide characters.

The unsigned argument shall be converted to unsigned decimal format in the style "ddddd". The precision specifies the minimum number of digits to appear; if the value being converted can be represented in fewer digits, it shall be expanded with leading zeros. The default precision shall be 1. The result of converting zero with an explicit precision of zero shall be no wide characters.

The unsigned argument shall be converted to unsigned hexadecimal format in the style "ddddd"; the letters "abcdef" are used. The precision specifies the minimum number of digits to appear; if the value being converted can be represented in fewer digits, it shall be expanded with leading zeros. The default precision shall be 1. The result of converting zero with an explicit precision of zero shall be no wide characters.

Equivalent to the x conversion specifier, except that letters "ABCDEFG" are used instead of "abcdef".

The double argument shall be converted to decimal notation in the style "-[−] dddd.ddd", where the number of digits after the radix character shall be equal to the precision specification. If the precision is missing, it shall be taken as 6; if the precision is explicitly zero and no ‘#’ flag is present, no radix character shall appear. If a radix character appears, at least one digit shall appear before it. The value shall be rounded in an implementation-defined manner to the appropriate number of digits.

A double argument representing an infinity shall be converted in one of the styles "-[−]inf" or "-[−]infinity"; which style is implementation-defined. A double argument representing a NaN shall be converted in one of the styles "-[−]nan" or "-[−]nan (n-char-sequence)"; which style, and the meaning of any n-char-sequence, is implementation-defined. The F conversion specifier produces "INF", "INFINITY", or "NAN" instead of "inf", "infinity", or "nan", respectively.

The double argument shall be converted in the style "-[−] dddd.ddd e±dd", where there shall be one digit before the radix character (which is non-zero if the argument is non-zero) and the number of digits after it shall be equal to the precision; if the precision is missing, it shall be taken as 6; if the precision is zero and no ‘#’ flag is present, no radix character shall appear. The value shall be rounded in an implementation-defined manner to the appropriate number of digits. The E conversion wide character shall produce a number with ‘E’ instead of ‘e’ introducing the exponent. The exponent shall always contain at least two digits. If the value is zero, the exponent shall be zero.

A double argument representing an infinity or NaN shall be converted in the style of an f or F conversion specifier.

The double argument shall be converted in the style f or e (or in the style F or E in the case of a G conversion specifier), with the precision specifying the number of significant digits. If an explicit precision is zero, it shall be taken as 1. The style used depends on the value converted; style e (or E) shall be used only if the exponent resulting from such a conversion is less than −4 or greater than or equal to the precision. Trailing zeros shall be removed from the fractional portion of the result; a radix character shall appear only if it is followed by a digit.

A double argument representing an infinity or NaN shall be converted in the style of an f or F conversion specifier.
A double argument representing a floating-point number shall be converted in the style "[-+0]xh.hhhdp±d", where there shall be one hexadecimal digit (which is non-zero if the argument is a normalized floating-point number and is otherwise unspecified) before the decimal-point wide character and the number of hexadecimal digits after it shall be equal to the precision; if the precision is missing and FLT_RADIX is a power of 2, then the precision shall be sufficient for an exact representation of the value; if the precision is missing and FLT_RADIX is not a power of 2, then the precision shall be sufficient to distinguish values of type double, except that trailing zeros may be omitted; if the precision is zero and the ‘#’ flag is not specified, no decimal-point wide character shall appear. The letters "abcdef" are used for a conversion and the letters "ABCDEF" for A conversion. The A conversion specifier produces a number with ‘X’ and ‘P’ instead of ‘x’ and ‘p’. The exponent shall always contain at least one digit, and only as many more digits as necessary to represent the decimal exponent of 2. If the value is zero, the exponent shall be zero.

A double argument representing an infinity or NaN shall be converted in the style of an E or F conversion specifier.

If no l (ell) qualifier is present, the int argument shall be converted to a wide character as if by calling the btowc() function and the resulting wide character shall be written. Otherwise, the wint_t argument shall be converted to wchar_t, and written.

If no l (ell) qualifier is present, the application shall ensure that the argument is a pointer to a character array containing a character sequence beginning in the initial shift state. Characters from the array shall be converted as if by repeated calls to the mbtowc() function, with the conversion state described by an mbstate_t object initialized to zero before the first character is converted, and written up to (but not including) the terminating null wide character. If the precision is specified, no more than that many wide characters shall be written. If the precision is not specified, or is greater than the size of the array, the application shall ensure that the array contains a null wide character.

If an l (ell) qualifier is present, the application shall ensure that the argument is a pointer to an array of type wchar_t. Wide characters from the array shall be written up to (but not including) a terminating null wide character. If no precision is specified, or is greater than the size of the array, the application shall ensure that the array contains a null wide character. If a precision is specified, no more than that many wide characters shall be written.

The application shall ensure that the argument is a pointer to void. The value of the pointer shall be converted to a sequence of printable wide characters in an implementation-defined manner.

The application shall ensure that the argument is a pointer to an integer into which is written the number of wide characters written to the output so far by this call to one of the fprintf() functions. No argument shall be converted, but one shall be consumed. If the conversion specification includes any flags, a field width, or a precision, the behavior is undefined.

| XSI | Equivalent to l.c. |
| XSI | Equivalent to l.s |

Output a ‘%’ wide character; no argument shall be converted. The entire conversion specification shall be %.
If a conversion specification does not match one of the above forms, the behavior is undefined.

In no case does a nonexistent or small field width cause truncation of a field; if the result of a conversion is wider than the field width, the field shall be expanded to contain the conversion result. Characters generated by fwprintf() and swprintf() shall be printed as if fputwc() had been called.

For a and A conversions, if FLT_RADIX is not a power of 2 and the result is not exactly representable in the given precision, the result should be one of the two adjacent numbers in hexadecimal floating style with the given precision, with the extra stipulation that the error should have a correct sign for the current rounding direction.

For e, E, f, F, g, and G conversion specifiers, if the number of significant decimal digits is at most DECIMAL_DIG, then the result should be correctly rounded. If the number of significant decimal digits is more than DECIMAL_DIG but the source value is exactly representable with DECIMAL_DIG digits, then the result should be an exact representation with trailing zeros. Otherwise, the source value is bounded by two adjacent decimal strings L < U, both having DECIMAL_DIG significant digits; the value of the resultant decimal string D should satisfy L <= D <= U, with the extra stipulation that the error should have a correct sign for the current rounding direction.

The st_ctime and st_mtime fields of the file shall be marked for update between the call to a successful execution of fwprintf() or wprintf() and the next successful completion of a call to fflush() or fclose() on the same stream, or a call to exit() or abort().

RETURN VALUE

Upon successful completion, these functions shall return the number of wide characters transmitted, excluding the terminating null wide character in the case of swprintf(), or a negative value if an output error was encountered, and set errno to indicate the error.

If n or more wide characters were requested to be written, swprintf() shall return a negative value, and set errno to indicate the error.

ERRORS

For the conditions under which fwprintf() and wprintf() fail and may fail, refer to fputwc().

In addition, all forms of fwprintf() may fail if:

- XSI [EILSEQ] A wide-character code that does not correspond to a valid character has been detected.
- XSI [EINVAL] There are insufficient arguments.

In addition, wprintf() and swprintf() may fail if:

- XSI [ENOMEM] Insufficient storage space is available.

EXAMPLES

To print the language-independent date and time format, the following statement could be used:

wprintf(format, weekday, month, day, hour, min);

For American usage, format could be a pointer to the wide-character string:

L"%s, %s %d, %d:%.2d\n"

producing the message:

Sunday, July 3, 10:02

whereas for German usage, format could be a pointer to the wide-character string:
fwprintf() Produces the message:

Sonntag, 3. Juli, 10:02

APPLICATION USAGE
None.

RATIONALE
None.

FUTURE DIRECTIONS
None.

CHANGE HISTORY

Issue 6
The Open Group Corrigendum U040/1 is applied to the RETURN VALUE section, describing the case if \( n \) or more wide characters are requested to be written using swprintf().

The DESCRIPTION is updated to avoid use of the term “must” for application requirements.

The following changes are made for alignment with the ISO/IEC 9899:1999 standard:

- The prototypes for fwprintf(), swprintf(), and wprintf() are updated.
- The DESCRIPTION is updated.
- The \( \text{hh} \), \( \text{ll} \), \( \text{j} \), \( \text{t} \), and \( \text{z} \) length modifiers are added.
- The \( \text{a} \), \( \text{A} \), and \( \text{F} \) conversion characters are added.
- XSI shading is removed from the description of character string representations of infinity and NaN floating-point values.

The DESCRIPTION is updated to use the terms “conversion specifier” and “conversion specification” consistently.

fwrite

NAME
fwrite — binary output

SYNOPSIS
#include <stdio.h>

size_t fwrite(const void *restrict ptr, size_t size, size_t nitems, FILE *restrict stream);

DESCRIPTION
The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-2001 defers to the ISO C standard.

The fwrite() function shall write, from the array pointed to by ptr, up to nitems elements whose size is specified by size, to the stream pointed to by stream. For each object, size calls shall be made to the fputc() function, taking the values (in order) from an array of unsigned char exactly overlaying the object. The file-position indicator for the stream (if defined) shall be advanced by the number of bytes successfully written. If an error occurs, the resulting value of the file-position indicator for the stream is unspecified.

The st_ctime and st_mtime fields of the file shall be marked for update between the successful execution of fwrite() and the next successful completion of a call to fflush() or fclose() on the same stream, or a call to exit() or abort().

RETURN VALUE
The fwrite() function shall return the number of elements successfully written, which may be less than nitems if a write error is encountered. If size or nitems is 0, fwrite() shall return 0 and the state of the stream remains unchanged. Otherwise, if a write error occurs, the error indicator for the stream shall be set, and errno shall be set to indicate the error.

ERRORS
Refer to fputc().

EXAMPLES
None.

APPLICATION USAGE
Because of possible differences in element length and byte ordering, files written using fwrite() are application-dependent, and possibly cannot be read using fread() by a different application or by the same application on a different processor.

RATIONALE
None.

FUTURE DIRECTIONS
None.

CHANGE HISTORY
First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 6
Extensions beyond the ISO C standard are marked.

The following changes are made for alignment with the ISO/IEC 9899:1999 standard:
• The `fwrite()` prototype is updated.

• The DESCRIPTION is updated to clarify how the data is written out using `fputc()`.
**NAME**
fwscanf, swscanf, wscanf — convert formatted wide-character input

**SYNOPSIS**

```c
#include <stdio.h>
#include <wchar.h>

int fwscanf(FILE *restrict stream, const wchar_t *restrict format, ...);
int swscanf(const wchar_t *restrict ws, const wchar_t *restrict format, ...);
int wscanf(const wchar_t *restrict format, ...);
```

**DESCRIPTION**

The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-2001 defers to the ISO C standard.

The `fwscanf()` function shall read from the named input `stream`. The `wscanf()` function shall read from the standard input stream `stdin`. The `swscanf()` function shall read from the wide-character string `ws`. Each function reads wide characters, interprets them according to a format, and stores the results in its arguments. Each expects, as arguments, a control wide-character string `format` described below, and a set of `pointer` arguments indicating where the converted input should be stored. The result is undefined if there are insufficient arguments for the format. If the `format` is exhausted while arguments remain, the excess arguments are evaluated but are otherwise ignored.

Conversions can be applied to the `n`th argument after the `format` in the argument list, rather than to the next unused argument. In this case, the conversion specifier wide character `%` (see below) is replaced by the sequence `"%n$"`, where `n` is a decimal integer in the range `[1,\{NL_ARGMAX}\]`. This feature provides for the definition of `format` wide-character strings that select arguments in an order appropriate to specific languages. In `format` wide-character strings containing the `"%n$"` form of conversion specifications, it is unspecified whether numbered arguments in the argument list can be referenced from the `format` wide-character string more than once.

The `format` can contain either form of a conversion specification—that is, `%` or `"%n$"`—but the two forms cannot normally be mixed within a single `format` wide-character string. The only exception to this is that `%%` or `%*` can be mixed with the `"%n$"` form. When numbered argument specifications are used, specifying the `N`th argument requires that all the leading arguments, from the first to the `(N-1)`th, are pointers.

The `fwscanf()` function in all its forms allows for detection of a language-dependent radix character in the input string, encoded as a wide-character value. The radix character is defined in the program’s locale (category `LC_NUMERIC`). In the POSIX locale, or in a locale where the radix character is not defined, the radix character shall default to a period (‘.’).

The `format` is a wide-character string composed of zero or more directives. Each directive is composed of one of the following: one or more white-space wide characters (<space>s, <tab>s, <newline>s, <vertical-tab>s, or <form-feed>s); an ordinary wide character (neither ‘%’ nor a white-space character); or a conversion specification. Each conversion specification is introduced by a ‘%’ or the sequence `"%n$"` after which the following appear in sequence:

- An optional assignment-suppressing character ‘*’.
- An optional non-zero decimal integer that specifies the maximum field width.
- An optional length modifier that specifies the size of the receiving object.
A conversion specifier wide character that specifies the type of conversion to be applied. The valid conversion specifiers are described below.

The `fwscanf()` functions shall execute each directive of the format in turn. If a directive fails, as detailed below, the function shall return. Failures are described as input failures (due to the unavailability of input bytes) or matching failures (due to inappropriate input).

A directive composed of one or more white-space wide characters is executed by reading input until no more valid input can be read, or up to the first wide character which is not a white-space wide character, which remains unread.

A directive that is an ordinary wide character shall be executed as follows. The next wide character is read from the input and compared with the wide character that comprises the directive; if the comparison shows that they are not equivalent, the directive shall fail, and the differing and subsequent wide characters remain unread. Similarly, if end-of-file, an encoding error, or a read error prevents a wide character from being read, the directive shall fail.

A directive that is a conversion specification defines a set of matching input sequences, as described below for each conversion wide character. A conversion specification is executed in the following steps.

Input white-space wide characters (as specified by `iswspace()`) shall be skipped, unless the conversion specification includes a `%`, `c`, or `n` conversion specifier.

An item shall be read from the input, unless the conversion specification includes an `n` conversion specifier wide character. An input item is defined as the longest sequence of input wide characters, not exceeding any specified field width, which is an initial subsequence of a matching sequence. The first wide character, if any, after the input item shall remain unread. If the length of the input item is zero, the execution of the conversion specification shall fail; this condition is a matching failure, unless end-of-file, an encoding error, or a read error prevented input from the stream, in which case it is an input failure.

Except in the case of a `%` conversion specifier, the input item (or, in the case of a `%n` conversion specification, the count of input wide characters) shall be converted to a type appropriate to the conversion wide character. If the input item is not a matching sequence, the execution of the conversion specification shall fail; this condition is a matching failure. Unless assignment suppression was indicated by a `*`, the result of the conversion shall be placed in the object pointed to by the first argument following the `format` argument that has not already received a conversion result if the conversion specification is introduced by `%`, or in the `n`th argument if introduced by the wide-character sequence `"%n$"`. If this object does not have an appropriate type, or if the result of the conversion cannot be represented in the space provided, the behavior is undefined.

The length modifiers and their meanings are:

- **hh**  Specifies that a following `d`, `i`, `o`, `u`, `x`, or `n` conversion specifier applies to an argument with type pointer to `signed char` or `unsigned char`.
- **h**   Specifies that a following `d`, `i`, `o`, `u`, `x`, or `n` conversion specifier applies to an argument with type pointer to `short` or `unsigned short`.
- **l**  (ell) Specifies that a following `d`, `i`, `o`, `u`, `x`, or `n` conversion specifier applies to an argument with type pointer to `long` or `unsigned long`; that a following `a`, `A`, `e`, `E`, `f`, `F`, `g`, or `G` conversion specifier applies to an argument with type pointer to `double`; or that a following `c`, `s`, or `l` conversion specifier applies to an argument with type pointer to `wchar_t`.

478 System Interfaces, Issue 6 — Copyright © 2001-2003, IEEE and The Open Group. All rights reserved.
1 Specifies that a following d, i, o, u, x, X, or n conversion specifier applies to an argument with type pointer to \texttt{long long} or \texttt{unsigned long long}.

j Specifies that a following d, i, o, u, x, X, or n conversion specifier applies to an argument with type pointer to \texttt{intmax_t} or \texttt{uintmax_t}.

z Specifies that a following d, i, o, u, x, X, or n conversion specifier applies to an argument with type pointer to \texttt{size_t} or the corresponding signed integer type.

t Specifies that a following d, i, o, u, x, X, or n conversion specifier applies to an argument with type pointer to \texttt{ptrdiff_t} or the corresponding \texttt{unsigned} type.

L Specifies that a following a, A, e, E, f, F, g, or G conversion specifier applies to an argument with type pointer to \texttt{long double}.

If a length modifier appears with any conversion specifier other than as specified above, the behavior is undefined.

The following conversion specifier wide characters are valid:

d Matches an optionally signed decimal integer, whose format is the same as expected for the subject sequence of \texttt{wcstol()} with the value 10 for the \texttt{base} argument. In the absence of a size modifier, the application shall ensure that the corresponding argument is a pointer to \texttt{int}.

i Matches an optionally signed integer, whose format is the same as expected for the subject sequence of \texttt{wcstol()} with 0 for the \texttt{base} argument. In the absence of a size modifier, the application shall ensure that the corresponding argument is a pointer to \texttt{int}.

o Matches an optionally signed octal integer, whose format is the same as expected for the subject sequence of \texttt{wcstoul()} with the value 8 for the \texttt{base} argument. In the absence of a size modifier, the application shall ensure that the corresponding argument is a pointer to \texttt{unsigned}.

u Matches an optionally signed decimal integer, whose format is the same as expected for the subject sequence of \texttt{wcstoul()} with the value 10 for the \texttt{base} argument. In the absence of a size modifier, the application shall ensure that the corresponding argument is a pointer to \texttt{unsigned}.

x Matches an optionally signed hexadecimal integer, whose format is the same as expected for the subject sequence of \texttt{wcstoul()} with the value 16 for the \texttt{base} argument. In the absence of a size modifier, the application shall ensure that the corresponding argument is a pointer to \texttt{unsigned}.

a, e, f, g Matches an optionally signed floating-point number, infinity, or NaN whose format is the same as expected for the subject sequence of \texttt{wcstod()} in the absence of a size modifier, the application shall ensure that the corresponding argument is a pointer to \texttt{float}.

If the \texttt{fprintf()} family of functions generates character string representations for infinity and NaN (a symbolic entity encoded in floating-point format) to support IEEE Std 754-1985, the \texttt{fscanf()} family of functions shall recognize them as input.

s Matches a sequence of non white-space wide characters. If no l (ell) qualifier is present, characters from the input field shall be converted as if by repeated calls to the \texttt{wcrtomb()} function, with the conversion state described by an \texttt{mbstate_t} object.
initialized to zero before the first wide character is converted. The application shall ensure that the corresponding argument is a pointer to a character array large enough to accept the sequence and the terminating null character, which shall be added automatically.

Otherwise, the application shall ensure that the corresponding argument is a pointer to an array of `wchar_t` large enough to accept the sequence and the terminating null wide character, which shall be added automatically.

Matches a non-empty sequence of wide characters from a set of expected wide characters (the `scanset`). If no `ell` qualifier is present, wide characters from the input field shall be converted as if by repeated calls to the `wctomb()` function, with the conversion state described by an `mbstate_t` object initialized to zero before the first wide character is converted. The application shall ensure that the corresponding argument is a pointer to a character array large enough to accept the sequence and the terminating null character, which shall be added automatically.

If an `ell` qualifier is present, the application shall ensure that the corresponding argument is a pointer to an array of `wchar_t` large enough to accept the sequence and the terminating null wide character, which shall be added automatically.

The conversion specification includes all subsequent wide characters in the format string up to and including the matching right square bracket (`[ ]`). The wide characters between the square brackets (the `scanset`) comprise the scanset, unless the wide character after the left square bracket is a circumflex (`ˆ`), in which case the scanset contains all wide characters that do not appear in the scanset between the circumflex and the right square bracket. If the conversion specification begins with "[ ]" or "[ ]", the right square bracket is included in the scanset and the next right square bracket is the matching right square bracket that ends the conversion specification; otherwise, the first right square bracket is the one that ends the conversion specification. If a `−` is in the scanset and is not the first wide character, nor the second where the first wide character is a `ˆ`, nor the last wide character, the behavior is implementation-defined.

Matches a sequence of wide characters of exactly the number specified by the field width (1 if no field width is present in the conversion specification).

If no `ell` length modifier is present, characters from the input field shall be converted as if by repeated calls to the `wctomb()` function, with the conversion state described by an `mbstate_t` object initialized to zero before the first wide character is converted. The corresponding argument shall be a pointer to the initial element of a character array large enough to accept the sequence. No null character is added.

If an `ell` length modifier is present, the corresponding argument shall be a pointer to the initial element of an array of `wchar_t` large enough to accept the sequence. No null wide character is added.

Otherwise, the application shall ensure that the corresponding argument is a pointer to an array of `wchar_t` large enough to accept the sequence. No null wide character is added.

Matches an implementation-defined set of sequences, which shall be the same as the set of sequences that is produced by the `%%` conversion specification of the corresponding `fprintf()` functions. The application shall ensure that the corresponding argument is a pointer to a pointer to `void`. The interpretation of the input item is implementation-defined. If the input item is a value converted earlier during the same program execution, the pointer that results shall compare equal to that value; otherwise, the
behavior of the %p conversion is undefined.

%n No input is consumed. The application shall ensure that the corresponding argument is a pointer to the integer into which is to be written the number of wide characters read from the input so far by this call to the fwscanf() functions. Execution of a %n conversion specification shall not increment the assignment count returned at the completion of execution of the function. No argument shall be converted, but one shall be consumed. If the conversion specification includes an assignment-suppressing wide character or a field width, the behavior is undefined.

C Equivalent to 1c.
S Equivalent to 1s.

%% Matches a single '%' wide character; no conversion or assignment shall occur. The complete conversion specification shall be %.

If a conversion specification is invalid, the behavior is undefined.

The conversion specifiers A, E, F, G, and X are also valid and shall be equivalent to, respectively, a, e, f, g, and x.

If end-of-file is encountered during input, conversion is terminated. If end-of-file occurs before any wide characters matching the current conversion specification (except for %n) have been read (other than leading white-space, where permitted), execution of the current conversion specification shall terminate with an input failure. Otherwise, unless execution of the current conversion specification is terminated with a matching failure, execution of the following conversion specification (if any) shall be terminated with an input failure.

Reaching the end of the string in swscanf() shall be equivalent to encountering end-of-file for fwsscanf().

If conversion terminates on a conflicting input, the offending input shall be left unread in the input. Any trailing white space (including <newline>) shall be left unread unless matched by a conversion specification. The success of literal matches and suppressed assignments is only directly determinable via the %n conversion specification.

The fwscanf() and wscanf() functions may mark the st_atime field of the file associated with stream for update. The st_atime field shall be marked for update by the first successful execution of fgetc(), fgetwc(), fgets(), fgetws(), fread(), getc(), getwc(), getchar(), getwchar(), gets(), fscanf(), or fwscanf() using stream that returns data not supplied by a prior call to ungetc().

RETURN VALUE

Upon successful completion, these functions shall return the number of successfully matched and assigned input items; this number can be zero in the event of an early matching failure. If the input ends before the first matching failure or conversion, EOF shall be returned. If a read error occurs, the error indicator for the stream is set, EOF shall be returned, and errno shall be set to indicate the error.

ERRORS

For the conditions under which the fwscanf() functions shall fail and may fail, refer to fgetwc().

In addition, fwscanf() may fail if:

EILSEQ Input byte sequence does not form a valid character.
EINV[AL] There are insufficient arguments.
EXAMPLES

The call:

```
int i, n; float x; char name[50];
n = wscanf(L"%d%f%s", &i, &x, name);
```

with the input line:
```
25 54.32E−1 Hamster
```

assigns to `n` the value 3, to `i` the value 25, to `x` the value 5.432, and `name` contains the string "Hamster".

The call:

```
int i; float x; char name[50];
(void) wscanf(L"%2d%f%*d %[0123456789]", &i, &x, name);
```

with input:
```
56789 0123 56a72
```

assigns 56 to `i`, 789.0 to `x`, skips 0123, and places the string "56\0" in `name`. The next call to `getchar()` shall return the character ‘a’.

APPLICATION USAGE

In format strings containing the ‘%’ form of conversion specifications, each argument in the argument list is used exactly once.

RATIONALE

None.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

Issue 6

The DESCRIPTION is updated to avoid use of the term “must” for application requirements.

The following changes are made for alignment with the ISO/IEC 9899:1999 standard:

- The prototypes for `fwscanf()` and `swscanf()` are updated.
- The DESCRIPTION is updated.
- The hh, ll, j, t, and z length modifiers are added.
- The a, A, and F conversion characters are added.

The DESCRIPTION is updated to use the terms ‘conversion specifier’ and ‘conversion specification’ consistently.
NAME
gai_strerror — address and name information error description

SYNOPSIS
#include <netdb.h>
const char *gai_strerror(int ecode);

DESCRIPTION
The gai_strerror() function shall return a text string describing an error value for the getaddrinfo() and getnameinfo() functions listed in the <netdb.h> header.

When the ecode argument is one of the following values listed in the <netdb.h> header:

[EAI_AGAIN]
[EAI_BADFLAGS]
[EAI_FAIL]
[EAI_FAMILY]
[EAI_MEMORY]
[EAI_NONAME]
[EAI_OVERFLOW]
[EAI_SERVICE]
[EAI_SOCKTYPE]
[EAI_SYSTEM]

the function return value shall point to a string describing the error. If the argument is not one of those values, the function shall return a pointer to a string whose contents indicate an unknown error.

RETURN VALUE
Upon successful completion, gai_strerror() shall return a pointer to an implementation-defined string.

ERRORS
No errors are defined.

EXAMPLES
None.

APPLICATION USAGE
None.

RATIONALE
None.

FUTURE DIRECTIONS
None.

SEE ALSO
getaddrinfo(), the Base Definitions volume of IEEE Std 1003.1-2001, <netdb.h>

CHANGE HISTORY
First released in Issue 6. Derived from the XNS, Issue 5.2 specification.

The Open Group Base Resolution bwg2001-009 is applied, which changes the return type from char * to const char *. This is for coordination with the IPnG Working Group.

NAME
gcvt — convert a floating-point number to a string (LEGACY)

SYNOPSIS
#include <stdlib.h>
char *gcvt(double value, int ndigit, char *buf);

DESCRIPTION
Refer to ecvt().
NAME
getaddrinfo — get address information

SYNOPSIS
#include <sys/socket.h>
#include <netdb.h>

int getaddrinfo(const char *restrict nodename,
const char *restrict servname,
const struct addrinfo *restrict hints,
struct addrinfo **restrict res);

DESCRIPTION
Refer to freeaddrinfo().
getc() — get a byte from a stream

#include <stdio.h>

int getc(FILE *stream);

The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-2001 defers to the ISO C standard.

The getc() function shall be equivalent to fgetc(), except that if it is implemented as a macro it may evaluate stream more than once, so the argument should never be an expression with side effects.

Refer to fgetc().

Refer to fgetc().

None.

If the integer value returned by getc() is stored into a variable of type char and then compared against the integer constant EOF, the comparison may never succeed, because sign-extension of a variable of type char on widening to integer is implementation-defined.

Since it may be implemented as a macro, getc() may treat incorrectly a stream argument with side effects. In particular, getc(*f++) does not necessarily work as expected. Therefore, use of this function should be preceded by "#undef getc" in such situations; fgetc() could also be used.

fgetc(), the Base Definitions volume of IEEE Std 1003.1-2001, <stdio.h>

First released in Issue 1. Derived from Issue 1 of the SVID.
NAME

getc_unlocked, getchar_unlocked, putc_unlocked, putchar_unlocked — stdio with explicit client locking

SYNOPSIS

```c
#include <stdio.h>

int getc_unlocked(FILE *stream);
int getchar_unlocked(void);
int putc_unlocked(int c, FILE *stream);
int putchar_unlocked(int c);
```

DESCRIPTION

Versions of the functions getc(), getchar(), putc(), and putchar() respectively named getc_unlocked(), getchar_unlocked(), putc_unlocked(), and putchar_unlocked() shall be provided which are functionally equivalent to the original versions, with the exception that they are not required to be implemented in a thread-safe manner. They may only safely be used within a scope protected by flockfile() (or ftrylockfile()) and funlockfile(). These functions may safely be used in a multi-threaded program if and only if they are called while the invoking thread owns the (FILE *) object, as is the case after a successful call to the flockfile() or ftrylockfile() functions.

RETURN VALUE

See getc(), getchar(), putc(), and putchar().

ERRORS

See getc(), getchar(), putc(), and putchar().

EXAMPLES

None.

APPLICATION USAGE

Since they may be implemented as macros, getc_unlocked() and putc_unlocked() may treat incorrectly a stream argument with side effects. In particular, getc_unlocked("f++") and putc_unlocked("f++") do not necessarily work as expected. Therefore, use of these functions in such situations should be preceded by the following statement as appropriate:

```c
#undef getc_unlocked
#undef putc_unlocked
```

RATIONALE

Some I/O functions are typically implemented as macros for performance reasons (for example, putc() and getc()). For safety, they need to be synchronized, but it is often too expensive to synchronize on every character. Nevertheless, it was felt that the safety concerns were more important; consequently, the getc(), getchar(), putc(), and putchar() functions are required to be thread-safe. However, unlocked versions are also provided with names that clearly indicate the unsafe nature of their operation but can be used to exploit their higher performance. These unlocked versions can be safely used only within explicitly locked program regions, using exported locking primitives. In particular, a sequence such as:

```c
flockfile(fileptr);
putc_unlocked('', fileptr);
putc_unlocked('', fileptr);
fprintf(fileptr, "Line 2\n");
funlockfile(fileptr);
```

is permissible, and results in the text sequence:
It would be wrong to have the standard names such as `getc()`, `putc()`, and so on, map to the "faster, but unsafe" rather than the "slower, but safe" versions. In either case, you would still want to inspect all uses of `getc()`, `putc()`, and so on, by hand when converting existing code. Choosing the safe bindings as the default, at least, results in correct code and maintains the "atomicity at the function" invariant. To do otherwise would introduce gratuitous synchronization errors into converted code. Other routines that modify the `stdio (FILE *)` structures or buffers are also safely synchronized.

Note that there is no need for functions of the form `getc_locked()`, `putc_locked()`, and so on, since this is the functionality of `getc()`, `putc()`, et al. It would be inappropriate to use a feature test macro to switch a macro definition of `getc()` between `getc_locked()` and `getc_unlocked()`, since the ISO C standard requires an actual function to exist, a function whose behavior could not be changed by the feature test macro. Also, providing both the `xxx_locked()` and `xxx_unlocked()` forms leads to the confusion of whether the suffix describes the behavior of the function or the circumstances under which it should be used.

Three additional routines, `flockfile()`, `ftrylockfile()`, and `funlockfile()` (which may be macros), are provided to allow the user to delineate a sequence of I/O statements that are executed synchronously.

The `ungetc()` function is infrequently called relative to the other functions/macros so no unlocked variation is needed.

**FUTURE DIRECTIONS**

None.

**SEE ALSO**

`getc()`, `getchar()`, `putc()`, `putchar()`, the Base Definitions volume of IEEE Std 1003.1-2001, `<stdio.h>`

**CHANGE HISTORY**

First released in Issue 5. Included for alignment with the POSIX Threads Extension.

**Issue 6**

These functions are marked as part of the Thread-Safe Functions option.

The Open Group Corrigendum U030/2 is applied, adding APPLICATION USAGE describing how applications should be written to avoid the case when the functions are implemented as macros.
NAME
getchar — get a byte from a stdin stream

SYNOPSIS
#include <stdio.h>
int getchar(void);

DESCRIPTION
The functionality described on this reference page is aligned with the ISO C standard. Any
conflict between the requirements described here and the ISO C standard is unintentional. This
The getchar() function shall be equivalent to getc(stdin).

RETURN VALUE
Refer to fgetc().

ERRORS
Refer to fgetc().

EXAMPLES
None.

APPLICATION USAGE
If the integer value returned by getchar() is stored into a variable of type char and then
compared against the integer constant EOF, the comparison may never succeed, because sign-
extension of a variable of type char on widening to integer is implementation-defined.

RATIONALE
None.

getchar_unlocked()

NAME
getchar_unlocked — stdio with explicit client locking

SYNOPSIS
#include <stdio.h>

int getchar_unlocked(void);

DESCRIPTION
Refer to getc_unlocked().
NAME
getcontext, setcontext — get and set current user context

SYNOPSIS
XSI
#include <ucontext.h>

int getcontext(ucontext_t *ucp);
int setcontext(const ucontext_t *ucp);

DESCRIPTION
The getcontext() function shall initialize the structure pointed to by ucp to the current user context of the calling thread. The ucontext_t type that ucp points to defines the user context and includes the contents of the calling thread's machine registers, the signal mask, and the current execution stack.

The setcontext() function shall restore the user context pointed to by ucp. A successful call to setcontext() shall not return; program execution resumes at the point specified by the ucp argument passed to setcontext(). The ucp argument should be created either by a prior call to getcontext() or makecontext(), or by being passed as an argument to a signal handler. If the ucp argument was created with getcontext(), program execution continues as if the corresponding call of getcontext() had just returned. If the ucp argument was created with makecontext(), program execution continues with the function passed to makecontext(). When that function returns, the thread shall continue as if after a call to setcontext() with the ucp argument that was input to makecontext(). If the uc_link member of the ucontext_t structure pointed to by the ucp argument is equal to 0, then this context is the main context, and the thread shall exit when this context returns. The effects of passing a ucp argument obtained from any other source are unspecified.

RETURN VALUE
Upon successful completion, setcontext() shall not return and getcontext() shall return 0; otherwise, a value of −1 shall be returned.

ERRORS
No errors are defined.

EXAMPLES
Refer to makecontext().

APPLICATION USAGE
When a signal handler is executed, the current user context is saved and a new context is created. If the thread leaves the signal handler via longjmp(), then it is unspecified whether the context at the time of the corresponding setjmp() call is restored and thus whether future calls to getcontext() provide an accurate representation of the current context, since the context restored by longjmp() does not necessarily contain all the information that setcontext() requires. Signal handlers should use siglongjmp() or setcontext() instead.

Conforming applications should not modify or access the uc_mcontext member of ucontext_t. A conforming application cannot assume that context includes any process-wide static data, possibly including errno. Users manipulating contexts should take care to handle these explicitly when required.

Use of contexts to create alternate stacks is not defined by this volume of IEEE Std 1003.1-2001.
getcontext()

RATIONALE
None.

FUTURE DIRECTIONS
None.

SEE ALSO
bsd_signal(), makecontext(), setcontext(), setjmp(), sigaction(), sigaltstack(), siglongjmp(),
sigprocmask(), sigsetjmp(), the Base Definitions volume of IEEE Std 1003.1-2001, <ucontext.h>

CHANGE HISTORY
First released in Issue 4, Version 2.

Issue 5
Moved from X/OPEN UNIX extension to BASE.

The following sentence was removed from the DESCRIPTION: “If the ucp argument was passed to a signal handler, program execution continues with the program instruction following the instruction interrupted by the signal.”
NAME
getcwd — get the pathname of the current working directory

SYNOPSIS
#include <unistd.h>
char *getcwd(char *buf, size_t size);

DESCRIPTION
The getcwd() function shall place an absolute pathname of the current working directory in the
array pointed to by buf, and return buf. The pathname copied to the array shall contain no
components that are symbolic links. The size argument is the size in bytes of the character array
pointed to by the buf argument. If buf is a null pointer, the behavior of getcwd() is unspecified.

RETURN VALUE
Upon successful completion, getcwd() shall return the buf argument. Otherwise, getcwd() shall
return a null pointer and set errno to indicate the error. The contents of the array pointed to by
buf are then undefined.

ERRORS
The getcwd() function shall fail if:

[EINVAL] The size argument is 0.
[ERANGE] The size argument is greater than 0, but is smaller than the length of the
pathname +1.

The getcwd() function may fail if:

[EACCES] Read or search permission was denied for a component of the pathname.
[ENOMEM] Insufficient storage space is available.

EXAMPLES
Determining the Absolute Pathname of the Current Working Directory
The following example returns a pointer to an array that holds the absolute pathname of the
current working directory. The pointer is returned in the ptr variable, which points to the buf
array where the pathname is stored.

#include <stdlib.h>
#include <unistd.h>
...
long size;
char *buf;
char *ptr;
size = pathconf(".", _PC_PATH_MAX);
if ((buf = (char *)malloc((size_t)size)) != NULL)
    ptr = getcwd(buf, (size_t)size);
...

APPLICATION USAGE
None.
getcwd( )

RATIONALE

Since the maximum pathname length is arbitrary unless \{PATH_MAX\} is defined, an application
generally cannot supply a \textit{buf} with size \{\text{\[PATH_MAX]\}}+1\).

Having \textit{getcwd()} take no arguments and instead use the \textit{malloc()} function to produce space for
the returned argument was considered. The advantage is that \textit{getcwd()} knows how big the
working directory pathname is and can allocate an appropriate amount of space. But the
programmer would have to use the \textit{free()} function to free the resulting object, or each use of
\textit{getcwd()} would further reduce the available memory. Also, \textit{malloc()} and \textit{free()} are used nowhere
else in this volume of IEEE Std 1003.1-2001. Finally, \textit{getcwd()} is taken from the SVID where it has
the two arguments used in this volume of IEEE Std 1003.1-2001.

The older function \textit{getwd()} was rejected for use in this context because it had only a buffer
argument and no \textit{size} argument, and thus had no way to prevent overwriting the buffer, except
to depend on the programmer to provide a large enough buffer.

On some implementations, if \textit{buf} is a null pointer, \textit{getcwd()} may obtain \textit{size} bytes of memory
using \textit{malloc()}. In this case, the pointer returned by \textit{getcwd()} may be used as the argument in a
subsequent call to \textit{free()}. Invoking \textit{getcwd()} with \textit{buf} as a null pointer is not recommended in
conforming applications.

If a program is operating in a directory where some (grand)parent directory does not permit
reading, \textit{getcwd()} may fail, as in most implementations it must read the directory to determine
the name of the file. This can occur if search, but not read, permission is granted in an
intermediate directory, or if the program is placed in that directory by some more privileged
process (for example, login). Including the \{EACCES\} error condition makes the reporting of the
error consistent and warns the application writer that \textit{getcwd()} can fail for reasons beyond the
control of the application writer or user. Some implementations can avoid this occurrence (for
example, by implementing \textit{getcwd()} using \textit{pwd}, where \textit{pwd} is a set-user-root process), thus the
error was made optional. Since this volume of IEEE Std 1003.1-2001 permits the addition of other
errors, this would be a common addition and yet one that applications could not be expected to
deal with without this addition.

FUTURE DIRECTIONS

None.

SEE ALSO

\textit{malloc()}, the Base Definitions volume of IEEE Std 1003.1-2001, \texttt{<unistd.h>}

CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 6

The following new requirements on POSIX implementations derive from alignment with the
Single UNIX Specification:

- The \{ENOMEM\} optional error condition is added.
NAME

gdate — convert user format date and time

SYNOPSIS

#include <time.h>

struct tm *getdate(const char *string);

DESCRIPTION

The getdate() function shall convert a string representation of a date or time into a broken-down
time.

The external variable or macro getdate_err is used by getdate() to return error values.

Templates are used to parse and interpret the input string. The templates are contained in a text
file identified by the environment variable DATEMSK. The DATEMSK variable should be set to
indicate the full pathname of the file that contains the templates. The first line in the template
that matches the input specification is used for interpretation and conversion into the internal
time format.

The following conversion specifications shall be supported:

%  Equivalent to %.
%a  Abbreviated weekday name.
%A  Full weekday name.
%b  Abbreviated month name.
%B  Full month name.
%c  Locale's appropriate date and time representation.
%C  Century number [00,99]; leading zeros are permitted but not required.
%d  Day of month [01,31]; the leading 0 is optional.
%d  Date as %m/%d/%y.
%e  Equivalent to %d.
%h  Abbreviated month name.
%H  Hour [00,23].
%I  Hour [01,12].
%m  Month number [01,12].
%M  Minute [00,59].
%n  Equivalent to <newline>.
%p  Locale's equivalent of either AM or PM.
%r  The locale's appropriate representation of time in AM and PM notation. In the POSIX
locale, this shall be equivalent to %I:%M:%S %p.
%R  Time as %H:%M.
%S  Seconds [00,60]. The range goes to 60 (rather than stopping at 59) to allow positive leap
seconds to be expressed. Since leap seconds cannot be predicted by any algorithm, leap
second data must come from some external source.
getdate()  System Interfaces

16360  \%t  Equivalent to <tab>.
16361  \%T  Time as \%H:\%M:\%S.
16362  \%w  Weekday number (Sunday = [0,6]).
16363  \%x  Locale's appropriate date representation.
16364  \%X  Locale's appropriate time representation.
16365  \%y  Year within century. When a century is not otherwise specified, values in the range [69,99] shall refer to years 1969 to 1999 inclusive, and values in the range [00,68] shall refer to years 2000 to 2068 inclusive.
16366  Note: It is expected that in a future version of IEEE Std 1003.1-2001 the default century inferred from a 2-digit year will change. (This would apply to all commands accepting a 2-digit year as input.)
16367  \%Y  Year as "ccyy" (for example, 2001).
16368  \%Z  Timezone name or no characters if no timezone exists. If the timezone supplied by \%Z is not the timezone that getdate() expects, an invalid input specification error shall result.
16369  The getdate() function calculates an expected timezone based on information supplied to the function (such as the hour, day, and month).
16370  The match between the template and input specification performed by getdate() shall be case-insensitive.
16371  The month and weekday names can consist of any combination of upper and lowercase letters.
16372  The process can request that the input date or time specification be in a specific language by setting the LC_TIME category (see setlocale()).
16373  Leading zeros are not necessary for the descriptors that allow leading zeros. However, at most two digits are allowed for those descriptors, including leading zeros. Extra whitespace in either the template file or in string shall be ignored.
16374  The results are undefined if the conversion specifications \%c, \%x, and \%X include unsupported conversion specifications.
16375  The following rules apply for converting the input specification into the internal format:
16376  • If \%Z is being scanned, then getdate() shall initialize the broken-down time to be the current time in the scanned timezone. Otherwise, it shall initialize the broken-down time based on the current local time as if localtime() had been called.
16377  • If only the weekday is given, the day chosen shall be the day, starting with today and moving into the future, which first matches the named day.
16378  • If only the month (and no year) is given, the month chosen shall be the month, starting with the current month and moving into the future, which first matches the named month. The first day of the month shall be assumed if no day is given.
16379  • If no hour, minute, and second are given, the current hour, minute, and second shall be assumed.
16380  • If no date is given, the hour chosen shall be the hour, starting with the current hour and moving into the future, which first matches the named hour.
16381  If a conversion specification in the DATEMSK file does not correspond to one of the conversion specifications above, the behavior is unspecified.
16382  The getdate() function need not be reentrant. A function that is not required to be reentrant is not required to be thread-safe.
RETURN VALUE
Upon successful completion, `getdate()` shall return a pointer to a `struct tm`. Otherwise, it shall return a null pointer and set `getdate_err` to indicate the error.

ERRORS
The `getdate()` function shall fail in the following cases, setting `getdate_err` to the value shown in the list below. Any changes to `errno` are unspecified.

1. The `DATEMSK` environment variable is null or undefined.
2. The template file cannot be opened for reading.
3. Failed to get file status information.
4. The template file is not a regular file.
5. An I/O error is encountered while reading the template file.
6. Memory allocation failed (not enough memory available).
7. There is no line in the template that matches the input.
8. Invalid input specification. For example, February 31; or a time is specified that cannot be represented in a `time_t` (representing the time in seconds since the Epoch).

EXAMPLES
1. The following example shows the possible contents of a template:
   ```
   %m
   %A %B %d, %Y, %H:%M:%S
   %A
   %B
   %m/%d/%y %I %p
   %d,%m,%Y %H:%M
   at %A the %dst of %B in %Y
   run job at %I %p,%B %dnd
   %A den %d. %B %Y %H.%M Uhr
   ```
2. The following are examples of valid input specifications for the template in Example 1:
   ```
   getdate("10/1/87 4 PM");
   getdate("Friday");
   getdate("Friday September 18, 1987, 10:30:30");
   getdate("24,9,1986 10:30");
   getdate("at monday the 1st of december in 1986");
   getdate("run job at 3 PM, december 2nd");
   ```
   If the `LC_TIME` category is set to a German locale that includes `freitag` as a weekday name and `oktober` as a month name, the following would be valid:
   ```
   getdate("freitag den 10. oktober 1986 10.30 Uhr");
   ```
3. The following example shows how local date and time specification can be defined in the template:
## getdate()

### Invocation Line in Template

<table>
<thead>
<tr>
<th>Invocation</th>
<th>Line in Template</th>
</tr>
</thead>
<tbody>
<tr>
<td>getdate(&quot;11/27/86&quot;)</td>
<td>%m/%d/%y</td>
</tr>
<tr>
<td>getdate(&quot;27.11.86&quot;)</td>
<td>%d.%m.%y</td>
</tr>
<tr>
<td>getdate(&quot;86-11-27&quot;)</td>
<td>%y-%m-%d</td>
</tr>
<tr>
<td>getdate(&quot;Friday 12:00:00&quot;)</td>
<td>%A %H:%M:%S</td>
</tr>
</tbody>
</table>

4. The following examples help to illustrate the above rules assuming that the current date is Mon Sep 22 12:19:47 EDT 1986 and the LC_TIME category is set to the default C locale:

<table>
<thead>
<tr>
<th>Input</th>
<th>Line in Template</th>
