  Branch to the : function bearing the `label`. If `label` is not specified, branch to the end of the script. The implementation shall support `labels` recognized as unique up to at least 8 characters; the actual length (greater than or equal to 8) that shall be supported by the implementation is unspecified. It is unspecified whether exceeding a label length causes an error or a silent truncation.

[2addr]c\
  text  Delete the pattern space. With a 0 or 1 address or at the end of a 2-address range, place `text` on the output and start the next cycle.

[2addr]d  Delete the pattern space and start the next cycle.

[2addr]D Delete the initial segment of the pattern space through the first <newline> and start the next cycle.

[2addr]g Replace the contents of the pattern space by the contents of the hold space.

[2addr]G Append to the pattern space a <newline> followed by the contents of the hold space.

[2addr]h Replace the contents of the hold space with the contents of the pattern space.

[2addr]H Append to the hold space a <newline> followed by the contents of the pattern space.
```
Write text to standard output.

(The letter ell.) Write the pattern space to standard output in a visually unambiguous form. The characters listed in the Base Definitions volume of IEEE Std 1003.1-2001, Table 5-1, Escape Sequences and Associated Actions (‘\\’, ‘\a’, ‘\b’, ‘\f’, ‘\n’, ‘\r’, ‘\t’, ‘\v’) shall be written as the corresponding escape sequence; the ‘\n’ in that table is not applicable. Non-printable characters not in that table shall be written as one three-digit octal number (with a preceding backslash) for each byte in the character (most significant byte first). If the size of a byte on the system is greater than 9 bits, the format used for non-printable characters is implementation-defined.

Long lines shall be folded, with the point of folding indicated by writing a backslash followed by a <newline>; the length at which folding occurs is unspecified, but should be appropriate for the output device. The end of each line shall be marked with a ‘$’.

Write the pattern space to standard output if the default output has not been suppressed, and replace the pattern space with the next line of input, less its terminating <newline>.

If no next line of input is available, the n command verb shall branch to the end of the script and quit without starting a new cycle.

Append the next line of input, less its terminating <newline>, to the pattern space, using an embedded <newline> to separate the appended material from the original material. Note that the current line number changes.

If no next line of input is available, the N command verb shall branch to the end of the script and quit without starting a new cycle or copying the pattern space to standard output.

Write the pattern space to standard output.

Write the pattern space, up to the first <newline>, to standard output.

Branch to the end of the script and quit without starting a new cycle.

Copy the contents of rfile to standard output as described previously. If rfile does not exist or cannot be read, it shall be treated as if it were an empty file, causing no error condition.

Substitute the replacement string for instances of the BRE in the pattern space. Any character other than backslash or <newline> can be used instead of a slash to delimit the BRE and the replacement. Within the BRE and the replacement, the BRE delimiter itself can be used as a literal character if it is preceded by a backslash.

The replacement string shall be scanned from beginning to end. An ampersand (‘&’) appearing in the replacement shall be replaced by the string matching the BRE. The special meaning of ‘&’ in this context can be suppressed by preceding it by a backslash. The characters ‘\n’, where n is a digit, shall be replaced by the text matched by the corresponding backreference expression. The special meaning of ‘\n’ where n is a digit in this context, can be suppressed by preceding it by a backslash. For each other backslash (‘\’) encountered, the following character shall lose its special meaning (if any). The meaning of a ‘\’ immediately followed...
by any character other than ' & ', ' \ ', a digit, or the delimiter character used for this command, is unspecified.

A line can be split by substituting a <newline> into it. The application shall escape the <newline> in the replacement by preceding it by a backslash. A substitution shall be considered to have been performed even if the replacement string is identical to the string that it replaces. Any backslash used to alter the default meaning of a subsequent character shall be discarded from the BRE or the replacement before evaluating the BRE or using the replacement.

The value of flags shall be zero or more of:

- **n**: Substitute for the nth occurrence only of the BRE found within the pattern space.
- **g**: Globally substitute for all non-overlapping instances of the BRE rather than just the first one. If both g and n are specified, the results are unspecified.
- **p**: Write the pattern space to standard output if a replacement was made.
- **w wfile**: Write. Append the pattern space to wfile if a replacement was made. A conforming application shall precede the wfile argument with one or more <blank>s. If the w flag is not the last flag value given in a concatenation of multiple flag values, the results are undefined.

```
[2addr]t [label]
```
Test. Branch to the : command verb bearing the label if any substitutions have been made since the most recent reading of an input line or execution of a t. If label is not specified, branch to the end of the script.

```
[2addr]w wfile
```
Append (write) the pattern space to wfile.

```
[2addr]x
```
Exchange the contents of the pattern and hold spaces.

```
[2addr]/string1string2/
```
Replace all occurrences of characters in string1 with the corresponding characters in string2. If a backslash followed by an ‘n’ appear in string1 or string2, the two characters shall be handled as a single <newline>. If the number of characters in string1 and string2 are not equal, or if any of the characters in string1 appear more than once, the results are undefined. Any character other than backslash or <newline> can be used instead of slash to delimit the strings. If the delimiter is not n, within string1 and string2, the delimiter itself can be used as a literal character if it is preceded by a backslash. If a backslash character is immediately followed by a backslash character in string1 or string2, the two backslash characters shall be counted as a single literal backslash character. The meaning of a backslash followed by any character that is not ‘n’, a backslash, or the delimiter character is undefined.

```
[0addr]:label
```
Do nothing. This command bears a label to which the b and t commands branch.

```
[1addr]=
```
Write the following to standard output:

```
"%d\n", <current line number>
```

```
[0addr]
```
Ignore this empty command.
Ignore the ‘#’ and the remainder of the line (treat them as a comment), with the single exception that if the first two characters in the script are "#n", the default output shall be suppressed; this shall be the equivalent of specifying -n on the command line.

EXIT STATUS
The following exit values shall be returned:

- 0   Successful completion.
- >0  An error occurred.

CONSEQUENCES OF ERRORS
Default.

APPLICATION USAGE
Regular expressions match entire strings, not just individual lines, but a <newline> is matched by `{|n` in a sed RE; a <newline> is not allowed by the general definition of regular expression in IEEE Std 1003.1-2001. Also note that `{|n` cannot be used to match a <newline> at the end of an arbitrary input line; <newline>s appear in the pattern space as a result of the N editing command.

EXAMPLES
This sed script simulates the BSD cat -s command, squeezing excess blank lines from standard input.

```bash
sed -n '
# Write non-empty lines.
/./ {
  p
  d
}
# Write a single empty line, then look for more empty lines.
/^$/ p
# Get next line, discard the held <newline> (empty line),
# and look for more empty lines.
:Empty
/^$/   {
  N
  s/.//
  b Empty
}
# Write the non-empty line before going back to search
# for the first in a set of empty lines.
  p
',
```

RATIONALE
This volume of IEEE Std 1003.1-2001 requires implementations to support at least ten distinct wfiles, matching historical practice on many implementations. Implementations are encouraged to support more, but conforming applications should not exceed this limit.

The exit status codes specified here are different from those in System V. System V returns 2 for garbled sed commands, but returns zero with its usage message or if the input file could not be opened. The standard developers considered this to be a bug.
The manner in which the I command writes non-printable characters was changed to avoid the historical backspace-overstrike method, and other requirements to achieve unambiguous output were added. See the RATIONALE for ed for details of the format chosen, which is the same as that chosen for sed.

This volume of IEEE Std 1003.1-2001 requires implementations to provide pattern and hold spaces of at least 8192 bytes, larger than the 4000 bytes spaces used by some historical implementations, but less than the 20480 bytes limit used in an early proposal. Implementations are encouraged to allocate dynamically larger pattern and hold spaces as needed.

The requirements for acceptance of <blank>s and <space>s in command lines has been made more explicit than in early proposals to describe clearly the historical practice and to remove confusion about the phrase "protect initial blanks [sic] and tabs from the stripping that is done on every script line" that appears in much of the historical documentation of the sed utility description of text. (Not all implementations are known to have stripped <blank>s from text lines, although they all have allowed leading <blank>s preceding the address on a command line.)

The treatment of ' # ' comments differs from the SVID which only allows a comment as the first line of the script, but matches BSD-derived implementations. The comment character is treated as a command, and it has the same properties in terms of being accepted with leading <blank>s; the BSD implementation has historically supported this.

Early proposals required that a script_file have at least one non-comment line. Some historical implementations have behaved in unexpected ways if this were not the case. The standard developers considered that this was incorrect behavior and that application developers should not have to avoid this feature. A correct implementation of this volume of IEEE Std 1003.1-2001 shall permit script_files that consist only of comment lines.

Early proposals indicated that if −e and −f options were intermixed, all −e options were processed before any −f options. This has been changed to process them in the order presented because it matches historical practice and is more intuitive.

The treatment of the p flag to the s command differs between System V and BSD-based systems when the default output is suppressed. In the two examples:

```
echo a | sed 's/a/A/p'
echo a | sed −n 's/a/A/p'
```

this volume of IEEE Std 1003.1-2001, BSD, System V documentation, and the SVID indicate that the first example should write two lines with A, whereas the second should write one. Some System V systems write the A only once in both examples because the p flag is ignored if the −n option is not specified.

This is a case of a diametrical difference between systems that could not be reconciled through the compromise of declaring the behavior to be unspecified. The SVID/BSD/System V documentation behavior was adopted for this volume of IEEE Std 1003.1-2001 because:

- No known documentation for any historic system describes the interaction between the p flag and the −n option.

- The selected behavior is more correct as there is no technical justification for any interaction between the p flag and the −n option. A relationship between −n and the p flag might imply that they are only used together, but this ignores valid scripts that interrupt the cyclical nature of the processing through the use of the D, d, q, or branching commands. Such scripts rely on the p suffix to write the pattern space because they do not make use of the default output at the “bottom” of the script.
Because the −n option makes the p flag unnecessary, any interaction would only be useful if
sed scripts were written to run both with and without the −n option. This is believed to be
unlikely. It is even more unlikely that programmers have coded the p flag expecting it to be
unnecessary. Because the interaction was not documented, the likelihood of a programmer
discovering the interaction and depending on it is further decreased.

Finally, scripts that break under the specified behavior produce too much output instead of
too little, which is easier to diagnose and correct.

The form of the substitute command that uses the n suffix was limited to the first 512 matches in
an early proposal. This limit has been removed because there is no reason an editor processing
lines of [LINE_MAX] length should have this restriction. The command s/a/A/2047 should be
able to substitute the 2,047th occurrence of a on a line.

The b, t, and : commands are documented to ignore leading white space, but no mention is
made of trailing white space. Historical implementations of sed assigned different locations to
the labels 'x' and "x ". This is not useful, and leads to subtle programming errors, but it is
historical practice, and changing it could theoretically break working scripts. Implementors are
encouraged to provide warning messages about labels that are never used or jumps to labels
that do not exist.

Historically, the sed ! and } editing commands did not permit multiple commands on a single
line using a semicolon as a command delimiter. Implementations are permitted, but not
required, to support this extension.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 5

The FUTURE DIRECTIONS section is added.

Issue 6

The following new requirements on POSIX implementations derive from alignment with the
Single UNIX Specification:

• Implementations are required to support at least ten wfile arguments in an editing command.

The EXTENDED DESCRIPTION is changed to align with the IEEE P1003.2b draft standard.

IEEE PASC Interpretation 1003.2 #190 is applied.

IEEE PASC Interpretation 1003.2 #203 is applied, clarifying the meaning of the backslash escape
sequences in a replacement string for a BRE.
NAME
sh — shell, the standard command language interpreter

SYNOPSIS
sh [-abcdefhimmnuvx] [−o option] [+abcdefhimmnuvx] [+o option]
   [command_file [argument...]]
sh −c [-abcdefhimmnuvx] [−o option] [+abcdefhimmnuvx] [+o option] command_string
   [command_name [argument...]]
sh −s [-abcdefhimmnuvx] [−o option] [+abcdefhimmnuvx] [+o option] [argument]

DESCRIPTION
The sh utility is a command language interpreter that shall execute commands read from a
command line string, the standard input, or a specified file. The application shall ensure that the
commands to be executed are expressed in the language described in Chapter 2 (on page 29).
Pathname expansion shall not fail due to the size of a file.
Shell input and output redirections have an implementation-defined offset maximum that is
established in the open file description.

OPTIONS
The sh utility shall conform to the Base Definitions volume of IEEE Std 1003.1-2001, Section 12.2,
Utility Syntax Guidelines, with an extension for support of a leading plus sign (‘+’) as noted
below.
The -a, -b, -C, -e, -f, -m, -n, -o option, -u, -v, and -x options are described as part of the set
utility in Section 2.14 (on page 64). The option letters derived from the set special built-in shall
also be accepted with a leading plus sign (‘+’) instead of a leading hyphen (meaning the reverse
case of the option as described in this volume of IEEE Std 1003.1-2001).
The following additional options shall be supported:
-c Read commands from the command_string operand. Set the value of special
parameter 0 (see Section 2.5.2 (on page 34)) from the value of the command_name
operand and the positional parameters ($1, $2, and so on) in sequence from the
remaining argument operands. No commands shall be read from the standard
input.
-i Specify that the shell is interactive; see below. An implementation may treat
specifying the -i option as an error if the real user ID of the calling process does
not equal the effective user ID or if the real group ID does not equal the effective
group ID.
-s Read commands from the standard input.

If there are no operands and the -c option is not specified, the -s option shall be assumed.
If the -i option is present, or if there are no operands and the shell’s standard input and standard
error are attached to a terminal, the shell is considered to be interactive.

OPERANDS
The following operands shall be supported:
-
A single hyphen shall be treated as the first operand and then ignored. If both ‘−’
and "−−" are given as arguments, or if other operands precede the single hyphen,
the results are undefined.
argument The positional parameters ($1, $2, and so on) shall be set to arguments, if any.
command_file The pathname of a file containing commands. If the pathname contains one or more slash characters, the implementation attempts to read that file; the file need not be executable. If the pathname does not contain a slash character:

- The implementation shall attempt to read that file from the current working directory; the file need not be executable.
- If the file is not in the current working directory, the implementation may perform a search for an executable file using the value of PATH, as described in Section 2.9.1.1 (on page 48).

Special parameter 0 (see Section 2.5.2 (on page 34)) shall be set to the value of command_file. If sh is called using a synopsis form that omits command_file, special parameter 0 shall be set to the value of the first argument passed to sh from its parent (for example, argv[0] for a C program), which is normally a pathname used to execute the sh utility.

command_name A string assigned to special parameter 0 when executing the commands in command_string. If command_name is not specified, special parameter 0 shall be set to the value of the first argument passed to sh from its parent (for example, argv[0] for a C program), which is normally a pathname used to execute the sh utility.

command_string A string that shall be interpreted by the shell as one or more commands, as if the string were the argument to the system() function defined in the System Interfaces volume of IEEE Std 1003.1-2001. If the command_string operand is an empty string, sh shall exit with a zero exit status.

STDIN The standard input shall be used only if one of the following is true:

- The −s option is specified.
- The −c option is not specified and no operands are specified.
- The script executes one or more commands that require input from standard input (such as a read command that does not redirect its input).

See the INPUT FILES section.

When the shell is using standard input and it invokes a command that also uses standard input, the shell shall ensure that the standard input file pointer points directly after the command it has read when the command begins execution. It shall not read ahead in such a manner that any characters intended to be read by the invoked command are consumed by the shell (whether interpreted by the shell or not) or that characters that are not read by the invoked command are not seen by the shell. When the command expecting to read standard input is started asynchronously by an interactive shell, it is unspecified whether characters are read by the command or interpreted by the shell.

If the standard input to sh is a FIFO or terminal device and is set to non-blocking reads, then sh shall enable blocking reads on standard input. This shall remain in effect when the command completes.

INPUT FILES The input file shall be a text file, except that line lengths shall be unlimited. If the input file is empty or consists solely of blank lines or comments, or both, sh shall exit with a zero exit status.
The following environment variables shall affect the execution of sh:

**ENV**
This variable, when and only when an interactive shell is invoked, shall be subjected to parameter expansion (see Section 2.6.2 (on page 37)) by the shell, and the resulting value shall be used as a pathname of a file containing shell commands to execute in the current environment. The file need not be executable. If the expanded value of ENV is not an absolute pathname, the results are unspecified. ENV shall be ignored if the real and effective user IDs or real and effective group IDs of the process are different.

**FCEDIT**
This variable, when expanded by the shell, shall determine the default value for the -e edit option's editor option-argument. If FCEDIT is null or unset, ed shall be used as the editor. This volume of IEEE Std 1003.1-2001 specifies the effects of this variable only for systems supporting the User Portability Utilities option.

**HISTFILE**
Determine a pathname naming a command history file. If the HISTFILE variable is not set, the shell may attempt to access or create a file .sh_history in the directory referred to by the HOME environment variable. If the shell cannot obtain both read and write access to, or create, the history file, it shall use an unspecified mechanism that allows the history to operate properly. (References to history ‘file’ in this section shall be understood to mean this unspecified mechanism in such cases.) An implementation may choose to access this variable only when initializing the history file; this initialization shall occur when fc or sh first attempt to retrieve entries from, or add entries to, the file, as the result of commands issued by the user, the file named by the ENV variable, or implementation-defined system start-up files. Implementations may choose to disable the history list mechanism for users with appropriate privileges who do not set HISTFILE; the specific circumstances under which this occurs are implementation-defined. If more than one instance of the shell is using the same history file, it is unspecified how updates to the history file from those shells interact. As entries are deleted from the history file, they shall be deleted oldest first. It is unspecified when history file entries are physically removed from the history file. This volume of IEEE Std 1003.1-2001 specifies the effects of this variable only for systems supporting the User Portability Utilities option.

**HISTSIZE**
Determine a decimal number representing the limit to the number of previous commands that are accessible. If this variable is unset, an unspecified default greater than or equal to 128 shall be used. The maximum number of commands in the history list is unspecified, but shall be at least 128. An implementation may choose to access this variable only when initializing the history file, as described under HISTFILE. Therefore, it is unspecified whether changes made to HISTSIZE after the history file has been initialized are effective.

**HOME**
Determine the pathname of the user's home directory. The contents of HOME are used in tilde expansion as described in Section 2.6.1 (on page 37). This volume of IEEE Std 1003.1-2001 specifies the effects of this variable only for systems supporting the User Portability Utilities option.

**IFS**
(Input Field Separators.) A string treated as a list of characters that shall be used for field splitting and to split lines into words with the read command. See Section 2.6.5 (on page 42). If IFS is not set, the shell shall behave as if the value of IFS were <space>, <tab>, and <newline>. Implementations may ignore the value of IFS in the environment at the time sh is invoked, treating IFS as if it were not set.
LANG

Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-2001, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

If set to a non-empty string value, override the values of all the other internationalization variables.

LC_COLLATE

Determine the behavior of range expressions, equivalence classes, and multi-character collating elements within pattern matching.

LC_CTYPE

Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files), which characters are defined as letters (character class alpha), and the behavior of character classes within pattern matching.

LC_MESSAGES

Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

MAIL

Determine a pathname of the user’s mailbox file for purposes of incoming mail notification. If this variable is set, the shell shall inform the user if the file named by the variable is created or if its modification time has changed. Informing the user shall be accomplished by writing a string of unspecified format to standard error prior to the writing of the next primary prompt string. Such check shall be performed only after the completion of the interval defined by the MAILCHECK variable after the last such check. The user shall be informed only if MAIL is set and MAILPATH is not set. This volume of IEEE Std 1003.1-2001 specifies the effects of this variable only for systems supporting the User Portability Utilities option.

MAILCHECK

Establish a decimal integer value that specifies how often (in seconds) the shell shall check for the arrival of mail in the files specified by the MAILPATH or MAIL variables. The default value shall be 600 seconds. If set to zero, the shell shall check before issuing each primary prompt. This volume of IEEE Std 1003.1-2001 specifies the effects of this variable only for systems supporting the User Portability Utilities option.

MAILPATH

Provide a list of pathnames and optional messages separated by colons. If this variable is set, the shell shall inform the user if any of the files named by the variable are created or if any of their modification times change. (See the preceding entry for MAIL for descriptions of mail arrival and user informing.) Each pathname can be followed by ‘%’ and a string that shall be subjected to parameter expansion and written to standard error when the modification time changes. If a ‘%’ character in the pathname is preceded by a backslash, it shall be treated as a literal ‘%’ in the pathname. The default message is unspecified.

The MAILPATH environment variable takes precedence over the MAIL variable. This volume of IEEE Std 1003.1-2001 specifies the effects of this variable only for systems supporting the User Portability Utilities option.

NLSPATH

Determine the location of message catalogs for the processing of LC_MESSAGES.

PATH

Establish a string formatted as described in the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 8, Environment Variables, used to effect command interpretation; see Section 2.9.1.1 (on page 48).
This variable shall represent an absolute pathname of the current working directory. Assignments to this variable may be ignored unless the value is an absolute pathname of the current working directory and there are no filename components of dot or dot-dot.

**ASYNCHRONOUS EVENTS**

Default.

**STDOUT**

See the STDERR section.

**STDERR**

Except as otherwise stated (by the descriptions of any invoked utilities or in interactive mode), standard error shall be used only for diagnostic messages.

**OUTPUT FILES**

None.

**EXTENDED DESCRIPTION**

See Chapter 2. The following additional capabilities are supported on systems supporting the User Portability Utilities option.

**Command History List**

When the `sh` utility is being used interactively, it shall maintain a list of commands previously entered from the terminal in the file named by the `HISTFILE` environment variable. The type, size, and internal format of this file are unspecified. Multiple `sh` processes can share access to the file for a user, if file access permissions allow this; see the description of the `HISTFILE` environment variable.

**Command Line Editing**

When `sh` is being used interactively from a terminal, the current command and the command history (see `fc`) can be edited using `vi`-mode command line editing. This mode uses commands, described below, similar to a subset of those described in the `vi` utility. Implementations may offer other command line editing modes corresponding to other editing utilities.

The command `set -o vi` shall enable `vi`-mode editing and place `sh` into `vi` insert mode (see **Command Line Editing (vi-mode)** (on page 855)). This command also shall disable any other editing mode that the implementation may provide. The command `set +o vi` disables `vi`-mode editing.

Certain block-mode terminals may be unable to support shell command line editing. If a terminal is unable to provide either edit mode, it need not be possible to `set -o vi` when using the `sh` on this terminal.

In the following sections, the characters `erase`, `interrupt`, `kill`, and `end-of-file` are those set by the `stty` utility.
Command Line Editing (vi-mode)

In vi editing mode, there shall be a distinguished line, the edit line. All the editing operations which modify a line affect the edit line. The edit line is always the newest line in the command history buffer.

With vi-mode enabled, sh can be switched between insert mode and command mode.

When in insert mode, an entered character shall be inserted into the command line, except as noted in vi Line Editing Insert Mode. Upon entering sh and after termination of the previous command, sh shall be in insert mode.

Typing an escape character shall switch sh into command mode (see vi Line Editing Command Mode (on page 856)). In command mode, an entered character shall either invoke a defined operation, be used as part of a multi-character operation, or be treated as an error. A character that is not recognized as part of an editing command shall terminate any specific editing command and shall alert the terminal. Typing the interrupt character in command mode shall cause sh to terminate command line editing on the current command line, reissue the prompt on the next line of the terminal, and reset the command history (see fc) so that the most recently executed command is the previous command (that is, the command that was being edited when it was interrupted is not reentered into the history).

In the following sections, the phrase “move the cursor to the beginning of the word” shall mean “move the cursor to the first character of the current word” and the phrase “move the cursor to the end of the word” shall mean “move the cursor to the last character of the current word”. The phrase “beginning of the command line” indicates the point between the end of the prompt string issued by the shell (or the beginning of the terminal line, if there is no prompt string) and the first character of the command text.

vi Line Editing Insert Mode

While in insert mode, any character typed shall be inserted in the current command line, unless it is from the following set.

- **<newline>** Execute the current command line. If the current command line is not empty, this line shall be entered into the command history (see fc).
- **erase** Delete the character previous to the current cursor position and move the current cursor position back one character. In insert mode, characters shall be erased from both the screen and the buffer when backspacing.
- **interrupt** Terminate command line editing with the same effects as described for interrupting command mode; see Command Line Editing (vi-mode).
- **kill** Clear all the characters from the input line.
- **<control>-V** Insert the next character input, even if the character is otherwise a special insert mode character.
- **<control>-W** Delete the characters from the one preceding the cursor to the preceding word boundary. The word boundary in this case is the closer to the cursor of either the beginning of the line or a character that is in neither the blank nor punct character classification of the current locale.
- **end-of-file** Interpreted as the end of input in sh. This interpretation shall occur only at the beginning of an input line. If end-of-file is entered other than at the beginning of the line, the results are unspecified.
Utilities

33170  \langle ESC\rangle        Place \textit{sh} into command mode.

\textbf{vi Line Editing Command Mode}

33172  In command mode for the command line editing feature, decimal digits not beginning with 0
that precede a command letter shall be remembered. Some commands use these decimal digits
as a count number that affects the operation.

The term \textit{motion command} represents one of the commands:

\begin{verbatim}
<space> 0 b f l w ^ $ ; E f T w \ | , B e h t
\end{verbatim}

If the current line is not the edit line, any command that modifies the current line shall cause the
content of the current line to replace the content of the edit line, and the current line shall
become the edit line. This replacement cannot be undone (see the \texttt{u} and \texttt{U} commands below).
The modification requested shall then be performed to the edit line. When the current line is the
edit line, the modification shall be done directly to the edit line.

Any command that is preceded by \textit{count} shall take a count (the numeric value of any preceding
decimal digits). Unless otherwise noted, this count shall cause the specified operation to repeat
by the number of times specified by the count. Also unless otherwise noted, a \textit{count} that is out of
range is considered an error condition and shall alert the terminal, but neither the cursor
position, nor the command line, shall change.

The terms \textit{word} and \textit{bigword} are used as defined in the \textit{vi} description. The term \textit{save buffer}
corresponds to the term \textit{unnamed buffer} in \textit{vi}.

The following commands shall be recognized in command mode:

\begin{itemize}
  \item \texttt{<newline>}: Execute the current command line. If the current command line is not empty, this
line shall be entered into the command history (see \texttt{fc}).
  \item \texttt{<control>-L}: Redraw the current command line. Position the cursor at the same location on the
redrawn line.
  \item \texttt{#}: Insert the character \texttt{'}\#\texttt{'} at the beginning of the current command line and treat the
resulting edit line as a comment. This line shall be entered into the command
history; see \texttt{fc}.
  \item \texttt{=} Display the possible shell word expansions (see Section 2.6 (on page 36)) of the
bigword at the current command line position.
\end{itemize}

\textbf{Note:} This does not modify the content of the current line, and therefore does not
cause the current line to become the edit line.

These expansions shall be displayed on subsequent terminal lines. If the bigword
contains none of the characters \texttt{'}?\texttt{', }\texttt{'}*\texttt{',} or \texttt{'}\[\texttt{', an asterisk (}\texttt{'}*\texttt{')} shall be
implicitly assumed at the end. If any directories are matched, these expansions
shall have a \texttt{'}\texttt{/} character appended. After the expansion, the line shall be
re redrawn, the cursor repositioned at the current cursor position, and \textit{sh} shall be
placed in command mode.

\texttt{\textbackslash}: Perform pathname expansion (see Section 2.6.6 (on page 42)) on the current
bigword, up to the largest set of characters that can be matched uniquely. If the
bigword contains none of the characters \texttt{'}?\texttt{', }\texttt{'}*\texttt{',} or \texttt{'}\[\texttt{', an asterisk (}\texttt{'}*\texttt{')} shall
be implicitly assumed at the end. This maximal expansion then shall replace the
original bigword in the command line, and the cursor shall be placed after this
expansion. If the resulting bigword completely and uniquely matches a directory, a
\texttt{'}\texttt{/} character shall be inserted directly after the bigword. If some other file is
completely matched, a single \texttt{<space>} shall be inserted after the bigword. After
this operation, sh shall be placed in insert mode.

* Perform pathname expansion on the current bigword and insert all expansions into the command to replace the current bigword, with each expansion separated by a single <space>. If at the end of the line, the current cursor position shall be moved to the first column position following the expansions and sh shall be placed in insert mode. Otherwise, the current cursor position shall be the last column position of the first character after the expansions and sh shall be placed in insert mode. If the current bigword contains none of the characters ‘?’,’*’, or ‘[’, before the operation, an asterisk shall be implicitly assumed at the end.

@letter Insert the value of the alias named _letter. The symbol letter represents a single alphabetic character from the portable character set; implementations may support additional characters as an extension. If the alias _letter contains other editing commands, these commands shall be performed as part of the insertion. If no alias _letter is enabled, this command shall have no effect.

[count]* Convert, if the current character is a lowercase letter, to the equivalent uppercase letter and vice versa, as prescribed by the current locale. The current cursor position then shall be advanced by one character. If the cursor was positioned on the last character of the line, the case conversion shall occur, but the cursor shall not advance. If the ‘˜’ command is preceded by a count, that number of characters shall be converted, and the cursor shall be advanced to the character position after the last character converted. If the count is larger than the number of characters after the cursor, this shall not be considered an error; the cursor shall advance to the last character on the line.

[count]. Repeat the most recent non-motion command, even if it was executed on an earlier command line. If the previous command was preceded by a count, and no count is given on the ‘.’ command, the count from the previous command shall be included as part of the repeated command. If the ‘.’ command is preceded by a count, this shall override any count argument to the previous command. The count specified in the ‘.’ command shall become the count for subsequent ‘.’ commands issued without a count.

[number]v Invoke the vi editor to edit the current command line in a temporary file. When the editor exits, the commands in the temporary file shall be executed and placed in the command history. If a number is included, it specifies the command number in the command history to be edited, rather than the current command line.

[count]{ell} Move the current cursor position to the next character position. If the cursor was positioned on the last character of the line, the terminal shall be alerted and the cursor shall not be advanced. If the count is larger than the number of characters after the cursor, this shall not be considered an error; the cursor shall advance to the last character on the line.

[count]{h} Move the current cursor position to the count th (default 1) previous character position. If the cursor was positioned on the first character of the line, the terminal shall be alerted and the cursor shall not be moved. If the count is larger than the number of characters before the cursor, this shall not be considered an error; the cursor shall move to the first character on the line.

[count]{w} Move to the start of the next word. If the cursor was positioned on the last character of the line, the terminal shall be alerted and the cursor shall not be
advanced. If the count is larger than the number of words after the cursor, this shall
not be considered an error; the cursor shall advance to the last character on the
line.

[count]W Move to the start of the next bigword. If the cursor was positioned on the last
count is larger than the number of bigwords after the cursor, this shall not be considered an error; the cursor shall advance to the last character on the
line.

[count]e Move to the end of the current word. If at the end of a word, move to the end of the
next word. If the cursor was positioned on the last character of the line, the
terminal shall be alerted and the cursor shall not be advanced. If the count is larger
than the number of words after the cursor, this shall not be considered an error; the
cursor shall advance to the last character on the line.

[count]E Move to the end of the current bigword. If at the end of a bigword, move to the
end of the next bigword. If the cursor was positioned on the last character of the line, the
terminal shall be alerted and the cursor shall not be advanced. If the count is larger
than the number of bigwords after the cursor, this shall not be considered an error; the
cursor shall advance to the last character on the line.

[count]b Move to the beginning of the current word. If at the beginning of a word, move to
the beginning of the previous word. If the cursor was positioned on the first
character of the line, the terminal shall be alerted and the cursor shall not be moved. If the count is larger than the number of words preceding the cursor, this
shall not be considered an error; the cursor shall return to the first character on the
line.

[count]B Move to the beginning of the current bigword. If at the beginning of a bigword, move to
the beginning of the previous bigword. If the cursor was positioned on the first
count is larger than the number of bigwords preceding the cursor, this shall not be considered an error; the cursor shall return to the first character on the
line.

^ Move the current cursor position to the first character on the input line that is not a
<blank>.

$ Move to the last character position on the current command line.

0 (Zero.) Move to the first character position on the current command line.

[count] Move to the countth character position on the current command line. If no number
is specified, move to the first position. The first character position shall be
numbered 1. If the count is larger than the number of characters on the line, this
shall not be considered an error; the cursor shall be placed on the last character on the
line.

[count]fc Move to the first occurrence of the character ‘c’ that occurs after the current
cursor position. If the cursor was positioned on the last character of the line, the
terminal shall be alerted and the cursor shall not be advanced. If the character ‘c’
does not occur in the line after the current cursor position, the terminal shall be
alerted and the cursor shall not be moved.

[count]Fc Move to the first occurrence of the character ‘c’ that occurs before the current
cursor position. If the cursor was positioned on the first character of the line, the
terminal shall be alerted and the cursor shall not be moved. If the character ‘c’
does not occur in the line before the current cursor position, the terminal shall be
alerted and the cursor shall not be moved.

Move to the character before the first occurrence of the character ‘c’ that occurs
after the current cursor position. If the cursor was positioned on the last character
of the line, the terminal shall be alerted and the cursor shall not be advanced. If the
character ‘c’ does not occur in the line after the current cursor position, the
terminal shall be alerted and the cursor shall not be moved.

Move to the character after the first occurrence of the character ‘c’ that occurs
before the current cursor position. If the cursor was positioned on the first
character of the line, the terminal shall be alerted and the cursor shall not be
moved. If the character ‘c’ does not occur in the line before the current cursor
position, the terminal shall be alerted and the cursor shall not be moved.

Repeat the most recent f, F, t, or T command. Any number argument on that
previous command shall be ignored. Errors are those described for the repeated
command.

Repeat the most recent f, F, t, or T command. Any number argument on that
previous command shall be ignored. However, reverse the direction of that
command.

Enter insert mode after the current cursor position. Characters that are entered
shall be inserted before the next character.

Enter insert mode after the end of the current command line.

Enter insert mode at the current cursor position. Characters that are entered shall
be inserted before the current character.

Enter insert mode at the beginning of the current command line.

Enter insert mode, replacing characters from the command line beginning at the
current cursor position.

Delete the characters between the current cursor position and the cursor position
that would result from the specified motion command. Then enter insert mode
before the first character following any deleted characters. If count is specified, it
shall be applied to the motion command. A count shall be ignored for the following
motion commands:

If the motion command is the character ‘c’, the current command line shall be
cleared and insert mode shall be entered. If the motion command would move the
current cursor position toward the beginning of the command line, the character
under the current cursor position shall not be deleted. If the motion command
would move the current cursor position toward the end of the command line, the
character under the current cursor position shall be deleted. If the count is larger
than the number of characters between the current cursor position and the end of
the command line toward which the motion command would move the cursor,
this shall not be considered an error; all of the remaining characters in the
aforementioned range shall be deleted and insert mode shall be entered. If the
motion command is invalid, the terminal shall be alerted, the cursor shall not be
moved, and no text shall be deleted.
C  Delete from the current character to the end of the line and enter insert mode at the
new end-of-line.

S  Clear the entire edit line and enter insert mode.

[count]r  Replace the current character with the character ‘c’. With a number count, replace the current and the following count–1 characters. After this command, the current cursor position shall be on the last character that was changed. If the count is larger than the number of characters after the cursor, this shall not be considered an error; all of the remaining characters shall be changed.

[count]l  Append a <space> after the current character position and then append the last bigword in the previous input line after the <space>. Then enter insert mode after the last character just appended. With a number count, append the countth bigword in the previous line.

[count]x  Delete the character at the current cursor position and place the deleted characters in the save buffer. If the cursor was positioned on the last character of the line, the character shall be deleted and the cursor position shall be moved to the previous character (the new last character). If the count is larger than the number of characters after the cursor, this shall not be considered an error; all the characters from the cursor to the end of the line shall be deleted.

[count]X  Delete the character before the current cursor position and place the deleted characters in the save buffer. The character under the current cursor position shall not change. If the cursor was positioned on the first character of the line, the terminal shall be alerted, and the X command shall have no effect. If the line contained a single character, the X command shall have no effect. If the line contained no characters, the terminal shall be alerted and the cursor shall not be moved. If the count is larger than the number of characters before the cursor, this shall not be considered an error; all the characters from before the cursor to the beginning of the line shall be deleted.

[count]d motion  Delete the characters between the current cursor position and the character position that would result from the motion command. A number count repeats the motion command count times. If the motion command would move toward the beginning of the command line, the character under the current cursor position shall not be deleted. If the motion command is d, the entire current command line shall be cleared. If the count is larger than the number of characters between the current cursor position and the end of the command line toward which the motion command would move the cursor, this shall not be considered an error; all of the remaining characters in the aforementioned range shall be deleted. The deleted characters shall be placed in the save buffer.

D  Delete all characters from the current cursor position to the end of the line. The deleted characters shall be placed in the save buffer.

[count]y motion  Yank (that is, copy) the characters from the current cursor position to the position resulting from the motion command into the save buffer. A number count shall be applied to the motion command. If the motion command would move toward the beginning of the command line, the character under the current cursor position shall not be included in the set of yanked characters. If the motion command is y, the entire current command line shall be yanked into the save buffer. The current cursor position shall be unchanged. If the count is larger than the number of
characters between the current cursor position and the end of the command line
toward which the motion command would move the cursor, this shall not be
considered an error; all of the remaining characters in the aforementioned range
shall be yanked.

\textbf{Y} \quad \text{Yank the characters from the current cursor position to the end of the line into the}
\text{save buffer. The current character position shall be unchanged.}

\textbf{[count]p} \quad \text{Put a copy of the current contents of the save buffer after the current cursor}
\text{position. The current cursor position shall be advanced to the last character put}
\text{from the save buffer. A count shall indicate how many copies of the save buffer}
\text{shall be put.}

\textbf{[count]P} \quad \text{Put a copy of the current contents of the save buffer before the current cursor}
\text{position. The current cursor position shall be moved to the last character put from}
\text{the save buffer. A count shall indicate how many copies of the save buffer shall be}
\text{put.}

\textbf{u} \quad \text{Undo the last command that changed the edit line. This operation shall not undo}
\text{the copy of any command line to the edit line.}

\textbf{U} \quad \text{Undo all changes made to the edit line. This operation shall not undo the copy of}
\text{any command line to the edit line.}

\textbf{[count]k} \quad \text{Set the current command line to be the count th previous command line in the shell}
\text{command history. If count is not specified, it shall default to 1. The cursor shall be}
\text{positioned on the first character of the new command. If a k or – command would}
\text{retreat past the maximum number of commands in effect for this shell (affected by}
\text{the HISTSIZE environment variable), the terminal shall be alerted, and the}
\text{command shall have no effect.}

\textbf{[count]j} \quad \text{Set the current command line to be the count th next command line in the shell}
\text{command history. If count is not specified, it shall default to 1. The cursor shall be}
\text{positioned on the first character of the new command. If a j or + command}
\text{advances past the edit line, the current command line shall be restored to the edit}
\text{line and the terminal shall be alerted.}

\textbf{[number]G} \quad \text{Set the current command line to be the oldest command line stored in the shell}
\text{command history. With a number number, set the current command line to be the}
\text{command line number in the history. If command line number does not exist, the}
\text{terminal shall be alerted and the command line shall not be changed.}

\textit{\textbf{/pattern<newline>}} \quad \text{Move backwards through the command history, searching for the specified}
\text{pattern, beginning with the previous command line. Patterns use the pattern}
\text{matching notation described in Section 2.13 (on page 62), except that the ‘^’}
\text{character shall have special meaning when it appears as the first character of}
\text{pattern. In this case, the ‘^’ is discarded and the characters after the ‘^’ shall be}
\text{matched only at the beginning of a line. Commands in the command history shall}
\text{be treated as strings, not as filenames. If the pattern is not found, the current}
\text{command line shall be unchanged and the terminal is alerted. If it is found in a}
\text{previous line, the current command line shall be set to that line and the cursor}
\text{shall be set to the first character of the new command line.}
If *pattern* is empty, the last non-empty pattern provided to / or ? shall be used. If there is no previous non-empty pattern, the terminal shall be alerted and the current command line shall remain unchanged.

?pattern

Move forwards through the command history, searching for the specified pattern, beginning with the next command line. Patterns use the pattern matching notation described in Section 2.13 (on page 62), except that the ‘ˆ’ character shall have special meaning when it appears as the first character of *pattern*. In this case, the ‘ˆ’ is discarded and the characters after the ‘ˆ’ shall be matched only at the beginning of a line. Commands in the command history shall be treated as strings, not as filenames. If the pattern is not found, the current command line shall be unchanged and the terminal alerted. If it is found in a following line, the current command line shall be set to that line and the cursor shall be set to the first character of the new command line.

If *pattern* is empty, the last non-empty pattern provided to / or ? shall be used. If there is no previous non-empty pattern, the terminal shall be alerted and the current command line shall remain unchanged.

n
Repeat the most recent / or ? command. If there is no previous / or ?, the terminal shall be alerted and the current command line shall remain unchanged.

N
Repeat the most recent / or ? command, reversing the direction of the search. If there is no previous / or ?, the terminal shall be alerted and the current command line shall remain unchanged.

EXIT STATUS
The following exit values shall be returned:

0 The script to be executed consisted solely of zero or more blank lines or comments, or both.

1-125 A non-interactive shell detected a syntax, redirection, or variable assignment error.

127 A specified *command_file* could not be found by a non-interactive shell.

Otherwise, the shell shall return the exit status of the last command it invoked or attempted to invoke (see also the *exit* utility in Section 2.14 (on page 64)).

CONSEQUENCES OF ERRORS
See Section 2.8.1 (on page 46).

APPLICATION USAGE
Standard input and standard error are the files that determine whether a shell is interactive when −i is not specified. For example:

```
sh > file
```

and:

```
sh 2> file
```

create interactive and non-interactive shells, respectively. Although both accept terminal input, the results of error conditions are different, as described in Section 2.8.1 (on page 46); in the second example a redirection error encountered by a special built-in utility aborts the shell.

A conforming application must protect its first operand, if it starts with a plus sign, by preceding it with the "−−" argument that denotes the end of the options.
Applications should note that the standard PATH to the shell cannot be assumed to be either /bin/sh or /usr/bin/sh, and should be determined by interrogation of the PATH returned by getconf PATH, ensuring that the returned pathname is an absolute pathname and not a shell built-in.

For example, to determine the location of the standard sh utility:

```bash
command −v sh
```

On some implementations this might return:

```
/usr/xpg4/bin/sh
```

Furthermore, on systems that support executable scripts (the "#!" construct), it is recommended that applications using executable scripts install them using getconf −v to determine the shell pathname and update the "#!" script appropriately as it is being installed (for example, with sed). For example:

```bash
# Installation time script to install correct POSIX shell pathname
#
# Get list of paths to check
#
Sifs=$IFS
IFS=:
set $(getconf PATH)
IFS=$Sifs
#
# Check each path for 'sh'
#
for i in @$
do
    if [ −f ${i}/sh ];
    then
        Pshell=${i}/sh
    fi
done
#
# This is the list of scripts to update. They should be of the form 'a
# ' and will be transformed to 'a'.
#
# Each script should begin:
#
# !INSTALLSHELLPATH −p
#
scripts="a b c"
#
# Transform each script
#
for i in ${scripts}
do
    sed −e "s|INSTALLSHELLPATH|${Pshell}|" < ${i}.source > ${i}
done
```

Shell and Utilities, Issue 6 — Copyright © 2001-2003, IEEE and The Open Group. All rights reserved.
EXAMPLES

1. Execute a shell command from a string:

   ```
   sh -c "cat myfile"
   ```

2. Execute a shell script from a file in the current directory:

   ```
   sh my_shell_cmds
   ```

RATIONALE

The `sh` utility and the `set` special built-in utility share a common set of options.

The KornShell ignores the contents of `IFS` upon entry to the script. A conforming application cannot rely on importing `IFS`. One justification for this, beyond security considerations, is to assist possible future shell compilers. Allowing `IFS` to be imported from the environment prevents many optimizations that might otherwise be performed via dataflow analysis of the script itself.

The text in the STDIN section about non-blocking reads concerns an instance of `sh` that has been invoked, probably by a C-language program, with standard input that has been opened using the O_NONBLOCK flag; see `open()` in the System Interfaces volume of IEEE Std 1003.1-2001. If the shell did not reset this flag, it would immediately terminate because no input data would be available yet and that would be considered the same as end-of-file.

The options associated with a restricted shell (command name `rsh` and the `-r` option) were excluded because the standard developers considered that the implied level of security could not be achieved and they did not want to raise false expectations.

On systems that support set-user-ID scripts, a historical trapdoor has been to link a script to the name `-i`. When it is called by a sequence such as:

   ```
   sh -
   ```

or by:

   ```
   #! usr/bin/sh -
   ```

the historical systems have assumed that no option letters follow. Thus, this volume of IEEE Std 1003.1-2001 allows the single hyphen to mark the end of the options, in addition to the use of the regular `−−` argument, because it was considered that the older practice was so pervasive. An alternative approach is taken by the KornShell, where real and effective user/group IDs must match for an interactive shell; this behavior is specifically allowed by this volume of IEEE Std 1003.1-2001.

Note: There are other problems with set-user-ID scripts that the two approaches described here do not resolve.

The initialization process for the history file can be dependent on the system start-up files, in that they may contain commands that effectively preempt the user’s settings of `HISTFILE` and `HISTSIZE`. For example, function definition commands are recorded in the history file, unless the `set −o nolog` option is set. If the system administrator includes function definitions in some system start-up file called before the `ENV` file, the history file is initialized before the user gets a chance to influence its characteristics. In some historical shells, the history file is initialized just after the `ENV` file has been processed. Therefore, it is implementation-defined whether changes made to `HISTFILE` after the history file has been initialized are effective.

The default messages for the various `MAIL`-related messages are unspecified because they vary across implementations. Typical messages are:
"you have mail\n"

or:

"you have new mail\n"

It is important that the descriptions of command line editing refer to the same shell as that in IEEE Std 1003.1-2001 so that interactive users can also be application programmers without having to deal with programmatic differences in their two environments. It is also essential that the utility name sh be specified because this explicit utility name is too firmly rooted in historical practice of application programs for it to change.

Consideration was given to mandating a diagnostic message when attempting to set vi-mode on terminals that do not support command line editing. However, it is not historical practice for the shell to be cognizant of all terminal types and thus be able to detect inappropriate terminals in all cases. Implementations are encouraged to supply diagnostics in this case whenever possible, rather than leaving the user in a state where editing commands work incorrectly.

In early proposals, the KornShell-derived emacs mode of command line editing was included, even though the emacs editor itself was not. The community of emacs proponents was adamant that the full emacs editor not be standardized because they were concerned that an attempt to standardize this very powerful environment would encourage vendors to ship strictly conforming versions lacking the extensibility required by the community. The author of the original emacs program also expressed his desire to omit the program. Furthermore, there were a number of historical systems that did not include emacs, or included it without supporting it, but there were very few that did not include and support vi. The shell emacs command line editing mode was finally omitted because it became apparent that the KornShell version and the editor being distributed with the GNU system had diverged in some respects. The author of emacs requested that the POSIX emacs mode either be deleted or have a significant number of unspecified conditions. Although the KornShell author agreed to consider changes to bring the shell into alignment, the standard developers decided to defer specification at that time. At the time, it was assumed that convergence on an acceptable definition would occur for a subsequent draft, but that has not happened, and there appears to be no impetus to do so. In any case, implementations are free to offer additional command line editing modes based on the exact models of editors their users are most comfortable with.

Early proposals had the following list entry in vi Line Editing Insert Mode (on page 855):

\ If followed by the erase or kill character, that character shall be inserted into the input line.
    Otherwise, the backslash itself shall be inserted into the input line.

However, this is not actually a feature of sh command line editing insert mode, but one of some historical terminal line drivers. Some conforming implementations continue to do this when the stty iexten flag is set.

FUTURE DIRECTIONS
None.

CHANGE HISTORY
First released in Issue 2.
Issue 5

The FUTURE DIRECTIONS section is added.

Text is added to the DESCRIPTION for the Large File Summit proposal.

Issue 6

The Open Group Corrigendum U029/2 is applied, correcting the second SYNOPSIS.

The Open Group Corrigendum U027/3 is applied, correcting a typographical error.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

• The option letters derived from the set special built-in are also accepted with a leading plus sign (‘+’).

• Large file extensions are added:
  — Pathname expansion does not fail due to the size of a file.
  — Shell input and output redirections have an implementation-defined offset maximum that is established in the open file description.

In the ENVIRONMENT VARIABLES section, the text “user's home directory” is updated to “directory referred to by the HOME environment variable”.

Descriptions for the ENV and PWD environment variables are included to align with the IEEE P1003.2b draft standard.

The normative text is reworded to avoid use of the term “must” for application requirements.
NAME
sleep — suspend execution for an interval

SYNOPSIS
sleep time

DESCRIPTION
The sleep utility shall suspend execution for at least the integral number of seconds specified by
the time operand.

OPTIONS
None.

OPERANDS
The following operand shall be supported:

time A non-negative decimal integer specifying the number of seconds for which to
suspend execution.

STDOUT
Not used.

INPUT FILES
None.

ENVIRONMENT VARIABLES
The following environment variables shall affect the execution of sleep:

LANG Provide a default value for the internationalization variables that are unset or null.
(See the Base Definitions volume of IEEE Std 1003.1-2001, Section 8.2,
Internationalization Variables for the precedence of internationalization variables
used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other
internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as
characters (for example, single-byte as opposed to multi-byte characters in
arguments).

LC_MESSAGES Determine the locale that should be used to affect the format and contents of
diagnostic messages written to standard error.

XSI NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

ASYNCHRONOUS EVENTS
If the sleep utility receives a SIGALRM signal, one of the following actions shall be taken:

1. Terminate normally with a zero exit status.
2. Effectively ignore the signal.
3. Provide the default behavior for signals described in the ASYNCHRONOUS EVENTS
section of Section 1.11 (on page 20). This could include terminating with a non-zero exit
status.

The sleep utility shall take the standard action for all other signals.
STDOUT
Not used.

STDERR
The standard error shall be used only for diagnostic messages.

OUTPUT FILES
None.

EXTENDED DESCRIPTION
None.

EXIT STATUS
The following exit values shall be returned:
0 The execution was successfully suspended for at least time seconds, or a SIGALRM signal was received. See the ASYNCHRONOUS EVENTS section.
>0 An error occurred.

CONSEQUENCES OF ERRORS
Default.

APPLICATION USAGE
None.

EXAMPLES
The sleep utility can be used to execute a command after a certain amount of time, as in:
(sleep 105; command) &
or to execute a command every so often, as in:
while true
do
command
sleep 37
done

RATIONALE
The exit status is allowed to be zero when sleep is interrupted by the SIGALRM signal because most implementations of this utility rely on the arrival of that signal to notify them that the requested finishing time has been successfully attained. Such implementations thus do not distinguish this situation from the successful completion case. Other implementations are allowed to catch the signal and go back to sleep until the requested time expires or to provide the normal signal termination procedures.

As with all other utilities that take integral operands and do not specify subranges of allowed values, sleep is required by this volume of IEEE Std 1003.1-2001 to deal with time requests of up to 2 147 483 647 seconds. This may mean that some implementations have to make multiple calls to the delay mechanism of the underlying operating system if its argument range is less than this.

FUTURE DIRECTIONS
None.

wait, the System Interfaces volume of IEEE Std 1003.1-2001, alarm(), sleep()
CHANGE HISTORY

First released in Issue 2.
NAME
   sort — sort, merge, or sequence check text files

SYNOPSIS
    sort [−m] [−o output] [−bdfinru] [−t char] [−k keydef]... [file...]
    sort −c [−bdfinru] [−t char] [−k keydef] [file]

DESCRIPTION
    The sort utility shall perform one of the following functions:

     1. Sort lines of all the named files together and write the result to the specified output.
     2. Merge lines of all the named (presorted) files together and write the result to the specified output.
     3. Check that a single input file is correctly presorted.

    Comparisons shall be based on one or more sort keys extracted from each line of input (or, if no sort keys are specified, the entire line up to, but not including, the terminating <newline>), and shall be performed using the collating sequence of the current locale.

OPTIONS
    The sort utility shall conform to the Base Definitions volume of IEEE Std 1003.1-2001, Section 12.2, Utility Syntax Guidelines, and the −k keydef option should follow the −b, −d, −f, −i, −n, and −r options.

    The following options shall be supported:

    −c       Check that the single input file is ordered as specified by the arguments and the collating sequence of the current locale. No output shall be produced; only the exit code shall be affected.
    −m       Merge only; the input file shall be assumed to be already sorted.
    −o output  Specify the name of an output file to be used instead of the standard output. This file can be the same as one of the input files.
    −u       Unique: suppress all but one in each set of lines having equal keys. If used with the −c option, check that there are no lines with duplicate keys, in addition to checking that the input file is sorted.

    The following options shall override the default ordering rules. When ordering options appear independent of any key field specifications, the requested field ordering rules shall be applied globally to all sort keys. When attached to a specific key (see −k), the specified ordering options shall override all global ordering options for that key.

    −d       Specify that only <blank>s and alphanumeric characters, according to the current setting of LC_CTYPE, shall be significant in comparisons. The behavior is undefined for a sort key to which −i or −n also applies.
    −f       Consider all lowercase characters that have uppercase equivalents, according to the current setting of LC_CTYPE, to be the uppercase equivalent for the purposes of comparison.
    −i       Ignore all characters that are non-printable, according to the current setting of LC_CTYPE.
    −n       Restrict the sort key to an initial numeric string, consisting of optional <blank>s, optional minus sign, and zero or more digits with an optional radix character and thousands separators (as defined in the current locale), which shall be sorted by
arithmetic value. An empty digit string shall be treated as zero. Leading zeros and signs on zeros shall not affect ordering.

\( \text{reverse sense of comparisons.} \)

The treatment of field separators can be altered using the options:

\( \text{Ignore leading } <\text{blank}>s \text{ when determining the starting and ending positions of a restricted sort key. If the } \text{\texttt{-b}} \text{ option is specified before the first } \text{\texttt{-k}} \text{ option, it shall be applied to all } \text{\texttt{-k}} \text{ options. Otherwise, the } \text{\texttt{-b}} \text{ option can be attached independently to each } \text{\texttt{-k}} \text{ field_start or field_end option-argument (see below).} \)

\( \text{Use char as the field separator character; char shall not be considered to be part of a field (although it can be included in a sort key). Each occurrence of char shall be significant (for example, } <\text{char}> <\text{char}> \text{ delimits an empty field). If } \text{\texttt{-t}} \text{ is not specified, } <\text{blank}>s \text{ shall be used as default field separators; each maximal non-empty sequence of } <\text{blank}>s \text{ that follows a non-} <\text{blank}> \text{ shall be a field separator.} \)

Sort keys can be specified using the options:

\( \text{The keydef argument is a restricted sort key field definition. The format of this definition is:} \)

\( \text{field_start[type], field_end[type]} \)

where \text{field_start} and \text{field_end} define a key field restricted to a portion of the line (see the EXTENDED DESCRIPTION section), and \text{type} is a modifier from the list of characters \text{'}b', \text{'}d', \text{'}f', \text{'}i', \text{'}n', \text{'}r'\text{'}. The \text{'}b' \text{ modifier shall behave like the } \text{\texttt{-b}} \text{ option, but shall apply only to the field_start or field_end to which it is attached. The other modifiers shall behave like the corresponding options, but shall apply only to the key field to which they are attached; they shall have this effect if specified with field_start, field_end, or both. If any modifier is attached to a field_start or to a field_end, no option shall apply to either. Implementations shall support at least nine occurrences of the } \text{\texttt{-k}} \text{ option, which shall be significant in command line order. If no } \text{\texttt{-k}} \text{ option is specified, a default sort key of the entire line shall be used.} \)

When there are multiple key fields, later keys shall be compared only after all earlier keys compare equal. Except when the } \text{\texttt{-u}} \text{ option is specified, lines that otherwise compare equal shall be ordered as if none of the options } \text{\texttt{-d}}, \text{\texttt{-f}}, \text{\texttt{-i}}, \text{\texttt{-n}}, \text{or } \text{\texttt{-k}} \text{ were present (but with } \text{\texttt{-r}} \text{ still in effect, if it was specified) and with all bytes in the lines significant to the comparison. The order in which lines that still compare equal are written is unspecified.}

\( \text{The following operand shall be supported:} \)

\( \text{A pathname of a file to be sorted, merged, or checked. If no } \text{\texttt{file}} \text{ operands are specified, or if a } \text{\texttt{file}} \text{ operand is } '\text{-}'\text{'}, \text{the standard input shall be used.} \)

\( \text{The standard input shall be used only if no } \text{\texttt{file}} \text{ operands are specified, or if a } \text{\texttt{file}} \text{ operand is } '\text{-}'\text{'}. \)

\( \text{The input files shall be text files, except that the } \text{\texttt{sort}} \text{ utility shall add a } <\text{newline}> \text{ to the end of a file ending with an incomplete last line.} \)
**ENVIRONMENT VARIABLES**

The following environment variables shall affect the execution of `sort`:

- **LANG**: Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-2001, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

- **LC_ALL**: If set to a non-empty string value, override the values of all the other internationalization variables.

- **LC_COLLATE**: Determine the locale for ordering rules.

- **LC_CTYPE**: Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files) and the behavior of character classification for the `−b`, `−d`, `−f`, `−i`, and `−n` options.

- **LC_MESSAGES**: Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

- **LC_NUMERIC**: Determine the locale for the definition of the radix character and thousands separator for the `−n` option.

- **XSI NLSPATH**: Determine the location of message catalogs for the processing of `LC_MESSAGES`.

**ASYNCHRONOUS EVENTS**

Default.

**STDOUT**

Unless the `−o` or `−c` options are in effect, the standard output shall contain the sorted input.

**STDERR**

The standard error shall be used for diagnostic messages. A warning message about correcting an incomplete last line of an input file may be generated, but need not affect the final exit status.

**OUTPUT FILES**

If the `−o` option is in effect, the sorted input shall be written to the file `output`.

**EXTENDED DESCRIPTION**

The notation:

```
−k field_start[type],field_end[type]
```

shall define a key field that begins at `field_start` and ends at `field_end` inclusive, unless `field_start` falls beyond the end of the line or after `field_end`, in which case the key field is empty. A missing `field_end` shall mean the last character of the line.

A field comprises a maximal sequence of non-separating characters and, in the absence of option `−t`, any preceding field separator.

The `field_start` portion of the `keydef` option-argument shall have the form:

```
field_number[.first_character]
```

Fields and characters within fields shall be numbered starting with 1. The `field_number` and `first_character` pieces, interpreted as positive decimal integers, shall specify the first character to be used as part of a sort key. If `first_character` is omitted, it shall refer to the first character of the
Utilities

sort

field.
The field_end portion of the keydef option-argument shall have the form:

\[
\text{field_number}[.\text{last_character}]
\]
The field_number shall be as described above for field_start. The last_character piece, interpreted as a non-negative decimal integer, shall specify the last character to be used as part of the sort key. If last_character evaluates to zero or .last_character is omitted, it shall refer to the last character of the field specified by field_number.

If the -b option or b type modifier is in effect, characters within a field shall be counted from the first non-<blank> in the field. (This shall apply separately to first_character and last_character.)

EXIT STATUS

The following exit values shall be returned:

- 0 All input files were output successfully, or -c was specified and the input file was correctly sorted.
- 1 Under the -c option, the file was not ordered as specified, or if the -c and -u options were both specified, two input lines were found with equal keys.
- >1 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

The default value for -t, <blank>, has different properties from, for example, -t"<space>". If a line contains:

\[
\text{<space><space>foo}
\]

the following treatment would occur with default separation as opposed to specifically selecting a <space>:

<table>
<thead>
<tr>
<th>Field</th>
<th>Default</th>
<th>-t &quot;&lt;space&gt;&quot;</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>empty</td>
<td>empty</td>
</tr>
<tr>
<td>2</td>
<td>empty</td>
<td>empty</td>
</tr>
<tr>
<td>3</td>
<td>empty</td>
<td>foo</td>
</tr>
</tbody>
</table>

The leading field separator itself is included in a field when -t is not used. For example, this command returns an exit status of zero, meaning the input was already sorted:

\[
\text{sort -c -k 2 <<eof}
\]
\[
\text{y<tab>b}
\]
\[
\text{x<space>a}
\]
\[
\text{eof}
\]

(assuming that a <tab> precedes the <space> in the current collating sequence). The field separator is not included in a field when it is explicitly set via -t. This is historical practice and allows usage such as:

\[
\text{sort -t "|" -k 2n <<eof}
\]
\[
\text{Atlanta|425022|Georgia}
\]
\[
\text{Birmingham|284413|Alabama}
\]
\[
\text{Columbia|100385|South Carolina}
\]
\[
\text{eof}
\]
where the second field can be correctly sorted numerically without regard to the non-numeric field separator.

The wording in the OPTIONS section clarifies that the −b, −d, −f, −i, −n, and −r options have to come before the first sort key specified if they are intended to apply to all specified keys. The way it is described in this volume of IEEE Std 1003.1-2001 matches historical practice, not historical documentation. The results are unspecified if these options are specified after a −k option.

The −f option might not work as expected in locales where there is not a one-to-one mapping between an uppercase and a lowercase letter.

**EXAMPLES**

1. The following command sorts the contents of *infile* with the second field as the sort key:

   ```
   sort −k 2,2 infile
   ```

2. The following command sorts, in reverse order, the contents of *infile1* and *infile2*, placing the output in *outfile* and using the second character of the second field as the sort key (assuming that the first character of the second field is the field separator):

   ```
   sort −r −o outfile −k 2.2,2.2 infile1 infile2
   ```

3. The following command sorts the contents of *infile1* and *infile2* using the second non-<blank> of the second field as the sort key:

   ```
   sort −k 2.2b,2.2b infile1 infile2
   ```

4. The following command prints the System V password file (user database) sorted by the numeric user ID (the third colon-separated field):

   ```
   sort −t : −k 3,3n /etc/passwd
   ```

5. The following command prints the lines of the already sorted file *infile*, suppressing all but one occurrence of lines having the same third field:

   ```
   sort −um −k 3.1,3.0 infile
   ```

**RATIONALE**

Examples in some historical documentation state that options −um with one input file keep the first in each set of lines with equal keys. This behavior was deemed to be an implementation artifact and was not standardized.

The −z option was omitted; it is not standard practice on most systems and is inconsistent with using *sort* to sort several files individually and then merge them together. The text concerning −z in historical documentation appeared to require implementations to determine the proper buffer length during the sort phase of operation, but not during the merge.

The −y option was omitted because of non-portability. The −M option, present in System V, was omitted because of non-portability in international usage.

An undocumented −T option exists in some implementations. It is used to specify a directory for intermediate files. Implementations are encouraged to support the use of the TMPDIR environment variable instead of adding an option to support this functionality.

The −k option was added to satisfy two objections. First, the zero-based counting used by *sort* is not consistent with other utility conventions. Second, it did not meet syntax guideline requirements.

Historical documentation indicates that “setting −n implies −b”. The description of −n already states that optional leading <blank>s are tolerated in doing the comparison. If −b is enabled,
rather than implied, by -n, this has unusual side effects. When a character offset is used in a
column of numbers (for example, to sort modulo 100), that offset is measured relative to the
most significant digit, not to the column. Based upon a recommendation from the author of the
original sort utility, the -b implication has been omitted from this volume of
IEEE Std 1003.1-2001, and an application wishing to achieve the previously mentioned side
effects has to code the -b flag explicitly.

FUTURE DIRECTIONS
None.

CHANGE HISTORY
First released in Issue 2.

Issue 6
IEEE PASC Interpretation 1003.2 #174 is applied, updating the DESCRIPTION of comparisons.
IEEE PASC Interpretation 1003.2 #168 is applied.
NAME
split — split files into pieces

SYNOPSIS
split [-l line_count][-a suffix_length][file[name]]
split -b n[k|m][-a suffix_length][file[name]]

DESCRIPTION
The split utility shall read an input file and write one or more output files. The default size of each output file shall be 1 000 lines. The size of the output files can be modified by specification of the -b or -l options. Each output file shall be created with a unique suffix. The suffix shall consist of exactly suffix_length lowercase letters from the POSIX locale. The letters of the suffix shall be used as if they were a base-26 digit system, with the first suffix to be created consisting of all 'a' characters, the second with a 'b' replacing the last 'a', and so on, until a name of all 'z' characters is created. By default, the names of the output files shall be 'x', followed by a two-character suffix from the character set as described above, starting with "aa", "ab", "ac", and so on, and continuing until the suffix "zz", for a maximum of 676 files.

If the number of files required exceeds the maximum allowed by the suffix length provided, such that the last allowable file would be larger than the requested size, the split utility shall fail after creating the last file with a valid suffix; split shall not delete the files it created with valid suffixes. If the file limit is not exceeded, the last file created shall contain the remainder of the input file, and may be smaller than the requested size.

OPTIONS

The following options shall be supported:
-a suffix_length
Use suffix_length letters to form the suffix portion of the filenames of the split file. If -a is not specified, the default suffix length shall be two. If the sum of the name operand and the suffix_length option-argument would create a filename exceeding {NAME_MAX} bytes, an error shall result; split shall exit with a diagnostic message and no files shall be created.

-b n
Split a file into pieces n bytes in size.

-b n[k|m]
Split a file into pieces n*1 024 bytes in size.

-b n[m]
Split a file into pieces n*1 048 576 bytes in size.

-l line_count
Specify the number of lines in each resulting file piece. The line_count argument is an unsigned decimal integer. The default is 1 000. If the input does not end with a <newline>, the partial line shall be included in the last output file.

OPERANDS
The following operands shall be supported:
file
The pathname of the ordinary file to be split. If no input file is given or file is ‘-‘, the standard input shall be used.

name
The prefix to be used for each of the files resulting from the split operation. If no name argument is given, 'x' shall be used as the prefix of the output files. The combined length of the basename of prefix and suffix_length cannot exceed {NAME_MAX} bytes. See the OPTIONS section.
STDIN
See the INPUT FILES section.

INPUT FILES
Any file can be used as input.

ENVIRONMENT VARIABLES
The following environment variables shall affect the execution of split:

LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-2001, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

ASYNCHRONOUS EVENTS
Default.

STDOUT Not used.

STDERR The standard error shall be used only for diagnostic messages.

OUTPUT FILES
The output files contain portions of the original input file; otherwise, unchanged.

EXTENDED DESCRIPTION
None.

EXIT STATUS
The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS
Default.
APPLICATION USAGE
None.

EXAMPLES
In the following examples foo is a text file that contains 5000 lines.

1. Create five files, xaa, xab, xac, xad, and xae:
   ```bash
   split foo
   ```

2. Create five files, but the suffixed portion of the created files consists of three letters, xaaa, xaab, xaac, xaad, and xaxe:
   ```bash
   split −a 3 foo
   ```

3. Create three files with four-letter suffixes and a supplied prefix, bar_aaaa, bar_aaab, and bar_aaac:
   ```bash
   split −a 4 −l 2000 foo bar_
   ```

4. Create as many files as are necessary to contain at most 20*1024 bytes, each with the default prefix of x and a five-letter suffix:
   ```bash
   split −a 5 −b 20k foo
   ```

RATIONALE
The −b option was added to provide a mechanism for splitting files other than by lines. While most uses of the −b option are for transmitting files over networks, some believed it would have additional uses.

The −a option was added to overcome the limitation of being able to create only 676 files.

Consideration was given to deleting this utility, using the rationale that the functionality provided by this utility is available via the csplit utility (see csplit). Upon reconsideration of the purpose of the User Portability Extension, it was decided to retain both this utility and the csplit utility because users use both utilities and have historical expectations of their behavior. Furthermore, the splitting on byte boundaries in split cannot be duplicated with the historical csplit.

The text “split shall not delete the files it created with valid suffixes” would normally be assumed, but since the related utility, csplit, does delete files under some circumstances, the historical behavior of split is made explicit to avoid misinterpretation.

FUTURE DIRECTIONS
None.

SEE ALSO
csplit

CHANGE HISTORY
First released in Issue 2.

Issue 6
This utility is marked as part of the User Portability Utilities option.

The APPLICATION USAGE section is added.

The obsolescent SYNOPSIS is removed.
NAME
strings — find printable strings in files

SYNOPSIS
strings [-a][-t format][-n number][file...]

DESCRIPTION
The strings utility shall look for printable strings in regular files and shall write those strings to standard output. A printable string is any sequence of four (by default) or more printable characters terminated by a <newline> or NUL character. Additional implementation-defined strings may be written; see localedef.

OPTIONS

The following options shall be supported:

- `a`   Scan files in their entirety. If -a is not specified, it is implementation-defined what portion of each file is scanned for strings.
- `n number` Specify the minimum string length, where the number argument is a positive decimal integer. The default shall be 4.
- `t format` Write each string preceded by its byte offset from the start of the file. The format shall be dependent on the single character used as the format option-argument:
  - `d` The offset shall be written in decimal.
  - `o` The offset shall be written in octal.
  - `x` The offset shall be written in hexadecimal.

OPERANDS
The following operand shall be supported:

- `file` A pathname of a regular file to be used as input. If no file operand is specified, the strings utility shall read from the standard input.

STDIN
See the INPUT FILES section.

INPUT FILES
The input files named by the utility arguments or the standard input shall be regular files of any format.

ENVIRONMENT VARIABLES
The following environment variables shall affect the execution of strings:

- `LANG` Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-2001, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
- `LC_ALL` If set to a non-empty string value, override the values of all the other internationalization variables.
- `LC_CTYPE` Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files) and to identify printable strings.
strings

LC_MESSAGES

Determine the locale that should be used to affect the format and contents of
diagnostic messages written to standard error.

XSI NLSPATH

Determine the location of message catalogs for the processing of LC_MESSAGES.

ASYNCHRONOUS EVENTS

Default.

STDOUT

Strings found shall be written to the standard output, one per line.

When the –t option is not specified, the format of the output shall be:

"%s", <string>

With the –to option, the format of the output shall be:

"%o %s", <byte offset>, <string>

With the –tx option, the format of the output shall be:

"%x %s", <byte offset>, <string>

With the –td option, the format of the output shall be:

"%d %s", <byte offset>, <string>

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

By default the data area (as opposed to the text, “bss”, or header areas) of a binary executable
file is scanned. Implementations document which areas are scanned.

Some historical implementations do not require NUL or <newline> terminators for strings to
permit those languages that do not use NUL as a string terminator to have their strings written.

EXAMPLES

None.

RATIONALE

Apart from rationalizing the option syntax and slight difficulties with object and executable
binary files, strings is specified to match historical practice closely. The –a and –n options were
introduced to replace the non-conforming – and –number options.

The –o option historically means different things on different implementations. Some use it to
mean “offset in decimal”, while others use it as “offset in octal”. Instead of trying to decide which
way would be least objectionable, the −t option was added. It was originally named −O to mean 
‘offset’, but was changed to −t to be consistent with od.

The ISO C standard function `isprint()` is restricted to a domain of unsigned char. This volume of 
IEEE Std 1003.1-2001 requires implementations to write strings as defined by the current locale.

**FUTURE DIRECTIONS**

None.

**SEE ALSO**

`localedef`, `nm`

**CHANGE HISTORY**

First released in Issue 4.

**Issue 6**

This utility is marked as part of the User Portability Utilities option.

The obsolescent SYNOPSIS is removed.

The normative text is reworded to avoid use of the term “must” for application requirements.
NAME
strip — remove unnecessary information from executable files (DEVELOPMENT)

SYNOPSIS
strip file...

DESCRIPTION
The strip utility shall remove from executable files named by the file operands any information
the implementor deems unnecessary for execution of those files. The nature of that information
is unspecified. The effect of strip shall be similar to the use of the –s option to c99 or for77.

OPTIONS
None.

OPERANDS
The following operand shall be supported:

file A pathname referring to an executable file.

STDIN
Not used.

INPUT FILES
The input files shall be in the form of executable files successfully produced by any compiler
defined by this volume of IEEE Std 1003.1-2001.

ENVIRONMENT VARIABLES
The following environment variables shall affect the execution of strip:

LANG Provide a default value for the internationalization variables that are unset or null.
(See the Base Definitions volume of IEEE Std 1003.1-2001, Section 8.2,
Internationalization Variables for the precedence of internationalization variables
used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other
internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as
characters (for example, single-byte as opposed to multi-byte characters in
arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of
diagnostic messages written to standard error.

XSI NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

ASYNCHRONOUS EVENTS
Default.

STDOUT
Not used.

STDERR
The standard error shall be used only for diagnostic messages.
The **strip** utility shall produce executable files of unspecified format.

**EXIT STATUS**

The following exit values shall be returned:

- `0` Successful completion.
- `>0` An error occurred.

**CONSEQUENCES OF ERRORS**

Default.

**APPLICATION USAGE**

None.

**EXAMPLES**

None.

**RATIONALE**

Historically, this utility has been used to remove the symbol table from an executable file. It was included since it is known that the amount of symbolic information can amount to several megabytes; the ability to remove it in a portable manner was deemed important, especially for smaller systems.

The behavior of **strip** is said to be the same as the `−s` option to a compiler. While the end result is essentially the same, it is not required to be identical.

**FUTURE DIRECTIONS**

None.

**SEE ALSO**

`ar`, `c99`, `fort77`

**CHANGE HISTORY**

First released in Issue 2.

This utility is marked as part of the Software Development Utilities option.
NAME
stty — set the options for a terminal

SYNOPSIS
stty [ −a | −g ]
stty operands

DESCRIPTION
The stty utility shall set or report on terminal I/O characteristics for the device that is its
standard input. Without options or operands specified, it shall report the settings of certain
characteristics, usually those that differ from implementation-defined defaults. Otherwise, it
shall modify the terminal state according to the specified operands. Detailed information about
the modes listed in the first five groups below are described in the Base Definitions volume of
IEEE Std 1003.1-2001, Chapter 11, General Terminal Interface. Operands in the Combination
Modes group (see Combination Modes (on page 889)) are implemented using operands in the
previous groups. Some combinations of operands are mutually-exclusive on some terminal
types; the results of using such combinations are unspecified.

Typical implementations of this utility require a communications line configured to use the
where none of these lines are available, and on lines not currently configured to support the
termios interface, some of the operands need not affect terminal characteristics.

OPTIONS
The stty utility shall conform to the Base Definitions volume of IEEE Std 1003.1-2001, Section

The following options shall be supported:

−a Write to standard output all the current settings for the terminal.

−g Write to standard output all the current settings in an unspecified form that can be
used as arguments to another invocation of the stty utility on the same system. The
form used shall not contain any characters that would require quoting to avoid
word expansion by the shell; see Section 2.6 (on page 36).

OPERANDS
The following operands shall be supported to set the terminal characteristics.

Control Modes

parenb (−parenb) Enable (disable) parity generation and detection. This shall have the effect of
setting (not setting) PARENB in the termios c_cflag field, as defined in the
Base Definitions volume of IEEE Std 1003.1-2001, Chapter 11, General
Terminal Interface.

parodd (−parodd) Select odd (even) parity. This shall have the effect of setting (not setting)
PARODD in the termios c_cflag field, as defined in the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 11, General Terminal Interface.

cs5 cs6 cs7 cs8 Select character size, if possible. This shall have the effect of setting CS5, CS6,
CS7, and CS8, respectively, in the termios c_cflag field, as defined in the Base

number Set terminal baud rate to the number given, if possible. If the baud rate is set
to zero, the modem control lines shall no longer be asserted. This shall have
the effect of setting the input and output *termios* baud rate values as defined in the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 11, General Terminal Interface.

**ispeed** *number*

Set terminal input baud rate to the number given, if possible. If the input baud rate is set to zero, the input baud rate shall be specified by the value of the output baud rate. This shall have the effect of setting the input *termios* baud rate values as defined in the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 11, General Terminal Interface.

**ospeed** *number*

Set terminal output baud rate to the number given, if possible. If the output baud rate is set to zero, the modem control lines shall no longer be asserted. This shall have the effect of setting the output *termios* baud rate values as defined in the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 11, General Terminal Interface.

**hupcl** (−**hupcl**) Stop asserting modem control lines (do not stop asserting modem control lines) on last close. This shall have the effect of setting (not setting) HUPCL in the *termios* c_cflag field, as defined in the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 11, General Terminal Interface.

**hup** (−**hup**)

Equivalent to hupcl(−hupcl).

**cstopb** (−**cstopb**) Use two (one) stop bits per character. This shall have the effect of setting (not setting) CSTOPB in the *termios* c_cflag field, as defined in the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 11, General Terminal Interface.

**cread** (−**cread**) Enable (disable) the receiver. This shall have the effect of setting (not setting) CREAD in the *termios* c_cflag field, as defined in the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 11, General Terminal Interface.

**clocal** (−**clocal**) Assume a line without (with) modem control. This shall have the effect of setting (not setting) CLOCAL in the *termios* c_cflag field, as defined in the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 11, General Terminal Interface.

It is unspecified whether *stty* shall report an error if an attempt to set a Control Mode fails.

**Input Modes**

**ignbrk** (−**ignbrk**) Ignore (do not ignore) break on input. This shall have the effect of setting (not setting) IGNBRK in the *termios* c_iflag field, as defined in the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 11, General Terminal Interface.

**brkint** (−**brkint**) Signal (do not signal) INTR on break. This shall have the effect of setting (not setting) BRKINT in the *termios* c_iflag field, as defined in the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 11, General Terminal Interface.

**ignpar** (−**ignpar**) Ignore (do not ignore) bytes with parity errors. This shall have the effect of setting (not setting) IGNPAR in the *termios* c_iflag field, as defined in the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 11, General Terminal Interface.

**parmrk** (−**parmrk**) Mark (do not mark) parity errors. This shall have the effect of setting (not setting) PARMRK in the *termios* c_iflag field, as defined in the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 11, General Terminal Interface.
inpk (−inpk) Enable (disable) input parity checking. This shall have the effect of setting (not setting) INPCK in the `termios_c_iflag` field, as defined in the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 11, General Terminal Interface.

istrip (−istrip) Strip (do not strip) input characters to seven bits. This shall have the effect of setting (not setting) ISTRIP in the `termios_c_iflag` field, as defined in the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 11, General Terminal Interface.

inlcr (−inlcr) Map (do not map) NL to CR on input. This shall have the effect of setting (not setting) INLCR in the `termios_c_iflag` field, as defined in the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 11, General Terminal Interface.

igncr (−igncr) Ignore (do not ignore) CR on input. This shall have the effect of setting (not setting) IGNCR in the `termios_c_iflag` field, as defined in the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 11, General Terminal Interface.

icrnl (−icrnl) Map (do not map) CR to NL on input. This shall have the effect of setting (not setting) ICRNL in the `termios_c_iflag` field, as defined in the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 11, General Terminal Interface.

ixon (−ixon) Enable (disable) START/STOP output control. Output from the system is stopped when the system receives STOP and started when the system receives START. This shall have the effect of setting (not setting) IXON in the `termios_c_iflag` field, as defined in the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 11, General Terminal Interface.

ixany (−ixany) Allow any character to restart output. This shall have the effect of setting (not setting) IXANY in the `termios_c_iflag` field, as defined in the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 11, General Terminal Interface.

ixoff (−ixoff) Request that the system send (not send) STOP characters when the input queue is nearly full and START characters to resume data transmission. This shall have the effect of setting (not setting) IXOFF in the `termios_c_iflag` field, as defined in the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 11, General Terminal Interface.

Output Modes

opost (−opost) Post-process output (do not post-process output; ignore all other output modes). This shall have the effect of setting (not setting) OPOST in the `termios_c_oflag` field, as defined in the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 11, General Terminal Interface.

ocrnl (−ocrnl) Map (do not map) CR to NL on output. This shall have the effect of setting (not setting) OCRNL in the `termios_c_oflag` field, as defined in the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 11, General Terminal Interface.

onocr (−onocr) Do not (do) output CR at column zero. This shall have the effect of setting (not setting) ONOCR in the `termios_c_oflag` field, as defined in the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 11, General Terminal Interface.

onlret (−onlret) The terminal newline key performs (does not perform) the CR function. This shall have the effect of setting (not setting) ONLRET in the `termios_c_oflag` field, as defined in the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 11, General Terminal Interface.
Utilities

ofill (−ofill) Use fill characters (use timing) for delays. This shall have the effect of setting (not setting) OFILL in the termios c_oflag field, as defined in the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 11, General Terminal Interface.

ofdel (−ofdel) Fill characters are DELs (NULs). This shall have the effect of setting (not setting) OFDEL in the termios c_oflag field, as defined in the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 11, General Terminal Interface.

cr0 cr1 cr2 cr3 Select the style of delay for CRs. This shall have the effect of setting CRDLY to CR0, CR1, CR2, or CR3, respectively, in the termios c_oflag field, as defined in the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 11, General Terminal Interface.

nl0 nl1 Select the style of delay for NL. This shall have the effect of setting NLDLY to NL0 or NL1, respectively, in the termios c_oflag field, as defined in the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 11, General Terminal Interface.

tab0 tab1 tab2 tab3 Select the style of delay for horizontal tabs. This shall have the effect of setting TABDLY to TAB0, TAB1, TAB2, or TAB3, respectively, in the termios c_oflag field, as defined in the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 11, General Terminal Interface. Note that TAB3 has the effect of expanding <tab>s to <space>s.

tabs (−tabs) Synonym for tab0 (tab3).

bs0 bs1 Select the style of delay for backspaces. This shall have the effect of setting BSDLY to BS0 or BS1, respectively, in the termios c_oflag field, as defined in the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 11, General Terminal Interface.

ff0 ff1 Select the style of delay for form-feeds. This shall have the effect of setting FFDLY to FF0 or FF1, respectively, in the termios c_oflag field, as defined in the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 11, General Terminal Interface.

vt0 vt1 Select the style of delay for vertical-tabs. This shall have the effect of setting VTDLY to VT0 or VT1, respectively, in the termios c_oflag field, as defined in the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 11, General Terminal Interface.

Local Modes

isig (−isig) Enable (disable) the checking of characters against the special control characters INTR, QUIT, and SUSP. This shall have the effect of setting (not setting) ISIG in the termios c_lflag field, as defined in the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 11, General Terminal Interface.

icanon (−icanon) Enable (disable) canonical input (ERASE and KILL processing). This shall have the effect of setting (not setting) ICANON in the termios c_lflag field, as defined in the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 11, General Terminal Interface.

iexten (−iexten) Enable (disable) any implementation-defined special control characters not currently controlled by icanon, isig, ixon, or ixoff. This shall have the effect of setting (not setting) IEXTEN in the termios c_lflag field, as defined in the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 11, General Terminal Interface.

**echo** (--echo)  
Echo back (do not echo back) every character typed. This shall have the effect of setting (not setting) ECHO in the **termios** c_lflag field, as defined in the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 11, General Terminal Interface.

**echoe** (--echoe)  
The ERASE character visually erases (does not erase) the last character in the current line from the display, if possible. This shall have the effect of setting (not setting) ECHOE in the **termios** c_lflag field, as defined in the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 11, General Terminal Interface.

**echok** (--echok)  
Echo (do not echo) NL after KILL character. This shall have the effect of setting (not setting) ECHOK in the **termios** c_lflag field, as defined in the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 11, General Terminal Interface.

**echonl** (--echonl)  
Echo (do not echo) NL, even if echo is disabled. This shall have the effect of setting (not setting) ECHONL in the **termios** c_lflag field, as defined in the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 11, General Terminal Interface.

**noflsh** (--noflsh)  
Disable (enable) flush after INTR, QUIT, SUSP. This shall have the effect of setting (not setting) NOFLSH in the **termios** c_lflag field, as defined in the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 11, General Terminal Interface.

**tostop** (--tostop)  
Send SIGTTOU for background output. This shall have the effect of setting (not setting) TOSTOP in the **termios** c_lflag field, as defined in the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 11, General Terminal Interface.

### Special Control Character Assignments

<control>-character string  
Set <control>-character to string. If <control>-character is one of the character sequences in the first column of the following table, the corresponding Base Definitions volume of IEEE Std 1003.1-2001, Chapter 11, General Terminal Interface control character from the second column shall be recognized. This has the effect of setting the corresponding element of the **termios** c_cc array (see the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 13, Headers, `<termios.h>`).
Enable `oddp`.

</table>

If `string` is a single character, the control character shall be set to that character. If `string` is the two-character sequence "^c" or the string `undef`, the control character shall be set to `_POSIX_VDISABLE`, if it is in effect for the device; if `_POSIX_VDISABLE` is not in effect for the device, it shall be treated as an error. In the POSIX locale, if `string` is a two-character sequence beginning with circumflex (`^`), and the second character is one of those listed in the "^c" column of the following table, the control character shall be set to the corresponding character value in the Value column of the table.

**Combination Modes**

 saved settings

Set the current terminal characteristics to the saved settings produced by the `−g` option.

 evenp or parity

Enable `parenb` and `cs7`; disable `parodd`.

 oddp

Enable `parenb`, `cs7`, and `parodd`.
--parity, --evenp, or --oddp
  Disable parenb, and set cs8.

raw (--raw or cooked)
  Enable (disable) raw input and output. Raw mode shall be equivalent to setting:

  stty cs8 erase ^- kill ^- intr ^- \ quit ^- eof ^- eol ^- --post --inpck

nl (--nl)
  Disable (enable) icrnl. In addition, --nl unsets inlcr and igncr.

ek  Reset ERASE and KILL characters back to system defaults.

 sane  Reset all modes to some reasonable, unspecified, values.

STDIN
  Although no input is read from standard input, standard input shall be used to get the current
  terminal I/O characteristics and to set new terminal I/O characteristics.

INPUT FILES
  None.

ENVIRONMENT VARIABLES
  The following environment variables shall affect the execution of stty:

  LANG   Provide a default value for the internationalization variables that are unset or null.
          (See the Base Definitions volume of IEEE Std 1003.1-2001, Section 8.2,
          Internationalization Variables for the precedence of internationalization variables
          used to determine the values of locale categories.)

  LC_ALL  If set to a non-empty string value, override the values of all the other
          internationalization variables.

  LC_CTYPE  This variable determines the locale for the interpretation of sequences of bytes of
          text data as characters (for example, single-byte as opposed to multi-byte
          characters in arguments) and which characters are in the class print.

  LC_MESSAGES  Determine the locale that should be used to affect the format and contents of
          diagnostic messages written to standard error.

  NLSPATH  Determine the location of message catalogs for the processing of LC_MESSAGES.

ASYNCHRONOUS EVENTS
  Default.

STDOUT
  If operands are specified, no output shall be produced.

          If the --g option is specified, stty shall write to standard output the current settings in a form that
          can be used as arguments to another instance of stty on the same system.

          If the --a option is specified, all of the information as described in the OPERANDS section shall
          be written to standard output. Unless otherwise specified, this information shall be written as
          <space>-separated tokens in an unspecified format, on one or more lines, with an unspecified
          number of tokens per line. Additional information may be written.

          If no options or operands are specified, an unspecified subset of the information written for the
          --a option shall be written.
If speed information is written as part of the default output, or if the −a option is specified and if
the terminal input speed and output speed are the same, the speed information shall be written
as follows:
"speed %d baud;", <speed>
Otherwise, speeds shall be written as:
"ispeed %d baud; ospeed %d baud;", <ispeed>, <ospeed>
In locales other than the POSIX locale, the word baud may be changed to something more
appropriate in those locales.
If control characters are written as part of the default output, or if the −a option is specified,
control characters shall be written as:
"%s = %s;", <control-character name>, <value>
where <value> is either the character, or some visual representation of the character if it is non-
printable, or the string undef if the character is disabled.

STDOUT
The standard error shall be used only for diagnostic messages.

OUTPUT FILES
None.

EXTENDED DESCRIPTION
None.

EXIT STATUS
The following exit values shall be returned:
0  The terminal options were read or set successfully.
>0  An error occurred.

CONSEQUENCES OF ERRORS
Default.

APPLICATION USAGE
The −g flag is designed to facilitate the saving and restoring of terminal state from the shell level.
For example, a program may:
saveterm="$(stty −g)"  # save terminal state
stty (new settings)    # set new state
...                  # ...
stty $saveterm        # restore terminal state
Since the format is unspecified, the saved value is not portable across systems.
Since the −a format is so loosely specified, scripts that save and restore terminal settings should
use the −g option.

EXAMPLES
None.

RATIONALE
The original stty description was taken directly from System V and reflected the System V
terminal driver termio. It has been modified to correspond to the terminal driver termios.
Output modes are specified only for XSI-conformant systems. All implementations are expected
to provide stty operands corresponding to all of the output modes they support.
The `stty` utility is primarily used to tailor the user interface of the terminal, such as selecting the preferred ERASE and KILL characters. As an application programming utility, `stty` can be used within shell scripts to alter the terminal settings for the duration of the script.

The `termios` section states that individual disabling of control characters is possible through the option `_POSIX_VDISABLE`. If enabled, two conventions currently exist for specifying this: System V uses "^", and BSD uses `undef`. Both are accepted by `stty` in this volume of IEEE Std 1003.1-2001. The other BSD convention of using the letter ‘u’ was rejected because it conflicts with the actual letter ‘u’, which is an acceptable value for a control character.

Early proposals did not specify the mapping of "^c" to control characters because the control characters were not specified in the POSIX locale character set description file requirements. The control character set is now specified in the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 3, Definitions so the historical mapping is specified. Note that although the mapping corresponds to control-character key assignments on many terminals that use the ISO/IEC 646: 1991 standard (or ASCII) character encodings, the mapping specified here is to the control characters, not their keyboard encodings. Since `termios` supports separate speeds for input and output, two new options were added to specify each distinctly.

Some historical implementations use standard input to get and set terminal characteristics; others use standard output. Since input from a login TTY is usually restricted to the owner while output to a TTY is frequently open to anyone, using standard input provides fewer chances of accidentally (or maliciously) altering the terminal settings of other users. Using standard input also allows `stty -a` and `stty -g` output to be redirected for later use. Therefore, usage of standard input is required by this volume of IEEE Std 1003.1-2001.

NAME

tabs — set terminal tabs

SYNOPSIS

tabs [ −n | −a | −a2 | −c | −c2 | −c3 | −f | −p | −s | −u ] [ +m[n] ] [ −T type ]

tabs [ −T type ] [ +[n] ] n1[,n2,...]

DESCRIPTION

The tabs utility shall display a series of characters that first clears the hardware terminal tab settings and then initializes the tab stops at the specified positions and optionally adjusts the margin.

The phrase “tab-stop position N” shall be taken to mean that, from the start of a line of output, tabbing to position N shall cause the next character output to be in the (N+1)th column position on that line. The maximum number of tab stops allowed is terminal-dependent.

It need not be possible to implement tabs on certain terminals. If the terminal type obtained from the TERM environment variable or −T option represents such a terminal, an appropriate diagnostic message shall be written to standard error and tabs shall exit with a status greater than zero.

OPTIONS

The tabs utility shall conform to the Base Definitions volume of IEEE Std 1003.1-2001, Section 12.2, Utility Syntax Guidelines, except for various extensions: the options −a2, −c2, and −c3 are multi-character.

The following options shall be supported:

−n Specify repetitive tab stops separated by a uniform number of column positions, n, where n is a single-digit decimal number. The default usage of tabs with no arguments shall be equivalent to tabs−8. When −0 is used, the tab stops shall be cleared and no new ones set.

−a 1,10,16,36,72
    Assembler, applicable to some mainframes.

−a2 1,10,16,40,72
    Assembler, applicable to some mainframes.

−c 1,8,12,16,20,55
    COBOL, normal format.

−c2 1,6,10,14,49
    COBOL, compact format (columns 1 to 6 omitted).

−c3 1,6,10,14,18,22,26,30,34,38,42,46,50,54,58,62,67
    COBOL compact format (columns 1 to 6 omitted), with more tabs than −c2.

−f 1,7,11,15,19,23
    FORTRAN

−p 1,5,9,13,17,21,25,29,33,37,41,45,49,53,57,61
    PL/1

−s 1,10,55
    SNOBOL

−u 1,12,20,44
    Assembler, applicable to some mainframes.
OPERANDS

The following operand shall be supported:

- \( n1[,n2,\ldots] \) A single command line argument that consists of tab-stop values separated using either commas or <blank>s. The application shall ensure that the tab-stop values are positive decimal integers in strictly ascending order. If any number (except the first one) is preceded by a plus sign, it is taken as an increment to be added to the previous value. For example, the tab lists 1,10,20,30 and 1,10,+10,+10 are considered to be identical.

STDOUT

If standard output is a terminal, the appropriate sequence to clear and set the tab stops may be written to standard output in an unspecified format. If standard output is not a terminal, undefined results occur.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.
EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0  Successful completion.

>0  An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

This utility makes use of the terminal’s hardware tabs and the \textit{stty tabs} option.

This utility is not recommended for application use.

Some integrated display units might not have escape sequences to set tab stops, but may be set by internal system calls. On these terminals, \textit{tabs} works if standard output is directed to the terminal; if output is directed to another file, however, \textit{tabs} fails.

EXAMPLES

None.

RATIONALE

Consideration was given to having the \textit{tput} utility handle all of the functions described in \textit{tabs}.

However, the separate \textit{tabs} utility was retained because it seems more intuitive to use a command named \textit{tabs} than \textit{tput} with a new option. The \textit{tput} utility does not support setting or clearing tabs, and no known historical version of \textit{tabs} supports the capability of setting arbitrary tab stops.

The System V \textit{tabs} interface is very complex; the version in this volume of IEEE Std 1003.1-2001 has a reduced feature list, but many of the features omitted were restored as XSI extensions even though the supported languages and coding styles are primarily historical.

There was considerable sentiment for specifying only a means of resetting the tabs back to a known state—presumably the “standard” of tabs every eight positions. The following features were omitted:

- Setting tab stops via the first line in a file, using \texttt{−f file}. Since even the SVID has no complete explanation of this feature, it is doubtful that it is in widespread use.

In an early proposal, a \texttt{−t tablist} option was added for consistency with \textit{expand}; this was later removed when inconsistencies with the historical list of tabs were identified.

Consideration was given to adding a \texttt{−p} option that would output the current tab settings so that they could be saved and then later restored. This was not accepted because querying the tab stops of the terminal is not a capability in historical \textit{terminfo} or \textit{termcap} facilities and might not be supported on a wide range of terminals.

FUTURE DIRECTIONS

None.

CHANGE HISTORY
First released in Issue 2.

Issue 6
This utility is marked as part of the User Portability Utilities option.
The normative text is reworded to avoid use of the term “must” for application requirements.
NAME
tail — copy the last part of a file

SYNOPSIS
tail [-f] [-c number] [-n number] [file]

DESCRIPTION
The tail utility shall copy its input file to the standard output beginning at a designated place.
Copying shall begin at the point in the file indicated by the -c number or -n number options. The
option-argument number shall be counted in units of lines or bytes, according to the options -n
and -c. Both line and byte counts start from 1.
Tails relative to the end of the file may be saved in an internal buffer, and thus may be limited in
length. Such a buffer, if any, shall be no smaller than {LINE_MAX}*10 bytes.

OPTIONS
The tail utility shall conform to the Base Definitions volume of IEEE Std 1003.1-2001, Section
The following options shall be supported:

-c number  The application shall ensure that the number option-argument is a decimal integer
which affects the location in the file, measured in bytes, to begin the copying:

<table>
<thead>
<tr>
<th>Sign</th>
<th>Copying Starts</th>
</tr>
</thead>
<tbody>
<tr>
<td>+</td>
<td>Relative to the beginning of the file.</td>
</tr>
<tr>
<td>-</td>
<td>Relative to the end of the file.</td>
</tr>
<tr>
<td>none</td>
<td>Relative to the end of the file.</td>
</tr>
</tbody>
</table>

The origin for counting shall be 1; that is, -c +1 represents the first byte of the file, -c -1 the last.

-f  If the input file is a regular file or if the file operand specifies a FIFO, do not
terminate after the last line of the input file has been copied, but read and copy
further bytes from the input file when they become available. If no file operand is
specified and standard input is a pipe, the -f option shall be ignored. If the input
file is not a FIFO, pipe, or regular file, it is unspecified whether or not the -f option
shall be ignored.

-n number  This option shall be equivalent to -c number, except the starting location in the file
shall be measured in lines instead of bytes. The origin for counting shall be 1; that
is, -n +1 represents the first line of the file, -n -1 the last.

If neither -c nor -n is specified, -n 10 shall be assumed.

OPERANDS
The following operand shall be supported:

file A pathname of an input file. If no file operands are specified, the standard input
shall be used.

STDIN
The standard input shall be used only if no file operands are specified. See the INPUT FILES
section.
INPUT FILES
If the −c option is specified, the input file can contain arbitrary data; otherwise, the input file shall be a text file.

ENVIRONMENT VARIABLES
The following environment variables shall affect the execution of tail:

LANG
Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-2001, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL
If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE
Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI_NLSPATH
Determine the location of message catalogs for the processing of LC_MESSAGES.

ASYNCHRONOUS EVENTS
Default.

STDOUT
The designated portion of the input file shall be written to standard output.

STDERR
The standard error shall be used only for diagnostic messages.

OUTPUT FILES
None.

EXTENDED DESCRIPTION
None.

EXIT STATUS
The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS
Default.

APPLICATION USAGE
The −c option should be used with caution when the input is a text file containing multi-byte characters; it may produce output that does not start on a character boundary.

Although the input file to tail can be any type, the results might not be what would be expected on some character special device files or on file types not described by the System Interfaces volume of IEEE Std 1003.1-2001. Since this volume of IEEE Std 1003.1-2001 does not specify the block size used when doing input, tail need not read all of the data from devices that only perform block transfers.
EXAMPLES
The -f option can be used to monitor the growth of a file that is being written by some other process. For example, the command:

tail -f fred

prints the last ten lines of the file fred, followed by any lines that are appended to fred between the time tail is initiated and killed. As another example, the command:

tail -f -c 15 fred

prints the last 15 bytes of the file fred, followed by any bytes that are appended to fred between the time tail is initiated and killed.

RATIONALE
This version of tail was created to allow conformance to the Utility Syntax Guidelines. The historical -b option was omitted because of the general non-portability of block-sized units of text. The -c option historically meant ‘‘characters’’, but this volume of IEEE Std 1003.1-2001 indicates that it means ‘‘bytes’’. This was selected to allow reasonable implementations when multi-byte characters are possible; it was not named -b to avoid confusion with the historical -b.

The origin of counting both lines and bytes is 1, matching all widespread historical implementations.

The restriction on the internal buffer is a compromise between the historical System V implementation of 4 096 bytes and the BSD 32 768 bytes.

The -f option has been implemented as a loop that sleeps for 1 second and copies any bytes that are available. This is sufficient, but if more efficient methods of determining when new data are available are developed, implementations are encouraged to use them.

Historical documentation indicates that tail ignores the -f option if the input file is a pipe (pipe and FIFO on systems that support FIFOs). On BSD-based systems, this has been true; on System V-based systems, this was true when input was taken from standard input, but it did not ignore the -f flag if a FIFO was named as the file operand. Since the -f option is not useful on pipes and all historical implementations ignore -f if no file operand is specified and standard input is a pipe, this volume of IEEE Std 1003.1-2001 requires this behavior. However, since the -f option is useful on a FIFO, this volume of IEEE Std 1003.1-2001 also requires that if standard input is a FIFO or a FIFO is named, the -f option shall not be ignored. Although historical behavior does not ignore the -f option for other file types, this is unspecified so that implementations are allowed to ignore the -f option if it is known that the file cannot be extended.

This was changed to the current form based on comments noting that -c was almost never used without specifying a number and that there was no need to specify -l if -n number was given.

FUTURE DIRECTIONS
None.

CHANGE HISTORY
First released in Issue 2.

Issue 6
The obsolescent SYNOPSIS lines and associated text are removed.
The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.
NAME

talk — talk to another user

SYNOPSIS

UP

talk address [terminal]

DESCRIPTION

The talk utility is a two-way, screen-oriented communication program.

When first invoked, talk shall send a message similar to:

Message from <unspecified string>
talk: connection requested by your_address
talk: respond with: talk your_address

to the specified address. At this point, the recipient of the message can reply by typing:

talk your_address

Once communication is established, the two parties can type simultaneously, with their output displayed in separate regions of the screen. Characters shall be processed as follows:

• Typing the alert character shall alert the recipient’s terminal.

• Typing <control>-L shall cause the sender’s screen regions to be refreshed.

• Typing the erase and kill characters shall affect the sender’s terminal in the manner described by the termios interface in the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 11, General Terminal Interface.

• Typing the interrupt or end-of-file characters shall terminate the local talk utility. Once the talk session has been terminated on one side, the other side of the talk session shall be notified that the talk session has been terminated and shall be able to do nothing except exit.

• Typing characters from LC_CTYPE classifications print or space shall cause those characters to be sent to the recipient’s terminal.

• When and only when the stty iexten local mode is enabled, the existence and processing of additional special control characters and multi-byte or single-byte functions shall be implementation-defined.

• Typing other non-printable characters shall cause implementation-defined sequences of printable characters to be sent to the recipient’s terminal.

Permission to be a recipient of a talk message can be denied or granted by use of the mesg utility. However, a user’s privilege may further constrain the domain of accessibility of other users’ terminals. The talk utility shall fail when the user lacks the appropriate privileges to perform the requested action.

Certain block-mode terminals do not have all the capabilities necessary to support the simultaneous exchange of messages required for talk. When this type of exchange cannot be supported on such terminals, the implementation may support an exchange with reduced levels of simultaneous interaction or it may report an error describing the terminal-related deficiency.

OPTIONS

None.
OPERANDS
The following operands shall be supported:

address    The recipient of the talk session. One form of address is the <user name>, as returned by the who utility. Other address formats and how they are handled are unspecified.

terminal   If the recipient is logged in more than once, the terminal argument can be used to indicate the appropriate terminal name. If terminal is not specified, the talk message shall be displayed on one or more accessible terminals in use by the recipient. The format of terminal shall be the same as that returned by the who utility.

STDIN
Characters read from standard input shall be copied to the recipient’s terminal in an unspecified manner. If standard input is not a terminal, talk shall write a diagnostic message and exit with a non-zero status.

INPUT FILES
None.

ENVIRONMENT VARIABLES
The following environment variables shall affect the execution of talk:

LANG     Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-2001, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL    If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE  Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files). If the recipient’s locale does not use an LC_CTYPE equivalent to the sender’s, the results are undefined.

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error and informative messages written to standard output.

NLSPATH
Determine the location of message catalogs for the processing of LC_MESSAGES.

TERM     Determine the name of the invoker’s terminal type. If this variable is unset or null, an unspecified default terminal type shall be used.

ASYNCRONOUS EVENTS
When the talk utility receives a SIGINT signal, the utility shall terminate and exit with a zero status. It shall take the standard action for all other signals.

STDOUT
If standard output is a terminal, characters copied from the recipient’s standard input may be written to standard output. Standard output also may be used for diagnostic messages. If standard output is not a terminal, talk shall exit with a non-zero status.

STDERR
None.
OUTPUT FILES
None.

EXTENDED DESCRIPTION
None.

EXIT STATUS
The following exit values shall be returned:

0 Successful completion.

>0 An error occurred or talk was invoked on a terminal incapable of supporting it.

CONSEQUENCES OF ERRORS
Default.

APPLICATION USAGE
Because the handling of non-printable, non-space characters is tied to the stty description of iexten, implementation extensions within the terminal driver can be accessed. For example, some implementations provide line editing functions with certain control character sequences.

EXAMPLES
None.

RATIONALE
The write utility was included in this volume of IEEE Std 1003.1-2001 since it can be implemented on all terminal types. The talk utility, which cannot be implemented on certain terminals, was considered to be a “better” communications interface. Both of these programs are in widespread use on historical implementations. Therefore, both utilities have been specified.

All references to networking abilities (talking to a user on another system) were removed as being outside the scope of this volume of IEEE Std 1003.1-2001.

Historical BSD and System V versions of talk terminate both of the conversations when either user breaks out of the session. This can lead to adverse consequences if a user unwittingly continues to enter text that is interpreted by the shell when the other terminates the session. Therefore, the version of talk specified by this volume of IEEE Std 1003.1-2001 requires both users to terminate their end of the session explicitly.

Only messages sent to the terminal of the invoking user can be internationalized in any way:

- The original “Message from &lt;unspecified string&gt; …” message sent to the terminal of the recipient cannot be internationalized because the environment of the recipient is as yet inaccessible to the talk utility. The environment of the invoking party is irrelevant.

- Subsequent communication between the two parties cannot be internationalized because the two parties may specify different languages in their environment (and non-portable characters cannot be mapped from one language to another).

- Neither party can be required to communicate in a language other than C and/or the one specified by their environment because unavailable terminal hardware support (for example, fonts) may be required.

The text in the STDOUT section reflects the usage of the verb “display” in this section; some talk implementations actually use standard output to write to the terminal, but this volume of IEEE Std 1003.1-2001 does not require that to be the case.

The format of the terminal name is unspecified, but the descriptions of ps, talk, who, and write require that they all use or accept the same format.
The handling of non-printable characters is partially implementation-defined because the details of mapping them to printable sequences is not needed by the user. Historical implementations, for security reasons, disallow the transmission of non-printable characters that may send commands to the other terminal.

FUTURE DIRECTIONS
None.

CHANGE HISTORY
First released in Issue 4.

Issue 6
This utility is marked as part of the User Portability Utilities option.
NAME
tee — duplicate standard input

SYNOPSIS
tee [−ai][file...]

DESCRIPTION
The tee utility shall copy standard input to standard output, making a copy in zero or more files.
The tee utility shall not buffer output.
If the −a option is not specified, output files shall be written (see Section 1.7.1.4 (on page 4).

OPTIONS
The tee utility shall conform to the Base Definitions volume of IEEE Std 1003.1-2001, Section 12.2,
Utility Syntax Guidelines.
The following options shall be supported:
−a Append the output to the files.
−i Ignore the SIGINT signal.

OPERANDS
The following operands shall be supported:
file A pathname of an output file. Processing of at least 13 file operands shall be supported.

STDIN
The standard input can be of any type.

INPUT FILES
None.

ENVIRONMENT VARIABLES
The following environment variables shall affect the execution of tee:
LANG Provide a default value for the internationalization variables that are unset or null.
(See the Base Definitions volume of IEEE Std 1003.1-2001, Section 8.2,
Internationalization Variables for the precedence of internationalization variables
used to determine the values of locale categories.)
LC_ALL If set to a non-empty string value, override the values of all the other
internationalization variables.
LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as
characters (for example, single-byte as opposed to multi-byte characters in
arguments).
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of
diagnostic messages written to standard error.

XSI NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

ASYNCHRONOUS EVENTS
Default, except that if the −i option was specified, SIGINT shall be ignored.
STDOUT
The standard output shall be a copy of the standard input.

STDERR
The standard error shall be used only for diagnostic messages.

OUTPUT FILES
If any file operands are specified, the standard input shall be copied to each named file.

EXTENDED DESCRIPTION
None.

EXIT STATUS
The following exit values shall be returned:
0 The standard input was successfully copied to all output files.
>0 An error occurred.

CONSEQUENCES OF ERRORS
If a write to any successfully opened file operand fails, writes to other successfully opened file operands and standard output shall continue, but the exit status shall be non-zero. Otherwise, the default actions specified in Section 1.11 (on page 20) apply.

APPLICATION USAGE
The tee utility is usually used in a pipeline, to make a copy of the output of some utility.
The file operand is technically optional, but tee is no more useful than cat when none is specified.

EXAMPLES
Save an unsorted intermediate form of the data in a pipeline:
... | tee unsorted | sort > sorted

RATIONALE
The buffering requirement means that tee is not allowed to use ISO C standard fully buffered or line-buffered writes. It does not mean that tee has to do 1-byte reads followed by 1-byte writes.
It should be noted that early versions of BSD ignore any invalid options and accept a single ‘−’ as an alternative to ‘−i’. They also print a message if unable to open a file:
"tee: cannot access %s\n", <pathname>

Historical implementations ignore write errors. This is explicitly not permitted by this volume of IEEE Std 1003.1-2001.

Some historical implementations use O_APPEND when providing append mode; others use the lseek() function to seek to the end-of-file after opening the file without O_APPEND. This volume of IEEE Std 1003.1-2001 requires functionality equivalent to using O_APPEND; see Section 1.7.1.4 (on page 4).

FUTURE DIRECTIONS
None.

CHANGE HISTORY
First released in Issue 2.
IEEE PASC Interpretation 1003.2 #168 is applied.
NAME
test — evaluate expression

SYNOPSIS
test [expression]
[ [expression] ]

DESCRIPTION
The test utility shall evaluate the expression and indicate the result of the evaluation by its exit status. An exit status of zero indicates that the expression evaluated as true and an exit status of 1 indicates that the expression evaluated as false.

In the second form of the utility, which uses "[]" rather than test, the application shall ensure that the square brackets are separate arguments.

OPTIONS

No options shall be supported.

OPERANDS
The application shall ensure that all operators and elements of primaries are presented as separate arguments to the test utility.

The following primaries can be used to construct expression:

- `file`
  True if file exists and is a block special file.
- `file`
  True if file exists and is a character special file.
- `file`
  True if file exists and is a directory.
- `file`
  True if file exists.
- `file`
  True if file exists and is a regular file.
- `file`
  True if file exists and its set-group-ID flag is set.
- `file`
  True if file exists and is a symbolic link.
- `file`
  True if file exists and is a symbolic link.
- `string`
  True if the length of string is non-zero.
- `file`
  True if file is a FIFO.
- `file`
  True if file exists and is readable. True shall indicate that permission to read from file will be granted, as defined in Section 1.7.1.4 (on page 4).
- `file`
  True if file exists and is a socket.
- `file`
  True if file exists and has a size greater than zero.
- `file_descriptor`
  True if the file whose file descriptor number is file_descriptor is open and is associated with a terminal.
- `file`
  True if file exists and its set-user-ID flag is set.
- `file`
  True if file exists and is writable. True shall indicate that permission to write from file will be granted, as defined in Section 1.7.1.4 (on page 4).
$x\ file$ True if $file$ exists and is executable. True shall indicate that permission to execute $file$ will be granted, as defined in Section 1.7.1.4 (on page 4). If $file$ is a directory, true shall indicate that permission to search $file$ will be granted.

$-z\ string$ True if the length of string $string$ is zero.

$string$ True if the string $string$ is not the null string.

$s1 = s2$ True if the strings $s1$ and $s2$ are identical.

$s1 \neq s2$ True if the strings $s1$ and $s2$ are not identical.

$n1 -eq n2$ True if the integers $n1$ and $n2$ are algebraically equal.

$n1 -ne n2$ True if the integers $n1$ and $n2$ are not algebraically equal.

$n1 -gt n2$ True if the integer $n1$ is algebraically greater than the integer $n2$.

$n1 -ge n2$ True if the integer $n1$ is algebraically greater than or equal to the integer $n2$.

$n1 -lt n2$ True if the integer $n1$ is algebraically less than the integer $n2$.

$n1 -le n2$ True if the integer $n1$ is algebraically less than or equal to the integer $n2$.

$expression1 -a expression2$ True if both $expression1$ and $expression2$ are true. The $-a$ binary primary is left associative. It has a higher precedence than $-o$.

$expression1 -o expression2$ True if either $expression1$ or $expression2$ is true. The $-o$ binary primary is left associative.

With the exception of the $-h\ file$ and $-L\ file$ primaries, if a $file$ argument is a symbolic link, $test$ shall evaluate the expression by resolving the symbolic link and using the file referenced by the link.

These primaries can be combined with the following operators:

$!\ expression$ True if $expression$ is false.

$( expression\ )$ True if $expression$ is true. The parentheses can be used to alter the normal precedence and associativity.

The primaries with two elements of the form:

$-primary\_operator\ primary\_operand$

are known as unary primaries. The primaries with three elements in either of the two forms:

$primary\_operand\ -primary\_operator\ primary\_operand$

$primary\_operand\ primary\_operator\ primary\_operand$

are known as binary primaries. Additional implementation-defined operators and $primary\_operators$ may be provided by implementations. They shall be of the form $-operator$ where the first character of $operator$ is not a digit.

The algorithm for determining the precedence of the operators and the return value that shall be generated is based on the number of arguments presented to $test$. (However, when using the "$\ [\ldots]\ $" form, the right-bracket final argument shall not be counted in this algorithm.)

In the following list, $1, \ 2, \ 3,$ and $4$ represent the arguments presented to $test$:

0 arguments: Exit false (1).
1 argument: Exit true (0) if $1 is not null; otherwise, exit false.

2 arguments:
- If $1 is ‘!’, exit true if $2 is null, false if $2 is not null.
- If $1 is a unary primary, exit true if the unary test is true, false if the unary test is false.
- Otherwise, produce unspecified results.

3 arguments:
- If $2 is a binary primary, perform the binary test of $1 and $3.
- If $1 is ‘!’, negate the two-argument test of $2 and $3.
- If $1 is ‘(’ and $3 is ‘)’, perform the unary test of $2.
- Otherwise, produce unspecified results.

4 arguments:
- If $1 is ‘!’, negate the three-argument test of $2, $3, and $4.
- If $1 is ‘(’ and $4 is ‘)’, perform the two-argument test of $2 and $3.
- Otherwise, the results are unspecified.

>4 arguments: The results are unspecified.

On XSI-conformant systems, combinations of primaries and operators shall be evaluated using the precedence and associativity rules described previously. In addition, the string comparison binary primaries ‘=’ and ‘!=’ shall have a higher precedence than any unary primary.

STDIN
Not used.

INPUT FILES
None.

ENVIRONMENT VARIABLES
The following environment variables shall affect the execution of test:

- LANG: Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-2001, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

- LC_ALL: If set to a non-empty string value, override the values of all the other internationalization variables.

- LC_CTYPE: Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

- LC_MESSAGES: Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

- NLSPATH: Determine the location of message catalogs for the processing of LC_MESSAGES.

ASYNCHRONOUS EVENTS
Default.
STDOUT
Not used.

STDERR
The standard error shall be used only for diagnostic messages.

OUTPUT FILES
None.

EXTENDED DESCRIPTION
None.

EXIT STATUS
The following exit values shall be returned:

- 0  expression evaluated to true.
- 1  expression evaluated to false or expression was missing.
- >1  An error occurred.

CONSEQUENCES OF ERRORS
Default.

APPLICATION USAGE
Scripts should be careful when dealing with user-supplied input that could be confused with primaries and operators. Unless the application writer knows all the cases that produce input to the script, invocations like:

```
test "$1" -a "$2"
```

should be written as:

```
test "$1" && test "$2"
```

to avoid problems if a user supplied values such as $1 set to ‘!’ and $2 set to the null string. That is, in cases where maximal portability is of concern, replace:

```
test expr1 -a expr2
```

with:

```
test expr1 && test expr2
```

and replace:

```
test expr1 -o expr2
```

with:

```
test expr1 || test expr2
```

but note that, in test, -a has higher precedence than -o while "&&" and "||" have equal precedence in the shell.

Parentheses or braces can be used in the shell command language to effect grouping.

Parentheses must be escaped when using sh; for example:

```
test \( expr1 -a expr2 \) -o expr3
```

This command is not always portable outside XSI-conformant systems. The following form can be used instead:
The two commands:

```
( test expr1 && test expr2 ) || test expr3
```

could not be used reliably on some historical systems. Unexpected results would occur if such a string expression were used and $1 expanded to ‘!’, ‘(’, or a known unary primary. Better constructs are:

```
test −n "$1"
test −z "$1"
```

respectively.

Historical systems have also been unreliable given the common construct:

```
test "$response" = "expected string"
```

One of the following is a more reliable form:

```
test "X$response" = "Xexpected string"
test "expected string" = "$response"
```

Note that the second form assumes that expected string could not be confused with any unary primary. If expected string starts with ‘−’, ‘(’, ‘!’, or even ‘=’, the first form should be used instead. Using the preceding rules without the XSI marked extensions, any of the three comparison forms is reliable, given any input. (However, note that the strings are quoted in all cases.)

Because the string comparison binary primaries, ‘=’ and "!=", have a higher precedence than any unary primary in the greater than 4 argument case, unexpected results can occur if arguments are not properly prepared. For example, in:

```
test −d $1 −o −d $2
```

If $1 evaluates to a possible directory name of ‘=’, the first three arguments are considered a string comparison, which shall cause a syntax error when the second −d is encountered. One of the following forms prevents this; the second is preferred:

```
test \( −d "$1" \) −o \( −d "$2" \)
test −d "$1" || test −d "$2"
```

Also in the greater than 4 argument case:

```
test "$1" = "bat" −a "$2" = "ball"
```

syntax errors occur if $1 evaluates to ‘(‘ or ‘)!‘. One of the following forms prevents this; the third is preferred:

```
test "X$1" = "Xbat" −a "X$2" = "Xball"
test "$1" = "bat" && test "$2" = "ball"
test "X$1" = "Xbat" && test "X$2" = "Xball"
```

**EXAMPLES**

1. Exit if there are not two or three arguments (two variations):

```
if [ $# −ne 2 −a $# −ne 3 ]; then exit 1; fi
if [ $# −lt 2 −o $# −gt 3 ]; then exit 1; fi
```
2. Perform a `mkdir` if a directory does not exist:

```bash
    test ! -d tempdir && mkdir tempdir
```

3. Wait for a file to become non-readable:

```bash
    while test -r thefile
do
        sleep 30
done
echo '"thefile" is no longer readable'
```

4. Perform a command if the argument is one of three strings (two variations):

```bash
    if [ "$1" = "pear" ] || [ "$1" = "grape" ] || [ "$1" = "apple" ]
then
    command
fi
```

```bash
    case "$1" in
      pear|grape|apple) command ;;
esac
```

RATIONAL

The KornShell-derived conditional command (double bracket `[[ ]]`) was removed from the shell command language description in an early proposal. Objections were raised that the real problem is misuse of the `test` command (`[]`), and putting it into the shell is the wrong way to fix the problem. Instead, proper documentation and a new shell reserved word (`!`) are sufficient.

Tests that require multiple `test` operations can be done at the shell level using individual invocations of the `test` command and shell logicals, rather than using the error-prone `−o` flag of `test`.

XSI-conformant systems support more than four arguments.

XSI-conformant systems support the combining of primaries with the following constructs:

- `expression1 −a expression2`
  - True if both `expression1` and `expression2` are true.
- `expression1 −o expression2`
  - True if at least one of `expression1` and `expression2` are true.
- `( expression )`
  - True if `expression` is true.

In evaluating these more complex combined expressions, the following precedence rules are used:

- The unary primaries have higher precedence than the algebraic binary primaries.
- The unary primaries have lower precedence than the string binary primaries.
- The unary and binary primaries have higher precedence than the unary string primary.
- The `!` operator has higher precedence than the `−a` operator, and the `−a` operator has higher precedence than the `−o` operator.
- The `−a` and `−o` operators are left associative.
- The parentheses can be used to alter the normal precedence and associativity.
The BSD and System V versions of −f are not the same. The BSD definition was:

−f file True if file exists and is not a directory.

The SVID version (true if the file exists and is a regular file) was chosen for this volume of IEEE Std 1003.1-2001 because its use is consistent with the −b, −c, −d, and −p operands (file exists and is a specific file type).

The −e primary, possessing similar functionality to that provided by the C shell, was added because it provides the only way for a shell script to find out if a file exists without trying to open the file. Since implementations are allowed to add additional file types, a portable script cannot use:

test −b foo −c foo −d foo −f foo −o −p foo

to find out if foo is an existing file. On historical BSD systems, the existence of a file could be determined by:

test −f foo −o −d foo

but there was no easy way to determine that an existing file was a regular file. An early proposal used the KornShell −a primary (with the same meaning), but this was changed to −e because there were concerns about the high probability of humans confusing the −a primary with the −a binary operator.

The following options were not included in this volume of IEEE Std 1003.1-2001, although they are provided by some implementations. These operands should not be used by new implementations for other purposes:

−k file True if file exists and its sticky bit is set.

−C file True if file is a contiguous file.

−V file True if file is a version file.

The following option was not included because it was undocumented in most implementations, has been removed from some implementations (including System V), and the functionality is provided by the shell (see Section 2.6.2 (on page 37).

−l string The length of the string string.

The −b, −c, −g, −p, −u, and −x operands are derived from the SVID; historical BSD does not provide them. The −k operand is derived from System V; historical BSD does not provide it.

On historical BSD systems, test −w directory always returned false because test tried to open the directory for writing, which always fails.

Some additional primaries newly invented or from the KornShell appeared in an early proposal as part of the conditional command ([[]]): s1 > s2, s1 < s2, str = pattern, str != pattern, f1 −nt f2, f1 −ot f2, and f1 −ef f2. They were not carried forward into the test utility when the conditional command was removed from the shell because they have not been included in the test utility built into historical implementations of the sh utility.

The −t file_descriptor primary is shown with a mandatory argument because the grammar is ambiguous if it can be omitted. Historical implementations have allowed it to be omitted, providing a default of 1.

**FUTURE DIRECTIONS**

None.

Section 1.7.1.4 (on page 4), find

CHANGE HISTORY
First released in Issue 2.

Issue 5
The FUTURE DIRECTIONS section is added.

Issue 6
The \texttt{−h} operand is added for symbolic links, and access permission requirements are clarified for
the \texttt{−r}, \texttt{−w}, and \texttt{−x} operands to align with the IEEE P1003.2b draft standard.
The normative text is reworded to avoid use of the term “must” for application requirements.
The \texttt{−L} and \texttt{−S} operands are added for symbolic links and sockets.

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/38 is applied, adding XSI margin marking
and shading to a line in the OPERANDS section referring to the use of parentheses as arguments
to the \texttt{test} utility.
NAME

time — time a simple command

SYNOPSIS

    time [-p] utility [argument...]

DESCRIPTION

The `time` utility shall invoke the utility named by the `utility` operand with arguments supplied as
the `argument` operands and write a message to standard error that lists timing statistics for the utility. The message shall include the following information:

- The elapsed (real) time between invocation of `utility` and its termination.
- The User CPU time, equivalent to the sum of the `tms_utime` and `tms_cutime` fields returned by the `times()` function defined in the System Interfaces volume of IEEE Std 1003.1-2001 for the process in which `utility` is executed.
- The System CPU time, equivalent to the sum of the `tms_stime` and `tms_cstime` fields returned by the `times()` function for the process in which `utility` is executed.

The precision of the timing shall be no less than the granularity defined for the size of the clock tick unit on the system, but the results shall be reported in terms of standard time units (for example, 0.02 seconds, 00:00:00.02, 1m33.75s, 365.21 seconds), not numbers of clock ticks.

When `time` is used as part of a pipeline, the times reported are unspecified, except when it is the sole command within a grouping command (see Section 2.9.4.1 (on page 52)) in that pipeline. For example, the commands on the left are unspecified; those on the right report on utilities `a` and `c`, respectively:

```
    time a | b | c  { time a } | b | c
    a | b | time c  a | b | (time c)
```

OPTIONS

The following option shall be supported:

- `-p` Write the timing output to standard error in the format shown in the STDERR section.

OPERANDS

The following operands shall be supported:

- `utility` The name of a utility that is to be invoked. If the `utility` operand names any of the special built-in utilities in Section 2.14 (on page 64), the results are undefined.
- `argument` Any string to be supplied as an argument when invoking the utility named by the `utility` operand.

STDIN

Not used.

INPUT FILES

None.
ENIRONMENT VARIABLES

The following environment variables shall affect the execution of time:

LANG Provide a default value for the internationalization variables that are unset or null.
(See the Base Definitions volume of IEEE Std 1003.1-2001, Section 8.2,
Internationalization Variables for the precedence of internationalization variables
used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other
internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as
characters (for example, single-byte as opposed to multi-byte characters in
arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of
diagnostic and informative messages written to standard error.

LC_NUMERIC
Determine the locale for numeric formatting.

PATH Determine the search path that shall be used to locate the utility to be invoked; see
the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 8, Environment
Variables.

ASYNCHRONOUS EVENTS
Default.

STDOUT
Not used.

STDERR
The standard error shall be used to write the timing statistics. If -p is specified, the following
format shall be used in the POSIX locale:

"real %f\nuser %f\nsys %f\n",

where each floating-point number shall be expressed in seconds. The precision used may be less
than the default six digits of %f, but shall be sufficiently precise to accommodate the size of the
clock tick on the system (for example, if there were 60 clock ticks per second, at least two digits
shall follow the radix character). The number of digits following the radix character shall be no
less than one, even if this always results in a trailing zero. The implementation may append
white space and additional information following the format shown here.

OUTPUT FILES
None.

EXTENDED DESCRIPTION
None.

EXIT STATUS
If the utility utility is invoked, the exit status of time shall be the exit status of utility; otherwise,
the time utility shall exit with one of the following values:

1-125 An error occurred in the time utility.
The utility specified by utility was found but could not be invoked.

The utility specified by utility could not be found.

**CONSEQUENCES OF ERRORS**

Default.

**APPLICATION USAGE**

The command, env, nice, nohup, time, and xargs utilities have been specified to use exit code 127 if an error occurs so that applications can distinguish “failure to find a utility” from “invoked utility exited with an error indication”. The value 127 was chosen because it is not commonly used for other meanings; most utilities use small values for “normal error conditions” and the values above 128 can be confused with termination due to receipt of a signal. The value 126 was chosen in a similar manner to indicate that the utility could be found, but not invoked. Some scripts produce meaningful error messages differentiating the 126 and 127 cases. The distinction between exit codes 126 and 127 is based on KornShell practice that uses 127 when all attempts to exec the utility fail with [ENOENT], and uses 126 when any attempt to exec the utility fails for any other reason.

**EXAMPLES**

It is frequently desirable to apply time to pipelines or lists of commands. This can be done by placing pipelines and command lists in a single file; this file can then be invoked as a utility, and the time applies to everything in the file.

Alternatively, the following command can be used to apply time to a complex command:

```
time sh -c 'complex-command-line'
```

**RATIONALE**

When the time utility was originally proposed to be included in the ISO POSIX-2: 1993 standard, questions were raised about its suitability for inclusion on the grounds that it was not useful for conforming applications, specifically:

- The underlying CPU definitions from the System Interfaces volume of IEEE Std 1003.1-2001 are vague, so the numeric output could not be compared accurately between systems or even between invocations.
- The creation of portable benchmark programs was outside the scope this volume of IEEE Std 1003.1-2001.

However, time does fit in the scope of user portability. Human judgement can be applied to the analysis of the output, and it could be very useful in hands-on debugging of applications or in providing subjective measures of system performance. Hence it has been included in this volume of IEEE Std 1003.1-2001.

The default output format has been left unspecified because historical implementations differ greatly in their style of depicting this numeric output. The -p option was invented to provide scripts with a common means of obtaining this information.

In the KornShell, time is a shell reserved word that can be used to time an entire pipeline, rather than just a simple command. The POSIX definition has been worded to allow this implementation. Consideration was given to invalidating this approach because of the historical model from the C shell and System V shell. However, since the System V time utility historically has not produced accurate results in pipeline timing (because the constituent processes are not all owned by the same parent process, as allowed by POSIX), it did not seem worthwhile to break historical KornShell usage.

The term utility is used, rather than command, to highlight the fact that shell compound commands, pipelines, special built-ins, and so on, cannot be used directly. However, utility
includes user application programs and shell scripts, not just the standard utilities.

**FUTURE DIRECTIONS**
None.

**CHANGE HISTORY**
First released in Issue 2.

**Issue 6**
This utility is marked as part of the User Portability Utilities option.
NAME

  touch — change file access and modification times

SYNOPSIS

  touch [-acm][-r ref_file][-t time] file...

DESCRIPTION

   The touch utility shall change the modification times, access times, or both of files. The
   modification time shall be equivalent to the value of the st_mtime member of the stat structure
   for a file, as described in the System Interfaces volume of IEEE Std 1003.1-2001; the access time
   shall be equivalent to the value of st_atime.

   The time used can be specified by the -t time option-argument, the corresponding time fields of
   the file referenced by the -r ref_file option-argument, or the date_time operand, as specified in the
   following sections. If none of these are specified, touch shall use the current time (the value
   returned by the equivalent of the time() function defined in the System Interfaces volume of

   For each file operand, touch shall perform actions equivalent to the following functions defined
   in the System Interfaces volume of IEEE Std 1003.1-2001:

   1. If file does not exist, a creat() function call is made with the file operand used as the path
      argument and the value of the bitwise-inclusive OR of S_IRUSR, S_IWUSR, S_IRGRP, S_IWGRP, S_IROTH,
      and S_IWOTH used as the mode argument.

   2. The utime() function is called with the following arguments:

      a. The file operand is used as the path argument.

      b. The utimbuf structure members actime and modtime are determined as described in
         the OPTIONS section.

OPTIONS

   The touch utility shall conform to the Base Definitions volume of IEEE Std 1003.1-2001, Section

   The following options shall be supported:

   -a Change the access time of file. Do not change the modification time unless -m is also specified.

   -c Do not create a specified file if it does not exist. Do not write any diagnostic
      messages concerning this condition.

   -m Change the modification time of file. Do not change the access time unless -a is also specified.

   -r ref_file Use the corresponding time of the file named by the pathname ref_file instead of
      the current time.

   -t time Use the specified time instead of the current time. The option-argument shall be a
decimal number of the form:

   [ [CC] YY] MMDDhhmm[. SS]

   where each two digits represents the following:

   MM The month of the year [01,12],

   DD The day of the month [01,31].
touch

Utilities

35574 hh The hour of the day [00,23].
35575 mm The minute of the hour [00,59].
35576 CC The first two digits of the year (the century).
35577 YY The second two digits of the year.
35578 SS The second of the minute [00,60].

Both CC and YY shall be optional. If neither is given, the current year shall be assumed. If YY is specified, but CC is not, CC shall be derived as follows:

<table>
<thead>
<tr>
<th>If YY is:</th>
<th>CC becomes:</th>
</tr>
</thead>
<tbody>
<tr>
<td>[69,99]</td>
<td>19</td>
</tr>
<tr>
<td>[00,68]</td>
<td>20</td>
</tr>
</tbody>
</table>

Note: It is expected that in a future version of IEEE Std 1003.1-2001 the default century inferred from a 2-digit year will change. (This would apply to all commands accepting a 2-digit year as input.)

The resulting time shall be affected by the value of the TZ environment variable. If the resulting time value precedes the Epoch, touch shall exit immediately with an error status. The range of valid times past the Epoch is implementation-defined, but it shall extend to at least the time 0 hours, 0 minutes, 0 seconds, January 1, 2038, Coordinated Universal Time. Some implementations may not be able to represent dates beyond January 18, 2038, because they use signed int as a time holder.

The range for SS is [00,60] rather than [00,59] because of leap seconds. If SS is 60, and the resulting time, as affected by the TZ environment variable, does not refer to a leap second, the resulting time shall be one second after a time where SS is 59. If SS is not given a value, it is assumed to be zero.

If neither the −a nor −m options were specified, touch shall behave as if both the −a and −m options were specified.

OPERANDS

The following operands shall be supported:

file A pathname of a file whose times shall be modified.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of touch:

LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-2001, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in
arguments).

- **LC_MESSAGES**: Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

- **XSI NLS_PATH**: Determine the location of message catalogs for the processing of `LC_MESSAGES`.

- **TZ**: Determine the timezone to be used for interpreting the `time` option-argument. If `TZ` is unset or null, an unspecified default timezone shall be used.

### ASYNCHRONOUS EVENTS

- Default.

### STDOUT

- Not used.

### STDERR

- The standard error shall be used only for diagnostic messages.

### OUTPUT FILES

- None.

### EXTENDED DESCRIPTION

- None.

### EXIT STATUS

The following exit values shall be returned:

- 0  The utility executed successfully and all requested changes were made.
- >0  An error occurred.

### CONSEQUENCES OF ERRORS

- Default.

### APPLICATION USAGE

The interpretation of time is taken to be 

- **seconds since the Epoch** (see the Base Definitions volume of IEEE Std 1003.1-2001, Section 4.14, Seconds Since the Epoch). It should be noted that implementations conforming to the System Interfaces volume of IEEE Std 1003.1-2001 do not take leap seconds into account when computing seconds since the Epoch. When \( SS=60 \) is used, the resulting time always refers to 1 plus \( seconds since the Epoch \) for a time when \( SS=59 \).

Although the \(-t \) `time` option-argument specifies values in 1969, the access time and modification time fields are defined in terms of seconds since the Epoch (00:00:00 on 1 January 1970 UTC). Therefore, depending on the value of `TZ` when `touch` is run, there is never more than a few valid hours in 1969 and there need not be any valid times in 1969.

One ambiguous situation occurs if \(-t \) `time` is not specified, \(-r \) `ref_file` is not specified, and the first operand is an eight or ten-digit decimal number. A portable script can avoid this problem by using:

- `touch -- file`
- or:
  - `touch ./file`

in this case.
EXAMPLES
None.

RATIONALE

The functionality of touch is described almost entirely through references to functions in the System Interfaces volume of IEEE Std 1003.1-2001. In this way, there is no duplication of effort required for describing such side effects as the relationship of user IDs to the user database, permissions, and so on.

There are some significant differences between the touch utility in this volume of IEEE Std 1003.1-2001 and those in System V and BSD systems. They are upwards-compatible for historical applications from both implementations:

1. In System V, an ambiguity exists when a pathname that is a decimal number leads the operands; it is treated as a time value. In BSD, no time value is allowed; files may only be touched to the current time. The -t time construct solves these problems for future conforming applications (note that the -t option is not historical practice).

2. The inclusion of the century digits, CC, is also new. Note that a ten-digit time value is treated as if YY, and not CC, were specified. The caveat about the range of dates following the Epoch was included as recognition that some implementations are not able to represent dates beyond 18 January 2038 because they use signed int as a time holder.

The -r option was added because several comments requested this capability. This option was named -f in an early proposal, but was changed because the -f option is used in the BSD version of touch with a different meaning.

At least one historical implementation of touch incremented the exit code if -c was specified and the file did not exist. This volume of IEEE Std 1003.1-2001 requires exit status zero if no errors occur.

FUTURE DIRECTIONS

Applications should use the -r or -t options.

SEE ALSO
date, the System Interfaces volume of IEEE Std 1003.1-2001, creat(), time(), utime(), the Base Definitions volume of IEEE Std 1003.1-2001, <sys/stat.h>

CHANGE HISTORY

First released in Issue 2.

Issue 6

The obsolescent date_time operand is removed.

The Open Group Corrigendum U027/1 is applied. This extends the range of valid time past the Epoch to at least the time 0 hours, 0 minutes, 0 seconds, January 1, 2038, Coordinated Universal Time. This is a new requirement on POSIX implementations.

The range for seconds is changed from [00,61] to [00,60] to align with the ISO/IEC 9899: 1999 standard, and to allow for positive leap seconds.
NAME
tput — change terminal characteristics

SYNOPSIS
tput [-T type] operand...

DESCRIPTION
The tput utility shall display terminal-dependent information. The manner in which this
information is retrieved is unspecified. The information displayed shall clear the terminal screen,
initialize the user’s terminal, or reset the user’s terminal, depending on the operand given. The
exact consequences of displaying this information are unspecified.

OPTIONS
The tput utility shall conform to the Base Definitions volume of IEEE Std 1003.1-2001, Section
The following option shall be supported:

-T type Indicate the type of terminal. If this option is not supplied and the TERM variable
is unset or null, an unspecified default terminal type shall be used. The setting of
type shall take precedence over the value in TERM.

OPERANDS
The following strings shall be supported as operands by the implementation in the POSIX locale:
clear Display the clear-screen sequence.
init Display the sequence that initializes the user’s terminal in an implementation-defined manner.
reset Display the sequence that resets the user’s terminal in an implementation-defined manner.

If a terminal does not support any of the operations described by these operands, this shall not
be considered an error condition.

STDIN
Not used.

INPUT FILES
None.

ENVIRONMENT VARIABLES
The following environment variables shall affect the execution of tput:

LANG Provide a default value for the internationalization variables that are unset or null.
(See the Base Definitions volume of IEEE Std 1003.1-2001, Section 8.2,
Internationalization Variables for the precedence of internationalization variables
used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other
internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as
characters (for example, single-byte as opposed to multi-byte characters in
arguments).

LC_MESSAGES Determine the locale that should be used to affect the format and contents of
diagnostic messages written to standard error.
Determine the location of message catalogs for the processing of `LC_MESSAGES`.

Determine the terminal type. If this variable is unset or null, and if the `-T` option is not specified, an unspecified default terminal type shall be used.

**ASYNCHRONOUS EVENTS**

Default.

**STDOUT**

If standard output is a terminal device, it may be used for writing the appropriate sequence to clear the screen or reset or initialize the terminal. If standard output is not a terminal device, undefined results occur.

**STDERR**

The standard error shall be used only for diagnostic messages.

**OUTPUT FILES**

None.

**EXTENDED DESCRIPTION**

None.

**EXIT STATUS**

The following exit values shall be returned:

- `0` The requested string was written successfully.
- `1` Unspecified.
- `2` Usage error.
- `3` No information is available about the specified terminal type.
- `4` The specified operand is invalid.
- `>4` An error occurred.

**CONSEQUENCES OF ERRORS**

If one of the operands is not available for the terminal, `tput` continues processing the remaining operands.

**APPLICATION USAGE**

The difference between resetting and initializing a terminal is left unspecified, as they vary greatly based on hardware types. In general, resetting is a more severe action.

Some terminals use control characters to perform the stated functions, and on such terminals it might make sense to use `tput` to store the initialization strings in a file or environment variable for later use. However, because other terminals might rely on system calls to do this work, the standard output cannot be used in a portable manner, such as the following non-portable constructs:

```
ClearVar='tput clear'
tput reset | mailx −s "Wake Up" ddg
```

**EXAMPLES**

1. Initialize the terminal according to the type of terminal in the environmental variable `TERM`. This command can be included in a `.profile` file.

   ```
tput init
   ```

2. Reset a 450 terminal.
35780 tput -T 450 reset

35781 RATIONALE
35782 The list of operands was reduced to a minimum for the following reasons:

35783 • The only features chosen were those that were likely to be used by human users interacting
   with a terminal.

35785 • Specifying the full `terminfo` set was not considered desirable, but the standard developers did
   not want to select among operands.

35787 • This volume of IEEE Std 1003.1-2001 does not attempt to provide applications with
   sophisticated terminal handling capabilities, as that falls outside of its assigned scope and
   intersects with the responsibilities of other standards bodies.

35790 The difference between resetting and initializing a terminal is left unspecified as this varies
35791 greatly based on hardware types. In general, resetting is a more severe action.

35792 The exit status of 1 is historically reserved for finding out if a Boolean operand is not set.
35793 Although the operands were reduced to a minimum, the exit status of 1 should still be reserved
35794 for the Boolean operands, for those sites that wish to support them.

35795 FUTURE DIRECTIONS
35796 None.

35797 SEE ALSO
35798 `stty`, `tabs`

35799 CHANGE HISTORY
35800 First released in Issue 4.

35802 This utility is marked as part of the User Portability Utilities option.
NAME
tr — translate characters

SYNOPSIS
tr [-c | -C] [-s] string1 string2
tr -s [-c | -C] string1
tr -d [-c | -C] string1
tr -ds [-c | -C] string1 string2

DESCRIPTION
The tr utility shall copy the standard input to the standard output with substitution or deletion
of selected characters. The options specified and the string1 and string2 operands shall control
translations that occur while copying characters and single-character collating elements.

OPTIONS
The tr utility shall conform to the Base Definitions volume of IEEE Std 1003.1-2001, Section 12.2,
Utility Syntax Guidelines.
The following options shall be supported:
-c Complement the set of values specified by string1. See the EXTENDED
DESCRIPTION section.
-C Complement the set of characters specified by string1. See the EXTENDED
DESCRIPTION section.
-d Delete all occurrences of input characters that are specified by string1.
-s Replace instances of repeated characters with a single character, as described in the
EXTENDED DESCRIPTION section.

OPERANDS
The following operands shall be supported:
string1, string2
Translation control strings. Each string shall represent a set of characters to be
converted into an array of characters used for the translation. For a detailed
description of how the strings are interpreted, see the EXTENDED DESCRIPTION
section.

STDIN
The standard input can be any type of file.

INPUT FILES
None.

ENVIRONMENT VARIABLES
The following environment variables shall affect the execution of tr:

LANG Provide a default value for the internationalization variables that are unset or null.
(See the Base Definitions volume of IEEE Std 1003.1-2001, Section 8.2,
Internationalization Variables for the precedence of internationalization variables
used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other
internationalization variables.

LC_COLLATE
Determine the locale for the behavior of range expressions and equivalence classes.
Utilities

tr

35846 **LC_TYPE**  Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments) and the behavior of character classes.

35849 **LC_MESSAGES**  Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

35852 **NLSPATH**  Determine the location of message catalogs for the processing of **LC_MESSAGES**.

35854 **ASYNCHRONOUS EVENTS**

35855 **STDOUT**  The tr output shall be identical to the input, with the exception of the specified transformations.

35857 **STDERR**  The standard error shall be used only for diagnostic messages.

35859 **OUTPUT FILES**

35860 None.

35862 **EXTENDED DESCRIPTION**

35863 The operands `string1` and `string2` (if specified) define two arrays of characters. The constructs in the following list can be used to specify characters or single-character collating elements. If any of the constructs result in multi-character collating elements, tr shall exclude, without a diagnostic, those multi-character elements from the resulting array.

35866 **character**  Any character not described by one of the conventions below shall represent itself.

35867 **\octal**  Octal sequences can be used to represent characters with specific coded values. An octal sequence shall consist of a backslash followed by the longest sequence of one, two, or three-octal-digit characters (01234567). The sequence shall cause the value whose encoding is represented by the one, two, or three-digit octal integer to be placed into the array. If the size of a byte on the system is greater than nine bits, the valid escape sequence used to represent a byte is implementation-defined. Multi-byte characters require multiple, concatenated escape sequences of this type, including the leading ‘`\`’ for each byte.

35873 **\character**  The backslash-escape sequences in the Base Definitions volume of IEEE Std 1003.1-2001, Table 5-1, Escape Sequences and Associated Actions (‘`\b`, ‘`\f`, ‘`\n`, ‘`\r`, ‘`\t`, ‘`\v’), shall be supported. The results of using any other character, other than an octal digit, following the backslash are unspecified.

35880 **c–c**  In the POSIX locale, this construct shall represent the range of collating elements between the range endpoints (as long as neither endpoint is an octal sequence of the form `\octal`), inclusive, as defined by the collation sequence. The characters or collating elements in the range shall be placed in the array in ascending collation sequence. If the second endpoint precedes the starting endpoint in the collation sequence, it is unspecified whether the range of collating elements is empty, or this construct is treated as invalid. In locales other than the POSIX locale, this construct has unspecified behavior.

35888 If either or both of the range endpoints are octal sequences of the form `\octal`, this shall represent the range of specific coded values between the two range endpoints, inclusive.
[\texttt{class:}] Represents all characters belonging to the defined character class, as defined by the current setting of the \texttt{LC\_CTYPE} locale category. The following character class names shall be accepted when specified in \texttt{string1}:

- \texttt{alnum}
- \texttt{blank}
- \texttt{digit}
- \texttt{lower}
- \texttt{punct}
- \texttt{upper}
- \texttt{alpha}
- \texttt{cntrl}
- \texttt{graph}
- \texttt{print}
- \texttt{space}
- \texttt{xdigit}

\texttt{xsi}

In addition, character class expressions of the form [\texttt{name:}] shall be recognized in those locales where the \texttt{name} keyword has been given a \texttt{charclass} definition in the \texttt{LC\_CTYPE} category.

When both the \texttt{−d} and \texttt{−s} options are specified, any of the character class names shall be valid in \texttt{string2}. Otherwise, only character class names \texttt{lower} or \texttt{upper} are valid in \texttt{string2} and then only if the corresponding character class (\texttt{upper} and \texttt{lower}, respectively) is specified in the same relative position in \texttt{string1}. Such a specification shall be interpreted as a request for case conversion. When [\texttt{lower:}] appears in \texttt{string1} and [\texttt{upper:}] appears in \texttt{string2}, the arrays shall contain the characters from the \texttt{toupper} mapping in the \texttt{LC\_CTYPE} category of the current locale. When [\texttt{upper:}] appears in \texttt{string1} and [\texttt{lower:}] appears in \texttt{string2}, the arrays shall contain the characters from the \texttt{tolower} mapping in the \texttt{LC\_CTYPE} category of the current locale. The first character from each mapping pair shall be in the array for \texttt{string1} and the second character from each mapping pair shall be in the array for \texttt{string2} in the same relative position.

Except for case conversion, the characters specified by a character class expression shall be placed in the array in an unspecified order.

If the name specified for \texttt{class} does not define a valid character class in the current locale, the behavior is undefined.

[\texttt{equiv=}]

Represents all characters or collating elements belonging to the same equivalence class as \texttt{equiv}, as defined by the current setting of the \texttt{LC\_COLLATE} locale category. An equivalence class expression shall be allowed only in \texttt{string1}, or in \texttt{string2} when it is being used by the combined \texttt{−d} and \texttt{−s} options. The characters belonging to the equivalence class shall be placed in the array in an unspecified order.

\texttt{x^n}

Represents \texttt{n} repeated occurrences of the character \texttt{x}. Because this expression is used to map multiple characters to one, it is only valid when it occurs in \texttt{string2}. If \texttt{n} is omitted or is zero, it shall be interpreted as large enough to extend the \texttt{string2}-based sequence to the length of the \texttt{string1}-based sequence. If \texttt{n} has a leading zero, it shall be interpreted as an octal value. Otherwise, it shall be interpreted as a decimal value.

When the \texttt{−d} option is not specified:

- Each input character found in the array specified by \texttt{string1} shall be replaced by the character in the same relative position in the array specified by \texttt{string2}. When the array specified by \texttt{string2} is shorter than the one specified by \texttt{string1}, the results are unspecified.
- If the \texttt{−C} option is specified, the complements of the characters specified by \texttt{string1} (the set of all characters in the current character set, as defined by the current setting of \texttt{LC\_CTYPE}, except for those actually specified in the \texttt{string1} operand) shall be placed in the array in ascending collation sequence, as defined by the current setting of \texttt{LC\_COLLATE}.
- If the \texttt{−c} option is specified, the complement of the values specified by \texttt{string1} shall be placed in the array in ascending order by binary value.
Because the order in which characters specified by character class expressions or equivalence class expressions is undefined, such expressions should only be used if the intent is to map several characters into one. An exception is case conversion, as described previously.

When the \texttt{-d} option is specified:

\begin{itemize}
\item Input characters found in the array specified by \texttt{string1} shall be deleted.
\item When the \texttt{-C} option is specified with \texttt{-d}, all characters except those specified by \texttt{string1} shall be deleted. The contents of \texttt{string2} are ignored, unless the \texttt{-s} option is also specified.
\item When the \texttt{-c} option is specified with \texttt{-d}, all values except those specified by \texttt{string1} shall be deleted. The contents of \texttt{string2} shall be ignored, unless the \texttt{-s} option is also specified.
\item The same string cannot be used for both the \texttt{-d} and the \texttt{-s} option; when both options are specified, both \texttt{string1} (used for deletion) and \texttt{string2} (used for squeezing) shall be required.
\end{itemize}

When the \texttt{-s} option is specified, after any deletions or translations have taken place, repeated sequences of the same character shall be replaced by one occurrence of the same character, if the character is found in the array specified by the last operand. If the last operand contains a character class, such as the following example:

\begin{verbatim}
tr \texttt{-s} '[[:space:]]'
\end{verbatim}

the last operand's array shall contain all of the characters in that character class. However, in a case conversion, as described previously, such as:

\begin{verbatim}
tr \texttt{-s} '[[:upper:]]' '[[:lower:]]'
\end{verbatim}

the last operand's array shall contain only those characters defined as the second characters in each of the \texttt{toupper} or \texttt{tolower} character pairs, as appropriate.

An empty string used for \texttt{string1} or \texttt{string2} produces undefined results.

\section{EXIT STATUS}

The following exit values shall be returned:

\begin{itemize}
\item 0 All input was processed successfully.
\item \texttt{>0} An error occurred.
\end{itemize}

\section{CONSEQUENCES OF ERRORS}

Default.

\section{APPLICATION USAGE}

If necessary, \texttt{string1} and \texttt{string2} can be quoted to avoid pattern matching by the shell.

If an ordinary digit (representing itself) is to follow an octal sequence, the octal sequence must use the full three digits to avoid ambiguity.

When \texttt{string2} is shorter than \texttt{string1}, a difference results between historical System V and BSD systems. A BSD system pads \texttt{string2} with the last character found in \texttt{string2}. Thus, it is possible to do the following:

\begin{verbatim}
tr 0123456789 d
\end{verbatim}

which would translate all digits to the letter \texttt{`d'}. Since this area is specifically unspecified in this volume of IEEE Std 1003.1-2001, both the BSD and System V behaviors are allowed, but a conforming application cannot rely on the BSD behavior. It would have to code the example in the following way:

\begin{verbatim}
tr 0123456789 '[d*]'
\end{verbatim}
It should be noted that, despite similarities in appearance, the string operands used by tr are not regular expressions.

Unlike some historical implementations, this definition of the tr utility correctly processes NUL characters in its input stream. NUL characters can be stripped by using:

```
tr -d '\000'
```

**EXAMPLES**

1. The following example creates a list of all words in `file1` one per line in `file2`, where a word is taken to be a maximal string of letters.

   ```
   tr -cs "[:alpha:]" "[\n*]" <file1 >file2
   ```

2. The next example translates all lowercase characters in `file1` to uppercase and writes the results to standard output.

   ```
   tr "[:lower:]" "[:upper:]" <file1
   ```

3. This example uses an equivalence class to identify accented variants of the base character 'e' in `file1`, which are stripped of diacritical marks and written to `file2`.

   ```
   tr "[=e=]" e <file1 >file2
   ```

**RATIONALE**

In some early proposals, an explicit option --n was added to disable the historical behavior of stripping NUL characters from the input. It was considered that automatically stripping NUL characters from the input was not correct functionality. However, the removal of --n in a later proposal does not remove the requirement that tr correctly process NUL characters in its input stream. NUL characters can be stripped by using `tr -d '\000'`.

Historical implementations of tr differ widely in syntax and behavior. For example, the BSD version has not needed the bracket characters for the repetition sequence. The tr utility syntax is based more closely on the System V and XPG3 model while attempting to accommodate historical BSD implementations. In the case of the short string2 padding, the decision was to UNSPECIFY the behavior and preserve System V and XPG3 scripts, which might find difficulty with the BSD method. The assumption was made that BSD users of tr have to make accommodations to meet the syntax defined here. Since it is possible to use the repetition sequence to duplicate the desired behavior, whereas there is no simple way to achieve the System V method, this was the correct, if not desirable, approach.

The use of octal values to specify control characters, while having historical precedents, is not portable. The introduction of escape sequences for control characters should provide the necessary portability. It is recognized that this may cause some historical scripts to break.

An early proposal included support for multi-character collating elements. It was pointed out that, while tr does employ some syntactical elements from REs, the aim of tr is quite different; ranges, for example, do not have a similar meaning (“any of the chars in the range matches”, versus “translate each character in the range to the output counterpart”). As a result, the previously included support for multi-character collating elements has been removed. What remains are ranges in current collation order (to support, for example, accented characters), character classes, and equivalence classes.

In XPG3 the [class:] and [equiv] conventions are shown with double brackets, as in RE syntax. However, tr does not implement RE principles; it just borrows part of the syntax. Consequently, [class:] and [equiv] should be regarded as syntactical elements on a par with [x*n], which is not an RE bracket expression.
The standard developers will consider changes to tr that allow it to translate characters between different character encodings, or they will consider providing a new utility to accomplish this.

On historical System V systems, a range expression requires enclosing square-brackets, such as:

```bash
tr '[a-z]' '[A-Z]'```

However, BSD-based systems did not require the brackets, and this convention is used here to avoid breaking large numbers of BSD scripts:

```bash
tr a-z A-Z```

The preceding System V script will continue to work because the brackets, treated as regular characters, are translated to themselves. However, any System V script that relied on "a-z" representing the three characters 'a', '-', and 'z' have to be rewritten as "az-".

The ISO POSIX-2: 1993 standard had a -c option that behaved similarly to the -C option, but did not supply functionality equivalent to the -c option specified in IEEE Std 1003.1-2001. This meant that historical practice of being able to specify tr -d\200-\377 (which would delete all bytes with the top bit set) would have no effect because, in the C locale, bytes with the values octal 200 to octal 377 are not characters.

The earlier version also said that octal sequences referred to collating elements and could be placed adjacent to each other to specify multi-byte characters. However, it was noted that this caused ambiguities because tr would not be able to tell whether adjacent octal sequences were intending to specify multi-byte characters or multiple single byte characters. IEEE Std 1003.1-2001 specifies that octal sequences always refer to single byte binary values.

FUTURE DIRECTIONS
None.

SEE ALSO
sed

CHANGE HISTORY
First released in Issue 2.

Issue 6
The -C operand is added, and the description of the -c operand is changed to align with the IEEE P1003.2b draft standard.

The normative text is reworded to avoid use of the term “must” for application requirements.
true

NAME
true — return true value

SYNOPSIS
true

DESCRIPTION
The true utility shall return with exit code zero.

OPTIONS
None.

OPERANDS
None.

STDIN
Not used.

INPUT FILES
None.

ENVIRONMENT VARIABLES
None.

ASYNCRONOUS EVENTS
Default.

STDOUT
Not used.

STDERR
Not used.

OUTPUT FILES
None.

EXTENDED DESCRIPTION
None.

EXIT STATUS
Zero.

CONSEQUENCES OF ERRORS
None.

APPLICATION USAGE
This utility is typically used in shell scripts, as shown in the EXAMPLES section. The special built-in utility : is sometimes more efficient than true.

EXAMPLES
This command is executed forever:
while true
do
    command
done
The *true* utility has been retained in this volume of IEEE Std 1003.1-2001, even though the shell special built-in `true` provides similar functionality, because *true* is widely used in historical scripts and is less cryptic to novice script readers.

**FUTURE DIRECTIONS**

None.

**SEE ALSO**

`false`, Section 2.9 (on page 47)

**CHANGE HISTORY**

First released in Issue 2.

**Issue 6**

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/39 is applied, replacing the terms “None” and “Default” from the STDERR and EXIT STATUS sections, respectively, with terms as defined in Section 1.11 (on page 20).
NAME
tsort — topological sort

SYNOPSIS
xtsi
tsort [file]

DESCRIPTION
The tsort utility shall write to standard output a totally ordered list of items consistent with a
partial ordering of items contained in the input.

The application shall ensure that the input consists of pairs of items (non-empty strings)
separated by <blank>s. Pairs of different items indicate ordering. Pairs of identical items
indicate presence, but not ordering.

OPTIONS
None.

OPERANDS
The following operand shall be supported:

file A pathname of a text file to order. If no file operand is given, the standard input
shall be used.

STDIN
The standard input shall be a text file that is used if no file operand is given.

INPUT FILES
The input file named by the file operand is a text file.

ENVIRONMENT VARIABLES
The following environment variables shall affect the execution of tsort:

LANG Provide a default value for the internationalization variables that are unset or null.
(See the Base Definitions volume of IEEE Std 1003.1-2001, Section 8.2,
Internationalization Variables for the precedence of internationalization variables
used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other
internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as
characters (for example, single-byte as opposed to multi-byte characters in
arguments and input files).

LC_MESSAGES

LC_MESSAGES

LC_MESSAGES

Determine the locale that should be used to affect the format and contents of
diagnostic messages written to standard error.

NLS_PATH

Determine the location of message catalogs for the processing of LC_MESSAGES.

ASYNCHRONOUS EVENTS
Default.

STDOUT
The standard output shall be a text file consisting of the order list produced from the partially
ordered input.
STDERR
The standard error shall be used only for diagnostic messages.

OUTPUT FILES
None.

EXTENDED DESCRIPTION
None.

EXIT STATUS
The following exit values shall be returned:
0   Successful completion.
>0  An error occurred.

CONSEQUENCES OF ERRORS
Default.

APPLICATION USAGE
The LC_COLLATE variable need not affect the actions of tsort. The output ordering is not
lexicographic, but depends on the pairs of items given as input.

EXAMPLES
The command:
```
ts ort <<EOF
abccde
gg
fgef
hh
EOF
```
produces the output:
```
a
b
c
d
e
f
g
h
```

RATIONALE
None.

FUTURE DIRECTIONS
None.

SEE ALSO
None.

CHANGE HISTORY
First released in Issue 2.

Issue 6
The normative text is reworded to avoid use of the term “must” for application requirements.
NAME
tty — return user’s terminal name

SYNOPSIS
tty

DESCRIPTION
The tty utility shall write to the standard output the name of the terminal that is open as
standard input. The name that is used shall be equivalent to the string that would be returned by
the ttyname() function defined in the System Interfaces volume of IEEE Std 1003.1-2001.

OPTIONS
The tty utility shall conform to the Base Definitions volume of IEEE Std 1003.1-2001, Section 12.2,
Utility Syntax Guidelines.

OPERANDS
None.

STDIN
While no input is read from standard input, standard input shall be examined to determine
whether or not it is a terminal, and, if so, to determine the name of the terminal.

INPUT FILES
None.

ENVIRONMENT VARIABLES
The following environment variables shall affect the execution of tty:
LANG Provide a default value for the internationalization variables that are unset or null.
(See the Base Definitions volume of IEEE Std 1003.1-2001, Section 8.2,
Internationalization Variables for the precedence of internationalization variables
used to determine the values of locale categories.)
LC_ALL If set to a non-empty string value, override the values of all the other
internationalization variables.
LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as
characters (for example, single-byte as opposed to multi-byte characters in
arguments).
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of
diagnostic messages written to standard error and informative messages written to
standard output.
XSI

NLSPATH
Determine the location of message catalogs for the processing of LC_MESSAGES.

ASYNCHRONOUS EVENTS
Default.

STDOUT
If standard input is a terminal device, a pathname of the terminal as specified by the ttyname()
function defined in the System Interfaces volume of IEEE Std 1003.1-2001 shall be written in the
following format:
"%s
", <terminal name>
Otherwise, a message shall be written indicating that standard input is not connected to a
terminal. In the POSIX locale, the tty utility shall use the format:
"not a tty\n"

**STDERR**
The standard error shall be used only for diagnostic messages.

**OUTPUT FILES**
None.

**EXTENDED DESCRIPTION**
None.

**EXIT STATUS**
The following exit values shall be returned:

0  Standard input is a terminal.
1  Standard input is not a terminal.
>1  An error occurred.

**CONSEQUENCES OF ERRORS**
Default.

**APPLICATION USAGE**
This utility checks the status of the file open as standard input against that of an implementation-defined set of files. It is possible that no match can be found, or that the match found need not be the same file as that which was opened for standard input (although they are the same device).

**EXAMPLES**
None.

**RATIONALE**
None.

**FUTURE DIRECTIONS**
None.

**SEE ALSO**

**CHANGE HISTORY**
First released in Issue 2.

**Issue 5**
The SYNOPSIS is changed to indicate two forms of the command, with the second form marked as obsolete. This is a clarification and does not change the functionality published in previous issues.

**Issue 6**
The obsolescent −s option is removed.
NAME

    type — write a description of command type

SYNOPSIS

    type name...

DESCRIPTION

    The type utility shall indicate how each argument would be interpreted if used as a command name.

OPTIONS

    None.

OPERANDS

    The following operand shall be supported:

    name   A name to be interpreted.

STDIN

    Not used.

INPUT FILES

    None.

ENVIRONMENT VARIABLES

    The following environment variables shall affect the execution of type:

    LANG   Provide a default value for the internationalization variables that are unset or null.
            (See the Base Definitions volume of IEEE Std 1003.1-2001, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

    LC_ALL  If set to a non-empty string value, override the values of all the other internationalization variables.

    LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

    LC_MESSAGES  Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

    NLSPATH   Determine the location of message catalogs for the processing of LC_MESSAGES.

    PATH      Determine the location of name, as described in the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 8, Environment Variables.

ASYNCHRONOUS EVENTS

    Default.

STDOUT

    The standard output of type contains information about each operand in an unspecified format.
    The information provided typically identifies the operand as a shell built-in, function, alias, or keyword, and where applicable, may display the operand’s pathname.
The standard error shall be used only for diagnostic messages.

None.

None.

The following exit values shall be returned:

0   Successful completion.

>0  An error occurred.

None.

Since type must be aware of the contents of the current shell execution environment (such as the lists of commands, functions, and built-ins processed by hash), it is always provided as a shell regular built-in. If it is called in a separate utility execution environment, such as one of the following:

nohup type writer
find . −type f | xargs type

it might not produce accurate results.

None.

None.

None.

command, hash

First released in Issue 2.
NAME
ulimit — set or report file size limit

SYNOPSIS
XSI
ulimit [-f][blocks]

DESCRIPTION
The ulimit utility shall set or report the file-size writing limit imposed on files written by the
shell and its child processes (files of any size may be read). Only a process with appropriate
privileges can increase the limit.

OPTIONS
The ulimit utility shall conform to the Base Definitions volume of IEEE Std 1003.1-2001, Section

The following option shall be supported:

-f Set (or report, if no blocks operand is present), the file size limit in blocks. The -f
option shall also be the default case.

OPERANDS
The following operand shall be supported:

blocks The number of 512-byte blocks to use as the new file size limit.

STDIN
Not used.

INPUT FILES
None.

ENVIRONMENT VARIABLES
The following environment variables shall affect the execution of ulimit:

LANG Provide a default value for the internationalization variables that are unset or null.
(See the Base Definitions volume of IEEE Std 1003.1-2001, Section 8.2,
Internationalization Variables for the precedence of internationalization variables
used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other
internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as
characters (for example, single-byte as opposed to multi-byte characters in
arguments).

LC_MESSAGES Determine the locale that should be used to affect the format and contents of
diagnostic messages written to standard error.

NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

ASYNCHRONOUS EVENTS
Default.

STDOUT
The standard output shall be used when no blocks operand is present. If the current number of
blocks is limited, the number of blocks in the current limit shall be written in the following
format:
"%d
", <number of 512-byte blocks>

If there is no current limit on the number of blocks, in the POSIX locale the following format shall be used:

"unlimited\n"

STDOUT

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 A request for a higher limit was rejected or an error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Since ulimit affects the current shell execution environment, it is always provided as a shell regular built-in. If it is called in a separate utility execution environment, such as one of the following:

nohup ulimit -f 10000
env ulimit 10000

it does not affect the file size limit of the caller’s environment.

Once a limit has been decreased by a process, it cannot be increased (unless appropriate privileges are involved), even back to the original system limit.

EXAMPLES

Set the file size limit to 51 200 bytes:

ulimit -f 100

RATIONALE

None.

FUTURE DIRECTIONS

None.

The System Interfaces volume of IEEE Std 1003.1-2001, ulimit()

CHANGE HISTORY

First released in Issue 2.
NAME

umask — get or set the file mode creation mask

SYNOPSIS

umask [-S] [mask]

DESCRIPTION

The umask utility shall set the file mode creation mask of the current shell execution environment (see Section 2.12 (on page 61)) to the value specified by the mask operand. This mask shall affect the initial value of the file permission bits of subsequently created files. If umask is called in a subshell or separate utility execution environment, such as one of the following:

(umask 002)
nohup umask ...
find . -exec umask ... \;

it shall not affect the file mode creation mask of the caller's environment.

If the mask operand is not specified, the umask utility shall write to standard output the value of the invoking process' file mode creation mask.

OPTIONS

The following option shall be supported:

-S

Produce symbolic output.

The default output style is unspecified, but shall be recognized on a subsequent invocation of umask on the same system as a mask operand to restore the previous file mode creation mask.

OPERANDS

The following operand shall be supported:

mask

A string specifying the new file mode creation mask. The string is treated in the same way as the mode operand described in the EXTENDED DESCRIPTION section for chmod.

For a symbolic_mode value, the new value of the file mode creation mask shall be the logical complement of the file permission bits portion of the file mode specified by the symbolic_mode string.

In a symbolic_mode value, the permissions op characters '+' and '−' shall be interpreted relative to the current file mode creation mask; '+' shall cause the bits for the indicated permissions to be cleared in the mask; '−' shall cause the bits for the indicated permissions to be set in the mask.

The interpretation of mode values that specify file mode bits other than the file permission bits is unspecified.

In the octal integer form of mode, the specified bits are set in the file mode creation mask.

The file mode creation mask shall be set to the resulting numeric value.

The default output of a prior invocation of umask on the same system with no operand also shall be recognized as a mask operand.
Utilities

umask

36456 **STDIN**

36457 Not used.

36458 **INPUT FILES**

36459 None.

36460 **ENVIRONMENT VARIABLES**

36461 The following environment variables shall affect the execution of **umask**:

36462 **LANG** Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-2001, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

36463 **LC_ALL** If set to a non-empty string value, override the values of all the other internationalization variables.

36464 **LC_CTYPE** Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

36465 **LC_MESSAGES** Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

36466 **NLSPATH** Determine the location of message catalogs for the processing of **LC_MESSAGES**.

36467 **ASYNCHRONOUS EVENTS**

36468 Default.

36469 **STDOUT** When the **mask** operand is not specified, the **umask** utility shall write a message to standard output that can later be used as a **umask** **mask** operand.

36470 If −S is specified, the message shall be in the following format:

36471 "u=%s,g=%s,o=%s\n", <owner permissions>, <group permissions>,

36472 <other permissions>

36473 where the three values shall be combinations of letters from the set \{r, w, x\}; the presence of a letter shall indicate that the corresponding bit is clear in the file mode creation mask.

36474 If a **mask** operand is specified, there shall be no output written to standard output.

36475 **STDERR** The standard error shall be used only for diagnostic messages.

36476 **OUTPUT FILES**

36477 None.

36478 **EXTENDED DESCRIPTION**

36479 None.

36491 **EXIT STATUS**

36492 The following exit values shall be returned:

36493 0 The file mode creation mask was successfully changed, or no **mask** operand was supplied.

36494 >0 An error occurred.
CONSEQUENCES OF ERRORS
Default.

APPLICATION USAGE
Since umask affects the current shell execution environment, it is generally provided as a shell regular built-in.

In contrast to the negative permission logic provided by the file mode creation mask and the octal number form of the mask argument, the symbolic form of the mask argument specifies those permissions that are left alone.

EXAMPLES
Either of the commands:

```bash
umask a=rx,ug+w
umask 002
```

sets the mode mask so that subsequently created files have their S_IWOTH bit cleared.

After setting the mode mask with either of the above commands, the umask command can be used to write out the current value of the mode mask:

```bash
$ umask
0002
```

(The output format is unspecified, but historical implementations use the octal integer mode format.)

```bash
$ umask -S
u=rwx,g=rwx,o=rx
```

Either of these outputs can be used as the mask operand to a subsequent invocation of the umask utility.

Assuming the mode mask is set as above, the command:

```bash
umask g-w
```

sets the mode mask so that subsequently created files have their S_IWGRP and S_IWOTH bits cleared.

The command:

```bash
umask -- -w
```

sets the mode mask so that subsequently created files have all their write bits cleared. Note that mask operands --, -w, -x or anything beginning with a hyphen, must be preceded by "--" to keep it from being interpreted as an option.

RATIONALE
Since umask affects the current shell execution environment, it is generally provided as a shell regular built-in. If it is called in a subshell or separate utility execution environment, such as one of the following:

```bash
(umask 002)
nohup umask ...
find . -exec umask ... \
```

it does not affect the file mode creation mask of the environment of the caller.

The description of the historical utility was modified to allow it to use the symbolic modes of chmod. The -s option used in early proposals was changed to -S because -s could be confused
with a *symbolic_mode* form of mask referring to the S_ISUID and S_ISGID bits.

The default output style is implementation-defined to permit implementors to provide migration to the new symbolic style at the time most appropriate to their users. A `-o` flag to force octal mode output was omitted because the octal mode may not be sufficient to specify all of the information that may be present in the file mode creation mask when more secure file access permission checks are implemented.

It has been suggested that trusted systems developers might appreciate ameliorating the requirement that the mode mask “affects” the file access permissions, since it seems access control lists might replace the mode mask to some degree. The wording has been changed to say that it affects the file permission bits, and it leaves the details of the behavior of how they affect the file access permissions to the description in the System Interfaces volume of IEEE Std 1003.1-2001.

**FUTURE DIRECTIONS**

None.

Chapter 2 (on page 29), `chmod`, the System Interfaces volume of IEEE Std 1003.1-2001, `umask()`

**CHANGE HISTORY**

First released in Issue 2.

**Issue 6**

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The octal mode is supported.
NAME
unalias — remove alias definitions

SYNOPSIS
unalias alias-name...
unalias -a

DESCRIPTION
The unalias utility shall remove the definition for each alias name specified. See Section 2.3.1 (on page 32). The aliases shall be removed from the current shell execution environment; see Section 2.12 (on page 61).

OPTIONS

The following option shall be supported:
-a Remove all alias definitions from the current shell execution environment.

OPERANDS
The following operand shall be supported:
alias-name The name of an alias to be removed.

STDIN
Not used.

INPUT FILES
None.

ENVIRONMENT VARIABLES
The following environment variables shall affect the execution of unalias:

LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-2001, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

ASYNCHRONOUS EVENTS
Default.

STDOUT
Not used.
The standard error shall be used only for diagnostic messages.

None.

None.

The following exit values shall be returned:

0  Successful completion.

>0  One of the alias-name operands specified did not represent a valid alias definition, or an error occurred.

Default.

Since unalias affects the current shell execution environment, it is generally provided as a shell regular built-in.

None.

The unalias description is based on that from historical KornShell implementations. Known differences exist between that and the C shell. The KornShell version was adopted to be consistent with all the other KornShell features in this volume of IEEE Std 1003.1-2001, such as command line editing.

The –a option is the equivalent of the unalias * form of the C shell and is provided to address security concerns about unknown aliases entering the environment of a user (or application) through the allowable implementation-defined predefined alias route or as a result of an ENV file. (Although unalias could be used to simplify the “secure” shell script shown in the command rationale, it does not obviate the need to quote all command names. An initial call to unalias –a would have to be quoted in case there was an alias for unalias.)

None.

Chapter 2 (on page 29), alias

First released in Issue 4.

This utility is marked as part of the User Portability Utilities option.
NAME
uname — return system name

SYNOPSIS
uname [−snrva]

DESCRIPTION
By default, the uname utility shall write the operating system name to standard output. When options are specified, symbols representing one or more system characteristics shall be written to the standard output. The format and contents of the symbols are implementation-defined. On systems conforming to the System Interfaces volume of IEEE Std 1003.1-2001, the symbols written shall be those supported by the uname() function as defined in the System Interfaces volume of IEEE Std 1003.1-2001.

OPTIONS

The following options shall be supported:

−a Behave as though all of the options −mnrsv were specified.
−m Write the name of the hardware type on which the system is running to standard output.
−n Write the name of this node within an implementation-defined communications network.
−r Write the current release level of the operating system implementation.
−s Write the name of the implementation of the operating system.
−v Write the current version level of this release of the operating system implementation.

If no options are specified, the uname utility shall write the operating system name, as if the −s option had been specified.

OPERANDS
None.

STDIN
Not used.

INPUT FILES
None.

ENVIRONMENT VARIABLES
The following environment variables shall affect the execution of uname:

LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-2001, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

Utilities

uname

36681  **LC_MESSAGES**  
36682  Determine the locale that should be used to affect the format and contents of  
36683  diagnostic messages written to standard error.

36684  **XSI**  
36685  **NLSPATH**  Determine the location of message catalogs for the processing of **LC_MESSAGES**.

36686  **ASYNCHRONOUS EVENTS**
36687  Default.

36688  **STDOUT**
36689  By default, the output shall be a single line of the following form:
36690  
36691  
36692  If the −a option is specified, the output shall be a single line of the following form:
36693  
36694  Additional implementation-defined symbols may be written; all such symbols shall be written at  
36695  the end of the line of output before the <newline>.
36696  If options are specified to select different combinations of the symbols, only those symbols shall  
36697  be written, in the order shown above for the −a option. If a symbol is not selected for writing, its  
36698  corresponding trailing <blank>s also shall not be written.

36699  **STDERR**
36700  The standard error shall be used only for diagnostic messages.

36701  **OUTPUT FILES**
36702  None.

36703  **EXTENDED DESCRIPTION**
36704  None.

36705  **EXIT STATUS**
36706  The following exit values shall be returned:
36707  
36708  >0  An error occurred.

36709  **CONSEQUENCES OF ERRORS**
36710  Default.

36711  **APPLICATION USAGE**
36712  Note that any of the symbols could include embedded <space>s, which may affect parsing  
36713  algorithms if multiple options are selected for output.
36714  The node name is typically a name that the system uses to identify itself for inter-system  
36715  communication addressing.

36716  **EXAMPLES**
36717  The following command:
36718  
36719  uname −sr  
36720  writes the operating system name and release level, separated by one or more <blank>s.
RATIONALE

It was suggested that this utility cannot be used portably since the format of the symbols is implementation-defined. The POSIX.1 working group could not achieve consensus on defining these formats in the underlying `uname()` function, and there was no expectation that this volume of IEEE Std 1003.1-2001 would be any more successful. Some applications may still find this historical utility of value. For example, the symbols could be used for system log entries or for comparison with operator or user input.

FUTURE DIRECTIONS

None.

The System Interfaces volume of IEEE Std 1003.1-2001, `uname()`

CHANGE HISTORY

First released in Issue 2.
NAME
uncompress — expand compressed data

SYNOPSIS
uncompress [-cfv][file...]

DESCRIPTION
The uncompress utility shall restore files to their original state after they have been compressed
using the compress utility. If no files are specified, the standard input shall be uncompressed to
the standard output. If the invoking process has appropriate privileges, the ownership, modes,
access time, and modification time of the original file shall be preserved.

This utility shall support the uncompressing of any files produced by the compress utility on the
same implementation. For files produced by compress on other systems, uncompress supports 9 to
14-bit compression (see compress, −b); it is implementation-defined whether values of −b greater
than 14 are supported.

OPTIONS
The uncompress utility shall conform to the Base Definitions volume of IEEE Std 1003.1-2001,
Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:
−c Write to standard output; no files are changed.
−f Do not prompt for overwriting files. Except when run in the background, if −f is
not given the user shall be prompted as to whether an existing file should be
overwritten. If the standard input is not a terminal and −f is not given, uncompress
shall write a diagnostic message to standard error and exit with a status greater
than zero.
−v Write messages to standard error concerning the expansion of each file.

OPERANDS
The following operand shall be supported:
file A pathname of a file. If file already has the .Z suffix specified, it shall be used as the
input file and the output file shall be named file with the .Z suffix removed.
Otherwise, file shall be used as the name of the output file and file with the .Z
suffix appended shall be used as the input file.

STDIN
The standard input shall be used only if no file operands are specified, or if a file operand is ‘−’.

INPUT FILES
Input files shall be in the format produced by the compress utility.

ENVIRONMENT VARIABLES
The following environment variables shall affect the execution of uncompress:
LANG Provide a default value for the internationalization variables that are unset or null.
(See the Base Definitions volume of IEEE Std 1003.1-2001, Section 8.2,
Internationalization Variables for the precedence of internationalization variables
used to determine the values of locale categories.)
LC_ALL If set to a non-empty string value, override the values of all the other
internationalization variables.
uncompress

**LC_TYPE**  Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

**LC_MESSAGES**  Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

**NLSPATH**  Determine the location of message catalogs for the processing of **LC_MESSAGES**.

**ASYNCHRONOUS EVENTS**

**STDOUT**  When there are no file operands or the −c option is specified, the uncompressed output is written to standard output.

**STDERR**  Prompts shall be written to the standard error output under the conditions specified in the DESCRIPTION and OPTIONS sections. The prompts shall contain the file pathname, but their format is otherwise unspecified. Otherwise, the standard error output shall be used only for diagnostic messages.

**OUTPUT FILES**  Output files are the same as the respective input files to compress.

**EXTENDED DESCRIPTION**

**EXIT STATUS**  The following exit values shall be returned:

- **0**  Successful completion.
- **>0**  An error occurred.

**CONSEQUENCES OF ERRORS**  The input file remains unmodified.

**APPLICATION USAGE**  The limit of 14 on the compress −b bits argument is to achieve portability to all systems (within the restrictions imposed by the lack of an explicit published file format). Some implementations based on 16-bit architectures cannot support 15 or 16-bit uncompression.

**EXAMPLES**  None.

**RATIONALE**  None.

**FUTURE DIRECTIONS**  None.

**SEE ALSO**  compress, zcat

**CHANGE HISTORY**  First released in Issue 4.
The normative text is reworded to avoid use of the term “must” for application requirements.
NAME
unexpand — convert spaces to tabs

SYNOPSIS
unexpand [ −a| −t tablist][file...]  

DESCRIPTION
The unexpand utility shall copy files or standard input to standard output, converting <blank>s at the beginning of each line into the maximum number of <tab>s followed by the minimum number of <space>s needed to fill the same column positions originally filled by the translated <blank>s. By default, tabstops shall be set at every eighth column position. Each <backspace> shall be copied to the output, and shall cause the column position count for tab calculations to be decremented; the count shall never be decremented to a value less than one.

OPTIONS

The following options shall be supported:

−a In addition to translating <blank>s at the beginning of each line, translate all sequences of two or more <blank>s immediately preceding a tab stop to the maximum number of <tab>s followed by the minimum number of <space>s needed to fill the same column positions originally filled by the translated <blank>s.

−t tablist Specify the tab stops. The application shall ensure that the tablist option-argument is a single argument consisting of a single positive decimal integer or multiple positive decimal integers, separated by <blank>s or commas, in ascending order. If a single number is given, tabs shall be set tablist column positions apart instead of the default 8. If multiple numbers are given, the tabs shall be set at those specific column positions.

The application shall ensure that each tab-stop position N is an integer value greater than zero, and the list shall be in strictly ascending order. This is taken to mean that, from the start of a line of output, tabbing to position N shall cause the next character output to be in the (N+1)th column position on that line. When the −t option is not specified, the default shall be the equivalent of specifying −t 8 (except for the interaction with −a, described below).

No <space>-to-<tab> conversions shall occur for characters at positions beyond the last of those specified in a multiple tab-stop list.

When −t is specified, the presence or absence of the −a option shall be ignored; conversion shall not be limited to the processing of leading <blank>s.

OPERANDS
The following operand shall be supported:

file A pathname of a text file to be used as input.

STDIN
See the INPUT FILES section.
The input files shall be text files.

The following environment variables shall affect the execution of `unexpand`:

- **LANG**: Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-2001, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

- **LC_ALL**: If set to a non-empty string value, override the values of all the other internationalization variables.

- **LC_CTYPE**: Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files), the processing of `<tab>`s and `<space>`s, and for the determination of the width in column positions each character would occupy on an output device.

- **LC_MESSAGES**: Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

- **XSI NLSPATH**: Determine the location of message catalogs for the processing of `LC_MESSAGES`.

The standard output shall be equivalent to the input files with the specified `<space>`-to-`<tab>` conversions.

The standard error shall be used only for diagnostic messages.

None.

None.

The following exit values shall be returned:

- **0**: Successful completion.
- **>0**: An error occurred.

Default.
APPLICATION USAGE

One non-intuitive aspect of unexpand is its restriction to leading spaces when neither –a nor –t is specified. Users who always want to convert all spaces in a file can easily alias unexpand to use the –a or –t 8 option.

EXAMPLES
None.

RATIONALE

On several occasions, consideration was given to adding a –t option to the unexpand utility to complement the –t in expand (see expand). The historical intent of unexpand was to translate multiple <blank>s into tab stops, where tab stops were a multiple of eight column positions on most UNIX systems. An early proposal omitted –t because it seemed outside the scope of the User Portability Utilities option; it was not described in any of the base documents. However, hard-coding tab stops every eight columns was not suitable for the international community and broke historical precedents for some vendors in the FORTRAN community, so –t was restored in conjunction with the list of valid extension categories considered by the standard developers. Thus, unexpand is now the logical converse of expand.

FUTURE DIRECTIONS
None.

SEE ALSO
expand, tabs

CHANGE HISTORY
First released in Issue 4.

Issue 6
This utility is marked as part of the User Portability Utilities option.

The definition of the LC_CTYPE environment variable is changed to align with the IEEE P1003.2b draft standard.

The normative text is reworded to avoid use of the term “must” for application requirements.
NAME
unget — undo a previous get of an SCCS file (DEVELOPMENT)

SYNOPSIS
xsi unget [-ns][-r SID] file...

DESCRIPTION
The unget utility shall reverse the effect of a get -e done prior to creating the intended new delta.

OPTIONS

The following options shall be supported:

- r SID Uniquely identify which delta is no longer intended. (This would have been specified by get as the new delta.) The use of this option is necessary only if two or more outstanding get commands for editing on the same SCCS file were done by the same person (login name).

- s Suppress the writing to standard output of the intended delta’s SID.

- n Retain the file that was obtained by get, which would normally be removed from the current directory.

OPERANDS
The following operands shall be supported:

file A pathname of an existing SCCS file or a directory. If file is a directory, the unget utility shall behave as though each file in the directory were specified as a named file, except that non-SCCS files (last component of the pathname does not begin with s.) and unreadable files shall be silently ignored.

If exactly one file operand appears, and it is ‘-’, the standard input shall be read; each line of the standard input shall be taken to be the name of an SCCS file to be processed. Non-SCCS files and unreadable files shall be silently ignored.

STDIN
The standard input shall be a text file used only when the file operand is specified as ‘-’. Each line of the text file shall be interpreted as an SCCS pathname.

INPUT FILES
Any SCCS files processed shall be files of an unspecified format.

ENVIRONMENT VARIABLES
The following environment variables shall affect the execution of unget:

LANG Provide a default value for the internationalization variables that are unset or null.
(See the Base Definitions volume of IEEE Std 1003.1-2001, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

Determine the location of message catalogs for the processing of LC_MESSAGES.

Default.

The standard output shall consist of a line for each file, in the following format:

"%s\n", <SID removed from file>

If there is more than one named file or if a directory or standard input is named, each pathname shall be written before each of the preceding lines:

"\n%s:\n", <pathname>

The standard error shall be used only for diagnostic messages.

Any SCCS files updated shall be files of an unspecified format. During processing of a file, a locking z-file, as described in get, and a q-file (a working copy of the p-file), may be created and deleted. The p-file and g-file, as described in get, shall be deleted.

None.

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

Default.

None.

None.

None.

None.

None.

First released in Issue 2.

The normative text is reworded to avoid use of the term "must" for application requirements.
NAME
uniq — report or filter out repeated lines in a file

SYNOPSIS
uniq [-c|-d|-u] [-f fields] [-s char] [input_file [output_file]]

DESCRIPTION
The uniq utility shall read an input file comparing adjacent lines, and write one copy of each
input line on the output. The second and succeeding copies of repeated adjacent input lines shall
not be written.
Repeated lines in the input shall not be detected if they are not adjacent.

OPTIONS
The uniq utility shall conform to the Base Definitions volume of IEEE Std 1003.1-2001, Section
The following options shall be supported:

-c Precede each output line with a count of the number of times the line occurred in
the input.

-d Suppress the writing of lines that are not repeated in the input.

-f fields Ignore the first fields fields on each input line when doing comparisons, where
fields is a positive decimal integer. A field is the maximal string matched by the
basic regular expression:

[[[:blank:]]*[^[:blank:]]]*

If the fields option-argument specifies more fields than appear on an input line, a
null string shall be used for comparison.

-s chars Ignore the first chars characters when doing comparisons, where chars shall be a
positive decimal integer. If specified in conjunction with the -f option, the first
chars characters after the first fields fields shall be ignored. If the chars option-
argument specifies more characters than remain on an input line, a null string shall
be used for comparison.

-u Suppress the writing of lines that are repeated in the input.

OPERANDS
The following operands shall be supported:

input_file A pathname of the input file. If the input_file operand is not specified, or if the
input_file is ‘-‘, the standard input shall be used.

output_file A pathname of the output file. If the output_file operand is not specified, the
standard output shall be used. The results are unspecified if the file named by
output_file is the file named by input_file.

STDIN
The standard input shall be used only if no input_file operand is specified or if input_file is ‘-‘.
See the INPUT FILES section.

INPUT FILES
The input file shall be a text file.
ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of `uniq`:

**LANG**  
Provide a default value for the internationalization variables that are unset or null.  
(See the Base Definitions volume of IEEE Std 1003.1-2001, Section 8.2,  
Internationalization Variables for the precedence of internationalization variables  
used to determine the values of locale categories.)

**LC_ALL**  
If set to a non-empty string value, override the values of all the other  
internationalization variables.

**LC_COLLATE**  
Determine the locale for ordering rules.

**LC_CTYPE**  
Determine the locale for the interpretation of sequences of bytes of text data as  
characters (for example, single-byte as opposed to multi-byte characters in  
arguments and input files) and which characters constitute a <blank> in the  
current locale.

**LC_MESSAGES**  
Determine the locale that should be used to affect the format and contents of  
diagnostic messages written to standard error.

**NLSPATH**  
Determine the location of message catalogs for the processing of `LC_MESSAGES`.

ASYNCHRONOUS EVENTS

Default.

**STDOUT**  
The standard output shall be used only if no `output_file` operand is specified. See the OUTPUT  
FILES section.

**STDERR**  
The standard error shall be used only for diagnostic messages.

**OUTPUT FILES**

If the `−c` option is specified, the output file shall be empty or each line shall be of the form:  
"%d %s", <number of duplicates>, <line>  
otherwise, the output file shall be empty or each line shall be of the form:  
"%s", <line>

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0  The utility executed successfully.

>0  An error occurred.

CONSEQUENCES OF ERRORS

Default.
APPLICATION USAGE

The sort utility can be used to cause repeated lines to be adjacent in the input file.

EXAMPLES

The following input file data (but flushed left) was used for a test series on uniq:

```
#01 foo0 bar0 foo1 bar1
#02 bar0 foo1 bar1 foo0
#03 foo0 bar0 foo1 bar1
#04
#05 foo0 bar0 foo1 bar1
#06 foo0 bar0 foo1 bar1
#07 bar0 foo1 bar1 foo0
```

What follows is a series of test invocations of the uniq utility that use a mixture of uniq options against the input file data. These tests verify the meaning of adjacent. The uniq utility views the input data as a sequence of strings delimited by '\n'. Accordingly, for the fields th member of the sequence, uniq interprets unique or repeated adjacent lines strictly relative to the fields +1 th member.

1. This first example tests the line counting option, comparing each line of the input file data starting from the second field:
   ```
   uniq -c -f 1 uniq_0I.t
   1 #01 foo0 bar0 foo1 bar1
   1 #02 bar0 foo1 bar1 foo0
   1 #03 foo0 bar0 foo1 bar1
   1 #04
   2 #05 foo0 bar0 foo1 bar1
   1 #07 bar0 foo1 bar1 foo0
   ```
   The number ‘2’, prefixing the fifth line of output, signifies that the uniq utility detected a pair of repeated lines. Given the input data, this can only be true when uniq is run using the –f 1 option (which shall cause uniq to ignore the first field on each input line).

2. The second example tests the option to suppress unique lines, comparing each line of the input file data starting from the second field:
   ```
   uniq -d -f 1 uniq_0I.t
   #05 foo0 bar0 foo1 bar1
   ```

3. This test suppresses repeated lines, comparing each line of the input file data starting from the second field:
   ```
   uniq -u -f 1 uniq_0I.t
   #01 foo0 bar0 foo1 bar1
   #02 bar0 foo1 bar1 foo0
   #03 foo0 bar0 foo1 bar1
   #04
   #07 bar0 foo1 bar1 foo0
   ```

4. This suppresses unique lines, comparing each line of the input file data starting from the third character:
   ```
   uniq -d -s 2 uniq_0I.t
   ```
   In the last example, the uniq utility found no input matching the above criteria.
RATIONALE
Some historical implementations have limited lines to be 1 080 bytes in length, which does not meet the implied [LINE_MAX] limit.

FUTURE DIRECTIONS
None.

uucp — system-to-system copy

SYNOPSIS
XSI
uucp [-cCdfjmr] [−n user] source-file... destination-file

DESCRIPTION
The uucp utility shall copy files named by the source-file argument to the destination-file argument. The files named can be on local or remote systems.

The uucp utility cannot guarantee support for all character encodings in all circumstances. For example, transmission data may be restricted to 7 bits by the underlying network, 8-bit data and filenames need not be portable to non-internationalized systems, and so on. Under these circumstances, it is recommended that only characters defined in the ISO/IEC 646: 1991 standard International Reference Version (equivalent to ASCII) 7-bit range of characters be used, and that only characters defined in the portable filename character set be used for naming files. The protocol for transfer of files is unspecified by IEEE Std 1003.1-2001.

Typical implementations of this utility require a communications line configured to use the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 11, General Terminal Interface, but other communications means may be used. On systems where there are no available communications means (either temporarily or permanently), this utility shall write an error message describing the problem and exit with a non-zero exit status.

OPTIONS

The following options shall be supported:

-c Do not copy local file to the spool directory for transfer to the remote machine (default).
- C Force the copy of local files to the spool directory for transfer.
- d Make all necessary directories for the file copy (default).
- f Do not make intermediate directories for the file copy.
- j Write the job identification string to standard output. This job identification can be used by uustat to obtain the status or terminate a job.
- m Send mail to the requester when the copy is completed.
- n user Notify user on the remote system that a file was sent.
- r Do not start the file transfer; just queue the job.

OPERANDS
The following operands shall be supported:

destination-file, source-file
A pathname of a file to be copied to, or from, respectively. Either name can be a pathname on the local machine, or can have the form:

system-name!pathname

where system-name is taken from a list of system names that uucp knows about.
The destination system-name can also be a list of names such as:
system-name!system-name!...!system-name!pathname

in which case, an attempt is made to send the file via the specified route to the destination. Care should be taken to ensure that intermediate nodes in the route are willing to forward information.

The shell pattern matching notation characters ‘?’,’*’, and "[...]" appearing in pathname shall be expanded on the appropriate system.

Pathnames can be one of:

1. An absolute pathname.
2. A pathname preceded by ‘~user’ where user is a login name on the specified system and is replaced by that user’s login directory. Note that if an invalid login is specified, the default is to the public directory (called PUBDIR; the actual location of PUBDIR is implementation-defined).
3. A pathname preceded by ‘~/destination’ where destination is appended to PUBDIR.  
   Note: This destination is treated as a filename unless more than one file is being transferred by this request or the destination is already a directory. To ensure that it is a directory, follow the destination with a ‘/’. For example, ‘~dan’ as the destination makes the directory PUBDIR/dan if it does not exist and puts the requested files in that directory.
4. Anything else shall be prefixed by the current directory.

If the result is an erroneous pathname for the remote system, the copy shall fail. If the destination-file is a directory, the last part of the source-file name shall be used.

The read, write, and execute permissions given by uucp are implementation-defined.

STDIN
Not used.

INPUT FILES
The files to be copied are regular files.

ENVIRONMENT VARIABLES
The following environment variables shall affect the execution of uucp:

LANG  Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-2001, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL  If set to a non-empty string value, override the values of all the other internationalization variables.

LC_COLLATE  Determine the locale for the behavior of ranges, equivalence classes, and multi-character collating elements within bracketed filename patterns.

LC_CTYPE  Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files) and the behavior of character classes within bracketed filename patterns (for example, "[[:lower:]]*").
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error, and informative messages written to standard output.

Determine the location of message catalogs for the processing of \texttt{LC\_MESSAGES}.

\texttt{NLSPATH}

Determine the location of message catalogs for the processing of \texttt{LC\_MESSAGES}.

\texttt{ASYNCHRONOUS EVENTS}

Default.

\texttt{STDOUT}

Not used.

\texttt{STDERR}

The standard error shall be used only for diagnostic messages.

\texttt{OUTPUT FILES}

The output files (which may be on other systems) are copies of the input files.

If \texttt{-m} is used, mail files are modified.

\texttt{EXTENDED DESCRIPTION}

None.

\texttt{EXIT STATUS}

The following exit values shall be returned:

0  Successful completion.

>0  An error occurred.

\texttt{CONSEQUENCES OF ERRORS}

Default.

\texttt{APPLICATION USAGE}

The domain of remotely accessible files can (and for obvious security reasons usually should) be severely restricted.

Note that the ‘!‘ character in addresses has to be escaped when using \texttt{csh} as a command interpreter because of its history substitution syntax. For \texttt{ksh} and \texttt{sh} the escape is not necessary, but may be used.

As noted above, shell metacharacters appearing in pathnames are expanded on the appropriate system. On an internationalized system, this is done under the control of local settings of \texttt{LC\_COLLATE} and \texttt{LC\_CTYPE}. Thus, care should be taken when using bracketed filename patterns, as collation and typing rules may vary from one system to another. Also be aware that certain types of expression (that is, equivalence classes, character classes, and collating symbols) need not be supported on non-internationalized systems.

\texttt{EXAMPLES}

None.

\texttt{RATIONALE}

None.

\texttt{FUTURE DIRECTIONS}

None.

CHANGE HISTORY

First released in Issue 2.

Issue 6

The LC_TIME and TZ entries are removed from the ENVIRONMENT VARIABLES section.

The UN margin codes and associated shading are removed from the -C, -f, -j, -n, and -r options in response to The Open Group Base Resolution bwg2001-003.
NAME
uudecode — decode a binary file

SYNOPSIS
uudecode [-o outfile] [file]

DESCRIPTION
The uudecode utility shall read a file, or standard input if no file is specified, that includes data
created by the uuencode utility. The uudecode utility shall scan the input file, searching for data
compatible with one of the formats specified in uuencode, and attempt to create or overwrite the
file described by the data (or overridden by the -o option). The pathname shall be contained in
the data or specified by the -o option. The file access permission bits and contents for the file to
be produced shall be contained in that data. The mode bits of the created file (other than
standard output) shall be set from the file access permission bits contained in the data; that is,
other attributes of the mode, including the file mode creation mask (see umask), shall not affect
the file being produced.

If the pathname of the file to be produced exists, and the user does not have write permission on
that file, uudecode shall terminate with an error. If the pathname of the file to be produced exists,
and the user has write permission on that file, the existing file shall be overwritten.

If the input data was produced by uuencode on a system with a different number of bits per byte
than on the target system, the results of uudecode are unspecified.

OPTIONS
The uudecode utility shall conform to the Base Definitions volume of IEEE Std 1003.1-2001,
Section 12.2, Utility Syntax Guidelines.

The following option shall be supported by the implementation:

-o outfile A pathname of a file that shall be used instead of any pathname contained in the
input data. Specifying an outfile option-argument of /dev/stdout shall indicate
standard output.

OPERANDS
The following operand shall be supported:

file The pathname of a file containing the output of uuencode.

STDOUT
See the INPUT FILES section.

INPUT FILES
The input files shall be files containing the output of uuencode.

ENVIRONMENT VARIABLES
The following environment variables shall affect the execution of uudecode:

LANG Provide a default value for the internationalization variables that are unset or null.
(See the Base Definitions volume of IEEE Std 1003.1-2001, Section 8.2,
Internationalization Variables for the precedence of internationalization variables
used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other
internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as
characters (for example, single-byte as opposed to multi-byte characters in
arguments and input files).
Determine the locale that should be used to affect the format and contents of
diagnostic messages written to standard error.

Determine the location of message catalogs for the processing of LC_MESSAGES.

Default.

If the file data header encoded by uuencode is – or /dev/stdout, or the –o /dev/stdout option
overrides the file data, the standard output shall be in the same format as the file originally
encoded by uuencode. Otherwise, the standard output shall not be used.

The standard error shall be used only for diagnostic messages.

The output file shall be in the same format as the file originally encoded by uuencode.

None.

The following exit values shall be returned:

Successful completion.

An error occurred.

The user who is invoking uudecode must have write permission on any file being created.

The output of uuencode is essentially an encoded bit stream that is not cognizant of byte
boundaries. It is possible that a 9-bit byte target machine can process input from an 8-bit source,
if it is aware of the requirement, but the reverse is unlikely to be satisfying. Of course, the only
data that is meaningful for such a transfer between architectures is generally character data.

Input files are not necessarily text files, as stated by an early proposal. Although the uuencode
output is a text file, that output could have been wrapped within another file or mail message
that is not a text file.

The –o option is not historical practice, but was added at the request of WG15 so that the user
could override the target pathname without having to edit the input data itself.

In early drafts, the [–o outfile] option-argument allowed the use of – to mean standard output.
The symbol – has only been used previously in IEEE Std 1003.1-2001 as a standard input
indicator. The developers of the standard did not wish to overload the meaning of – in this
manner. The /dev/stdout concept exists on most modern systems. The /dev/stdout syntax does
not refer to a new special file. It is just a magic cookie to specify standard output.
FUTURE DIRECTIONS
None.

umask, uuencode

CHANGE HISTORY
First released in Issue 4.

Issue 6
This utility is marked as part of the User Portability Utilities option.
The –o outfile option is added, as specified in the IEEE P1003.2b draft standard.
The normative text is reworded to avoid use of the term “must” for application requirements.
NAME
uuencode — encode a binary file

SYNOPSIS
uuencode [-m] [file] decode_pathname

DESCRIPTION
The uuencode utility shall write an encoded version of the named input file, or standard input if no file is specified, to standard output. The output shall be encoded using one of the algorithms described in the STDOUT section and shall include the file access permission bits (in chmod octal or symbolic notation) of the input file and the decode_pathname, for re-creation of the file on another system that conforms to this volume of IEEE Std 1003.1-2001.

OPTIONS

The following option shall be supported by the implementation:

-m Encode the output using the MIME Base64 algorithm described in STDOUT. If -m is not specified, the historical algorithm described in STDOUT shall be used.

OPERANDS
The following operands shall be supported:

decode_pathname
The pathname of the file into which the uudecode utility shall place the decoded file. Specifying a decode_pathname operand of /dev/stdout shall indicate that uuencode is to use standard output. If there are characters in decode_pathname that are not in the portable filename character set the results are unspecified.

file A pathname of the file to be encoded.

STDIN
See the INPUT FILES section.

INPUT FILES
Input files can be files of any type.

ENVIRONMENT VARIABLES
The following environment variables shall affect the execution of uuencode:

LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-2001, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
uuencode Base64 Algorithm

The standard output shall be a text file (encoded in the character set of the current locale) that begins with the line:

"BEGIN-BASE64\%s\%s\n", <mode>, <decode_pathname>

and ends with the line:

"====\n"

In both cases, the lines shall have no preceding or trailing <blank>s.

The encoding process represents 24-bit groups of input bits as output strings of four encoded characters. Proceeding from left to right, a 24-bit input group shall be formed by concatenating three 8-bit input groups. Each 24-bit input group then shall be treated as four concatenated 6-bit groups, each of which shall be translated into a single digit in the Base64 alphabet. When encoding a bit stream via the Base64 encoding, the bit stream shall be presumed to be ordered with the most-significant bit first. That is, the first bit in the stream shall be the high-order bit in the first byte, and the eighth bit shall be the low-order bit in the first byte, and so on. Each 6-bit group is used as an index into an array of 64 printable characters, as shown in Table 4-21.

<tr>
<td>49</td>
<td>x</td>
</tr>
<tr>
<td>50</td>
<td>y</td>
</tr>
</tbody>
</table>

The character referenced by the index shall be placed in the output string.

The output stream (encoded bytes) shall be represented in lines of no more than 76 characters each. All line breaks or other characters not found in the table shall be ignored by decoding software (see uudecode).

Special processing shall be performed if fewer than 24 bits are available at the end of a message or encapsulated part of a message. A full encoding quantum shall always be completed at the
end of a message. When fewer than 24 input bits are available in an input group, zero bits shall
be added (on the right) to form an integral number of 6-bit groups. Output character positions
that are not required to represent actual input data shall be set to the character '='. Since all
Base64 input is an integral number of octets, only the following cases can arise:

1. The final quantum of encoding input is an integral multiple of 24 bits; here, the final unit of
   encoded output shall be an integral multiple of 4 characters with no '=' padding.
2. The final quantum of encoding input is exactly 16 bits; here, the final unit of encoded
   output shall be three characters followed by one '=' padding character.
3. The final quantum of encoding input is exactly 8 bits; here, the final unit of encoded output
   shall be two characters followed by two '=' padding characters.

A terminating "====" evaluates to nothing and denotes the end of the encoded data.

uuencode Historical Algorithm
The standard output shall be a text file (encoded in the character set of the current locale) that
begins with the line:
"begin\%s\%s\n" <mode>, <decode_pathname>
and ends with the line:
"end\n"
In both cases, the lines shall have no preceding or trailing blank>s.

The algorithm that shall be used for lines in between begin and end takes three octets as input
and writes four characters of output by splitting the input at six-bit intervals into four octets,
containing data in the lower six bits only. These octets shall be converted to characters by adding
a value of 0x20 to each octet, so that each octet is in the range [0x20,0x5f], and then it shall be
assumed to represent a printable character in the ISO/IEC 646:1991 standard encoded character
set. It then shall be translated into the corresponding character codes for the codeset in use in the
current locale. (For example, the octet 0x41, representing 'A', would be translated to 'A' in the
current codeset, such as 0xc1 if it were EBCDIC.)

Where the bits of two octets are combined, the least significant bits of the first octet shall be
shifted left and combined with the most significant bits of the second octet shifted right. Thus
the three octets A, B, C shall be converted into the four octets:

0x20 + (( A >> 2 ) & 0x3F)
0x20 + (((A << 4) | ((B >> 4) & 0xF)) & 0x3F)
0x20 + (((B << 2) | ((C >> 6) & 0x3)) & 0x3F)
0x20 + ( ( C ) & 0x3F)

These octets then shall be translated into the local character set.

Each encoded line contains a length character, equal to the number of characters to be decoded
plus 0x20 translated to the local character set as described above, followed by the encoded
characters. The maximum number of octets to be encoded on each line shall be 45.

STDERR
The standard error shall be used only for diagnostic messages.

OUTPUT FILES
None.
EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

The file is expanded by 35 percent (each three octets become four, plus control information) causing it to take longer to transmit.

Since this utility is intended to create files to be used for data interchange between systems with possibly different codesets, and to represent binary data as a text file, the ISO/IEC 646:1991 standard was chosen for a midpoint in the algorithm as a known reference point. The output from uuencode is a text file on the local system. If the output were in the ISO/IEC 646:1991 standard codeset, it might not be a text file (at least because the <newline>s might not match), and the goal of creating a text file would be defeated. If this text file was then carried to another machine with the same codeset, it would be perfectly compatible with that system's uudecode. If it was transmitted over a mail system or sent to a machine with a different codeset, it is assumed that, as for every other text file, some translation mechanism would convert it (by the time it reached a user on the other system) into an appropriate codeset. This translation only makes sense from the local codeset, not if the file has been put into a ISO/IEC 646:1991 standard representation first. Similarly, files processed by uuencode can be placed in pax archives, intermixed with other text files in the same codeset.

EXAMPLES

None.

RATIONALE

A new algorithm was added at the request of the international community to parallel work in RFC 2045 (MIME). As with the historical uuencode format, the Base64 Content-Transfer-Encoding is designed to represent arbitrary sequences of octets in a form that is not humanly readable. A 65-character subset of the ISO/IEC 646:1991 standard is used, enabling 6 bits to be represented per printable character. (The extra 65th character, '=' , is used to signify a special processing function.)

This subset has the important property that it is represented identically in all versions of the ISO/IEC 646:1991 standard, including US ASCII, and all characters in the subset are also represented identically in all versions of EBCDIC. The historical uuencode algorithm does not share this property, which is the reason that a second algorithm was added to the ISO POSIX-2 standard.

The string "====" was used for the termination instead of the end used in the original format because the latter is a string that could be valid encoded input.

In an early draft, the −m option was named −b (for Base64), but it was renamed to reflect its relationship to the RFC 2045. A −u was also present to invoke the default algorithm, but since this was not historical practice, it was omitted as being unnecessary.

See the RATIONALE section in uudecode for the derivation of the /dev/stdout symbol.
FUTURE DIRECTIONS
None.

SEE ALSO
chmod, mailx, uudecode

CHANGE HISTORY
First released in Issue 4.

Issue 6
This utility is marked as part of the User Portability Utilities option.
The Base64 algorithm and the ability to output to /dev/stdout are added as specified in the
IEEE P1003.2b draft standard.
NAME
uustat — uucp status inquiry and job control

SYNOPSIS
XSI
uustat [ −q | −k jobid | −r jobid ]
uustat [ −s system ] [ −u user ]

DESCRIPTION
The uustat utility shall display the status of, or cancel, previously specified uucp requests, or provide general status on uucp connections to other systems.

When no options are given, uustat shall write to standard output the status of all uucp requests issued by the current user.

Typical implementations of this utility require a communications line configured to use the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 11, General Terminal Interface, but other communications means may be used. On systems where there are no available communications means (either temporarily or permanently), this utility shall write an error message describing the problem and exit with a non-zero exit status.

OPTIONS

The following options shall be supported:

−q Write the jobs queued for each machine.

−k jobid Kill the uucp request whose job identification is jobid. The application shall ensure that the killed uucp request belongs to the person invoking uustat unless that user has appropriate privileges.

−r jobid Rejuvenate jobid. The files associated with jobid are touched so that their modification time is set to the current time. This prevents the cleanup program from deleting the job until the jobs modification time reaches the limit imposed by the program.

−s system Write the status of all uucp requests for remote system system.

−u user Write the status of all uucp requests issued by user.

OPERANDS
None.

STDIN
Not used.

INPUT FILES
None.

ENVIRONMENT VARIABLES
The following environment variables shall affect the execution of uustat:

LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-2001, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
If set to a non-empty string value, override the values of all the other
internationalization variables.

Determine the locale for the interpretation of sequences of bytes of text data as
caracters (for example, single-byte as opposed to multi-byte characters in
arguments).

Determine the locale that should be used to affect the format and contents of
diagnostic messages written to standard error, and informative messages written
to standard output.

Determine the location of message catalogs for the processing of \textit{LC\_MESSAGES}.

\textbf{ASYNCHRONOUS EVENTS}

Default.

The standard output shall consist of information about each job selected, in an unspecified
format. The information shall include at least the job ID, the user ID or name, and the remote
system name.

The standard error shall be used only for diagnostic messages.

None.

None.

The following exit values shall be returned:

\begin{itemize}
  \item[0] Successful completion.
  \item[>0] An error occurred.
\end{itemize}

Default.

None.

None.

None.

None.

First released in Issue 2.
The normative text is reworded to avoid use of the term “must” for application requirements.

The \texttt{LC\_TIME} and \texttt{TZ} entries are removed from the \texttt{ENVIRONMENT VARIABLES} section.

The UN margin code and associated shading are removed from the \texttt{−q} option in response to The Open Group Base Resolution bwg2001-003.
NAME
uux — remote command execution

SYNOPSIS

XSI
uux [-np] command-string

uux [-jnp] command-string

DESCRIPTION

The uux utility shall gather zero or more files from various systems, execute a shell pipeline (see
Section 2.9 (on page 47)) on a specified system, and then send the standard output of the
command to a file on a specified system. Only the first command of a pipeline can have a
system-name! prefix. All other commands in the pipeline shall be executed on the system of the
first command.

The following restrictions are applicable to the shell pipeline processed by uux:

• In gathering files from different systems, pathname expansion shall not be performed by uux.
Thus, a request such as:

   uux "c99 remays!/*.c"

would attempt to copy the file named literally *.c to the local system.

• The redirection operators ">>, "<<", "|", and "|&" shall not be accepted. Any use of
these redirection operators shall cause this utility to write an error message describing the
problem and exit with a non-zero exit status.

• The reserved word ! cannot be used at the head of the pipeline to modify the exit status. (See
the command-string operand description below.)

• Alias substitution shall not be performed.

A filename can be specified as for uucp; it can be an absolute pathname, a pathname preceded by
-name (which is replaced by the corresponding login directory), a pathname specified as */dest
(dest is prefixed by the public directory called PUBDIR; the actual location of PUBDIR is
implementation-defined), or a simple filename (which is prefixed by uux with the current
directory). See uucp for the details.

The execution of commands on remote systems shall take place in an execution directory known
to the uucp system. All files required for the execution shall be put into this directory unless they
already reside on that machine. Therefore, the application shall ensure that non-local filenames
(without path or machine reference) are unique within the uux request.

The uux utility shall attempt to get all files to the execution system. For files that are output files,
the application shall ensure that the filename is escaped using parentheses.

The remote system shall notify the user by mail if the requested command on the remote system
was disallowed or the files were not accessible. This notification can be turned off by the -n
option.

Typical implementations of this utility require a communications line configured to use the Base
Definitions volume of IEEE Std 1003.1-2001, Chapter 11, General Terminal Interface, but other
communications means may be used. On systems where there are no available communications
means (either temporarily or permanently), this utility shall write an error message describing
the problem and exit with a non-zero exit status.

The uux utility cannot guarantee support for all character encodings in all circumstances. For
example, transmission data may be restricted to 7 bits by the underlying network, 8-bit data and
_filenames need not be portable to non-internationalized systems, and so on. Under these circumstances, it is recommended that only characters defined in the ISO/IEC 646:1991 standard International Reference Version (equivalent to ASCII) 7-bit range of characters be used and that only characters defined in the portable filename character set be used for naming files.

**OPTIONS**

The following options shall be supported:

- `-p` Make the standard input to `uux` the standard input to the `command-string`.
- `-j` Write the job identification string to standard output. This job identification can be used by `uustat` to obtain the status or terminate a job.
- `-n` Do not notify the user if the command fails.

**OPERANDS**
The following operand shall be supported:

- `command-string`
  
  A string made up of one or more arguments that are similar to normal command arguments, except that the command and any filenames can be prefixed by `system-name`!. A null `system-name` shall be interpreted as the local system.

**STDIN**
The standard input shall not be used unless the `−` or `−p` option is specified; in those cases, the standard input shall be made the standard input of the `command-string`.

**INPUT FILES**
Input files shall be selected according to the contents of `command-string`.

**ENVIRONMENT VARIABLES**
The following environment variables shall affect the execution of `uux`:

- `LANG`
  
  Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-2001, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

- `LC_ALL`
  
  If set to a non-empty string value, override the values of all the other internationalization variables.

- `LC_CTYPE`
  
  Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

- `LC_MESSAGES`
  
  Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

- `NLSPATH`
  
  Determine the location of message catalogs for the processing of `LC_MESSAGES`.

**ASYNCHRONOUS EVENTS**
Default.
STDOUT
The standard output shall not be used unless the −j option is specified; in that case, the job
identification string shall be written to standard output in the following format:
"%s\n", <jobid>

STDERR
The standard error shall be used only for diagnostic messages.

OUTPUT FILES
Output files shall be created or written, or both, according to the contents of command-string.
If −n is not used, mail files shall be modified following any command or file-access failures on
the remote system.

EXTENDED DESCRIPTION
None.

EXIT STATUS
The following exit values shall be returned:
0 Successful completion.
>0 An error occurred.

CONSEQUENCES OF ERRORS
Default.

APPLICATION USAGE
Note that, for security reasons, many installations limit the list of commands executable on
behalf of an incoming request from uux. Many sites permit little more than the receipt of mail
via uux.
Any characters special to the command interpreter should be quoted either by quoting the entire
command-string or quoting the special characters as individual arguments.
As noted in uucp, shell pattern matching notation characters appearing in pathnames are
expanded on the appropriate local system. This is done under the control of local settings of
LC_COLLATE and LC_CTYPE. Thus, care should be taken when using bracketed filename
patterns, as collation and typing rules may vary from one system to another. Also be aware that
certain types of expression (that is, equivalence classes, character classes, and collating symbols)
ned not be supported on non-internationalized systems.

EXAMPLES
1. The following command gets file1 from system a and file2 from system b, executes diff on
the local system, and puts the results in file.diff in the local PUBDIR directory. (PUBDIR is
the uucp public directory on the local system.)
uux "!diff a!/usr/file1 b!/a4/file2 >!˜/file.diff"

2. The following command fails because uux places all files copied to a system in the same
working directory. Although the files xyz are from two different systems, their filenames
are the same and conflict.
uux "!diff a!/usr1/xyz b!/usr2/xyz >!˜/xyz.diff"

3. The following command succeeds (assuming diff is permitted on system a) because the file
local to system a is not copied to the working directory, and hence does not conflict with
the file from system c.
uux "a!diff a!/usr/xyz c!/usr/xyz >!~/xyz.diff"

**RATIONALE**
None.

**FUTURE DIRECTIONS**
None.

NAME
val — validate SCCS files (DEVELOPMENT)

SYNOPSIS
val 
val [-s][-m name][-r SID][-y type] file...

DESCRIPTION
The val utility shall determine whether the specified file is an SCCS file meeting the
characteristics specified by the options.

OPTIONS
The val utility shall conform to the Base Definitions volume of IEEE Std 1003.1-2001, Section 12.2,
Utility Syntax Guidelines, except that the usage of the ‘−’ operand is not strictly as intended by
the guidelines (that is, reading options and operands from standard input).

The following options shall be supported:
−m name Specify a name, which is compared with the SCCS %M% keyword in file; see get.
−r SID Specify a SID (SCCS Identification String), an SCCS delta number. A check shall be
made to determine whether the SID is ambiguous (for example, −r 1 is ambiguous
because it physically does not exist but implies 1.1, 1.2, and so on, which may
exist) or invalid (for example, −r 1.0 or −r 1.1.0 are invalid because neither case can
exist as a valid delta number). If the SID is valid and not ambiguous, a check shall
be made to determine whether it actually exists.
−s Silence the diagnostic message normally written to standard output for any error
that is detected while processing each named file on a given command line.
−y type Specify a type, which shall be compared with the SCCS %Y% keyword in file; see
get.

OPERANDS
The following operands shall be supported:
file A pathname of an existing SCCS file. If exactly one file operand appears, and it is
‘−’, the standard input shall be read: each line shall be independently processed
as if it were a command line argument list. (However, the line is not subjected to
any of the shell word expansions, such as parameter expansion or quote removal.)

STDIN
The standard input shall be a text file used only when the file operand is specified as ‘−’.

INPUT FILES
Any SCCS files processed shall be files of an unspecified format.

ENVIRONMENT VARIABLES
The following environment variables shall affect the execution of val:
LANG Provide a default value for the internationalization variables that are unset or null.
(See the Base Definitions volume of IEEE Std 1003.1-2001, Section 8.2,
Internationalization Variables for the precedence of internationalization variables
used to determine the values of locale categories.)
LC_ALL If set to a non-empty string value, override the values of all the other
internationalization variables.
Utilities

LC_TYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error, and informative messages written to standard output.

NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

ASYNCHRONOUS EVENTS

STDOUT The standard output shall consist of informative messages about either:

1. Each file processed
2. Each command line read from standard input

If the standard input is not used, for each file operand yielding a discrepancy, the output line shall have the following format:

"%s: %s\n", <pathname>, <unspecified string>

If standard input is used, a line of input shall be written before each of the preceding lines for files containing discrepancies:

"%s:\n", <input line>

STDERR Not used.

OUTPUT FILES None.

EXTENDED DESCRIPTION None.

EXIT STATUS The 8-bit code returned by val shall be a disjunction of the possible errors; that is, it can be interpreted as a bit string where set bits are interpreted as follows:

0x80 = Missing file argument.
0x40 = Unknown or duplicate option.
0x20 = Corrupted SCCS file.
0x10 = Cannot open file or file not SCCS.
0x08 = SID is invalid or ambiguous.
0x04 = SID does not exist.
0x02 = %Y%, −y mismatch.
0x01 = %M%, −m mismatch.

Note that val can process two or more files on a given command line and can process multiple command lines (when reading the standard input). In these cases an aggregate code shall be returned: a logical OR of the codes generated for each command line and file processed.
CONSEQUENCES OF ERRORS
Default.

APPLICATION USAGE
Since the val exit status sets the 0x80 bit, shell applications checking "$?" cannot tell if it terminated due to a missing file argument or receipt of a signal.

EXAMPLES
In a directory with three SCCS files—s.x (of t type ‘text’), s.y, and s.z (a corrupted file)—the following command could produce the output shown:

```bash
val - <<EOF
-y source s.x
-y source s.x
-s.z
EOF
```

RATIONALE
None.

FUTURE DIRECTIONS
None.

CHANGE HISTORY
First released in Issue 2.

Issue 6
The Open Group Corrigendum U025/4 is applied, correcting a typographical error in the EXIT STATUS.
NAME

vi — screen-oriented (visual) display editor

SYNOPSIS

vi [-r][-c command][-t tagstring][-w size][file ...]

DESCRIPTION

This utility shall be provided on systems that both support the User Portability Utilities option and define the POSIX2_CHAR_TERM symbol. On other systems it is optional.

The vi (visual) utility is a screen-oriented text editor. Only the open and visual modes of the editor are described in IEEE Std 1003.1-2001; see the line editor ex for additional editing capabilities used in vi. The user can switch back and forth between vi and ex and execute ex commands from within vi.

This reference page uses the term edit buffer to describe the current working text. No specific implementation is implied by this term. All editing changes are performed on the edit buffer, and no changes to it shall affect any file until an editor command writes the file.

When using vi, the terminal screen acts as a window into the editing buffer. Changes made to the editing buffer shall be reflected in the screen display; the position of the cursor on the screen shall indicate the position within the editing buffer.

Certain terminals do not have all the capabilities necessary to support the complete vi definition. When these commands cannot be supported on such terminals, this condition shall not produce an error message such as "not an editor command" or report a syntax error. The implementation may either accept the commands and produce results on the screen that are the result of an unsuccessful attempt to meet the requirements of this volume of IEEE Std 1003.1-2001 or report an error describing the terminal-related deficiency.

OPTIONS

The following options shall be supported:

-c command See the ex command description of the -c option.
-r See the ex command description of the -r option.
-R See the ex command description of the -R option.
-t tagstring See the ex command description of the -t option.
-w size See the ex command description of the -w option.

OPERANDS

See the OPERANDS section of the ex command for a description of the operands supported by the vi command.

STDIN

If standard input is not a terminal device, the results are undefined. The standard input consists of a series of commands and input text, as described in the EXTENDED DESCRIPTION section.

If a read from the standard input returns an error, or if the editor detects an end-of-file condition from the standard input, it shall be equivalent to a SIGHUP asynchronous event.
INPUT FILES
See the INPUT FILES section of the ex command for a description of the input files supported by the vi command.

ENVIRONMENT VARIABLES
See the ENVIRONMENT VARIABLES section of the ex command for the environment variables that affect the execution of the vi command.

ASYNCHRONOUS EVENTS
See the ASYNCHRONOUS EVENTS section of the ex for the asynchronous events that affect the execution of the vi command.

STDOUT
If standard output is not a terminal device, undefined results occur.
Standard output may be used for writing prompts to the user, for informational messages, and for writing lines from the file.

STDERR
If standard output is not a terminal device, undefined results occur.
The standard error shall be used only for diagnostic messages.

OUTPUT FILES
See the OUTPUT FILES section of the ex command for a description of the output files supported by the vi command.

EXTENDED DESCRIPTION
If the terminal does not have the capabilities necessary to support an unspecified portion of the vi definition, implementations shall start initially in ex mode or open mode. Otherwise, after initialization, vi shall be in command mode; text input mode can be entered by one of several commands used to insert or change text. In text input mode, <ESC> can be used to return to command mode; other uses of <ESC> are described later in this section; see Terminate Command or Input Mode (on page 996).

Initialization in ex and vi
See Initialization in ex and vi (on page 358) for a description of ex and vi initialization for the vi utility.

Command Descriptions in vi
The following symbols are used in this reference page to represent arguments to commands.

buffer
See the description of buffer in the EXTENDED DESCRIPTION section of the ex utility; see Command Descriptions in ex (on page 368).
In open and visual mode, when a command synopsis shows both [buffer] and [count] preceding the command name, they can be specified in either order.

count
A positive integer used as an optional argument to most commands, either to give a repeat count or as a size. This argument is optional and shall default to 1 unless otherwise specified.
The Synopsis lines for the vi commands <control>-G, <control>-L, <control>-R, <control>-[, %, &], D, m, M, Q, u, U, and ZZ do not have count as an optional argument. Regardless, it shall not be an error to specify a count to these commands, and any specified count shall be ignored.
motion  An optional trailing argument used by the !, <, >, c, d, and y commands, which is used to indicate the region of text that shall be affected by the command. The motion can be either one of the command characters repeated or one of several other vi commands (listed in the following table). Each of the applicable commands specifies the region of text matched by repeating the command; each command that can be used as a motion command specifies the region of text it affects.

Commands that take motion arguments operate on either lines or characters, depending on the circumstances. When operating on lines, all lines that fall partially or wholly within the text region specified for the command shall be affected. When operating on characters, only the exact characters in the specified text region shall be affected. Each motion command specifies this individually.

When commands that may be motion commands are not used as motion commands, they shall set the current position to the current line and column as specified.

The following commands shall be valid cursor motion commands:

- `<apostrophe>` (-jH
- `<carriage-return>` ($) k L
- `<comma>` ([[% l M
- `<control>-H` [][ n N
- `<control>-N` {;tT
- `<control>-P` }?wW
- `<grave accent>` ^ b B
- `<newline>` + e E
- `<space>` | f F
- `<zero>` / h G

Any count that is specified to a command that has an associated motion command shall be applied to the motion command. If a count is applied to both the command and its associated motion command, the effect shall be multiplicative.

The following symbols are used in this section to specify locations in the edit buffer:

- current character
  The character that is currently indicated by the cursor.

- end of a line
  The point located between the last non-<newline> (if any) and the terminating <newline> of a line. For an empty line, this location coincides with the beginning of the line.

- end of the edit buffer
  The location corresponding to the end of the last line in the edit buffer.

The following symbols are used in this section to specify command actions:

- bigword
  In the POSIX locale, vi shall recognize four kinds of bigwords:

  1. A maximal sequence of non-<blank>s preceded and followed by <blank>s or the beginning or end of a line or the edit buffer

  2. One or more sequential blank lines

  3. The first character in the edit buffer

  4. The last non-<newline> in the edit buffer
In the POSIX locale, `vi` shall recognize five kinds of words:

1. A maximal sequence of letters, digits, and underscores, delimited at both ends by:
   - Characters other than letters, digits, or underscores
   - The beginning or end of a line
   - The beginning or end of the edit buffer

2. A maximal sequence of characters other than letters, digits, underscores, or `<blank>`s, delimited at both ends by:
   - A letter, digit, underscore
   - `<blank>`s
   - The beginning or end of a line
   - The beginning or end of the edit buffer

3. One or more sequential blank lines

4. The first character in the edit buffer

5. The last non-`<newline>` in the edit buffer

### section boundary

A section boundary is one of the following:

1. A line whose first character is a `<form-feed>`
2. A line whose first character is an open curly brace (`{'`)
3. A line whose first character is a period and whose second and third characters match a two-character pair in the sections edit option (see `ed`)
4. A line whose first character is a period and whose only other character matches the first character of a two-character pair in the sections edit option, where the second character of the two-character pair is a `<space>`
5. The first line of the edit buffer
6. The last line of the edit buffer if the last line of the edit buffer is empty or if it is a `|` or `)` command; otherwise, the last non-`<newline>` of the last line of the edit buffer

### paragraph boundary

A paragraph boundary is one of the following:

1. A section boundary
2. A line whose first character is a period and whose second and third characters match a two-character pair in the paragraphs edit option (see `ed`)
3. A line whose first character is a period and whose only other character matches the first character of a two-character pair in the paragraphs edit option, where the second character of the two-character pair is a `<space>`
4. One or more sequential blank lines

### remembered search direction

See the description of remembered search direction in `ed`. 
sentence boundary

A sentence boundary is one of the following:

1. A paragraph boundary
2. The first non-<blank> that occurs after a paragraph boundary
3. The first non-<blank> that occurs after a period (', '), exclamation mark ('! '), or question mark ('? '), followed by two <space>es or the end of a line; any number of closing parenthesis (')'), closing brackets ('[]'), double quote ('"'), or single quote ('''') characters can appear between the punctuation mark and the two <space>es or end-of-line

In the remainder of the description of the vi utility, the term “buffer line” refers to a line in the edit buffer and the term “display line” refers to the line or lines on the display screen used to display one buffer line. The term “current line” refers to a specific “buffer line”.

If there are display lines on the screen for which there are no corresponding buffer lines because they correspond to lines that would be after the end of the file, they shall be displayed as a single tilde (‘˜’) character, plus the terminating <newline>.

The last line of the screen shall be used to report errors or display informational messages. It shall also be used to display the input for “line-oriented commands” (l, ?, ;, and !). When a line-oriented command is executed, the editor shall enter text input mode on the last line on the screen, using the respective command characters as prompt characters. (In the case of the ! command, the associated motion shall be entered by the user before the editor enters text input mode.) The line entered by the user shall be terminated by a <newline>, a non-<control>V-escaped <carriage-return>, or unescaped <ESC>. It is unspecified if more characters than require a display width minus one column number of screen columns can be entered.

If any command is executed that overwrites a portion of the screen other than the last line of the screen (for example, the ex suspend or ! commands), other than the ex shell command, the user shall be prompted for a character before the screen is refreshed and the edit session continued.

<tab>s shall take up the number of columns on the screen set by the tabstop edit option (see ed), unless there are less than that number of columns before the display margin that will cause the displayed line to be folded; in this case, they shall only take up the number of columns up to that boundary.

The cursor shall be placed on the current line and relative to the current column as specified by each command described in the following sections.

In open mode, if the current line is not already displayed, then it shall be displayed.

In visual mode, if the current line is not displayed, then the lines that are displayed shall be expanded, scrolled, or redrawn to cause an unspecified portion of the current line to be displayed. If the screen is redrawn, no more than the number of display lines specified by the value of the window edit option shall be displayed (unless the current line cannot be completely displayed in the number of display lines specified by the window edit option) and the current line shall be positioned as close to the center of the displayed lines as possible (within the constraints imposed by the distance of the line from the beginning or end of the edit buffer). If the current line is before the first line in the display and the screen is scrolled, an unspecified portion of the current line shall be placed on the first line of the display. If the current line is after the last line in the display and the screen is scrolled, an unspecified portion of the current line shall be placed on the last line of the display.

In visual mode, if a line from the edit buffer (other than the current line) does not entirely fit into the lines at the bottom of the display that are available for its presentation, the editor may
choose not to display any portion of the line. The lines of the display that do not contain text
from the edit buffer for this reason shall each consist of a single ‘@’ character.

In visual mode, the editor may choose for unspecified reasons to not update lines in the display
to correspond to the underlying edit buffer text. The lines of the display that do not correctly
correspond to text from the edit buffer for this reason shall consist of a single ‘@’ character
(plus the terminating <newline>), and the <control>-R command shall cause the editor to
update the screen to correctly represent the edit buffer.

Open and visual mode commands that set the current column set it to a column position in the
display, and not a character position in the line. In this case, however, the column position in the
display shall be calculated for an infinite width display; for example, the column related to a
character that is part of a line that has been folded onto additional screen lines will be offset from
the display line column where the buffer line begins, not from the beginning of a particular
display line.

The display cursor column in the display is based on the value of the current column, as follows,
with each rule applied in turn:

1. If the current column is after the last display line column used by the displayed line, the
display cursor column shall be set to the last display line column occupied by the last non-
<newline> in the current line; otherwise, the display cursor column shall be set to the
current column.

2. If the character of which some portion is displayed in the display line column specified by
the display cursor column requires more than a single display line column:

   a. If in text input mode, the display cursor column shall be adjusted to the first display
      line column in which any portion of that character is displayed.
   
   b. Otherwise, the display cursor column shall be adjusted to the last display line
      column in which any portion of that character is displayed.

The current column shall not be changed by these adjustments to the display cursor column.

If an error occurs during the parsing or execution of a vi command:

- The terminal shall be alerted. Execution of the vi command shall stop, and the cursor (for
  example, the current line and column) shall not be further modified.

- Unless otherwise specified by the following command sections, it is unspecified whether an
  informational message shall be displayed.

- Any partially entered vi command shall be discarded.

- If the vi command resulted from a map expansion, all characters from that map expansion
  shall be discarded, except as otherwise specified by the map command (see ed).

- If the vi command resulted from the execution of a buffer, no further commands caused by
  the execution of the buffer shall be executed.
**Page Backwards**

*Synopsis:* \([\text{count}] \text{ <control>-B}\)

If in open mode, the `<control>-B` command shall behave identically to the `z` command. Otherwise, if the current line is the first line of the edit buffer, it shall be an error.

If the `window edit option` is less than 3, display a screen where the last line of the display shall be some portion of:

\[(\text{current first line}) - 1\]

otherwise, display a screen where the first line of the display shall be some portion of:

\[(\text{current first line}) - \text{count} \times ((\text{window edit option}) - 2)\]

If this calculation would result in a line that is before the first line of the edit buffer, the first line of the display shall display some portion of the first line of the edit buffer.

*Current line:* If no lines from the previous display remain on the screen, set to the last line of the display; otherwise, set to \((\text{line} - \text{the number of new lines displayed on this screen})\).

*Current column:* Set to non-<blank>.

**Scroll Forward**

*Synopsis:* \([\text{count}] \text{ <control>-D}\)

If the current line is the last line of the edit buffer, it shall be an error.

If no `count` is specified, `count` shall default to the `count` associated with the previous `<control>-D` or `<control>-U` command. If there was no previous `<control>-D` or `<control>-U` command, `count` shall default to the value of the `scroll edit option`.

If in open mode, write lines starting with the line after the current line, until `count` lines or the last line of the file have been written.

*Current line:* If the current line + `count` is past the last line of the edit buffer, set to the last line of the edit buffer; otherwise, set to the current line + `count`.

*Current column:* Set to non-<blank>.

**Scroll Forward by Line**

*Synopsis:* \([\text{count}] \text{ <control>-E}\)

Display the line count lines after the last line currently displayed.

If the last line of the edit buffer is displayed, it shall be an error. If there is no line `count` lines after the last line currently displayed, the last line of the display shall display some portion of the last line of the edit buffer.

*Current line:* Unchanged if the previous current character is displayed; otherwise, set to the first line displayed.

*Current column:* Unchanged.
Page Forward

Synopsis: \[\text{[count]} \text{ <control>-F}\]

If in open mode, the \texttt{<control>-F} command shall behave identically to the \texttt{z} command. Otherwise, if the current line is the last line of the edit buffer, it shall be an error.

If the \texttt{window} edit option is less than 3, display a screen where the first line of the display shall be some portion of:

\[(\text{current last line}) + 1\]

otherwise, display a screen where the first line of the display shall be some portion of:

\[(\text{current first line}) + \text{count} \times ((\text{window edit option}) - 2)\]

If this calculation would result in a line that is after the last line of the edit buffer, the last line of the display shall display some portion of the last line of the edit buffer.

Current line: If no lines from the previous display remain on the screen, set to the first line of the display; otherwise, set to (line + the number of new lines displayed on this screen).

Current column: Set to non-<blank>.

Display Information

Synopsis: \texttt{<control>-G}

This command shall be equivalent to the \texttt{ex file} command.

Move Cursor Backwards

Synopsis: \[\text{[count]} \text{ <control>-H}\]

the current erase character (see \texttt{stty})

If there are no characters before the current character on the current line, it shall be an error. If there are less than \text{count} previous characters on the current line, \text{count} shall be adjusted to the number of previous characters on the line.

If used as a motion command:

1. The text region shall be from the character before the starting cursor up to and including the \text{count}th character before the starting cursor.

2. Any text copied to a buffer shall be in character mode.

If not used as a motion command:

Current line: Unchanged.

Current column: Set to (column – the number of columns occupied by \text{count} characters ending with the previous current column).
Move Down

Synopsis: \[[\text{count}] \langle \text{newline} \rangle\]
\[[\text{count}] \langle \text{control}\rangle-J\]
\[[\text{count}] \langle \text{control}\rangle-M\]
\[[\text{count}] \langle \text{control}\rangle-N\]
\[[\text{count}] \ j\]
\[[\text{count}] \langle \text{carriage-return} \rangle\]
\[[\text{count}] \ +\]

If there are less than \text{count} lines after the current line in the edit buffer, it shall be an error.

If used as a motion command:
1. The text region shall include the starting line and the next \text{count} – 1 lines.
2. Any text copied to a buffer shall be in line mode.

If not used as a motion command:
Current line: Set to current line + \text{count}.
Current column: Set to non-<blank> for the <carriage-return>, <control>-M, and + commands; otherwise, unchanged.

Clear and Redisplay

Synopsis: \[\langle \text{control}\rangle-L\]

If in open mode, clear the screen and redisplay the current line. Otherwise, clear and redisplay the screen.
Current line: Unchanged.
Current column: Unchanged.

Move Up

Synopsis: \[[\text{count}] \langle \text{control}\rangle-P\]
\[[\text{count}] \ k\]
\[[\text{count}] \ -\]

If there are less than \text{count} lines before the current line in the edit buffer, it shall be an error.

If used as a motion command:
1. The text region shall include the starting line and the previous \text{count} lines.
2. Any text copied to a buffer shall be in line mode.

If not used as a motion command:
Current line: Set to current line – \text{count}.
Current column: Set to non-<blank> for the – command; otherwise, unchanged.
Redraw Screen

Synopsis: <control>-R

If any lines have been deleted from the display screen and flagged as deleted on the terminal using the @ convention (see the beginning of the EXTENDED DESCRIPTION section), they shall be redisplayed to match the contents of the edit buffer.

It is unspecified whether lines flagged with @ because they do not fit on the terminal display shall be affected.

Current line: Unchanged.
Current column: Unchanged.

Scroll Backward

Synopsis: [count] <control>-U

If the current line is the first line of the edit buffer, it shall be an error.

If no count is specified, count shall default to the count associated with the previous <control>-D or <control>-U command. If there was no previous <control>-D or <control>-U command, count shall default to the value of the scroll edit option.

Current line: If count is greater than the current line, set to 1; otherwise, set to the current line – count.
Current column: Set to non-<blank>.

Scroll Backward by Line

Synopsis: [count] <control>-Y

Display the line count lines before the first line currently displayed.

If the current line is the first line of the edit buffer, it shall be an error. If this calculation would result in a line that is before the first line of the edit buffer, the first line of the display shall display some portion of the first line of the edit buffer.

Current line: Unchanged if the previous current character is displayed; otherwise, set to the first line displayed.
Current column: Unchanged.

Edit the Alternate File

Synopsis: <control>-^ ^

This command shall be equivalent to the ex edit command, with the alternate pathname as its argument.

Terminate Command or Input Mode

Synopsis: <ESC>

If a partial vi command (as defined by at least one, non-count character) has been entered, discard the count and the command character(s).

Otherwise, if no command characters have been entered, and the <ESC> was the result of a map expansion, the terminal shall be alerted and the <ESC> character shall be discarded, but it shall not be an error.
Otherwise, it shall be an error.

Current line: Unchanged.
Current column: Unchanged.

Search for tagstring

Synopsis: <control>-

If the current character is not a word or <blank>, it shall be an error.

This command shall be equivalent to the ex tag command, with the argument to that command defined as follows.

If the current character is a <blank>:

1. Skip all <blank>s after the cursor up to the end of the line.
2. If the end of the line is reached, it shall be an error.

Then, the argument to the ex tag command shall be the current character and all subsequent characters, up to the first non-word character or the end of the line.

Move Cursor Forward

Synopsis: [count] <space>

If there are less than count non-<newline>s after the cursor on the current line, count shall be adjusted to the number of non-<newline>s after the cursor on the line.

If used as a motion command:

1. If the current or count th character after the cursor is the last non-<newline> in the line, the text region shall be comprised of the current character up to and including the last non-<newline> in the line. Otherwise, the text region shall be from the current character up to, but not including, the count th character after the cursor.
2. Any text copied to a buffer shall be in character mode.

If not used as a motion command:

If there are no non-<newline>s after the current character on the current line, it shall be an error.

Current line: Unchanged.
Current column: Set to the last column that displays any portion of the count th character after the current character.

Replace Text with Results from Shell Command

Synopsis: [count] ! motion shell-commands <newline>

If the motion command is the ! command repeated:

1. If the edit buffer is empty and no count was supplied, the command shall be the equivalent of the ex:read ! command, with the text input, and no text shall be copied to any buffer.
2. Otherwise:
   a. If there are less than count –1 lines after the current line in the edit buffer, it shall be an error.
The text region shall be from the current line up to and including the next \textit{count} − 1 lines.

Otherwise, the text region shall be the lines in which any character of the text region specified by the motion command appear.

Any text copied to a buffer shall be in line mode.

This command shall be equivalent to the \textit{ex !} command for the specified lines.

\textbf{Move Cursor to End-of-Line}

\textit{Synopsis:} \quad [\textit{count}] \$\newline

It shall be an error if there are less than \((\textit{count} − 1)\) lines after the current line in the edit buffer.

If used as a motion command:

1. If \textit{count} is 1:
   a. It shall be an error if the line is empty.
   b. Otherwise, the text region shall consist of all characters from the starting cursor to the last non-<newline> in the line, inclusive, and any text copied to a buffer shall be in character mode.

2. Otherwise, if the starting cursor position is at or before the first non-<blank> in the line, the text region shall consist of the current and the next \textit{count} − 1 lines, and any text saved to a buffer shall be in line mode.

3. Otherwise, the text region shall consist of all characters from the starting cursor to the last non-<newline> in the line that is \textit{count} − 1 lines forward from the current line, and any text copied to a buffer shall be in character mode.

If not used as a motion command:

\textit{Current line}: Set to the current line + \textit{count} − 1.

\textit{Current column}: The current column is set to the last display line column of the last non-<newline> in the line, or column position 1 if the line is empty.

The current column shall be adjusted to be on the last display line column of the last non-<newline> of the current line as subsequent commands change the current line, until a command changes the current column.

\textbf{Move to Matching Character}

\textit{Synopsis:} \quad \%

If the character at the current position is not a parenthesis, bracket, or curly brace, search forward in the line to the first one of those characters. If no such character is found, it shall be an error.

The matching character shall be the parenthesis, bracket, or curly brace matching the parenthesis, bracket, or curly brace, respectively, that was at the current position or that was found on the current line.

Matching shall be determined as follows, for an open parenthesis:

1. Set a counter to 1.
2. Search forwards until a parenthesis is found or the end of the edit buffer is reached.
3. If the end of the edit buffer is reached, it shall be an error.
4. If an open parenthesis is found, increment the counter by 1.
5. If a close parenthesis is found, decrement the counter by 1.
6. If the counter is zero, the current character is the matching character.

Matching for a close parenthesis shall be equivalent, except that the search shall be backwards, from the starting character to the beginning of the buffer, a close parenthesis shall increment the counter by 1, and an open parenthesis shall decrement the counter by 1.

Matching for brackets and curly braces shall be equivalent, except that searching shall be done for open and close brackets or open and close curly braces. It is implementation-defined whether other characters are searched for and matched as well.

If used as a motion command:

1. If the matching cursor was after the starting cursor in the edit buffer, and the starting cursor position was at or before the first non-<blank> non-<newline> in the starting line, and the matching cursor position was at or after the last non-<blank> non-<newline> in the matching line, the text region shall consist of the current line to the matching line, inclusive, and any text copied to a buffer shall be in line mode.

2. If the matching cursor was before the starting cursor in the edit buffer, and the starting cursor position was at or after the last non-<blank> non-<newline> in the starting line, and the matching cursor position was at or before the first non-<blank> non-<newline> in the matching line, the text region shall consist of the current line to the matching line, inclusive, and any text copied to a buffer shall be in line mode.

3. Otherwise, the text region shall consist of the starting character to the matching character, inclusive, and any text copied to a buffer shall be in character mode.

If not used as a motion command:

Current line: Set to the line where the matching character is located.

Current column: Set to the last column where any portion of the matching character is displayed.

Repeat Substitution

Synopsis: &

Repeat the previous substitution command. This command shall be equivalent to the ex & command with the current line as its addresses, and without options, count, or flags.

Return to Previous Context at Beginning of Line

Synopsis: ' character

It shall be an error if there is no line in the edit buffer marked by character.

If used as a motion command:

1. If the starting cursor is after the marked cursor, then the locations of the starting cursor and the marked cursor in the edit buffer shall be logical swapped.

2. The text region shall consist of the starting line up to and including the marked line, and any text copied to a buffer shall be in line mode.

If not used as a motion command:
Current line: Set to the line referenced by the mark.

Current column: Set to non-<blank>.

Return to Previous Context

Synopsis: `character`

It shall be an error if the marked line is no longer in the edit buffer. If the marked line no longer contains a character in the saved numbered character position, it shall be as if the marked position is the first non-<blank>.

If used as a motion command:

1. It shall be an error if the marked cursor references the same character in the edit buffer as the starting cursor.
2. If the starting cursor is after the marked cursor, then the locations of the starting cursor and the marked cursor in the edit buffer shall be logically swapped.
3. If the starting line is empty or the starting cursor is at or before the first non-<blank> non-
   <newline> of the starting line, and the marked cursor line is empty or the marked cursor references the first character of the marked cursor line, the text region shall consist of all lines containing characters from the starting cursor to the line before the marked cursor line, inclusive, and any text copied to a buffer shall be in line mode.
4. Otherwise, if the marked cursor line is empty or the marked cursor references a character at or before the first non-<blank> non-
   <newline> of the marked cursor line, the region of text shall be from the starting cursor to the last non-<newline> of the line before the marked cursor line, inclusive, and any text copied to a buffer shall be in character mode.
5. Otherwise, the region of text shall be from the starting cursor (inclusive), to the marked
   cursor (exclusive), and any text copied to a buffer shall be in character mode.

If not used as a motion command:

Current line: Set to the line referenced by the mark.

Current column: Set to the last column in which any portion of the character referenced by the mark is displayed.

Return to Previous Section

Synopsis: `[count]` `[[`}

Move the cursor backward through the edit buffer to the first character of the previous section boundary, `count` times.

If used as a motion command:

1. If the starting cursor was at the first character of the starting line or the starting line was empty, and the first character of the boundary was the first character of the boundary line, the text region shall consist of the current line up to and including the line where the `count`th next boundary starts, and any text copied to a buffer shall be in line mode.
2. If the boundary was the last line of the edit buffer or the last non-<newline> of the last line of the edit buffer, the text region shall consist of the last character in the edit buffer up to and including the starting character, and any text saved to a buffer shall be in character mode.
3. Otherwise, the text region shall consist of the starting character up to but not including the first character in the count th next boundary, and any text copied to a buffer shall be in character mode.

If not used as a motion command:

Current line: Set to the line where the count th next boundary in the edit buffer starts.

Current column: Set to the last column in which any portion of the first character of the count th next boundary is displayed, or column position 1 if the line is empty.

Move to Next Section

Synopsis: [count]

Move the cursor forward through the edit buffer to the first character of the next section boundary, count times.

If used as a motion command:

1. If the starting cursor was at the first character of the starting line or the starting line was empty, and the first character of the boundary was the first character of the boundary line, the text region shall consist of the current line up to and including the line where the count th previous boundary starts, and any text copied to a buffer shall be in line mode.

2. If the boundary was the first line of the edit buffer, the text region shall consist of the first character in the edit buffer up to but not including the starting character, and any text copied to a buffer shall be in character mode.

3. Otherwise, the text region shall consist of the first character in the count th previous section boundary up to but not including the starting character, and any text copied to a buffer shall be in character mode.

If not used as a motion command:

Current line: Set to the line where the count th previous boundary in the edit buffer starts.

Current column: Set to the last column in which any portion of the first character of the count th previous boundary is displayed, or column position 1 if the line is empty.

Move to First Non-blank Position on Current Line

Synopsis: ^

If used as a motion command:

1. If the line has no non-blank non-newline s, or if the cursor is at the first non-blank non-newline of the line, it shall be an error.

2. If the cursor is before the first non-blank non-newline of the line, the text region shall be comprised of the current character, up to, but not including, the first non-blank non-newline of the line.

3. If the cursor is after the first non-blank non-newline of the line, the text region shall be from the character before the starting cursor up to and including the first non-blank non-newline of the line.

4. Any text copied to a buffer shall be in character mode.

If not used as a motion command:
Current line: Unchanged.

Current column: Set to non-<blank>.

**Current and Line Above**

**Synopsis:** \[count\] 

If there are less than \(count - 1\) lines after the current line in the edit buffer, it shall be an error.

If used as a motion command:

1. If \(count\) is less than 2, the text region shall be the current line.
2. Otherwise, the text region shall include the starting line and the next \(count - 1\) lines.
3. Any text copied to a buffer shall be in line mode.

If not used as a motion command:

**Current line:** Set to current line + \(count - 1\).

**Current column:** Set to non-<blank>.

**Move Back to Beginning of Sentence**

**Synopsis:** \[count\] ( 

Move backward to the beginning of a sentence. This command shall be equivalent to the [ command, with the exception that sentence boundaries shall be used instead of section boundaries.

**Move Forward to Beginning of Sentence**

**Synopsis:** \[count\] )

Move forward to the beginning of a sentence. This command shall be equivalent to the ] command, with the exception that sentence boundaries shall be used instead of section boundaries.

**Move Back to Preceding Paragraph**

**Synopsis:** \[count\] {

Move back to the beginning of the preceding paragraph. This command shall be equivalent to the [ command, with the exception that paragraph boundaries shall be used instead of section boundaries.

**Move Forward to Next Paragraph**

**Synopsis:** \[count\] }

Move forward to the beginning of the next paragraph. This command shall be equivalent to the ] command, with the exception that paragraph boundaries shall be used instead of section boundaries.
Move to Specific Column Position

Synopsis: \[\text{[count]} | \]

For the purposes of this command, lines that are too long for the current display and that have been folded shall be treated as having a single, 1-based, number of columns.

If there are less than count columns in which characters from the current line are displayed on the screen, count shall be adjusted to be the last column in which any portion of the line is displayed on the screen.

If used as a motion command:

1. If the line is empty, or the cursor character is the same as the character on the count th column of the line, it shall be an error.
2. If the cursor is before the count th column of the line, the text region shall be comprised of the current character, up to but not including the character on the count th column of the line.
3. If the cursor is after the count th column of the line, the text region shall be from the character before the starting cursor up to and including the character on the count th column of the line.
4. Any text copied to a buffer shall be in character mode.

If not used as a motion command:

Current line: Unchanged.
Current column: Set to the last column in which any portion of the character that is displayed in the count column of the line is displayed.

Reverse Find Character

Synopsis: \[\text{[count]} , \]

If the last F, f, T, or t command was F, f, T, or t, this command shall be equivalent to an f, F, t, or T command, respectively, with the specified count and the same search character.

If there was no previous F, f, T, or t command, it shall be an error.

Repeat

Synopsis: \[\text{[count]} . \]

Repeat the last !, <, >, A, C, D, I, J, O, P, R, S, X, Y, a, c, d, i, o, p, r, s, x, y, or ^ command. It shall be an error if none of these commands have been executed. Commands (other than commands that enter text input mode) executed as a result of map expansions, shall not change the value of the last repeatable command.

Repeated commands with associated motion commands shall repeat the motion command as well; however, any specified count shall replace the count(s) that were originally specified to the repeated command or its associated motion command.

If the motion component of the repeated command is f, F, t, or T, the repeated command shall not set the remembered search character for the ; and , commands.

If the repeated command is p or P, and the buffer associated with that command was a numeric buffer named with a number less than 9, the buffer associated with the repeated command shall be set to be the buffer named by the name of the previous buffer logically incremented by 1.
If the repeated character is a text input command, the input text associated with that command is repeated literally:

- Input characters are neither macro or abbreviation-expanded.
- Input characters are not interpreted in any special way with the exception that `<newline>`, `<carriage-return>`, and `<control>-T` behave as described in Input Mode Commands in `vi` (on page 1022).

**Current line:** Set as described for the repeated command.

**Current column:** Set as described for the repeated command.

### Find Regular Expression

**Synopsis:**

```
/                 
```

If the input line contains no non-`<newline>`s, it shall be equivalent to a line containing only the last regular expression encountered. The enhanced regular expressions supported by `vi` are described in Regular Expressions in `ex` (on page 391).

Otherwise, the line shall be interpreted as one or more regular expressions, optionally followed by an address offset or a `vi` `z` command.

If the regular expression is not the last regular expression on the line, or if a line offset or `z` command is specified, the regular expression shall be terminated by an unescaped `'/'` character, which shall not be used as part of the regular expression. If the regular expression is not the first regular expression on the line, it shall be preceded by zero or more `<blank>`s, a semicolon, zero or more `<blank>`s, and a leading `'/'` character, which shall not be interpreted as part of the regular expression. It shall be an error to precede any regular expression with any characters other than these.

Each search shall begin from the character after the first character of the last match (or, if it is the first search, after the cursor). If the `wrapscan` edit option is set, the search shall continue to the character before the starting cursor character; otherwise, to the end of the edit buffer. It shall be an error if any search fails to find a match, and an informational message to this effect shall be displayed.

An optional address offset (see Addressing in `ex` (on page 361)) can be specified after the last regular expression by including a trailing `'/'` character after the regular expression and specifying the address offset. This offset will be from the line containing the match for the last regular expression specified. It shall be an error if the line offset would indicate a line address less than 1 or greater than the last line in the edit buffer. An address offset of zero shall be supported. It shall be an error to follow the address offset with any other characters than `<blank>`s.

If not used as a motion command, an optional `z` command (see Redraw Window (on page 1021)) can be specified after the last regular expression by including a trailing `'/'` character after the regular expression, zero or more `<blank>`s, a `'z'`, zero or more `<blank>`s, an optional new `window` edit option value, zero or more `<blank>`s, and a location character. The effect shall be as if the `z` command was executed after the `/` command. It shall be an error to follow the `z` command with any other characters than `<blank>`s.

The remembered search direction shall be set to forward.

If used as a motion command:

1. It shall be an error if the last match references the same character in the edit buffer as the starting cursor.
2. If any address offset is specified, the last match shall be adjusted by the specified offset as described previously.

3. If the starting cursor is after the last match, then the locations of the starting cursor and the last match in the edit buffer shall be logically swapped.

4. If any address offset is specified, the text region shall consist of all lines containing characters from the starting cursor to the last match line, inclusive, and any text copied to a buffer shall be in line mode.

5. Otherwise, if the starting line is empty or the starting cursor is at or before the first non-<blank> non-<newline> of the starting line, and the last match line is empty or the last match starts at the first character of the last match line, the text region shall consist of all lines containing characters from the starting cursor to the line before the last match line, inclusive, and any text copied to a buffer shall be in line mode.

6. Otherwise, if the last match line is empty or the last match begins at a character at or before the first non-<blank> non-<newline> of the last match line, the region of text shall be from the current cursor to the last non-<newline> of the line before the last match line, inclusive, and any text copied to a buffer shall be in character mode.

7. Otherwise, the region of text shall be from the current cursor (inclusive), to the first character of the last match (exclusive), and any text copied to a buffer shall be in character mode.

If not used as a motion command:

- **Current line**: If a match is found, set to the last matched line plus the address offset, if any; otherwise, unchanged.
- **Current column**: Set to the last column on which any portion of the first character in the last matched string is displayed, if a match is found; otherwise, unchanged.

### Move to First Character in Line

**Synopsis**: 0 (zero)

Move to the first character on the current line. The character '0' shall not be interpreted as a command if it is immediately preceded by a digit.

If used as a motion command:

1. If the cursor character is the first character in the line, it shall be an error.

2. The text region shall be from the character before the cursor character up to and including the first character in the line.

3. Any text copied to a buffer shall be in character mode.

If not used as a motion command:

- **Current line**: Unchanged.
- **Current column**: The last column in which any portion of the first character in the line is displayed, or if the line is empty, unchanged.
Execute an ex Command

Synopsis: 

Execute one or more ex commands.

If any portion of the screen other than the last line of the screen was overwritten by any ex command (except shell), vi shall display a message indicating that it is waiting for an input from the user, and shall then read a character. This action may also be taken for other, unspecified reasons.

If the next character entered is a ‘:’, another ex command shall be accepted and executed. Any other character shall cause the screen to be refreshed and vi shall return to command mode.

Current line: As specified for the ex command.

Current column: As specified for the ex command.

Repeat Find

Synopsis: [count] ;

This command shall be equivalent to the last F, f, T, or t command, with the specified count, and with the same search character used for the last F, f, T, or t command. If there was no previous F, f, T, or t command, it shall be an error.

Shift Left

Synopsis: [count] < motion

If the motion command is the < command repeated:

1. If there are less than count –1 lines after the current line in the edit buffer, it shall be an error.

2. The text region shall be from the current line, up to and including the next count –1 lines.

Shift any line in the text region specified by the count and motion command one shiftwidth (see the ex shiftwidth option) toward the start of the line, as described by the ex < command. The unshifted lines shall be copied to the unnamed buffer in line mode.

Current line: If the motion was from the current cursor position toward the end of the edit buffer, unchanged. Otherwise, set to the first line in the edit buffer that is part of the text region specified by the motion command.

Current column: Set to non-<blank>.

Shift Right

Synopsis: [count] > motion

If the motion command is the > command repeated:

1. If there are less than count –1 lines after the current line in the edit buffer, it shall be an error.

2. The text region shall be from the current line, up to and including the next count –1 lines.

Shift any line with characters in the text region specified by the count and motion command one shiftwidth (see the ex shiftwidth option) away from the start of the line, as described by the ex > command. The unshifted lines shall be copied into the unnamed buffer in line mode.
Current line: If the motion was from the current cursor position toward the end of the edit buffer, unchanged. Otherwise, set to the first line in the edit buffer that is part of the text region specified by the motion command.

Current column: Set to non-<blank>.

Scan Backwards for Regular Expression

Synopsis: `?`

Scan backwards; the `?` command shall be equivalent to the `/` command (see Find Regular Expression (on page 1004)) with the following exceptions:

1. The input prompt shall be a `'?'`.
2. Each search shall begin from the character before the first character of the last match (or, if it is the first search, the character before the cursor character).
3. The search direction shall be from the cursor toward the beginning of the edit buffer, and the `wrapscan` edit option shall affect whether the search wraps to the end of the edit buffer and continues.
4. The remembered search direction shall be set to backward.

Execute

Synopsis: `@buffer`

If the `buffer` is specified as `@`, the last buffer executed shall be used. If no previous buffer has been executed, it shall be an error.

Behave as if the contents of the named buffer were entered as standard input. After each line of a line-mode buffer, and all but the last line of a character mode buffer, behave as if a `<newline>` were entered as standard input.

If an error occurs during this process, an error message shall be written, and no more characters resulting from the execution of this command shall be processed.

If a `count` is specified, behave as if that count were entered as user input before the characters from the `@ buffer` were entered.

Current line: As specified for the individual commands.

Current column: As specified for the individual commands.

Reverse Case

Synopsis: `[count] ~`

Reverse the case of the current character and the next `count` −1 characters, such that lowercase characters that have uppercase counterparts shall be changed to uppercase characters, and uppercase characters that have lowercase counterparts shall be changed to lowercase characters, as prescribed by the current locale. No other characters shall be affected by this command.

If there are less than `count` −1 characters after the cursor in the edit buffer, `count` shall be adjusted to the number of characters after the cursor in the edit buffer minus 1.

For the purposes of this command, the next character after the last non-<newline> on the line shall be the next character in the edit buffer.

Current line: Set to the line including the `(count−1)th` character after the cursor.
Current column: Set to the last column in which any portion of the \((count-1)\)th character after the cursor is displayed.

Append

Synopsis:  \([count] a\)

Enter text input mode after the current cursor position. No characters already in the edit buffer shall be affected by this command. A \(count\) shall cause the input text to be appended \(count - 1\) more times to the end of the input.

Current line/column: As specified for the text input commands (see Input Mode Commands in vi (on page 1022)).

Append at End-of-Line

Synopsis:  \([count] A\)

This command shall be equivalent to the \(vi\) command:

\($ [ count ] a\)

(see Append).

Move Backward to Preceding Word

Synopsis:  \([count] b\)

With the exception that words are used as the delimiter instead of bigwords, this command shall be equivalent to the \(B\) command.

Move Backward to Preceding Bigword

Synopsis:  \([count] B\)

If the edit buffer is empty or the cursor is on the first character of the edit buffer, it shall be an error. If less than \(count\) bigwords begin between the cursor and the start of the edit buffer, \(count\) shall be adjusted to the number of bigword beginnings between the cursor and the start of the edit buffer.

If used as a motion command:

1. The text region shall be from the first character of the \(count\)th previous bigword beginning up to but not including the cursor character.

2. Any text copied to a buffer shall be in character mode.

If not used as a motion command:

Current line: Set to the line containing the current column.

Current column: Set to the last column upon which any part of the first character of the \(count\)th previous bigword is displayed.
Change

Synopsis: \([\text{buffer}] \ [\text{count}] \ c \ \text{motion}\)

If the motion command is the \(c\) command repeated:

1. The buffer text shall be in line mode.
2. If there are less than \(\text{count} - 1\) lines after the current line in the edit buffer, it shall be an error.
3. The text region shall be from the current line up to and including the next \(\text{count} - 1\) lines.

Otherwise, the buffer text mode and text region shall be as specified by the motion command.

The replaced text shall be copied into \(\text{buffer}\), if specified, and into the unnamed buffer. If the text to be replaced contains characters from more than a single line, or the buffer text is in line mode, the replaced text shall be copied into the numeric buffers as well.

If the buffer text is in line mode:

1. Any lines that contain characters in the region shall be deleted, and the editor shall enter text input mode at the beginning of a new line which shall replace the first line deleted.
2. If the \text{autoindent} edit option is set, \text{autoindent} characters equal to the \text{autoindent} characters on the first line deleted shall be inserted as if entered by the user.

Otherwise, if characters from more than one line are in the region of text:

1. The text shall be deleted.
2. Any text remaining in the last line in the text region shall be appended to the first line in the region, and the last line in the region shall be deleted.
3. The editor shall enter text input mode after the last character not deleted from the first line in the text region, if any; otherwise, on the first column of the first line in the region.

Otherwise:

1. If the glyph for \('\$'\) is smaller than the region, the end of the region shall be marked with a \('\$'\).
2. The editor shall enter text input mode, overwriting the region of text.

Current line/column: As specified for the text input commands (see \text{Input Mode Commands in vi} (on page 1022)).

Change to End-of-Line

Synopsis: \([\text{buffer}] \ [\text{count}] \ C\)

This command shall be equivalent to the \text{vi} command:

\([\text{buffer}] \ [\text{count}] \ c\$\)

See the \(c\) command.
Delete

Synopsis: \texttt{[buffer]} \texttt{[count]} \texttt{d} \texttt{motion}

If the motion command is the \texttt{d} command repeated:

1. The buffer text shall be in line mode.
2. If there are less than \texttt{count} – 1 lines after the current line in the edit buffer, it shall be an error.
3. The text region shall be from the current line up to and including the next \texttt{count} – 1 lines.

Otherwise, the buffer text mode and text region shall be as specified by the motion command.

If in open mode, and the current line is deleted, and the line remains on the display, an ‘@’ character shall be displayed as the first glyph of that line.

Delete the region of text into \texttt{buffer}, if specified, and into the unnamed buffer. If the text to be deleted contains characters from more than a single line, or the buffer text is in line mode, the deleted text shall be copied into the numeric buffers, as well.

Current line: Set to the first text region line that appears in the edit buffer, unless that line has been deleted, in which case it shall be set to the last line in the edit buffer, or line 1 if the edit buffer is empty.

Current column:

1. If the line is empty, set to column position 1.
2. Otherwise, if the buffer text is in line mode or the motion was from the cursor toward the end of the edit buffer:
   a. If a character from the current line is displayed in the current column, set to the last column that displays any portion of that character.
   b. Otherwise, set to the last column in which any portion of any character in the line is displayed.
3. Otherwise, if a character is displayed in the column that began the text region, set to the last column that displays any portion of that character.
4. Otherwise, set to the last column in which any portion of any character in the line is displayed.

Delete to End-of-Line

Synopsis: \texttt{[buffer]} \texttt{D}

Delete the text from the current position to the end of the current line; equivalent to the \textit{vi} command:

\texttt{[buffer]} \texttt{d$}
Move to End-of-Word

Synopsis: \([\text{count}] \text{ e}\)

With the exception that words are used instead of bigwords as the delimiter, this command shall be equivalent to the \(E\) command.

Move to End-of-Bigword

Synopsis: \([\text{count}] \text{ E}\)

If the edit buffer is empty it shall be an error. If less than \(\text{count}\) bigwords end between the cursor and the end of the edit buffer, \(\text{count}\) shall be adjusted to the number of bigword endings between the cursor and the end of the edit buffer.

If used as a motion command:

1. The text region shall be from the last character of the \(\text{count}\)th next bigword up to and including the cursor character.
2. Any text copied to a buffer shall be in character mode.

If not used as a motion command:

Current line: Set to the line containing the current column.
Current column: Set to the last column upon which any part of the last character of the \(\text{count}\)th next bigword is displayed.

Find Character in Current Line (Forward)

Synopsis: \([\text{count}] \text{ f character}\)

It shall be an error if \(\text{count}\) occurrences of the character do not occur after the cursor in the line.

If used as a motion command:

1. The text range shall be from the cursor character up to and including the \(\text{count}\)th occurrence of the specified character after the cursor.
2. Any text copied to a buffer shall be in character mode.

If not used as a motion command:

Current line: Unchanged.
Current column: Set to the last column in which any portion of the \(\text{count}\)th occurrence of the specified character after the cursor appears in the line.

Find Character in Current Line (Reverse)

Synopsis: \([\text{count}] \text{ F character}\)

It shall be an error if \(\text{count}\) occurrences of the character do not occur before the cursor in the line.

If used as a motion command:

1. The text region shall be from the \(\text{count}\)th occurrence of the specified character before the cursor, up to, but not including the cursor character.
2. Any text copied to a buffer shall be in character mode.

If not used as a motion command:
Current line: Unchanged.

Current column: Set to the last column in which any portion of the count\textsuperscript{th} occurrence of the specified character before the cursor appears in the line.

**Move to Line**

**Synopsis:** \([\text{count}]\ G\)

If count is not specified, it shall default to the last line of the edit buffer. If count is greater than the last line of the edit buffer, it shall be an error.

If used as a motion command:

1. The text region shall be from the cursor line up to and including the specified line.
2. Any text copied to a buffer shall be in line mode.

If not used as a motion command:

Current line: Set to count if count is specified; otherwise, the last line.

Current column: Set to non-<blank>.

**Move to Top of Screen**

**Synopsis:** \([\text{count}]\ H\)

If the beginning of the line count greater than the first line of which any portion appears on the display does not exist, it shall be an error.

If used as a motion command:

1. If in open mode, the text region shall be the current line.
2. Otherwise, the text region shall be from the starting line up to and including (the first line of the display + count −1).
3. Any text copied to a buffer shall be in line mode.

If not used as a motion command:

If in open mode, this command shall set the current column to non-<blank> and do nothing else.

Otherwise, it shall set the current line and current column as follows.

Current line: Set to (the first line of the display + count −1).

Current column: Set to non-<blank>.

**Insert Before Cursor**

**Synopsis:** \([\text{count}]\ i\)

Enter text input mode before the current cursor position. No characters already in the edit buffer shall be affected by this command. A count shall cause the input text to be appended count −1 more times to the end of the input.

Current line/column: As specified for the text input commands (see Input Mode Commands in vi (on page 1022)).
Insert at Beginning of Line

Synopsis:  \([count] \ I\)

This command shall be equivalent to the \(vi\) command \([\text{count}] i\).

Join

Synopsis:  \([count] \ J\)

If the current line is the last line in the edit buffer, it shall be an error.

This command shall be equivalent to the \(ex\) join command with no addresses, and an \(ex\) command \(\text{count}\) value of 1 if \(\text{count}\) was not specified or if a \(\text{count}\) of 1 was specified, and an \(ex\) command \(\text{count}\) value of \(\text{count} - 1\) for any other value of \(\text{count}\), except that the current line and column shall be set as follows.

Current line: Unchanged.

Current column: The last column in which any portion of the character following the last character in the initial line is displayed, or the last non-<newline> in the line if no characters were appended.

Move to Bottom of Screen

Synopsis:  \([count] \ L\)

If the beginning of the line \(\text{count}\) less than the last line of which any portion appears on the display does not exist, it shall be an error.

If used as a motion command:

1. If in open mode, the text region shall be the current line.

2. Otherwise, the text region shall include all lines from the starting cursor line to (the last line of the display \(-(\text{count} - 1)\)).

3. Any text copied to a buffer shall be in line mode.

If not used as a motion command:

1. If in open mode, this command shall set the current column to non-<blank> and do nothing else.

2. Otherwise, it shall set the current line and current column as follows.

Current line: Set to (the last line of the display \(-(\text{count} - 1)\)).

Current column: Set to non-<blank>.

Mark Position

Synopsis:  \(m\ \text{letter}\)

This command shall be equivalent to the \(ex\) mark command with the specified character as an argument.
Move to Middle of Screen

Synopsis: $M$

The middle line of the display shall be calculated as follows:

$(\text{the top line of the display}) + (((\text{number of lines displayed}) +1)/2) -1$

If used as a motion command:

1. If in open mode, the text region shall be the current line.
2. Otherwise, the text region shall include all lines from the starting cursor line up to and including the middle line of the display.
3. Any text copied to a buffer shall be in line mode.

If not used as a motion command:

1. If in open mode, this command shall set the current column to non-<blank> and do nothing else.
2. Otherwise, it shall set the current line and current column as follows.
   - Current line: Set to the middle line of the display.
   - Current column: Set to non-<blank>.

Repeat Regular Expression Find (Forward)

Synopsis: $n$

If the remembered search direction was forward, the $n$ command shall be equivalent to the $vi$ / command with no characters entered by the user. Otherwise, it shall be equivalent to the $vi$ ? command with no characters entered by the user.

If the $n$ command is used as a motion command for the ! command, the editor shall not enter text input mode on the last line on the screen, and shall behave as if the user entered a single '!' character as the text input.

Repeat Regular Expression Find (Reverse)

Synopsis: $N$

Scan for the next match of the last pattern given to / or ?, but in the reverse direction; this is the reverse of $n$.

If the remembered search direction was forward, the $N$ command shall be equivalent to the $vi$ ? command with no characters entered by the user. Otherwise, it shall be equivalent to the $vi$ / command with no characters entered by the user. If the $N$ command is used as a motion command for the ! command, the editor shall not enter text input mode on the last line on the screen, and shall behave as if the user entered a single '!' character as the text input.

Insert Empty Line Below

Synopsis: $o$

Enter text input mode in a new line appended after the current line. A $count$ shall cause the input text to be appended $count -1$ more times to the end of the already added text, each time starting on a new, appended line.

Current line/column: As specified for the text input commands (see Input Mode Commands in vi (on page 1022)).
Insert Empty Line Above

Synopsis:  \( O \)

Enter text input mode in a new line inserted before the current line. A \( count \) shall cause the input text to be appended \( count -1 \) more times to the end of the already added text, each time starting on a new, appended line.

Current line/column: As specified for the text input commands (see Input Mode Commands in vi (on page 1022)).

Put from Buffer Following

Synopsis:  \([buffer]\) p

If no \( buffer \) is specified, the unnamed buffer shall be used.

If the buffer text is in line mode, the text shall be appended below the current line, and each line of the buffer shall become a new line in the edit buffer. A \( count \) shall cause the buffer text to be appended \( count -1 \) more times to the end of the already added text, each time starting on a new, appended line.

If the buffer text is in character mode, the text shall be appended into the current line after the cursor, and each line of the buffer other than the first and last shall become a new line in the edit buffer. A \( count \) shall cause the buffer text to be appended \( count -1 \) more times to the end of the already added text, each time starting after the last added character.

Current line: If the buffer text is in line mode, set the line to line +1; otherwise, unchanged.

Current column: If the buffer text is in line mode:

1. If there is a non-<blank> in the first line of the buffer, set to the last column on which any portion of the first non-<blank> in the line is displayed.
2. If there is no non-<blank> in the first line of the buffer, set to the last column on which any portion of the last non-<newline> in the first line of the buffer is displayed.

If the buffer text is in character mode:

1. If the text in the buffer is from more than a single line, then set to the last column on which any portion of the first character from the buffer is displayed.
2. Otherwise, if the buffer is the unnamed buffer, set to the last column on which any portion of the last character from the buffer is displayed.
3. Otherwise, set to the first column on which any portion of the first character from the buffer is displayed.

Put from Buffer Before

Synopsis:  \([buffer]\) P

If no \( buffer \) is specified, the unnamed buffer shall be used.

If the buffer text is in line mode, the text shall be inserted above the current line, and each line of the buffer shall become a new line in the edit buffer. A \( count \) shall cause the buffer text to be appended \( count -1 \) more times to the end of the already added text, each time starting on a new, appended line.

If the buffer text is in character mode, the text shall be inserted into the current line before the cursor, and each line of the buffer other than the first and last shall become a new line in the edit buffer. A \( count \) shall cause the buffer text to be appended \( count -1 \) more times to the end of the
already added text, each time starting after the last added character.

Current line: Unchanged.

Current column: If the buffer text is in line mode:

1. If there is a non-<blank> in the first line of the buffer, set to the last column on which any portion of that character is displayed.
2. If there is no non-<blank> in the first line of the buffer, set to the last column on which any portion of the last non-<newline> in the first line of the buffer is displayed.

If the buffer text is in character mode:

1. If the buffer is the unnamed buffer, set to the last column on which any portion of the last character from the buffer is displayed.
2. Otherwise, set to the first column on which any portion of the first character from the buffer is displayed.

Enter ex Mode

Synopsis: Q

Leave visual or open mode and enter ex command mode.

Current line: Unchanged.

Current column: Unchanged.

Replace Character

Synopsis: [count] r character

Replace the count characters at and after the cursor with the specified character. If there are less than count non-<newline>s at and after the cursor on the line, it shall be an error.

If character is <control>-V, any next character other than the <newline> shall be stripped of any special meaning and used as a literal character.

If character is <ESC>, no replacement shall be made and the current line and current column shall be unchanged.

If character is <carriage-return> or <newline>, count new lines shall be appended to the current line. All but the last of these lines shall be empty. count characters at and after the cursor shall be discarded, and any remaining characters after the cursor in the current line shall be moved to the last of the new lines. If the autoindent edit option is set, they shall be preceded by the same number of autoindent characters found on the line from which the command was executed.

Current line: Unchanged unless the replacement character is a <carriage-return> or <newline>, in which case it shall be set to line + count.

Current column: Set to the last column position on which a portion of the last replaced character is displayed, or if the replacement character caused new lines to be created, set to non-<blank>.
Replace Characters

Synopsis: R

Enter text input mode at the current cursor position possibly replacing text on the current line. A

count shall cause the input text to be appended count -1 more times to the end of the input.

Current line/column: As specified for the text input commands (see Input Mode Commands in vi
(on page 1022)).

Substitute Character

Synopsis: [buffer] [count] s

This command shall be equivalent to the vi command:

[buffer] [count] c<space>

Substitute Lines

Synopsis: [buffer] [count] S

This command shall be equivalent to the vi command:

[buffer] [count] c_

Move Cursor to Before Character (Forward)

Synopsis: [count] t character

It shall be an error if count occurrences of the character do not occur after the cursor in the line.

If used as a motion command:

1. The text region shall be from the cursor up to but not including the count th occurrence of
   the specified character after the cursor.

2. Any text copied to a buffer shall be in character mode.

If not used as a motion command:

Current line: Unchanged.

Current column: Set to the last column in which any portion of the character before the count th
occurrence of the specified character after the cursor appears in the line.

Move Cursor to After Character (Reverse)

Synopsis: [count] T character

It shall be an error if count occurrences of the character do not occur before the cursor in the line.

If used as a motion command:

1. If the character before the cursor is the specified character, it shall be an error.

2. The text region shall be from the character before the cursor up to but not including the
   count th occurrence of the specified character before the cursor.

3. Any text copied to a buffer shall be in character mode.

If not used as a motion command:
Current line: Unchanged.

Current column: Set to the last column in which any portion of the character after the countth occurrence of the specified character before the cursor appears in the line.

**Undo**

**Synopsis:** \( u \)

This command shall be equivalent to the ex undo command except that the current line and current column shall be set as follows:

Current line: Set to the first line added or changed if any; otherwise, move to the line preceding any deleted text if one exists; otherwise, move to line 1.

Current column: If undoing an ex command, set to the first non-<blank>.

Otherwise, if undoing a text input command:

1. If the command was a C, c, O, o, R, S, or s command, the current column shall be set to the value it held when the text input command was entered.

2. Otherwise, set to the last column in which any portion of the first character after the deleted text is displayed, or, if no non-<newline>s follow the text deleted from this line, set to the last column in which any portion of the last non-<newline> in the line is displayed, or 1 if the line is empty.

Otherwise, if a single line was modified (that is, not added or deleted) by the u command:

1. If text was added or changed, set to the last column in which any portion of the first character added or changed is displayed.

2. If text was deleted, set to the last column in which any portion of the first character after the deleted text is displayed, or, if no non-<newline>s follow the deleted text, set to the last column in which any portion of the last non-<newline> in the line is displayed, or 1 if the line is empty.

Otherwise, set to non-<blank>.

**Undo Current Line**

**Synopsis:** \( U \)

Restore the current line to its state immediately before the most recent time that it became the current line.

Current line: Unchanged.

Current column: Set to the first column in the line in which any portion of the first character in the line is displayed.

**Move to Beginning of Word**

**Synopsis:** \([count] w\)

With the exception that words are used as the delimiter instead of bigwords, this command shall be equivalent to the \( W \) command.
Move to Beginning of Bigword

Synopsis: \([\text{count}] \ W\)

If the edit buffer is empty, it shall be an error. If there are less than \(\text{count}\) bigwords between the cursor and the end of the edit buffer, \(\text{count}\) shall be adjusted to move the cursor to the last bigword in the edit buffer.

If used as a motion command:

1. If the associated command is \(c\), \(\text{count}\) is 1, and the cursor is on a <blank>, the region of text shall be the current character and no further action shall be taken.

2. If there are less than \(\text{count}\) bigwords between the cursor and the end of the edit buffer, then the command shall succeed, and the region of text shall include the last character of the edit buffer.

3. If there are <blank>s or an end-of-line that precede the \(\text{count}\) th bigword, and the associated command is \(c\), the region of text shall be up to and including the last character before the preceding <blank>s or end-of-line.

4. If there are <blank>s or an end-of-line that precede the bigword, and the associated command is \(d\) or \(y\), the region of text shall be up to and including the last <blank> before the start of the bigword or end-of-line.

5. Any text copied to a buffer shall be in character mode.

If not used as a motion command:

1. If the cursor is on the last character of the edit buffer, it shall be an error.

Current line: Set to the line containing the current column.

Current column: Set to the last column in which any part of the first character of the \(\text{count}\) th next bigword is displayed.

Delete Character at Cursor

Synopsis: \([\text{buffer}] \ [\text{count}] \ x\)

Delete the \(\text{count}\) characters at and after the current character into \(\text{buffer}\), if specified, and into the unnamed buffer.

If the line is empty, it shall be an error. If there are less than \(\text{count}\) non-<newline>s at and after the cursor on the current line, \(\text{count}\) shall be adjusted to the number of non-<newline>s at and after the cursor.

Current line: Unchanged.

Current column: If the line is empty, set to column position 1. Otherwise, if there were \(\text{count}\) or less non-<newline>s at and after the cursor on the current line, set to the last column that displays any part of the last non-<newline> of the line. Otherwise, unchanged.
Delete Character Before Cursor

Synopsis: \[ \text{[buffer]} \ [\text{count}] \ X \]

Delete the count characters before the current character into buffer, if specified, and into the unnamed buffer.

If there are no characters before the current character on the current line, it shall be an error. If there are less than count previous characters on the current line, count shall be adjusted to the number of previous characters on the line.

Current line: Unchanged.

Current column: Set to (current column – the width of the deleted characters).

Yank

Synopsis: \[ \text{[buffer]} \ [\text{count}] \ y \ \text{motion} \]

Copy (yank) the region of text into buffer, if specified, and into the unnamed buffer.

If the motion command is the y command repeated:

1. The buffer shall be in line mode.
2. If there are less than count –1 lines after the current line in the edit buffer, it shall be an error.
3. The text region shall be from the current line up to and including the next count –1 lines.

Otherwise, the buffer text mode and text region shall be as specified by the motion command.

Current line: If the motion was from the current cursor position toward the end of the edit buffer, unchanged. Otherwise, set to the first line in the edit buffer that is part of the text region specified by the motion command.

Current column:

1. If the motion was from the current cursor position toward the end of the edit buffer, unchanged.
2. Otherwise, if the current line is empty, set to column position 1.
3. Otherwise, set to the last column that displays any part of the first character in the file that is part of the text region specified by the motion command.

Yank Current Line

Synopsis: \[ \text{[buffer]} \ [\text{count}] \ Y \]

This command shall be equivalent to the vi command:

\[ \text{[buffer]} \ [\text{count}] \ y_ \]
Redraw Window

If in open mode, the \texttt{z} command shall have the Synopsis:

\textit{Synopsis: } \texttt{[count]} \texttt{z}

If \texttt{count} is not specified, it shall default to the \texttt{window} edit option \texttt{−1}. The \texttt{z} command shall be equivalent to the \texttt{ex z} command, with a type character of \texttt{=} and a \texttt{count} of \texttt{count \texttt{−2}}, except that the current line and current column shall be set as follows, and the \texttt{window} edit option shall not be affected. If the calculation for the \texttt{count} argument would result in a negative number, the \texttt{count} argument to the \texttt{ex z} command shall be zero. A blank line shall be written after the last line is written.

\textit{Current line: Unchanged.}

\textit{Current column: Unchanged.}

If not in open mode, the \texttt{z} command shall have the following Synopsis:

\textit{Synopsis: } \texttt{[line]} \texttt{z} \texttt{[count]} \texttt{character}

If \texttt{line} is not specified, it shall default to the current line. If \texttt{line} is specified, but is greater than the number of lines in the edit buffer, it shall default to the number of lines in the edit buffer.

If \texttt{count} is specified, the value of the \texttt{window} edit option shall be set to \texttt{count} (as described in the \texttt{ex window} command), and the screen shall be redrawn.

\texttt{line} shall be placed as specified by the following characters:

\begin{itemize}
  \item \texttt{<newline>, <carriage-return>}
    \begin{itemize}
      \item Place the beginning of the line on the first line of the display.
      \item Place the beginning of the line in the center of the display. The middle line of the display shall be calculated as described for the \texttt{M} command.
      \item Place an unspecified portion of the line on the last line of the display.
    \end{itemize}
  \item \texttt{+}
    \begin{itemize}
      \item If \texttt{line} was specified, equivalent to the \texttt{<newline>} case. If \texttt{line} was not specified, display a screen where the first line of the display shall be (current last line) +1. If there are no lines after the last line in the display, it shall be an error.
    \end{itemize}
  \item \texttt{^}
    \begin{itemize}
      \item If \texttt{line} was specified, display a screen where the last line of the display shall contain an unspecified portion of the first line of a display that had an unspecified portion of the specified line on the last line of the display. If this calculation results in a line before the beginning of the edit buffer, display the first screen of the edit buffer.
      \end{itemize}
\end{itemize}

\textit{Current line: If \texttt{line} and the \texttt{‘^’} character were specified:}

1. If the first screen was displayed as a result of the command attempting to display lines before the beginning of the edit buffer: if the first screen was already displayed, unchanged; otherwise, set to (current first line \texttt{−1}).

2. Otherwise, set to the last line of the display.

If \texttt{line} and the \texttt{‘+’} character were specified, set to the first line of the display.

Otherwise, if \texttt{line} was specified, set to \texttt{line}.
Otherwise, unchanged.

Current column: Set to non-<blank>.

Exit

Synopsis: ZZ

This command shall be equivalent to the ex xit command with no addresses, trailing !, or filename (see the ex xit command).

Input Mode Commands in vi

In text input mode, the current line shall consist of zero or more of the following categories, plus the terminating <newline>:

1. Characters preceding the text input entry point
   Characters in this category shall not be modified during text input mode.

2. autoindent characters
   autoindent characters shall be automatically inserted into each line that is created in text input mode, either as a result of entering a <newline> or <carriage-return> while in text input mode, or as an effect of the command itself; for example, O or o (see the ex autoindent command), as if entered by the user.

   It shall be possible to erase autoindent characters with the <control>-D command; it is unspecified whether they can be erased by <control>-H, <control>-U, and <control>-W characters. Erasing any autoindent character turns the glyph into erase-columns and deletes the character from the edit buffer, but does not change its representation on the screen.

3. Text input characters
   Text input characters are the characters entered by the user. Erasing any text input character turns the glyph into erase-columns and deletes the character from the edit buffer, but does not change its representation on the screen.

   Each text input character entered by the user (that does not have a special meaning) shall be treated as follows:

   a. The text input character shall be appended to the last character in the edit buffer from the first, second, or third categories.

   b. If there are no erase-columns on the screen, the text input command was the R command, and characters in the fifth category from the original line follow the cursor, the next such character shall be deleted from the edit buffer. If the slowopen edit option is not set, the corresponding glyph on the screen shall become erase-columns.

   c. If there are erase-columns on the screen, as many columns as they occupy, or as are necessary, shall be overwritten to display the text input character. (If only part of a multi-column glyph is overwritten, the remainder shall be left on the screen, and continue to be treated as erase-columns; it is unspecified whether the remainder of the glyph is modified in any way.)

   d. If additional display line columns are needed to display the text input character:

      1. If the slowopen edit option is set, the text input characters shall be displayed on subsequent display line columns, overwriting any characters displayed in
those columns.

2. Otherwise, any characters currently displayed on or after the column on the display line where the text input character is to be displayed shall be pushed ahead the number of display line columns necessary to display the rest of the text input character.

4. Erase-columns

Erase-columns are not logically part of the edit buffer, appearing only on the screen, and may be overwritten on the screen by subsequent text input characters. When text input mode ends, all erase-columns shall no longer appear on the screen.

Erase-columns are initially the region of text specified by the \texttt{c} command (see \texttt{Change} (on page 1009)); however, erasing \texttt{autoindent} or text input characters causes the glyphs of the erased characters to be treated as erase-columns.

5. Characters following the text region for the \texttt{c} command, or the text input entry point for all other commands

Characters in this category shall not be modified during text input mode, except as specified in category 3.b. for the \texttt{R} text input command, or as <blank>s deleted when a <newline> or <carriage-return> is entered.

It is unspecified whether it is an error to attempt to erase past the beginning of a line that was created by the entry of a <newline> or <carriage-return> during text input mode. If it is not an error, the editor shall behave as if the erasing character was entered immediately after the last text input character entered on the previous line, and all of the non-<newline>s on the current line shall be treated as erase-columns.

When text input mode is entered, or after a text input mode character is entered (except as specified for the special characters below), the cursor shall be positioned as follows:

1. On the first column that displays any part of the first erase-column, if one exists

2. Otherwise, if the \texttt{slowopen} edit option is set, on the first display line column after the last character in the first, second, or third categories, if one exists

3. Otherwise, the first column that displays any part of the first character in the fifth category, if one exists

4. Otherwise, the display line column after the last character in the first, second, or third categories, if one exists

5. Otherwise, on column position 1

The characters that are updated on the screen during text input mode are unspecified, other than that the last text input character shall always be updated, and, if the \texttt{slowopen} edit option is not set, the current cursor character shall always be updated.

The following specifications are for command characters entered during text input mode.
Utilities

NUL

Synopsis:  NUL

If the first character of the text input is a NUL, the most recently input text shall be input as if entered by the user, and then text input mode shall be exited. The text shall be input literally; that is, characters are neither macro or abbreviation expanded, nor are any characters interpreted in any special manner. It is unspecified whether implementations shall support more than 256 bytes of remembered input text.

<control>-D

Synopsis:  <control>-D

The <control>-D character shall have no special meaning when in text input mode for a line-oriented command (see Command Descriptions in vi (on page 988)).

This command need not be supported on block-mode terminals.

If the cursor does not follow an autoindent character, or an autoindent character and a ‘0’ or ‘ˆ’ character:

1. If the cursor is in column position 1, the <control>-D character shall be discarded and no further action taken.
2. Otherwise, the <control>-D character shall have no special meaning.

If the last input character was a ‘0’, the cursor shall be moved to column position 1.

Otherwise, if the last input character was a ‘ˆ’, the cursor shall be moved to column position 1. In addition, the autoindent level for the next input line shall be derived from the same line from which the autoindent level for the current input line was derived.

Otherwise, the cursor shall be moved back to the column after the previous shiftwidth (see the ex shiftwidth command) boundary.

All of the glyphs on columns between the starting cursor position and (inclusively) the ending cursor position shall become erase-columns as described in Input Mode Commands in vi (on page 1022).

Current line: Unchanged.

Current column: Set to 1 if the <control>-D was preceded by a ‘ˆ’ or ‘0’; otherwise, set to (column −1) −((column −2) % shiftwidth).

<control>-H

Synopsis:  <control>-H

If in text input mode for a line-oriented command, and there are no characters to erase, text input mode shall be terminated, no further action shall be done for this command, and the current line and column shall be unchanged.

If there are characters other than autoindent characters that have been input on the current line before the cursor, the cursor shall move back one character.

Otherwise, if there are autoindent characters on the current line before the cursor, it is implementation-defined whether the <control>-H command is an error or if the cursor moves back one autoindent character.

Otherwise, if the cursor is in column position 1 and there are previous lines that have been input, it is implementation-defined whether the <control>-H command is an error or if it is equivalent
to entering <control>-H after the last input character on the previous input line.

Otherwise, it shall be an error.

All of the glyphs on columns between the starting cursor position and (inclusively) the ending
cursor position shall become erase-columns as described in Input Mode Commands in vi (on
page 1022).

The current erase character (see stty) shall cause an equivalent action to the <control>-H
command, unless the previously inserted character was a backslash, in which case it shall be as
if the literal current erase character had been inserted instead of the backslash.

Current line: Unchanged, unless previously input lines are erased, in which case it shall be set to
line −1.

Current column: Set to the first column that displays any portion of the character backed up
over.

Synopsis:
<newline>
<carriage-return>
<control>-J
<control>-M

If input was part of a line-oriented command, text input mode shall be terminated and the
command shall continue execution with the input provided.

Otherwise, terminate the current line. If there are no characters other than autoindent characters
on the line, all characters on the line shall be discarded. Otherwise, it is unspecified whether the
autoindent characters in the line are modified by entering these characters.

Continue text input mode on a new line appended after the current line. If the slowopen edit
option is set, the lines on the screen below the current line shall not be pushed down, but the
first of them shall be cleared and shall appear to be overwritten. Otherwise, the lines of the
screen below the current line shall be pushed down.

If the autoindent edit option is set, an appropriate number of autoindent characters shall be
added as a prefix to the line as described by the ex autoindent edit option.

All columns after the cursor that are erase-columns (as described in Input Mode Commands in
vi (on page 1022)) shall be discarded.

If the autoindent edit option is set, all <blank>s immediately following the cursor shall be
discarded.

All remaining characters after the cursor shall be transferred to the new line, positioned after any
autoindent characters.

Current line: Set to current line +1.

Current column: Set to the first column that displays any portion of the first character after the
autoindent characters on the new line, if any, or the first column position after the last
autoindent character, if any, or column position 1.
<control>-T

Synopsis: <control>-T

The <control>-T character shall have no special meaning when in text input mode for a line-oriented command (see Command Descriptions in vi (on page 988)).

This command need not be supported on block-mode terminals.

Behave as if the user entered the minimum number of <blank>s necessary to move the cursor forward to the column position after the next shiftwidth (see the ex shiftwidth command) boundary.

Current line: Unchanged.

Current column: Set to column + shiftwidth - ((column -1) % shiftwidth).

<control>-U

Synopsis: <control>-U

If there are characters other than autoindent characters that have been input on the current line before the cursor, the cursor shall move to the first character input after the autoindent characters.

Otherwise, if there are autoindent characters on the current line before the cursor, it is implementation-defined whether the <control>-U command is an error or if the cursor moves to the first column position on the line.

Otherwise, if the cursor is in column position 1 and there are previous lines that have been input, it is implementation-defined whether the <control>-U command is an error or if it is equivalent to entering <control>-U after the last input character on the previous input line.

Otherwise, it shall be an error.

All of the glyphs on columns between the starting cursor position and (inclusively) the ending cursor position shall become erase-columns as described in Input Mode Commands in vi (on page 1022).

The current kill character (see stty) shall cause an equivalent action to the <control>-U command, unless the previously inserted character was a backslash, in which case it shall be as if the literal current kill character had been inserted instead of the backslash.

Current line: Unchanged, unless previously input lines are erased, in which case it shall be set to line −1.

Current column: Set to the first column that displays any portion of the last character backed up over.

<control>-V

Synopsis: <control>-V

Allow the entry of any subsequent character, other than <control>-J or the <newline>, as a literal character, removing any special meaning that it may have to the editor in text input mode. If a <control>-V or <control>-Q is entered before a <control>-J or <newline>, the <control>-V or <control>-Q character shall be discarded, and the <control>-J or <newline> shall behave as described in the <newline> command character during input mode.
For purposes of the display only, the editor shall behave as if a ‘^’ character was entered, and
the cursor shall be positioned as if overwriting the ‘^’ character. When a subsequent character
is entered, the editor shall behave as if that character was entered instead of the original
<control>-V or <control>-Q character.

Current line: Unchanged.
Current column: Unchanged.

<control>-W

Synopsis: <control>-W

If there are characters other than autoindent characters that have been input on the current line
before the cursor, the cursor shall move back over the last word preceding the cursor (including
any <blank>s between the end of the last word and the current cursor); the cursor shall not
move to before the first character after the end of any autoindent characters.

Otherwise, if there are autoindent characters on the current line before the cursor, it is
implementation-defined whether the <control>-W command is an error or if the cursor moves to
the first column position on the line.

Otherwise, if the cursor is in column position 1 and there are previous lines that have been input,
it is implementation-defined whether the <control>-W command is an error or if it is equivalent
to entering <control>-W after the last input character on the previous input line.

Otherwise, it shall be an error.

All of the glyphs on columns between the starting cursor position and (inclusively) the ending
cursor position shall become erase-columns as described in Input Mode Commands in vi (on
page 1022).

Current line: Unchanged, unless previously input lines are erased, in which case it shall be set to
line −1.

Current column: Set to the first column that displays any portion of the last character backed up
over.

<ESC>

Synopsis: <ESC>

If input was part of a line-oriented command:

1. If interrupt was entered, text input mode shall be terminated and the editor shall return to
command mode. The terminal shall be alerted.

2. If <ESC> was entered, text input mode shall be terminated and the command shall
continue execution with the input provided.

Otherwise, terminate text input mode and return to command mode.

Any autoindent characters entered on newly created lines that have no other non-<newline>s
shall be deleted.

Any leading autoindent and <blank>s on newly created lines shall be rewritten to be the
minimum number of <blank>s possible.

The screen shall be redisplayed as necessary to match the contents of the edit buffer.

Current line: Unchanged.
Current column:
1. If there are text input characters on the current line, the column shall be set to the last
column where any portion of the last text input character is displayed.
2. Otherwise, if a character is displayed in the current column, unchanged.
3. Otherwise, set to column position 1.

EXIT STATUS
The following exit values shall be returned:
0 Successful completion.
>0 An error occurred.

CONSEQUENCES OF ERRORS
When any error is encountered and the standard input is not a terminal device file, vi shall not
write the file or return to command or text input mode, and shall terminate with a non-zero exit
status.
Otherwise, when an unrecoverable error is encountered it shall be equivalent to a SIGHUP
asynchronous event.
Otherwise, when an error is encountered, the editor shall behave as specified in Command
Descriptions in vi (on page 988).

APPLICATION USAGE
None.

EXAMPLES
None.

RATIONALE
See the RATIONALE for ex for more information on vi. Major portions of the vi utility
specification point to ex to avoid inadvertent divergence. While ex and vi have historically been
implemented as a single utility, this is not required by IEEE Std 1003.1-2001.

It is recognized that portions of vi would be difficult, if not impossible, to implement
satisfactorily on a block-mode terminal, or a terminal without any form of cursor addressing,
thus it is not a mandatory requirement that such features should work on all terminals. It is the
intention, however, that a vi implementation should provide the full set of capabilities on all
terminals capable of supporting them.

Historically, vi exited immediately if the standard input was not a terminal. IEEE Std 1003.1-2001
permits, but does not require, this behavior. An end-of-file condition is not equivalent to an
end-of-file character. A common end-of-file character, <control>-D, is historically a vi command.

The text in the STDOUT section reflects the usage of the verb display in this section; some
implementations of vi use standard output to write to the terminal, but IEEE Std 1003.1-2001
does not require that to be the case.

Historically, implementations reverted to open mode if the terminal was incapable of
supporting full visual mode. IEEE Std 1003.1-2001 requires this behavior. Historically, the open
mode of vi behaved roughly equivalently to the visual mode, with the exception that only a
single line from the edit buffer (one "buffer line") was kept current at any time. This line was
normally displayed on the next-to-last line of a terminal with cursor addressing (and the last line
performed its normal visual functions for line-oriented commands and messages). In addition,
some few commands behaved differently in open mode than in visual mode.

IEEE Std 1003.1-2001 requires conformance to historical practice.
Historically, *ex* and *vi* implementations have expected text to proceed in the usual European/Latin order of left to right, top to bottom. There is no requirement in IEEE Std 1003.1-2001 that this be the case. The specification was deliberately written using words like “before”, “after”, “first”, and “last” in order to permit implementations to support the natural text order of the language.

Historically, lines past the end of the edit buffer were marked with single tilde (˜) characters; that is, if the one-based display was 20 lines in length, and the last line of the file was on line one, then lines 2-20 would contain only a single ˜ character.

Historically, the *vi* editor attempted to display only complete lines at the bottom of the screen (it did display partial lines at the top of the screen). If a line was too long to fit in its entirety at the bottom of the screen, the screen lines where the line would have been displayed were displayed as single ˜ characters, instead of displaying part of the line. IEEE Std 1003.1-2001 permits, but does not require, this behavior. Implementations are encouraged to attempt always to display a complete line at the bottom of the screen when doing scrolling or screen positioning by buffer lines.

Historically, lines marked with ˜ were also used to minimize output to dumb terminals over slow lines; that is, changes local to the cursor were updated, but changes to lines on the screen that were not close to the cursor were simply marked with an ˜ sign instead of being updated to match the current text. IEEE Std 1003.1-2001 permits, but does not require this feature because it is used ever less frequently as terminals become smarter and connections are faster.

**Initialization in ex and vi**

Historically, *vi* always had a line in the edit buffer, even if the edit buffer was “empty”. For example:

1. The ex command = executed from visual mode wrote “1” when the buffer was empty.

2. Writes from visual mode of an empty edit buffer wrote files of a single character (a <newline>), while writes from ex mode of an empty edit buffer wrote empty files.

3. Put and read commands into an empty edit buffer left an empty line at the top of the edit buffer.

For consistency, IEEE Std 1003.1-2001 does not permit any of these behaviors.

Historically, *vi* did not always return the terminal to its original modes; for example, ICRNL was modified if it was not originally set. IEEE Std 1003.1-2001 does not permit this behavior.

**Command Descriptions in vi**

Motion commands are among the most complicated aspects of *vi* to describe. With some exceptions, the text region and buffer type effect of a motion command on a *vi* command are described on a case-by-case basis. The descriptions of text regions in IEEE Std 1003.1-2001 are not intended to imply direction; that is, an inclusive region from line \( n \) to line \( n+5 \) is identical to a region from line \( n+5 \) to line \( n \). This is of more than academic interest—movements to marks can be in either direction, and, if the wrapscan option is set, so can movements to search points.

Historically, lines are always stored into buffers in text order; that is, from the start of the edit buffer to the end. IEEE Std 1003.1-2001 requires conformance to historical practice.

Historically, command counts were applied to any associated motion, and were multiplicative to any supplied motion count. For example, \( 2cw \) is the same as \( c2w \), and \( 2c3w \) is the same as \( c6w \). IEEE Std 1003.1-2001 requires this behavior. Historically, *vi* commands that used bigwords, words, paragraphs, and sentences as objects treated groups of empty lines, or lines that contained only <blank>s, inconsistently. Some commands treated them as a single entity, while
others treated each line separately. For example, the \textit{w}, \textit{W}, and \textit{B} commands treated groups of empty lines as individual words; that is, the command would move the cursor to each new empty line. The \textit{e} and \textit{E} commands treated groups of empty lines as a single word; that is, the first use would move past the group of lines. The \textit{b} command would just beep at the user, or if done from the start of the line as a motion command, fail in unexpected ways. If the lines contained only (or ended with) \texttt{<blank>}s, the \textit{w} and \textit{W} commands would just beep at the user, the \textit{E} and \textit{e} commands would treat the group as a single word, and the \textit{B} and \textit{b} commands would treat the lines as individual words. For consistency and simplicity of specification, IEEE Std 1003.1-2001 requires that all \textit{vi} commands treat groups of empty or blank lines as a single entity, and that movement through lines ending with \texttt{<blank>}s be consistent with other movements.

Historically, \textit{vi} documentation indicated that any number of double quotes were skipped after punctuation marks at sentence boundaries; however, implementations only skipped single quotes. IEEE Std 1003.1-2001 requires both to be skipped.

Historically, the first and last characters in the edit buffer were word boundaries. This historical practice is required by IEEE Std 1003.1-2001.

Historically, \textit{vi} attempted to update the minimum number of columns on the screen possible, which could lead to misleading information being displayed. IEEE Std 1003.1-2001 makes no requirements other than that the current character being entered is displayed correctly, leaving all other decisions in this area up to the implementation.

Historically, lines were arbitrarily folded between columns of any characters that required multiple column positions on the screen, with the exception of tabs, which terminated at the right-hand margin. IEEE Std 1003.1-2001 permits the former and requires the latter. Implementations that do not arbitrarily break lines between columns of characters that occupy multiple column positions should not permit the cursor to rest on a column that does not contain any part of a character.

The historical \textit{vi} had a problem in that all movements were by buffer lines, not by display or screen lines. This is often the right thing to do; for example, single line movements, such as \texttt{j} or \texttt{k}, should work on buffer lines. Commands like \texttt{dj}, or \texttt{j.}, where \texttt{.} is a change command, only make sense for buffer lines. It is not, however, the right thing to do for screen motion or scrolling commands like \texttt{<control>-D}, \texttt{<control>-F}, and \texttt{H}. If the window is fairly small, using buffer lines in these cases can result in completely random motion; for example, \texttt{I<control>-D} can result in a completely changed screen, without any overlap. This is clearly not what the user wanted. The problem is even worse in the case of the \texttt{H}, \texttt{L}, and \texttt{M} commands—as they position the cursor at the first non-\texttt{<blank>} of the line, they may all refer to the same location in large lines, and will result in no movement at all.

In addition, if the line is larger than the screen, using buffer lines can make it impossible to display parts of the line—there are not any commands that do not display the beginning of the line in historical \textit{vi}, and if both the beginning and end of the line cannot be on the screen at the same time, the user suffers. Finally, the page and half-page scrolling commands historically moved to the first non-\texttt{<blank>} in the new line. If the line is approximately the same size as the screen, this is inadequate because the cursor before and after a \texttt{<control>-D} command will refer to the same location on the screen.

Implementations of \textit{ex} and \textit{vi} exist that do not have these problems because the relevant commands (\texttt{<control>-B}, \texttt{<control>-D}, \texttt{<control>-F}, \texttt{<control>-U}, \texttt{<control>-Y}, \texttt{<control>-E}, \texttt{H}, \texttt{L}, and \texttt{M}) operate on display (screen) lines, not (edit) buffer lines.

IEEE Std 1003.1-2001 does not permit this behavior by default because the standard developers believed that users would find it too confusing. However, historical practice has been relaxed.
For example, `ex` and `vi` historically attempted, albeit sometimes unsuccessfully, to never put part of a line on the last lines of a screen; for example, if a line would not fit in its entirety, no part of the line was displayed, and the screen lines corresponding to the line contained single ‘@’ characters. This behavior is permitted, but not required by IEEE Std 1003.1-2001, so that it is possible for implementations to support long lines in small screens more reasonably without changing the commands to be oriented to the display (instead of oriented to the buffer). IEEE Std 1003.1-2001 also permits implementations to refuse to edit any edit buffer containing a line that will not fit on the screen in its entirety.

The display area (for example, the value of the `window` edit option) has historically been “grown”, or expanded, to display new text when local movements are done in displays where the number of lines displayed is less than the maximum possible. Expansion has historically been the first choice, when the target line is less than the maximum possible expansion value away. Scrolling has historically been the next choice, done when the target line is less than half a display away, and otherwise, the screen was redrawn. There were exceptions, however, in that `ex` commands generally always caused the screen to be redrawn. IEEE Std 1003.1-2001 does not specify a standard behavior because there may be external issues, such as connection speed, the number of characters necessary to redraw as opposed to scroll, or terminal capabilities that implementations will have to accommodate.

The current line in IEEE Std 1003.1-2001 maps one-to-one to a buffer line in the file. The current column does not. There are two different column values that are described by IEEE Std 1003.1-2001. The first is the current column value as set by many of the `vi` commands. This value is remembered for the lifetime of the editor. The second column value is the actual position on the screen where the cursor rests. The two are not always the same. For example, when the cursor is backed by a multi-column character, the actual cursor position on the screen has historically been the last column of the character in command mode, and the first column of the character in input mode.

Commands that set the current line, but that do not set the current cursor value (for example, `j` and `$` attempt to get as close as possible to the remembered column position, so that the cursor tends to restrict itself to a vertical column as the user moves around in the edit buffer. IEEE Std 1003.1-2001 requires conformance to historical practice, requiring that the display location of the cursor on the display line be adjusted from the current column value as necessary to support this historical behavior.

Historically, only a single line (and for some terminals, a single line minus 1 column) of characters could be entered by the user for the line-oriented commands; that is, `, `!, `/`, or `?`. IEEE Std 1003.1-2001 permits, but does not require, this limitation.

Historically, “soft” errors in `vi` caused the terminal to be alerted, but no error message was displayed. As a general rule, no error message was displayed for errors in command execution in `vi`, when the error resulted from the user attempting an invalid or impossible action, or when a searched-for object was not found. Examples of soft errors included `h` at the left margin, `<control>-B` or `[[` at the beginning of the file, `2G` at the end of the file, and so on. In addition, errors such as `%`, `|`, `!`, `N`, `f`, `F`, `t`, and `T` failing to find the searched-for object were soft as well. Less consistently, `l` and `?` displayed an error message if the pattern was not found, `/`, `?`, `N`, and `n` displayed an error message if no previous regular expression had been specified, and `;` did not display an error message if no previous `f`, `F`, `t`, or `T` command had occurred. Also, behavior in this area might reasonably be based on a runtime evaluation of the speed of a network connection. Finally, some implementations have provided error messages for soft errors in order to assist naive users, based on the value of a verbose edit option. IEEE Std 1003.1-2001 does not list specific errors for which an error message shall be displayed. Implementations should conform to historical practice in the absence of any strong reason to diverge.
Page Backwards

The <control>-B and <control>-F commands historically considered it an error to attempt to page past the beginning or end of the file, whereas the <control>-D and <control>-U commands simply moved to the beginning or end of the file. For consistency, IEEE Std 1003.1-2001 requires the latter behavior for all four commands. All four commands still consider it an error if the current line is at the beginning (<control>-B, <control>-U) or end (<control>-F, <control>-D) of the file. Historically, the <control>-B and <control>-F commands skip two lines in order to include overlapping lines when a single command is entered. This makes less sense in the presence of a count, as there will be, by definition, no overlapping lines. The actual calculation used by historical implementations of the vi editor for <control>-B was:

\[
((\text{current first line}) - \text{count} \times (\text{window edit option})) + 2
\]

and for <control>-F was:

\[
((\text{current first line}) + \text{count} \times (\text{window edit option})) - 2
\]

This calculation does not work well when intermixing commands with and without counts; for example, 3<control>-F is not equivalent to entering the <control>-F command three times, and is not reversible by entering the <control>-B command three times. For consistency with other vi commands that take counts, IEEE Std 1003.1-2001 requires a different calculation.

Scroll Forward

The 4BSD and System V implementations of vi differed on the initial value used by the scroll command. 4BSD used:

\[
((\text{window edit option}) + 1) / 2
\]

while System V used the value of the scroll edit option. The System V version is specified by IEEE Std 1003.1-2001 because the standard developers believed that it was more intuitive and permitted the user a method of setting the scroll value initially without also setting the number of lines that are displayed.

Scroll Forward by Line

Historically, the <control>-E and <control>-Y commands considered it an error if the last and first lines, respectively, were already on the screen. IEEE Std 1003.1-2001 requires conformance to historical practice. Historically, the <control>-E and <control>-Y commands had no effect in open mode. For simplicity and consistency of specification, IEEE Std 1003.1-2001 requires that they behave as usual, albeit with a single line screen.

Clear and Redisplay

The historical <control>-L command refreshed the screen exactly as it was supposed to be currently displayed, replacing any ‘@’ characters for lines that had been deleted but not updated on the screen with refreshed ‘@’ characters. The intent of the <control>-L command is to refresh when the screen has been accidentally overwritten; for example, by a write command from another user, or modem noise.
Redraw Screen

The historical `<control>-R` command redisplayed only when necessary to update lines that had been deleted but not updated on the screen and that were flagged with `@` characters. There is no requirement that the screen be in any way refreshed if no lines of this form are currently displayed. IEEE Std 1003.1-2001 permits implementations to extend this command to refresh lines on the screen flagged with `@` characters because they are too long to be displayed in the current framework; however, the current line and column need not be modified.

Search for tagstring

Historically, the first non-<blank> at or after the cursor was the first character, and all subsequent characters that were word characters, up to the end of the line, were included. For example, with the cursor on the leading space or on the `#` character in the text `"#bar@"`, the tag was `"#bar"`. On the character `b` it was `"bar"`, and on the `a` it was `"ar"`. IEEE Std 1003.1-2001 requires this behavior.

Replace Text with Results from Shell Command

Historically, the `<`, `>`, and `!` commands considered most cursor motions other than line-oriented motions an error; for example, the command `>/foo<CR>` succeeded, while the command `>l` failed, even though the text region described by the two commands might be identical. For consistency, all three commands only consider entire lines and not partial lines, and the region is defined as any line that contains a character that was specified by the motion.

Move to Matching Character

Other matching characters have been left implementation-defined in order to allow extensions such as matching `<` and `>` for searching HTML, or `#ifdef`, `#else`, and `#endif` for searching C source.

Repeat Substitution

IEEE Std 1003.1-2001 requires that any `c` and `g` flags specified to the previous substitute command be ignored; however, the `r` flag may still apply, if supported by the implementation.

Return to Previous (Context or Section)

The `[`, `]`, `{`, and `>` commands are all affected by “section boundaries”, but in some historical implementations not all of the commands recognize the same section boundaries. This is a bug, not a feature, and a unique section-boundary algorithm was not described for each command. One special case that is preserved is that the sentence command moves to the end of the last line of the edit buffer while the other commands go to the beginning, in order to preserve the traditional character cut semantics of the sentence command. Historically, vi section boundaries at the beginning and end of the edit buffer were the first non-<blank> on the first and last lines of the edit buffer if one exists; otherwise, the last character of the first and last lines of the edit buffer if one exists. To increase consistency with other section locations, this has been simplified by IEEE Std 1003.1-2001 to the first character of the first and last lines of the edit buffer, or the first and the last lines of the edit buffer if they are empty.

Sentence boundaries were problematic in the historical vi. They were not only the boundaries as defined for the section and paragraph commands, but they were the first non-<blank> that occurred after those boundaries, as well. Historically, the vi section commands were documented as taking an optional window size as a `count` preceding the command. This was not implemented in historical versions, so IEEE Std 1003.1-2001 requires that the `count` repeat the command, for consistency with other vi commands.
Repeat

Historically, mapped commands other than text input commands could not be repeated using
the period command. IEEE Std 1003.1-2001 requires conformance to historical practice.

The restrictions on the interpretation of special characters (for example, <control>-H) in the
repetition of text input mode commands is intended to match historical practice. For example,
given the input sequence:

```
iab<control>-H<control>-H<control>-Hdef<escape>
```

the user should be informed of an error when the sequence is first entered, but not during a
command repetition. The character <control>-T is specifically exempted from this restriction.

Historical implementations of vi ignored <control>-T characters that were input in the original
command during command repetition. IEEE Std 1003.1-2001 prohibits this behavior.

Find Regular Expression

Historically, commands did not affect the line searched to or from if the motion command was a
search (/?, N, n) and the final position was the start/end of the line. There were some special
cases and vi was not consistent. IEEE Std 1003.1-2001 does not permit this behavior, for
consistency. Historical implementations permitted but were unable to handle searches as
motion commands that wrapped (that is, due to the edit option wrapscan) to the original
location. IEEE Std 1003.1-2001 requires that this behavior be treated as an error.

Historically, the syntax "/*RE/*" was used to force the command to cut text in line mode.
IEEE Std 1003.1-2001 requires conformance to historical practice.

Historically, in open mode, a z specified to a search command redisplayed the current line
instead of displaying the current screen with the current line highlighted. For consistency and
simplicity of specification, IEEE Std 1003.1-2001 does not permit this behavior.

Historically, trailing z commands were permitted and ignored if entered as part of a search used
as a motion command. For consistency and simplicity of specification, IEEE Std 1003.1-2001 does
not permit this behavior.

Execute an ex Command

Historically, vi implementations restricted the commands that could be entered on the colon
command line (for example, append and change), and some other commands were known to
cause them to fail catastrophically. For consistency, IEEE Std 1003.1-2001 does not permit these
restrictions. When executing an ex command by entering ; it is not possible to enter a <newline>
as part of the command because it is considered the end of the command. A different approach
is to enter ex command mode by using the vi Q command (and later resuming visual mode with
the ex vi command). In ex command mode, the single-line limitation does not exist. So, for
example, the following is valid:

```
Q
s/break here/break\n
here/
vi
```

IEEE Std 1003.1-2001 requires that, if the ex command overwrites any part of the screen that
would be erased by a refresh, vi pauses for a character from the user. Historically, this character
could be any character; for example, a character input by the user before the message appeared,
or even a mapped character. This is probably a bug, but implementations that have tried to be
more rigorous by requiring that the user enter a specific character, or that the user enter a
character after the message was displayed, have been forced by user indignation back into

Shift Left (Right)

Refer to the Rationale for the ! and / commands. Historically, the < and > commands sometimes moved the cursor to the first non-blank (for example if the command was repeated or with _ as the motion command), and sometimes left it unchanged. IEEE Std 1003.1-2001 does not permit this inconsistency, requiring instead that the cursor always move to the first non-blank. Historically, the < and > commands did not support buffer arguments, although some implementations allow the specification of an optional buffer. This behavior is neither required nor disallowed by IEEE Std 1003.1-2001.

Execute

Historically, buffers could execute other buffers, and loops, infinite and otherwise, were possible. IEEE Std 1003.1-2001 requires conformance to historical practice. The *buffer syntax of ex is not required in vi, because it is not historical practice and has been used in some vi implementations to support additional scripting languages.

Reverse Case

Historically, the command ignored any associated count, and acted only on the characters in the current line. For consistency with other vi commands, IEEE Std 1003.1-2001 requires that an associated count act on the next count characters, and that the command move to subsequent lines if warranted by count, to make it possible to modify large pieces of text in a reasonably efficient manner. There exist vi implementations that optionally require an associated motion command for the command. Implementations supporting this functionality are encouraged to base it on the tildedop edit option and handle the text regions and cursor positioning identically to the yank command.

Append

Historically, counts specified to the A, a, I, and i commands repeated the input of the first line count times, and did not repeat the subsequent lines of the input text. IEEE Std 1003.1-2001 requires that the entire text input be repeated count times.

Move Backward to Preceding Word

Historically, vi became confused if word commands were used as motion commands in empty files. IEEE Std 1003.1-2001 requires that this be an error. Historical implementations of vi had a large number of bugs in the word movement commands, and they varied greatly in behavior in the presence of empty lines, "words" made up of a single character, and lines containing only blanks. For consistency and simplicity of specification, IEEE Std 1003.1-2001 does not permit this behavior.

Change to End-of-Line

Some historical implementations of the C command did not behave as described by IEEE Std 1003.1-2001 when the $ key was remapped because they were implemented by pushing the $ key onto the input queue and reprocessing it. IEEE Std 1003.1-2001 does not permit this behavior. Historically, the C, S, and s commands did not copy replaced text into the numeric buffers. For consistency and simplicity of specification, IEEE Std 1003.1-2001 requires that they behave like their respective c commands in all respects.
Delete

Historically, lines in open mode that were deleted were scrolled up, and an @ glyph written over the beginning of the line. In the case of terminals that are incapable of the necessary cursor motions, the editor erased the deleted line from the screen. IEEE Std 1003.1-2001 requires conformance to historical practice; that is, if the terminal cannot display the ‘@’ character, the line cannot remain on the screen.

Delete to End-of-Line

Some historical implementations of the D command did not behave as described by IEEE Std 1003.1-2001 when the $ key was remapped because they were implemented by pushing the $ key onto the input queue and reprocessing it. IEEE Std 1003.1-2001 does not permit this behavior.

Join

An historical oddity of vi is that the commands J, 1J, and 2J are all equivalent. IEEE Std 1003.1-2001 requires conformance to historical practice. The vi J command is specified in terms of the ex join command with an ex command count value. The address correction for a count that is past the end of the edit buffer is necessary for historical compatibility for both ex and vi.

Mark Position

Historical practice is that only lowercase letters, plus ‘ ‘ and ‘ ’, could be used to mark a cursor position. IEEE Std 1003.1-2001 requires conformance to historical practice, but encourages implementations to support other characters as marks as well.

Repeat Regular Expression Find (Forward and Reverse)

Historically, the N and n commands could not be used as motion components for the c command. With the exception of the cN command, which worked if the search crossed a line boundary, the text region would be discarded, and the user would not be in text input mode. For consistency and simplicity of specification, IEEE Std 1003.1-2001 does not permit this behavior.

Insert Empty Line (Below and Above)

Historically, counts to the O and o commands were used as the number of physical lines to open, if the terminal was dumb and the slowopen option was not set. This was intended to minimize traffic over slow connections and repainting for dumb terminals. IEEE Std 1003.1-2001 does not permit this behavior, requiring that a count to the open command behave as for other text input commands. This change to historical practice was made for consistency, and because a superset of the functionality is provided by the slowopen edit option.

Put from Buffer (Following and Before)

Historically, counts to the p and P commands were ignored if the buffer was a line mode buffer, but were (mostly) implemented as described in IEEE Std 1003.1-2001 if the buffer was a character mode buffer. Because implementations exist that do not have this limitation, and because pasting lines multiple times is generally useful, IEEE Std 1003.1-2001 requires that count be supported for all p and P commands.

Historical implementations of vi were widely known to have major problems in the p and P commands, particularly when unusual regions of text were copied into the edit buffer. The standard developers viewed these as bugs, and they are not permitted for consistency and
simplicity of specification.

Historically, a P or p command (or an ex put command executed from open or visual mode) executed in an empty file, left an empty line as the first line of the file. For consistency and simplicity of specification, IEEE Std 1003.1-2001 does not permit this behavior.

Replace Character

Historically, the r command did not correctly handle the erase and word erase characters as arguments, nor did it handle an associated count greater than 1 with a <carriage-return> argument, for which it replaced count characters with a single <newline>. IEEE Std 1003.1-2001 does not permit these inconsistencies.

Historically, the r command permitted the <control>-V escaping of entered characters, such as <ESC> and the <carriage-return>; however, it required two leading <control>-V characters instead of one. IEEE Std 1003.1-2001 requires that this be changed for consistency with the other text input commands of vi.

Historically, it is an error to enter the r command if there are less than count characters at or after the cursor in the line. While a reasonable and unambiguous extension would be to permit the r command on empty lines, it would require that too large a count be adjusted to match the number of characters at or after the cursor for consistency, which is sufficiently different from historical practice to be avoided. IEEE Std 1003.1-2001 requires conformance to historical practice.

Replace Characters

Historically, if there were autoindent characters in the line on which the R command was run, and autoindent was set, the first <newline> would be properly indented and no characters would be replaced by the <newline>. Each additional <newline> would replace n characters, where n was the number of characters that were needed to indent the rest of the line to the proper indentation level. This behavior is a bug and is not permitted by IEEE Std 1003.1-2001.

Undo

Historical practice for cursor positioning after undoing commands was mixed. In most cases, when undoing commands that affected a single line, the cursor was moved to the start of added or changed text, or immediately after deleted text. However, if the user had moved from the line being changed, the column was either set to the first non-<blank>, returned to the origin of the command, or remained unchanged. When undoing commands that affected multiple lines or entire lines, the cursor was moved to the first character in the first line restored. As an example of how inconsistent this was, a search, followed by an o text input command, followed by an undo would return the cursor to the location where the o command was entered, but a cw command followed by an o command followed by an undo would return the cursor to the first non-<blank> of the line. IEEE Std 1003.1-2001 requires the most useful of these behaviors, and discards the least useful, in the interest of consistency and simplicity of specification.
Historically, the **yank** command did not move to the end of the motion if the motion was in the forward direction. It moved to the end of the motion if the motion was in the backward direction, except for the _command, or for the G and ' commands when the end of the motion was on the current line. This was further complicated by the fact that for a number of motion commands, the **yank** command moved the cursor but did not update the screen; for example, a subsequent command would move the cursor from the end of the motion, even though the cursor on the screen had not reflected the cursor movement for the **yank** command. IEEE Std 1003.1-2001 requires that all **yank** commands associated with backward motions move the cursor to the end of the motion for consistency, and specifically, to make ' commands as motions consistent with search patterns as motions.

### Yank Current Line

Some historical implementations of the Y command did not behave as described by IEEE Std 1003.1-2001 when the ' _' key was remapped because they were implemented by pushing the ' _' key onto the input queue and reprocessing it. IEEE Std 1003.1-2001 does not permit this behavior.

### Redraw Window

Historically, the z command always redrew the screen. This is permitted but not required by IEEE Std 1003.1-2001, because of the frequent use of the z command in macros such as map n nz. for screen positioning, instead of its use to change the screen size. The standard developers believed that expanding or scrolling the screen offered a better interface for users. The ability to redraw the screen is preserved if the optional new window size is specified, and in the <control>-L and <control>-R commands.

The semantics of z' are confusing at best. Historical practice is that the screen before the screen that ended with the specified line is displayed. IEEE Std 1003.1-2001 requires conformance to historical practice.

Historically, the z command would not display a partial line at the top or bottom of the screen. If the partial line would normally have been displayed at the bottom of the screen, the command worked, but the partial line was replaced with ' @' characters. If the partial line would normally have been displayed at the top of the screen, the command would fail. For consistency and simplicity of specification, IEEE Std 1003.1-2001 does not permit this behavior.

Historically, the z command with a line specification of 1 ignored the command. For consistency and simplicity of specification, IEEE Std 1003.1-2001 does not permit this behavior.

Historically, the z command did not set the cursor column to the first non-<blank> for the character if the first screen was to be displayed, and was already displayed. For consistency and simplicity of specification, IEEE Std 1003.1-2001 does not permit this behavior.

### Input Mode Commands in vi

Historical implementations of vi did not permit the user to erase more than a single line of input, or to use normal erase characters such as line erase, word erase, and erase autoindent characters. As there exist implementations of vi that do not have these limitations, both behaviors are permitted, but only historical practice is required. In the case of these extensions, vi is required to pause at the autoindent and previous line boundaries.

Historical implementations of vi updated only the portion of the screen where the current cursor character was displayed. For example, consider the vi input keystrokes:
Historically, the <tab> would overwrite the characters "abcd" when it was displayed. Other implementations replace only the 'a' character with the <tab>, and then push the rest of the characters ahead of the cursor. Both implementations have problems. The historical implementation is probably visually nicer for the above example; however, for the keystrokes:

```
abcd<escape>0C<tab>
```

the historical implementation results in the string "bcd" disappearing and then magically reappearing when the <ESC> character is entered. IEEE Std 1003.1-2001 requires the former behavior when overwriting erase-columns—that is, overwriting characters that are no longer logically part of the edit buffer—and the latter behavior otherwise.

Historical implementations of vi discarded the <control>-D and <control>-T characters when they were entered at places where their command functionality was not appropriate. IEEE Std 1003.1-2001 requires that the <control>-T functionality always be available, and that <control>-D be treated as any other key when not operating on autoindent characters.

**NULL**

Some historical implementations of vi limited the number of characters entered using the NUL input character to 256 bytes. IEEE Std 1003.1-2001 permits this limitation; however, implementations are encouraged to remove this limit.

**<control>-D**

See also Rationale for the input mode command <newline>. The hidden assumptions in the <control>-D command (and in the vi autoindent specification in general) is that <space>s take up a single column on the screen and that <tab>s are comprised of an integral number of <space>s.

**<newline>**

Implementations are permitted to rewrite autoindent characters in the line when <newline>, <carriage-return>, <control>-D, and <control>-T are entered, or when the shift commands are used, because historical implementations have both done so and found it necessary to do so. For example, a <control>-D when the cursor is preceded by a single <tab>, with tabstop set to 8, and shiftwidth set to 3, will result in the <tab> being replaced by several <space>s.

**<control>-T**

See also the Rationale for the input mode command <newline>. Historically, <control>-T only worked if no non-<blank>s had yet been input in the current input line. In addition, the characters inserted by <control>-T were treated as autoindent characters, and could not be erased using normal user erase characters. Because implementations exist that do not have these limitations, and as moving to a column boundary is generally useful, IEEE Std 1003.1-2001 requires that both limitations be removed.
Historically, `vi` used `^V`, regardless of the value of the literal-next character of the terminal. IEEE Std 1003.1-2001 requires conformance to historical practice.

The uses described for `<control>-V` can also be accomplished with `<control>-Q`, which is useful on terminals that use `<control>-V` for the down-arrow function. However, most historical implementations use `<control>-Q` for the `termios` START character, so the editor will generally not receive the `<control>-Q` unless `stty ixon` mode is set to off. (In addition, some historical implementations of `vi` explicitly set `ixon` mode to on, so it was difficult for the user to set it to off.) Any of the command characters described in IEEE Std 1003.1-2001 can be made ineffective by their selection as `termios` control characters, using the `stty` utility or other methods described in the System Interfaces volume of IEEE Std 1003.1-2001.

Historically, SIGINT alerted the terminal when used to end input mode. This behavior is permitted, but not required, by IEEE Std 1003.1-2001.

FUTURE DIRECTIONS

CHANGE HISTORY

First released in Issue 2.

Issue 5

The FUTURE DIRECTIONS section is added.

Issue 6

This utility is marked as part of the User Portability Utilities option.

The APPLICATION USAGE section is added.

The obsolescent SYNOPSIS is removed.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The `reindent` command description is added.

The `vi` utility has been extensively rewritten for alignment with the IEEE P1003.2b draft standard.

IEEE PASC Interpretations 1003.2 #57, #62, #63, #64, #78, and #188 are applied.

IEEE PASC Interpretation 1003.2 #207 is applied, clarifying the description of the `R` command in a manner similar to the descriptions of other text input mode commands such as `i`, `o`, and `O`.

The `−l` option is removed.

NAME
wait — await process completion

SYNOPSIS
wait [pid...]

DESCRIPTION
When an asynchronous list (see Section 2.9.3.1 (on page 50)) is started by the shell, the process ID
of the last command in each element of the asynchronous list shall become known in the current
shell execution environment; see Section 2.12 (on page 61).

If the wait utility is invoked with no operands, it shall wait until all process IDs known to the
invoking shell have terminated and exit with a zero exit status.

If one or more pid operands are specified that represent known process IDs, the wait utility shall
wait until all of them have terminated. If one or more pid operands are specified that represent
unknown process IDs, wait shall treat them as if they were known process IDs that exited with
exit status 127. The exit status returned by the wait utility shall be the exit status of the process
requested by the last pid operand.

The known process IDs are applicable only for invocations of wait in the current shell execution
environment.

OPTIONS
None.

OPERANDS
The following operand shall be supported:

pid One of the following:

1. The unsigned decimal integer process ID of a command, for which the utility
   is to wait for the termination.

2. A job control job ID (see the Base Definitions volume of IEEE Std 1003.1-2001,
   Section 3.203, Job Control Job ID) that identifies a background process group
to be waited for. The job control job ID notation is applicable only for
invocations of wait in the current shell execution environment; see Section
2.12 (on page 61). The exit status of wait shall be determined by the last
command in the pipeline.

Note: The job control job ID type of pid is only available on systems supporting
the User Portability Utilities option.

STDIN
Not used.

INPUT FILES
None.

ENVIRONMENT VARIABLES
The following environment variables shall affect the execution of wait:

LANG Provide a default value for the internationalization variables that are unset or null.
(See the Base Definitions volume of IEEE Std 1003.1-2001, Section 8.2,
Internationalization Variables for the precedence of internationalization variables
used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other
internationalization variables.
wait

Utilities

40081 LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

40084 LC_MESSAGES Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

40087 XSI NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

40088 ASYNCHRONOUS EVENTS
40089 Default.

40090 STDOUT
40091 Not used.

40092 STDERR
40093 The standard error shall be used only for diagnostic messages.

40094 OUTPUT FILES
40095 None.

40096 EXTENDED DESCRIPTION
40097 None.

40098 EXIT STATUS
40099 If one or more operands were specified, all of them have terminated or were not known by the invoking shell, and the status of the last operand specified is known, then the exit status of wait shall be the exit status information of the command indicated by the last operand specified. If the process terminated abnormally due to the receipt of a signal, the exit status shall be greater than 128 and shall be distinct from the exit status generated by other signals, but the exact value is unspecified. (See the kill -l option.) Otherwise, the wait utility shall exit with one of the following values:

0 The wait utility was invoked with no operands and all process IDs known by the invoking shell have terminated.

1-126 The wait utility detected an error.

127 The command identified by the last pid operand specified is unknown.

40110 CONSEQUENCES OF ERRORS
40111 Default.

40112 APPLICATION USAGE
40113 On most implementations, wait is a shell built-in. If it is called in a subshell or separate utility execution environment, such as one of the following:

   (wait)

   nohup wait ...

   find . -exec wait ... \

   it returns immediately because there are no known process IDs to wait for in those environments.

   Historical implementations of interactive shells have discarded the exit status of terminated background processes before each shell prompt. Therefore, the status of background processes was usually lost unless it terminated while wait was waiting for it. This could be a serious problem when a job that was expected to run for a long time actually terminated quickly with a syntax or initialization error because the exit status returned was usually zero if the requested
wait

process ID was not found. This volume of IEEE Std 1003.1-2001 requires the implementation to keep the status of terminated jobs available until the status is requested, so that scripts like:

```bash
j1&
p1=$!
j2&
wait $p1
echo Job 1 exited with status $?
wait $!
```

work without losing status on any of the jobs. The shell is allowed to discard the status of any process if it determines that the application cannot get the process ID for that process from the shell. It is also required to remember only |CHILD_MAX| number of processes in this way. Since the only way to get the process ID from the shell is by using the ’!’ shell parameter, the shell is allowed to discard the status of an asynchronous list if "$!" was not referenced before another asynchronous list was started. (This means that the shell only has to keep the status of the last asynchronous list started if the application did not reference "$!". If the implementation of the shell is smart enough to determine that a reference to "$!" was not saved anywhere that the application can retrieve it later, it can use this information to trim the list of saved information. Note also that a successful call to wait with no operands discards the exit status of all asynchronous lists.)

If the exit status of wait is greater than 128, there is no way for the application to know if the waited-for process exited with that value or was killed by a signal. Since most utilities exit with small values, there is seldom any ambiguity. Even in the ambiguous cases, most applications just need to know that the asynchronous job failed; it does not matter whether it detected an error and failed or was killed and did not complete its job normally.

**EXAMPLES**

Although the exact value used when a process is terminated by a signal is unspecified, if it is known that a signal terminated a process, a script can still reliably determine which signal by using kill as shown by the following script:

```bash
sleep 1000&
pid=$!
kill -kill $pid
wait $pid
echo $pid was terminated by a SIG$(kill −l $?) signal.
```

If the following sequence of commands is run in less than 31 seconds:

```bash
sleep 257 | sleep 31 &
jobs −l %
```

either of the following commands returns the exit status of the second sleep in the pipeline:

```bash
wait <pid of sleep 31>
wait %
```

**RATIONALE**

The description of wait does not refer to the waitpid() function from the System Interfaces volume of IEEE Std 1003.1-2001 because that would needlessly overspecify this interface. However, the wording means that wait is required to wait for an explicit process when it is given an argument so that the status information of other processes is not consumed. Historical implementations use the wait() function defined in the System Interfaces volume of IEEE Std 1003.1-2001 until wait() returns the requested process ID or finds that the requested
process does not exist. Because this means that a shell script could not reliably get the status of
all background children if a second background job was ever started before the first job finished,
it is recommended that the \texttt{wait} utility use a method such as the functionality provided by the
\texttt{waitpid()} function.

The ability to wait for multiple \texttt{pid} operands was adopted from the KornShell.

This new functionality was added because it is needed to determine the exit status of any
asynchronous list accurately. The only compatibility problem that this change creates is for a
script like

\begin{verbatim}
while sleep 60 do 
  job& echo Job started $(date) as $! done
\end{verbatim}

which causes the shell to monitor all of the jobs started until the script terminates or runs out of
memory. This would not be a problem if the loop did not reference \texttt{"$!"} or if the script would
occasionally \texttt{wait} for jobs it started.

\textbf{FUTURE DIRECTIONS}

None.

\texttt{waitpid()}.

\textbf{CHANGE HISTORY}

First released in Issue 2.
NAME
wc — word, line, and byte or character count

SYNOPSIS
wc [-c | -m] [-lw] [file ...]

DESCRIPTION
The wc utility shall read one or more input files and, by default, write the number of <newline>s, words, and bytes contained in each input file to the standard output.

The utility also shall write a total count for all named files, if more than one input file is specified.

The wc utility shall consider a word to be a non-zero-length string of characters delimited by white space.

OPTIONS

The following options shall be supported:

- c Write to the standard output the number of bytes in each input file.
- l Write to the standard output the number of <newline>s in each input file.
- m Write to the standard output the number of characters in each input file.
- w Write to the standard output the number of words in each input file.

When any option is specified, wc shall report only the information requested by the specified options.

OPERANDS
The following operand shall be supported:

file A pathname of an input file. If no file operands are specified, the standard input shall be used.

STDIN
The standard input shall be used only if no file operands are specified. See the INPUT FILES section.

INPUT FILES
The input files may be of any type.

ENVIRONMENT VARIABLES
The following environment variables shall affect the execution of wc:

LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-2001, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files) and which characters are defined as white space characters.
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error and informative messages written to standard output.

**NLSPATH**

Determine the location of message catalogs for the processing of `LC_MESSAGES`.

**ASYNCHRONOUS EVENTS**

Default.

By default, the standard output shall contain an entry for each input file of the form:

```
%d %d %d %s
```

If the `-m` option is specified, the number of characters shall replace the `<bytes>` field in this format.

If any options are specified and the `-l` option is not specified, the number of `<newline>`s shall not be written.

If any options are specified and the `-w` option is not specified, the number of words shall not be written.

If any options are specified and neither `-c` nor `-m` is specified, the number of bytes or characters shall not be written.

If no input `<file>` operands are specified, no name shall be written and no `<blank>`s preceding the pathname shall be written.

If more than one input `<file>` operand is specified, an additional line shall be written, of the same format as the other lines, except that the word `total` (in the POSIX locale) shall be written instead of a pathname and the total of each column shall be written as appropriate. Such an additional line, if any, is written at the end of the output.

The standard error shall be used only for diagnostic messages.

**OUTPUT FILES**

None.

**EXTENDED DESCRIPTION**

None.

The following exit values shall be returned:

0   Successful completion.

>0  An error occurred.

**CONSEQUENCES OF ERRORS**

Default.
APPLICATION USAGE
The −m option is not a switch, but an option at the same level as −c. Thus, to produce the full
default output with character counts instead of bytes, the command required is:
wc −mlw

EXAMPLES
None.

RATIONALE
The output file format pseudo-printf() string differs from the System V version of wc:
"%7d%7d%7d %s\n"
which produces possibly ambiguous and unparsable results for very large files, as it assumes no
number shall exceed six digits.
Some historical implementations use only <space>, <tab>, and <newline> as word separators.
The equivalent of the ISO C standard isspace() function is more appropriate.
The −c option stands for “character” count, even though it counts bytes. This stems from the
sometimes erroneous historical view that bytes and characters are the same size. Due to
international requirements, the −m option (reminiscent of “multi-byte”) was added to obtain
actual character counts.
Early proposals only specified the results when input files were text files. The current
specification more closely matches historical practice. (Bytes, words, and <newline>s are
counted separately and the results are written when an end-of-file is detected.)
Historical implementations of the wc utility only accepted one argument to specify the options
−c, −l, and −w. Some of them also had multiple occurrences of an option cause the
corresponding count to be written multiple times and had the order of specification of the
options affect the order of the fields on output, but did not document either of these. Because
common usage either specifies no options or only one option, and because none of this was
documented, the changes required by this volume of IEEE Std 1003.1-2001 should not break
many historical applications (and do not break any historical conforming applications).

FUTURE DIRECTIONS
None.

CHANGE HISTORY
First released in Issue 2.
what

NAME
what — identify SCCS files (DEVELOPMENT)

SYNOPSIS
what [-s] file...

DESCRIPTION
The what utility shall search the given files for all occurrences of the pattern that get (see get)
substitutes for the %Z% keyword (@(#)) and shall write to standard output what follows
until the first occurrence of one of the following:

"    > newline \ NUL

OPTIONS
The what utility shall conform to the Base Definitions volume of IEEE Std 1003.1-2001, Section

The following option shall be supported:
-s Quit after finding the first occurrence of the pattern in each file.

OPERANDS
The following operands shall be supported:
file A pathname of a file to search.

STDIN
Not used.

INPUT FILES
The input files shall be of any file type.

ENVIRONMENT VARIABLES
The following environment variables shall affect the execution of what:

LANG Provide a default value for the internationalization variables that are unset or null.
(See the Base Definitions volume of IEEE Std 1003.1-2001, Section 8.2,
Internationalization Variables for the precedence of internationalization variables
used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other
internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as
characters (for example, single-byte as opposed to multi-byte characters in
arguments and input files).

LC_MESSAGES Determine the locale that should be used to affect the format and contents of
diagnostic messages written to standard error.

NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

ASYNCHRONOUS EVENTS
Default.

STDOUT
The standard output shall consist of the following for each file operand:

"%s:\n\t%s\n", <pathname>, <identification string>
Utilities

40345 **STDERR**
40346 The standard error shall be used only for diagnostic messages.

40347 **OUTPUT FILES**
40348 None.

40349 **EXTENDED DESCRIPTION**
40350 None.

40351 **EXIT STATUS**
40352 The following exit values shall be returned:
40353 0 Any matches were found.
40354 1 Otherwise.

40355 **CONSEQUENCES OF ERRORS**
40356 Default.

40357 **APPLICATION USAGE**
40358 The *what* utility is intended to be used in conjunction with the SCCS command *get*, which automatically inserts identifying information, but it can also be used where the information is inserted by any other means.
40359 When the string "@(#)" is included in a library routine in a shared library, it might not be found in an *a.out* file using that library routine.

40360 **EXAMPLES**
40361 If the C-language program in file *f.c* contains:
40362 char ident[] = "@(#)identification information";
40363 and *f.c* is compiled to yield *f.o* and *a.out*, then the command:
40364 what *f.c* *f.o* *a.out*
40365 writes:
40366  *f.c*:
40367   identification information
40368   ...
40369  *f.o*:
40370   identification information
40371   ...
40372  *a.out*:
40373   identification information
40374   ...

40375 **RATIONALE**
40376 None.

40377 **FUTURE DIRECTIONS**
40378 None.

40381 *get*

40382 **CHANGE HISTORY**
40383 First released in Issue 2.
NAME
who — display who is on the system

SYNOPSIS
who [-mTu]
who [-mu] [-s[ -bHlprt]] [file]
who [-mTu] [-abdHlprt][file]
who -q [file]
who am i
who am I

DESCRIPTION
The who utility shall list various pieces of information about accessible users. The domain of accessibility is implementation-defined.

Based on the options given, who can also list the user’s name, terminal line, login time, elapsed time since activity occurred on the line, and the process ID of the command interpreter for each current system user.

OPTIONS

The following options shall be supported. The metavariables, such as <line>, refer to fields described in the STDOUT section.

- a Process the implementation-defined database or named file with the -b, -d, -l, -p, -r, -t, -T and -u options turned on.
- b Write the time and date of the last reboot.
- d Write a list of all processes that have expired and not been respawned by the init system process. The <exit> field shall appear for dead processes and contain the termination and exit values of the dead process. This can be useful in determining why a process terminated.
- H Write column headings above the regular output.
- l (The letter ell.) List only those lines on which the system is waiting for someone to login. The <name> field shall be LOGIN in such cases. Other fields shall be the same as for user entries except that the <state> field does not exist.
- m Output only information about the current terminal.
- p List any other process that is currently active and has been previously spawned by init.
- q (Quick.) List only the names and the number of users currently logged on. When this option is used, all other options shall be ignored.
- r Write the current run-level of the init process.
- s List only the <name>, <line>, and <time> fields. This is the default case.
- t Indicate the last change to the system clock.
Show the state of each terminal, as described in the STDOUT section.

Write “idle time” for each displayed user in addition to any other information. The idle time is the time since any activity occurred on the user’s terminal. The method of determining this is unspecified. This option shall list only those users who are currently logged in. The <name> is the user’s login name. The <line> is the name of the line as found in the directory /dev. The <time> is the time that the user logged in. The <activity> is the number of hours and minutes since activity last occurred on that particular line. A dot indicates that the terminal has seen activity in the last minute and is therefore “current”. If more than twenty-four hours have elapsed or the line has not been used since boot time, the entry shall be marked <old>. This field is useful when trying to determine whether a person is working at the terminal or not. The <pid> is the process ID of the user’s login process.

The following operands shall be supported:

- am i, am I
  In the POSIX locale, limit the output to describing the invoking user, equivalent to the -m option. The am and i or I must be separate arguments.

- file
  Specify a pathname of a file to substitute for the implementation-defined database of logged-on users that who uses by default.

Not used.

None.

The following environment variables shall affect the execution of who:

- LANG
  Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-2001, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

- LC_ALL
  If set to a non-empty string value, override the values of all the other internationalization variables.

- LC_CTYPE
  Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

- LC_MESSAGES
  Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

- LC_TIME
  Determine the locale used for the format and contents of the date and time strings.

- NLSPATH
  Determine the location of message catalogs for the processing of LC_MESSAGES.

- TZ
  Determine the timezone used when writing date and time information. If TZ is unset or null, an unspecified default timezone shall be used.

Default.

The following environment variables shall affect the execution of who:

- LANG
  Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-2001, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

- LC_ALL
  If set to a non-empty string value, override the values of all the other internationalization variables.

- LC_CTYPE
  Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

- LC_MESSAGES
  Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

- LC_TIME
  Determine the locale used for the format and contents of the date and time strings.

- NLSPATH
  Determine the location of message catalogs for the processing of LC_MESSAGES.

- TZ
  Determine the timezone used when writing date and time information. If TZ is unset or null, an unspecified default timezone shall be used.

Default.
The who utility shall write its default format to the standard output in an implementation-defined format, subject only to the requirement of containing the information described above.

XSI-conformant systems shall write the default information to the standard output in the following general format:

```
<name>[<state>]<line><time>[<activity>][<pid>][<comment>][<exit>]
```

The following format shall be used for the −T option:

```
"%s %c %s %s\n" <name>, <terminal state>, <terminal name>,
<time of login>
```

where <terminal state> is one of the following characters:

+ The terminal allows write access to other users.
− The terminal denies write access to other users.
? The terminal write-access state cannot be determined.

In the POSIX locale, the <time of login> shall be equivalent in format to the output of:

```
date +"%b %e %H:%M"
```

If the −u option is used with −T, the idle time shall be added to the end of the previous format in an unspecified format.

The standard error shall be used only for diagnostic messages.

None.

None.

The following exit values shall be returned:

```
0 Successful completion.
>0 An error occurred.
```

Default.

The name init used for the system process is the most commonly used on historical systems, but it may vary.

The “domain of accessibility” referred to is a broad concept that permits interpretation either on a very secure basis or even to allow a network-wide implementation like the historical rwho.

None.

Due to differences between historical implementations, the base options provided were a compromise to allow users to work with those functions. The standard developers also considered removing all the options, but felt that these options offered users valuable functionality. Additional options to match historical systems are available on XSI-conformant
It is recognized that the `who` command may be of limited usefulness, especially in a multi-level secure environment. The standard developers considered, however, that having some standard method of determining the “accessibility” of other users would aid user portability.

No format was specified for the default `who` output for systems not supporting the XSI Extension. In such a user-oriented command, designed only for human use, this was not considered to be a deficiency.

The format of the terminal name is unspecified, but the descriptions of `ps`, `talk`, and `write` require that they use the same format.

It is acceptable for an implementation to produce no output for an invocation of `who mil`.

**FUTURE DIRECTIONS**

None.

**SEE ALSO**

`mesg`

**CHANGE HISTORY**

First released in Issue 2.

**Issue 6**

This utility is marked as part of the User Portability Utilities option.

The TZ entry is added to the ENVIRONMENT VARIABLES section.
NAME
    write — write to another user

SYNOPSIS
    write user_name [terminal]

DESCRIPTION
    The write utility shall read lines from the user’s standard input and write them to the terminal of another user. When first invoked, it shall write the message:

    Message from sender-login-id (sending-terminal) [date]...

to user_name. When it has successfully completed the connection, the sender’s terminal shall be alerted twice to indicate that what the sender is typing is being written to the recipient’s terminal.

    If the recipient wants to reply, this can be accomplished by typing:

    write sender-login-id [sending-terminal]

    upon receipt of the initial message. Whenever a line of input as delimited by an NL, EOF, or EOL special character (see the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 11, General Terminal Interface) is accumulated while in canonical input mode, the accumulated data shall be written on the other user’s terminal. Characters shall be processed as follows:

    • Typing <alert> shall write the alert character to the recipient’s terminal.

    • Typing the erase and kill characters shall affect the sender’s terminal in the manner described by the termios interface in the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 11, General Terminal Interface.

    • Typing the interrupt or end-of-file characters shall cause write to write an appropriate message ("EOT\n" in the POSIX locale) to the recipient’s terminal and exit.

    • Typing characters from LC_CTYPE classifications print or space shall cause those characters to be sent to the recipient’s terminal.

    • When and only when the stty iexten local mode is enabled, the existence and processing of additional special control characters and multi-byte or single-byte functions is implementation-defined.

    • Typing other non-printable characters shall cause implementation-defined sequences of printable characters to be written to the recipient’s terminal.

    To write to a user who is logged in more than once, the terminal argument can be used to indicate which terminal to write to; otherwise, the recipient’s terminal is selected in an implementation-defined manner and an informational message is written to the sender’s standard output, indicating which terminal was chosen.

    Permission to be a recipient of a write message can be denied or granted by use of the mesg utility. However, a user’s privilege may further constrain the domain of accessibility of other users’ terminals. The write utility shall fail when the user lacks the appropriate privileges to perform the requested action.

OPTIONS
    None.
OPERANDS
The following operands shall be supported:

user_name  Login name of the person to whom the message shall be written. The application shall ensure that this operand is of the form returned by the who utility.

terminal   Terminal identification in the same format provided by the who utility.

STDIN
Lines to be copied to the recipient’s terminal are read from standard input.

INPUT FILES
None.

ENVIRONMENT VARIABLES
The following environment variables shall affect the execution of write:

LANG        Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-2001, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL  If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE   Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files). If the recipient’s locale does not use an LC_CTYPE equivalent to the sender’s, the results are undefined.

LC_MESSAGES  Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error and informative messages written to standard output.

NLSPATH   Determine the location of message catalogs for the processing of LC_MESSAGES.

ASYNCHRONOUS EVENTS
If an interrupt signal is received, write shall write an appropriate message on the recipient’s terminal and exit with a status of zero. It shall take the standard action for all other signals.

STDOUT
An informational message shall be written to standard output if a recipient is logged in more than once.

STDERR
The standard error shall be used only for diagnostic messages.

OUTPUT FILES
The recipient’s terminal is used for output.

EXTENDED DESCRIPTION
None.

EXIT STATUS
The following exit values shall be returned:

0  Successful completion.

>0  The addressed user is not logged on or the addressed user denies permission.
CONSEQUENCES OF ERRORS
Default.

APPLICATION USAGE
The `talk` utility is considered by some users to be a more usable utility on full-screen terminals.

EXAMPLES
None.

RATIONALE
The `write` utility was included in this volume of IEEE Std 1003.1-2001 since it can be implemented on all terminal types. The standard developers considered the `talk` utility, which cannot be implemented on certain terminals, to be a "better" communications interface. Both of these programs are in widespread use on historical implementations. Therefore, the standard developers decided that both utilities should be specified.

The format of the terminal name is unspecified, but the descriptions of `ps`, `talk`, `who`, and `write` require that they all use or accept the same format.

FUTURE DIRECTIONS
None.

CHANGE HISTORY
First released in Issue 2.

Issue 5
The FUTURE DIRECTIONS section is added.

Issue 6
This utility is marked as part of the User Portability Utilities option.

The normative text is reworded to avoid use of the term "must" for application requirements.
NAME
xargs — construct argument lists and invoke utility

SYNOPSIS
          [-s size] [utility [argument...]]

DESCRIPTION
The xargs utility shall construct a command line consisting of the utility and argument operands
specified followed by as many arguments read in sequence from standard input as fit in length
and number constraints specified by the options. The xargs utility shall then invoke the
constructed command line and wait for its completion. This sequence shall be repeated until one
of the following occurs:

• An end-of-file condition is detected on standard input.
• The logical end-of-file string (see the -E eofstr option) is found on standard input after
double-quote processing, apostrophe processing, and backslash escape processing (see next
paragraph).
• An invocation of a constructed command line returns an exit status of 255.

The application shall ensure that arguments in the standard input are separated by unquoted
<blank>s, unescaped <blank>s, or <newline>s. A string of zero or more non-double-quote (""")
characters and non-<newline>s can be quoted by enclosing them in double-quotes. A string of
zero or more non-apostrophe ("'") characters and non-<newline>s can be quoted by enclosing
them in apostrophes. Any unquoted character can be escaped by preceding it with a backslash.
The utility named by utility shall be executed one or more times until the end-of-file is reached
or the logical end-of-file string is found. The results are unspecified if the utility named by utility
attempts to read from its standard input.

The generated command line length shall be the sum of the size in bytes of the utility name and
each argument treated as strings, including a null byte terminator for each of these strings. The
xargs utility shall limit the command line length such that when the command line is invoked,
the combined argument and environment lists (see the exec family of functions in the System
Interfaces volume of IEEE Std 1003.1-2001) shall not exceed {ARG_MAX}−2 048 bytes. Within
this constraint, if neither the -n nor the -s option is specified, the default command line length
shall be at least {LINE_MAX}.

OPTIONS
The xargs utility shall conform to the Base Definitions volume of IEEE Std 1003.1-2001, Section

The following options shall be supported:

-E eofstr Use eofstr as the logical end-of-file string. If -E is not specified, it is unspecified
whether the logical end-of-file string is the underscore character ('_') or the end-
of-file string capability is disabled. When eofstr is the null string, the logical end-
of-file string capability shall be disabled and underscore characters shall be taken
literally.

-I replstr Insert mode: utility is executed for each line from standard input, taking the entire
line as a single argument, inserting it in arguments for each occurrence of replstr. A
maximum of five arguments in arguments can each contain one or more instances
of replstr. Any <blank>s at the beginning of each line shall be ignored.
Constructed arguments cannot grow larger than 255 bytes. Option -x shall be
forced on.
The utility shall be executed for each non-empty number lines of arguments from standard input. The last invocation of utility shall be with fewer lines of arguments if fewer than number remain. A line is considered to end with the first <newline> unless the last character of the line is a <blank>; a trailing <blank> signals continuation to the next non-empty line, inclusive. The −L and −n options are mutually-exclusive; the last one specified shall take effect.

Invoke utility using as many standard input arguments as possible, up to number (a positive decimal integer) arguments maximum. Fewer arguments shall be used if:

- The command line length accumulated exceeds the size specified by the −s option (or [LINE_MAX] if there is no −s option).
- The last iteration has fewer than number, but not zero, operands remaining.

Prompt mode: the user is asked whether to execute utility at each invocation. Trace mode (−t) is turned on to write the command instance to be executed, followed by a prompt to standard error. An affirmative response read from /dev/tty shall execute the command; otherwise, that particular invocation of utility shall be skipped.

Invoke utility using as many standard input arguments as possible yielding a command line length less than size (a positive decimal integer) bytes. Fewer arguments shall be used if:

- The total number of arguments exceeds that specified by the −n option.
- The total number of lines exceeds that specified by the −L option.
- End-of-file is encountered on standard input before size bytes are accumulated.

Values of size up to at least [LINE_MAX] bytes shall be supported, provided that the constraints specified in the DESCRIPTION are met. It shall not be considered an error if a value larger than that supported by the implementation or exceeding the constraints specified in the DESCRIPTION is given; xargs shall use the largest value it supports within the constraints.

Enable trace mode. Each generated command line shall be written to standard error just prior to invocation.

Terminate if a command line containing number arguments (see the −n option above) or number lines (see the −L option above) will not fit in the implied or specified size (see the −s option above).

The name of the utility to be invoked, found by search path using the PATH environment variable, described in the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 8, Environment Variables. If utility is omitted, the default shall be the echo utility. If the utility operand names any of the special built-in utilities in Section 2.14 (on page 64), the results are undefined.

An initial option or operand for the invocation of utility.

The standard input shall be a text file. The results are unspecified if an end-of-file condition is detected immediately following an escaped <newline>.

Shell and Utilities, Issue 6 — Copyright © 2001-2003, IEEE and The Open Group. All rights reserved.
**INPUT FILES**

The file `/dev/tty` shall be used to read responses required by the `−p` option.

**ENVIRONMENT VARIABLES**

The following environment variables shall affect the execution of `xargs`:

- **LANG**
  Provide a default value for the internationalization variables that are unset or null.
  (See the Base Definitions volume of IEEE Std 1003.1-2001, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

- **LC_ALL**
  If set to a non-empty string value, override the values of all the other internationalization variables.

- **LC_COLLATE**
  Determine the locale for the behavior of ranges, equivalence classes, and multi-character collating elements used in the extended regular expression defined for the `yesexpr` locale keyword in the `LC_MESSAGES` category.

- **LC_CTYPE**
  Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files) and the behavior of character classes used in the extended regular expression defined for the `yesexpr` locale keyword in the `LC_MESSAGES` category.

- **LC_MESSAGES**
  Determine the locale for the processing of affirmative responses and that should be used to affect the format and contents of diagnostic messages written to standard error.

- **NLSPATH**
  Determine the location of message catalogs for the processing of `LC_MESSAGES`.

- **PATH**
  Determine the location of utility, as described in the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 8, Environment Variables.

**ASYNCHRONOUS EVENTS**

Default.

**STDOUT**

Not used.

**STDERR**

The standard error shall be used for diagnostic messages and the `−t` and `−p` options. If the `−t` option is specified, the utility and its constructed argument list shall be written to standard error, as it will be invoked, prior to invocation. If `−p` is specified, a prompt of the following format shall be written (in the POSIX locale):

```
"? . . . "
```

at the end of the line of the output from `−t`.

**OUTPUT FILES**

None.

**EXTENDED DESCRIPTION**

None.
EXIT STATUS

The following exit values shall be returned:

0        All invocations of utility returned exit status zero.
1-125    A command line meeting the specified requirements could not be assembled, one or
         more of the invocations of utility returned a non-zero exit status, or some other error
         occurred.
126      The utility specified by utility was found but could not be invoked.
127      The utility specified by utility could not be found.

CONSEQUENCES OF ERRORS

If a command line meeting the specified requirements cannot be assembled, the utility cannot be
invoked, an invocation of the utility is terminated by a signal, or an invocation of the utility exits
with exit status 255, the xargs utility shall write a diagnostic message and exit without
processing any remaining input.

APPLICATION USAGE

The 255 exit status allows a utility being used by xargs to tell xargs to terminate if it knows no
further invocations using the current data stream will succeed. Thus, utility should explicitly exit
with an appropriate value to avoid accidentally returning with 255.

Note that input is parsed as lines; <blank>s separate arguments. If xargs is used to bundle output
of commands like find dir -print or ls into commands to be executed, unexpected results are
likely if any filenames contain any <blank>s or <newline>s. This can be fixed by using find to
call a script that converts each file found into a quoted string that is then piped to xargs. Note
that the quoting rules used by xargs are not the same as in the shell. They were not made
consistent here because existing applications depend on the current rules and the shell syntax is
not fully compatible with it. An easy rule that can be used to transform any string into a quoted
form that xargs interprets correctly is to precede each character in the string with a backslash.

On implementations with a large value for {ARG_MAX}, xargs may produce command lines
longer than {LINE_MAX}. For invocation of utilities, this is not a problem. If xargs is being used
to create a text file, users should explicitly set the maximum command line length with the −s
option.

The command, env, nice, nohup, time, and xargs utilities have been specified to use exit code 127 if
an error occurs so that applications can distinguish “failure to find a utility” from “invoked
utility exited with an error indication”. The value 127 was chosen because it is not commonly
used for other meanings; most utilities use small values for “normal error conditions” and the
values above 128 can be confused with termination due to receipt of a signal. The value 126 was
chosen in a similar manner to indicate that the utility could be found, but not invoked. Some
scripts produce meaningful error messages differentiating the 126 and 127 cases. The distinction
between exit codes 126 and 127 is based on KornShell practice that uses 127 when all attempts to
exec the utility fail with [ENOENT], and uses 126 when any attempt to exec the utility fails for
any other reason.

EXAMPLES

1. The following command combines the output of the parenthesised commands onto one
   line, which is then written to the end-of-file log:

   \(\text{\((\text{logname; date; printf }^\%\%s\text{\n }^\"\$0 \"\star\\text{)} \mid xargs >>\text{log}\)}\)

2. The following command invokes diff with successive pairs of arguments originally typed
   as command line arguments (assuming there are no embedded <blank>s in the elements of
   the original argument list):
In the following commands, the user is asked which files in the current directory are to be archived. The files are archived into arch; a, one at a time, or b, many at a time.

a. ls | xargs -p -L 1 ar -r arch
b. ls | xargs -p -L 1 | xargs ar -r arch

The following executes with successive pairs of arguments originally typed as command line arguments:

echo $* | xargs -n 2 diff

On XSI-conformant systems, the following moves all files from directory $1 to directory $2, and echoes each move command just before doing it:

ls $1 | xargs -I{ } -t mv $1/{ } $2/{ }

RATIONALE

The xargs utility was usually found only in System V-based systems; BSD systems included an apply utility that provided functionality similar to xargs -n number. The SVID lists xargs as a software development extension. This volume of IEEE Std 1003.1-2001 does not share the view that it is used only for development, and therefore it is not optional.

The classic application of the xargs utility is in conjunction with the find utility to reduce the number of processes launched by a simplistic use of the find -exec combination. The xargs utility is also used to enforce an upper limit on memory required to launch a process. With this basis in mind, this volume of IEEE Std 1003.1-2001 selected only the minimal features required.

Although the 255 exit status is mostly an accident of historical implementations, it allows a utility being used by xargs to tell xargs to terminate if it knows no further invocations using the current data stream shall succeed. Any non-zero exit status from a utility falls into the 1-125 range when xargs exits. There is no statement of how the various non-zero utility exit status codes are accumulated by xargs. The value could be the addition of all codes, their highest value, the last one received, or a single value such as 1. Since no algorithm is arguably better than the others, and since many of the standard utilities say little more (portably) than "pass/fail", no new algorithm was invented.

Several other xargs options were withdrawn because simple alternatives already exist within this volume of IEEE Std 1003.1-2001. For example, the -i replstr option can be just as efficiently performed using a shell for loop. Since xargs calls an exec function with each input line, the -i option does not usually exploit the grouping capabilities of xargs.

The requirement that xargs never produces command lines such that invocation of utility is within 2048 bytes of hitting the POSIX exec {ARG_MAX} limitations is intended to guarantee that the invoked utility has room to modify its environment variables and command line arguments and still be able to invoke another utility. Note that the minimum {ARG_MAX} allowed by the System Interfaces volume of IEEE Std 1003.1-2001 is 4096 bytes and the minimum value allowed by this volume of IEEE Std 1003.1-2001 is 2048 bytes; therefore, the 2048 bytes difference seems reasonable. Note, however, that xargs may never be able to invoke a utility if the environment passed in to xargs comes close to using {ARG_MAX} bytes.

The version of xargs required by this volume of IEEE Std 1003.1-2001 is required to wait for the completion of the invoked command before invoking another command. This was done because historical scripts using xargs assumed sequential execution. Implementations wanting to provide parallel operation of the invoked utilities are encouraged to add an option enabling parallel invocation, but should still wait for termination of all of the children before xargs terminates normally.
The \texttt{-e} option was omitted from the ISO POSIX-2:1993 standard in the belief that the \texttt{EOFstr}
option-argument was recognized only when it was on a line by itself and before quote and
escape processing were performed, and that the logical end-of-file processing was only enabled
if a \texttt{-e} option was specified. In that case, a simple \texttt{sed} script could be used to duplicate the \texttt{-e}
functionality. Further investigation revealed that:

\begin{itemize}
  \item The logical end-of-file string was checked for after quote and escape processing, making a \texttt{sed}
  script that provided equivalent functionality much more difficult to write.
  \item The default was to perform logical end-of-file processing with an underscore as the logical
  end-of-file string.
\end{itemize}

To correct this misunderstanding, the \texttt{-E EOFstr} option was adopted from the X/Open Portability
Guide. Users should note that the description of the \texttt{-E} option matches historical documentation
of the \texttt{-e} option (which was not adopted because it did not support the Utility Syntax
Guidelines), by saying that if \texttt{EOFstr} is the null string, logical end-of-file processing is disabled.

Historical implementations of \texttt{xargs} actually did not disable logical end-of-file processing; they
treated a null argument found in the input as a logical end-of-file string. (A null \texttt{string} argument
could be generated using single or double quotes (\textquoteleft{} \textquoteleft{} or \”\”). Since this behavior was not
documented historically, it is considered to be a bug.

\textbf{FUTURE DIRECTIONS}

None.

\textbf{SEE ALSO}

Chapter 2 (on page 29), \texttt{echo}, \texttt{find}, the System Interfaces volume of IEEE Std 1003.1-2001, \texttt{exec}

\textbf{CHANGE HISTORY}

First released in Issue 2.

\textbf{Issue 5}

A second FUTURE DIRECTION is added.

\textbf{Issue 6}

The obsolescent \texttt{-e}, \texttt{-i}, and \texttt{-l} options are removed.

The following new requirements on POSIX implementations derive from alignment with the
Single UNIX Specification:

\begin{itemize}
  \item The \texttt{-p} option is added.
  \item In the INPUT FILES section, the file \texttt{/dev/tty} is used to read responses required by the \texttt{-p}
    option.
  \item The STDERR section is updated to describe the \texttt{-p} option.
\end{itemize}

The description of the \texttt{-E} option is aligned with the ISO POSIX-2: 1993 standard.

The normative text is reworded to avoid use of the term “must” for application requirements.
NAME
yacc — yet another compiler compiler (DEVELOPMENT)

SYNOPSIS
CD
yacc [-dltv] [-b file_prefix] [-p sym_prefix] grammar

DESCRIPTION
The yacc utility shall read a description of a context-free grammar in grammar and write C source code, conforming to the ISO C standard, to a code file, and optionally header information into a header file, in the current directory. The C code shall define a function and related routines and macros for an automaton that executes a parsing algorithm meeting the requirements in Algorithms (on page 1074).

The form and meaning of the grammar are described in the EXTENDED DESCRIPTION section.

The C source code and header file shall be produced in a form suitable as input for the C compiler (see c99).

OPTIONS

The following options shall be supported:

-b file_prefix Use file_prefix instead of y as the prefix for all output filenames. The code file y.tab.c, the header file y.tab.h (created when -d is specified), and the description file y.output (created when -v is specified), shall be changed to file_prefix.tab.c, file_prefix.tab.h, and file_prefix.output, respectively.

-d Write the header file; by default only the code file is written. The #define statements associate the token codes assigned by yacc with the user-declared token names. This allows source files other than y.tab.c to access the token codes.

-l Produce a code file that does not contain any #line constructs. If this option is not present, it is unspecified whether the code file or header file contains #line directives. This should only be used after the grammar and the associated actions are fully debugged.

-p sym_prefix Use sym_prefix instead of yy as the prefix for all external names produced by yacc. The names affected shall include the functions yyparse(), yylex(), and yyerror(), and the variables yylval, yychar, and yydebug. (In the remainder of this section, the six symbols cited are referenced using their default names only as a notational convenience.) Local names may also be affected by the -p option; however, the -p option shall not affect #define symbols generated by yacc.

-t Modify conditional compilation directives to permit compilation of debugging code in the code file. Runtime debugging statements shall always be contained in the code file, but by default conditional compilation directives prevent their compilation.

-v Write a file containing a description of the parser and a report of conflicts generated by ambiguities in the grammar.
OPERAANDS

The following operand is required:

grammar A pathname of a file containing instructions, hereafter called grammar, for which a
parser is to be created. The format for the grammar is described in the EXTENDED
DESCRIPTION section.

STDIN

Not used.

INPUT FILES

The file grammar shall be a text file formatted as specified in the EXTENDED DESCRIPTION
section.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of yacc:

LANG Provide a default value for the internationalization variables that are unset or null.
(See the Base Definitions volume of IEEE Std 1003.1-2001, Section 8.2,
Internationalization Variables for the precedence of internationalization variables
used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other
internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as
characters (for example, single-byte as opposed to multi-byte characters in
arguments and input files).

LC_MESSAGES Determine the locale that should be used to affect the format and contents of
diagnostic messages written to standard error.

XSI NLS_PATH Determine the location of message catalogs for the processing of LC_MESSAGES.

The LANG and LC_* variables affect the execution of the yacc utility as stated. The main() function defined in Yacc Library (on page 1074) shall call:

setlocale(LC_ALL, ")"

and thus the program generated by yacc shall also be affected by the contents of these variables
at runtime.

ASYNCRONOUS EVENTS

Default.

STDOUT

Not used.

STDERR

If shift/reduce or reduce/reduce conflicts are detected in grammar, yacc shall write a report of
those conflicts to the standard error in an unspecified format.

Standard error shall also be used for diagnostic messages.

OUTPUT FILES

The code file, the header file, and the description file shall be text files. All are described in the
following sections.
Code File

This file shall contain the C source code for the `yyparse()` function. It shall contain code for the various semantic actions with macro substitution performed on them as described in the EXTENDED DESCRIPTION section. It also shall contain a copy of the `#define` statements in the header file. If a `%union` declaration is used, the declaration for YYSTYPE shall also be included in this file.

Header File

The header file shall contain `#define` statements that associate the token numbers with the token names. This allows source files other than the code file to access the token codes. If a `%union` declaration is used, the declaration for YYSTYPE and an `extern YYSTYPE yylval` declaration shall also be included in this file.

Description File

The description file shall be a text file containing a description of the state machine corresponding to the parser, using an unspecified format. Limits for internal tables (see Limits (on page 1075)) shall also be reported, in an implementation-defined manner. (Some implementations may use dynamic allocation techniques and have no specific limit values to report.)

EXTENDED DESCRIPTION

The `yacc` command accepts a language that is used to define a grammar for a target language to be parsed by the tables and code generated by `yacc`. The language accepted by `yacc` as a grammar for the target language is described below using the `yacc` input language itself.

The input grammar includes rules describing the input structure of the target language and code to be invoked when these rules are recognized to provide the associated semantic action. The code to be executed shall appear as bodies of text that are intended to be C-language code. The C-language inclusions are presumed to form a correct function when processed by `yacc` into its output files. The code included in this way shall be executed during the recognition of the target language.

Given a grammar, the `yacc` utility generates the files described in the OUTPUT FILES section. The code file can be compiled and linked using `c99`. If the declaration and programs sections of the grammar file did not include definitions of `main()`, `yylex()`, and `yyerror()`, the compiled output requires linking with externally supplied versions of those functions. Default versions of `main()` and `yyerror()` are supplied in the `yacc` library and can be linked in by using the `-ly` operand to `c99`. The `yacc` library interfaces need not support interfaces with other than the default yy symbol prefix. The application provides the lexical analyzer function, `yylex();` the lex utility is specifically designed to generate such a routine.

Input Language

The application shall ensure that every specification file consists of three sections in order: `declarations`, `grammar rules`, and `programs`, separated by double percent signs ("%%"). The declarations and programs sections can be empty. If the latter is empty, the preceding "%%" mark separating it from the rules section can be omitted.

The input is free form text following the structure of the grammar defined below.
Lexical Structure of the Grammar

The <blank>s, <newline>s, and <form-feed>s shall be ignored, except that the application shall ensure that they do not appear in names or multi-character reserved symbols. Comments shall be enclosed in "/* ... */", and can appear wherever a name is valid.

Names are of arbitrary length, made up of letters, periods (‘.’), underscores (‘_’), and non-initial digits. Uppercase and lowercase letters are distinct. Conforming applications shall not use names beginning in yy or YY since the yacc parser uses such names. Many of the names appear in the final output of yacc, and thus they should be chosen to conform with any additional rules created by the C compiler to be used. In particular they appear in #define statements.

A literal shall consist of a single character enclosed in single-quotes (‘ ’). All of the escape sequences supported for character constants by the ISO C standard shall be supported by yacc.

The relationship with the lexical analyzer is discussed in detail below.

The application shall ensure that the NUL character is not used in grammar rules or literals.

Declarations Section

The declarations section is used to define the symbols used to define the target language and their relationship with each other. In particular, much of the additional information required to resolve ambiguities in the context-free grammar for the target language is provided here.

Usually yacc assigns the relationship between the symbolic names it generates and their underlying numeric value. The declarations section makes it possible to control the assignment of these values.

It is also possible to keep semantic information associated with the tokens currently on the parse stack in a user-defined C-language union, if the members of the union are associated with the various names in the grammar. The declarations section provides for this as well.

The first group of declarators below all take a list of names as arguments. That list can optionally be preceded by the name of a C union member (called a tag below) appearing within ‘<’ and ‘>’. (As an exception to the typographical conventions of the rest of this volume of IEEE Std 1003.1-2001, in this case <tag> does not represent a metavariable, but the literal angle bracket characters surrounding a symbol.) The use of tag specifies that the tokens named on this line shall be of the same C type as the union member referenced by tag. This is discussed in more detail below.

For lists used to define tokens, the first appearance of a given token can be followed by a positive integer (as a string of decimal digits). If this is done, the underlying value assigned to it for lexical purposes shall be taken to be that number.

The following declares name to be a token:

%token [tag] name [number] [name [number]]...

If tag is present, the C type for all tokens on this line shall be declared to be the type referenced by tag. If a positive integer, number, follows a name, that value shall be assigned to the token.

The following declares name to be a token, and assigns precedence to it:

%left [tag] name [number] [name [number]]...
%right [tag] name [number] [name [number]]...

One or more lines, each beginning with one of these symbols, can appear in this section. All tokens on the same line have the same precedence level and associativity; the lines are in order.
of increasing precedence or binding strength. %left denotes that the operators on that line are
left associative, and %right similarly denotes right associative operators. If tag is present, it shall
declare a C type for names as described for %token.

The following declares name to be a token, and indicates that this cannot be used associatively:
%nonassoc [tag] name [number] [name [number]]...

If the parser encounters associative use of this token it reports an error. If tag is present, it shall
declare a C type for names as described for %token.

The following declares that union member names are non-terminals, and thus it is required to
have a tag field at its beginning:
%type <tag> name...

Because it deals with non-terminals only, assigning a token number or using a literal is also
prohibited. If this construct is present, yacc shall perform type checking; if this construct is not
present, the parse stack shall hold only the int type.

Every name used in grammar not defined by a %token, %left, %right, or %nonassoc declaration
is assumed to represent a non-terminal symbol. The yacc utility shall report an error for any
non-terminal symbol that does not appear on the left side of at least one grammar rule.

Once the type, precedence, or token number of a name is specified, it shall not be changed. If the
first declaration of a token does not assign a token number, yacc shall assign a token number.
Once this assignment is made, the token number shall not be changed by explicit assignment.

The following declarators do not follow the previous pattern.

The following declares the non-terminal name to be the start symbol, which represents the largest,
most general structure described by the grammar rules:
%start name

By default, it is the left-hand side of the first grammar rule; this default can be overridden with
this declaration.

The following declares the yacc value stack to be a union of the various types of values desired:
%union { body of union (in C) }

By default, the values returned by actions (see below) and the lexical analyzer shall be of type
int. The yacc utility keeps track of types, and it shall insert corresponding union member names
in order to perform strict type checking of the resulting parser.

Alternatively, given that at least one <tag> construct is used, the union can be declared in a
header file (which shall be included in the declarations section by using a #include construct
within %{ and %}), and a typedef used to define the symbol YYSTYPE to represent this union.
The effect of %union is to provide the declaration of YYSTYPE directly from the yacc input.

C-language declarations and definitions can appear in the declarations section, enclosed by the
following marks:
{ ... }

These statements shall be copied into the code file, and have global scope within it so that they
can be used in the rules and program sections.

The application shall ensure that the declarations section is terminated by the token %%. 
Grammar Rules in yacc

The rules section defines the context-free grammar to be accepted by the function `yacc` generates, and associates with those rules C-language actions and additional precedence information. The grammar is described below, and a formal definition follows.

The rules section is comprised of one or more grammar rules. A grammar rule has the form:

```
A : BODY ;
```

The symbol `A` represents a non-terminal name, and `BODY` represents a sequence of zero or more names, literals, and semantic actions that can then be followed by optional precedence rules.

Only the names and literals participate in the formation of the grammar; the semantic actions and precedence rules are used in other ways. The colon and the semicolon are `yacc` punctuation.

If there are several successive grammar rules with the same left-hand side, the vertical bar `|` can be used to avoid rewriting the left-hand side; in this case the semicolon appears only after the last rule. The `BODY` part can be empty (or empty of names and literals) to indicate that the non-terminal symbol matches the empty string.

The `yacc` utility assigns a unique number to each rule. Rules using the vertical bar notation are distinct rules. The number assigned to the rule appears in the description file.

The elements comprising a `BODY` are:

- `name`, `literal` These form the rules of the grammar: `name` is either a token or a non-terminal; `literal` stands for itself (less the lexically required quotation marks).

- `semantic action` With each grammar rule, the user can associate actions to be performed each time the rule is recognized in the input process. (Note that the word "action" can also refer to the actions of the parser—shift, reduce, and so on.)

These actions can return values and can obtain the values returned by previous actions. These values are kept in objects of type `YYSTYPE` (see `%union`). The result value of the action shall be kept on the parse stack with the left-hand side of the rule, to be accessed by other reductions as part of their right-hand side. By using the `<tag>` information provided in the declarations section, the code generated by `yacc` can be strictly type checked and contain arbitrary information. In addition, the lexical analyzer can provide the same kinds of values for tokens, if desired.

An action is an arbitrary C statement and as such can do input or output, call subprograms, and alter external variables. An action is one or more C statements enclosed in curly braces `{` and `}`.

Certain pseudo-variables can be used in the action. These are macros for access to data structures known internally to `yacc`.

- `$$` The value of the action can be set by assigning it to `$$`. If type checking is enabled and the type of the value to be assigned cannot be determined, a diagnostic message may be generated.

- `$number` This refers to the value returned by the component specified by the token `number` in the right side of a rule, reading from left to right; `number` can be zero or negative. If `number` is zero or negative, it refers to the data associated with the name on the parser's stack preceding the leftmost symbol of the current rule. (That is, "$0" refers to the name immediately preceding the leftmost name in the current rule to be found on the parser's stack and "$−1" refers to the symbol to its
left.) If number refers to an element past the current point in the rule, or beyond the bottom of the stack, the result is undefined. If type checking is enabled and the type of the value to be assigned cannot be determined, a diagnostic message may be generated.

$<$tag$>$number $<$tag$>$ This imposes on the reference the type of the union member referenced by tag. This construction is applicable when a reference to a left context value occurs in the grammar, and provides yacc with a means for selecting a type.

Actions can occur anywhere in a rule (not just at the end); an action can access values returned by actions to its left, and in turn the value it returns can be accessed by actions to its right. An action appearing in the middle of a rule shall be equivalent to replacing the action with a new non-terminal symbol and adding an empty rule with that non-terminal symbol on the left-hand side. The semantic action associated with the new rule shall be equivalent to the original action. The use of actions within rules might introduce conflicts that would not otherwise exist.

By default, the value of a rule shall be the value of the first element in it. If the first element does not have a type (particularly in the case of a literal) and type checking is turned on by %type, an error message shall result.

precedence The keyword %prec can be used to change the precedence level associated with a particular grammar rule. Examples of this are in cases where a unary and binary operator have the same symbolic representation, but need to be given different precedences, or where the handling of an ambiguous if-else construction is necessary. The reserved symbol %prec can appear immediately after the body of the grammar rule and can be followed by a token name or a literal. It shall cause the precedence of the grammar rule to become that of the following token name or literal. The action for the rule as a whole can follow %prec.

If a program section follows, the application shall ensure that the grammar rules are terminated by %%. 

Programs Section

The programs section can include the definition of the lexical analyzer yylex(), and any other functions; for example, those used in the actions specified in the grammar rules. It is unspecified whether the programs section precedes or follows the semantic actions in the output file; therefore, if the application contains any macro definitions and declarations intended to apply to the code in the semantic actions, it shall place them within "%{ . . . %}" in the declarations section.
Input Grammar

The following input to `yacc` yields a parser for the input to `yacc`. This formal syntax takes precedence over the preceding text syntax description.

The lexical structure is defined less precisely; Lexical Structure of the Grammar (on page 1066) defines most terms. The correspondence between the previous terms and the tokens below is as follows.

**IDENTIFIER** This corresponds to the concept of `name`, given previously. It also includes literals as defined previously.

**C_IDENTIFIER** This is a name, and additionally it is known to be followed by a colon. A literal cannot yield this token.

**NUMBER** A string of digits (a non-negative decimal integer).

**TYPE, LEFT, MARK, LCURL, RCURL**

These correspond directly to `%type`, `%left`, `%%`, `%`, and `%`.

This indicates C-language source code, with the possible inclusion of ‘$’ macros as discussed previously.

```
Conflicts

The parser produced for an input grammar may contain states in which conflicts occur. The conflicts occur because the grammar is not LALR(1). An ambiguous grammar always contains at least one LALR(1) conflict. The `yacc` utility shall resolve all conflicts, using either default rules or user-specified precedence rules.

Conflicts are either shift/reduce conflicts or reduce/reduce conflicts. A shift/reduce conflict is where, for a given state and lookahead symbol, both a shift action and a reduce action are possible. A reduce/reduce conflict is where, for a given state and lookahead symbol, reductions by two different rules are possible.

The rules below describe how to specify what actions to take when a conflict occurs. Not all shift/reduce conflicts can be successfully resolved this way because the conflict may be due to something other than ambiguity, so incautious use of these facilities can cause the language accepted by the parser to be much different from that which was intended. The description file shall contain sufficient information to understand the cause of the conflict. Where ambiguity is the reason either the default or explicit rules should be adequate to produce a working parser.

The declared precedences and associativities (see Declarations Section (on page 1066)) are used to resolve parsing conflicts as follows:

1. A precedence and associativity is associated with each grammar rule; it is the precedence and associativity of the last token or literal in the body of the rule. If the `%prec` keyword is used, it overrides this default. Some grammar rules might not have both precedence and associativity.

2. If there is a shift/reduce conflict, and both the grammar rule and the input symbol have precedence and associativity associated with them, then the conflict is resolved in favor of the action (shift or reduce) associated with the higher precedence. If the precedences are the same, then the associativity is used; left associative implies reduce, right associative implies shift, and non-associative implies an error in the string being parsed.

3. When there is a shift/reduce conflict that cannot be resolved by rule 2, the shift is done. Conflicts resolved this way are counted in the diagnostic output described in Error Handling.

4. When there is a reduce/reduce conflict, a reduction is done by the grammar rule that occurs earlier in the input sequence. Conflicts resolved this way are counted in the diagnostic output described in Error Handling.

Conflicts resolved by precedence or associativity shall not be counted in the shift/reduce and reduce/reduce conflicts reported by `yacc` on either standard error or in the description file.

Error Handling

The token `error` shall be reserved for error handling. The name `error` can be used in grammar rules. It indicates places where the parser can recover from a syntax error. The default value of `error` shall be 256. Its value can be changed using a `%token` declaration. The lexical analyzer should not return the value of `error`.

The parser shall detect a syntax error when it is in a state where the action associated with the lookahead symbol is `error`. A semantic action can cause the parser to initiate error handling by executing the macro `YYERROR`. When `YYERROR` is executed, the semantic action passes control back to the parser. `YYERROR` cannot be used outside of semantic actions.

When the parser detects a syntax error, it normally calls `yerror()` with the character string "syntax error" as its argument. The call shall not be made if the parser is still recovering...
from a previous error when the error is detected. The parser is considered to be recovering from a previous error until the parser has shifted over at least three normal input symbols since the last error was detected or a semantic action has executed the macro `yyerrok`. The parser shall not call `yyerror` when `YYERROR` is executed.

The macro function `YYRECOVERING` shall return 1 if a syntax error has been detected and the parser has not yet fully recovered from it. Otherwise, zero shall be returned.

When a syntax error is detected by the parser, the parser shall check if a previous syntax error has been detected. If a previous error was detected, and if no normal input symbols have been shifted since the preceding error was detected, the parser checks if the lookahead symbol is an endmarker (see Interface to the Lexical Analyzer). If it is, the parser shall return with a non-zero value. Otherwise, the lookahead symbol shall be discarded and normal parsing shall resume.

When `YYERROR` is executed or when the parser detects a syntax error and no previous error has been detected, or at least one normal input symbol has been shifted since the previous error was detected, the parser shall pop back one state at a time until the parse stack is empty or the current state allows a shift over `error`. If the parser empties the parse stack, it shall return with a non-zero value. Otherwise, it shall shift over `error` and then resume normal parsing. If the parser reads a lookahead symbol before the error was detected, that symbol shall still be the lookahead symbol when parsing is resumed.

The macro `yyerrok` in a semantic action shall cause the parser to act as if it has fully recovered from any previous errors. The macro `yyclearin` shall cause the parser to discard the current lookahead token. If the current lookahead token has not yet been read, `yyclearin` shall have no effect.

The macro `YYACCEPT` shall cause the parser to return with the value zero. The macro `YYABORT` shall cause the parser to return with a non-zero value.

**Interface to the Lexical Analyzer**

The `yylex()` function is an integer-valued function that returns a token number representing the kind of token read. If there is a value associated with the token returned by `yylex()` (see the discussion of `tag` above), it shall be assigned to the external variable `yylval`.

If the parser and `yylex()` do not agree on these token numbers, reliable communication between them cannot occur. For (single-byte character) literals, the token is simply the numeric value of the character in the current character set. The numbers for other tokens can either be chosen by `yacc`, or chosen by the user. In either case, the `#define` construct of C is used to allow `yylex()` to return these numbers symbolically. The `#define` statements are put into the code file, and the header file if that file is requested. The set of characters permitted by `yacc` in an identifier is larger than that permitted by C. Token names found to contain such characters shall not be included in the `#define` declarations.

If the token numbers are chosen by `yacc`, the tokens other than literals shall be assigned numbers greater than 256, although no order is implied. A token can be explicitly assigned a number by following its first appearance in the declarations section with a number. Names and literals not defined this way retain their default definition. All token numbers assigned by `yacc` shall be unique and distinct from the token numbers used for literals and user-assigned tokens. If duplicate token numbers cause conflicts in parser generation, `yacc` shall report an error; otherwise, it is unspecified whether the token assignment is accepted or an error is reported.

The end of the input is marked by a special token called the `endmarker`, which has a token number that is zero or negative. (These values are invalid for any other token.) All lexical analyzers shall return zero or negative as a token number upon reaching the end of their input. If
the tokens up to, but excluding, the endmarker form a structure that matches the start symbol, the parser shall accept the input. If the endmarker is seen in any other context, it shall be considered an error.

**Completing the Program**

In addition to `yyparse()` and `yylex()`, the functions `yyerror()` and `main()` are required to make a complete program. The application can supply `main()` and `yyerror()`, or those routines can be obtained from the `yacc` library.

**Yacc Library**

The following functions shall appear only in the `yacc` library accessible through the `-ly` operand to `c99`; they can therefore be redefined by a conforming application:

```c
int main(void)
{
    This function shall call `yyparse()` and exit with an unspecified value. Other actions within this function are unspecified.
}
```

```c
int yyerror(const char *s)
{
    This function shall write the NUL-terminated argument to standard error, followed by a <newline>.
}
```

The order of the `-ly` and `-ll` operands given to `c99` is significant; the application shall either provide its own `main()` function or ensure that `-ly` precedes `-ll`.

**Debugging the Parser**

The parser generated by `yacc` shall have diagnostic facilities in it that can be optionally enabled at either compile time or at runtime (if enabled at compile time). The compilation of the runtime debugging code is under the control of `YYDEBUG`, a preprocessor symbol. If `YYDEBUG` has a non-zero value, the debugging code shall be included. If its value is zero, the code shall not be included.

In parsers where the debugging code has been included, the external `int yydebug` can be used to turn debugging on (with a non-zero value) and off (zero value) at runtime. The initial value of `yydebug` shall be zero.

When `-t` is specified, the code file shall be built such that, if `YYDEBUG` is not already defined at compilation time (using the `c99 -D YYDEBUG` option, for example), `YYDEBUG` shall be set explicitly to 1. When `-t` is not specified, the code file shall be built such that, if `YYDEBUG` is not already defined, it shall be set explicitly to zero.

The format of the debugging output is unspecified but includes at least enough information to determine the shift and reduce actions, and the input symbols. It also provides information about error recovery.

**Algorithms**

The parser constructed by `yacc` implements an LALR(1) parsing algorithm as documented in the literature. It is unspecified whether the parser is table-driven or direct-coded.

A parser generated by `yacc` shall never request an input symbol from `yylex()` while in a state where the only actions other than the error action are reductions by a single rule.

The literature of parsing theory defines these concepts.
Utilities

The *yacc* utility may have several internal tables. The minimum maximums for these tables are shown in the following table. The exact meaning of these values is implementation-defined. The implementation shall define the relationship between these values and between them and any error messages that the implementation may generate should it run out of space for any internal structure. An implementation may combine groups of these resources into a single pool as long as the total available to the user does not fall below the sum of the sizes specified by this section.

<table>
<thead>

<tr>
<td>{MEMSIZE}</td>
<td>5 200</td>
<td></td>
<td>Length of rules. The total length, in names (tokens and non-terminals), of all the rules of the grammar. The left-hand side is counted for each rule, even if it is not explicitly repeated, as specified in <em>Grammar Rules in yacc</em> (on page 1068).</td>
</tr>
<tr>
<td>{ACTSIZE}</td>
<td>4 000</td>
<td></td>
<td>Number of actions. “Actions” here (and in the description file) refer to parser actions (shift, reduce, and so on) not to semantic actions defined in <em>Grammar Rules in yacc</em> (on page 1068).</td>
</tr>
</tbody>
</table>

**EXIT STATUS**

The following exit values shall be returned:

- 0  Successful completion.
- >0  An error occurred.

**CONSEQUENCES OF ERRORS**

If any errors are encountered, the run is aborted and *yacc* exits with a non-zero status. Partial code files and header files may be produced. The summary information in the description file shall always be produced if the −v flag is present.

**APPLICATION USAGE**

Historical implementations experience name conflicts on the names *yacc.tmp*, *yacc.acts*, *yacc.debug*, *y.tab.c*, *y.tab.h*, and *y.output* if more than one copy of *yacc* is running in a single directory at one time. The −b option was added to overcome this problem. The related problem of allowing multiple *yacc* parsers to be placed in the same file was addressed by adding a −p option to override the previously hard-coded *yy* variable prefix.

The description of the −p option specifies the minimal set of function and variable names that cause conflict when multiple parsers are linked together. YYPARSE does not need to be changed. Instead, the programmer can use −b to give the header files for different parsers different names, and then the file with the *yylex()* for a given parser can include the header for that parser. Names such as *yyclearerr* do not need to be changed because they are used only in the actions; they do not have linkage. It is possible that an implementation has other names, either internal ones for implementing things such as *yyclearerr*, or providing non-standard features that it wants to change with −p.
Unary operators that are the same token as a binary operator in general need their precedence adjusted. This is handled by the \%prec advisory symbol associated with the particular grammar rule defining that unary operator. (See Grammar Rules in yacc (on page 1068).) Applications are not required to use this operator for unary operators, but the grammars that do not require it are rare.

EXAMPLES

Access to the yacc library is obtained with library search operands to c99. To use the yacc library main():

c99 y.tab.c -l y

Both the lex library and the yacc library contain main(). To access the yacc main():

c99 y.tab.c lex.yy.c -l y -l l

This ensures that the yacc library is searched first, so that its main() is used.

The historical yacc libraries have contained two simple functions that are normally coded by the application programmer. These functions are similar to the following code:

```c
#include <locale.h>
int main(void)
{
    extern int yyparse();
    setlocale(LC_ALL, "");
    /* If the following parser is one created by lex, the application must be careful to ensure that LC_CTYPE and LC_COLLATE are set to the POSIX locale. */
    (void) yyparse();
    return (0);
}

#include <stdio.h>
int yyerror(const char *msg)
{
    (void) fprintf(stderr, "%s\n", msg);
    return (0);
}
```

RATIONALE

The references in Referenced Documents (on page xxxi) may be helpful in constructing the parser generator. The referenced DeRemer and Pennello article (along with the works it references) describes a technique to generate parsers that conform to this volume of IEEE Std 1003.1-2001. Work in this area continues to be done, so implementors should consult current literature before doing any new implementations. The original Knuth article is the theoretical basis for this kind of parser, but the tables it generates are impractically large for reasonable grammars and should not be used. The "equivalent to" wording is intentional to assure that the best tables that are LALR(1) can be generated.

There has been confusion between the class of grammars, the algorithms needed to generate parsers, and the algorithms needed to parse the languages. They are all reasonably orthogonal. In particular, a parser generator that accepts the full range of LR(1) grammars need not generate a table any more complex than one that accepts SLR(1) (a relatively weak class of LR grammars) for a grammar that happens to be SLR(1). Such an implementation need not recognize the case, either; table compression can yield the SLR(1) table (or one even smaller than that) without
recognizing that the grammar is SLR(1). The speed of an LR(1) parser for any class is dependent
more upon the table representation and compression (or the code generation if a direct parser is
generated) than upon the class of grammar that the table generator handles.

The speed of the parser generator is somewhat dependent upon the class of grammar it handles.
However, the original Knuth article algorithms for constructing LR parsers were judged by its
author to be impractically slow at that time. Although full LR is more complex than LALR(1), as
computer speeds and algorithms improve, the difference (in terms of acceptable wall-clock
execution time) is becoming less significant.

Potential authors are cautioned that the referenced DeRemer and Pennello article previously
cited identifies a bug (an over-simplification of the computation of LALR(1) lookahead sets) in
some of the LALR(1) algorithm statements that preceded it to publication. They should take the
time to seek out that paper, as well as current relevant work, particularly Aho's.

The −b option was added to provide a portable method for permitting yacc to work on multiple
separate parsers in the same directory. If a directory contains more than one yacc grammar, and
both grammars are constructed at the same time (by, for example, a parallel make program),
conflict results. While the solution is not historical practice, it corrects a known deficiency in
historical implementations. Corresponding changes were made to all sections that referenced
the filenames y.tab.c (now "the code file"), y.tab.h (now "the header file"), and y.output (now
"the description file").

The grammar for yacc input is based on System V documentation. The textual description shows
there that the '; ' is required at the end of the rule. The grammar and the implementation do not
require this. (The use of C_IDENTIFIER causes a reduce to occur in the right place.)

Also, in that implementation, the constructs such as %token can be terminated by a semicolon,
but this is not permitted by the grammar. The keywords such as %token can also appear in
uppercase, which is again not discussed. In most places where ' % ' is used, ' \ ' can be
substituted, and there are alternate spellings for some of the symbols (for example, %LEFT can
be "%<" or even "\<").

Historically, <tag> can contain any characters except ' >', including white space, in the
implementation. However, since the tag must reference an ISO C standard union member, in
practice conforming implementations need to support only the set of characters for ISO C
standard identifiers in this context.

Some historical implementations are known to accept actions that are terminated by a period.
Historical implementations often allow ' $ ' in names. A conforming implementation does not
need to support either of these behaviors.

Deciding when to use %prec illustrates the difficulty in specifying the behavior of yacc. There
may be situations in which the grammar is not, strictly speaking, in error, and yet yacc cannot
interpret it unambiguously. The resolution of ambiguities in the grammar can in many instances
be resolved by providing additional information, such as using %type or %union declarations. It
is often easier and it usually yields a smaller parser to take this alternative when it is
appropriate.

The size and execution time of a program produced without the runtime debugging code is
usually smaller and slightly faster in historical implementations.

Statistics messages from several historical implementations include the following types of
information:

n/512 terminals, n/300 non-terminals
n/600 grammar rules, n/1500 states
n shift/reduce, n reduce/reduce conflicts reported
n/350 working sets used
Memory: states, etc. n/15000, parser n/15000
n/600 distinct lookahead sets
n extra closures
n shift entries, n exceptions
n goto entries
n entries saved by goto default
Optimizer space used: input n/15000, output n/15000
n table entries, n zero
Maximum spread: n, Maximum offset: n

The report of internal tables in the description file is left implementation-defined because all
aspects of these limits are also implementation-defined. Some implementations may use
dynamic allocation techniques and have no specific limit values to report.

The format of the y.output file is not given because specification of the format was not seen to
enhance applications portability. The listing is primarily intended to help human users
understand and debug the parser; use of y.output by a conforming application script would be
unusual. Furthermore, implementations have not produced consistent output and no popular
format was apparent. The format selected by the implementation should be human-readable, in
addition to the requirement that it be a text file.

Standard error reports are not specifically described because they are seldom of use to
conforming applications and there was no reason to restrict implementations.

Some implementations recognize "={" as equivalent to '{' because it appears in historical
documentation. This construction was recognized and documented as obsolete as long ago as
1978, in the referenced Yacc: Yet Another Compiler-Compiler. This volume of IEEE Std 1003.1-2001
chose to leave it as obsolete and omit it.

Multi-byte characters should be recognized by the lexical analyzer and returned as tokens. They
should not be returned as multi-byte character literals. The token error that is used for error
recovery is normally assigned the value 256 in the historical implementation. Thus, the token
value 256, which is used in many multi-byte character sets, is not available for use as the value
of a user-defined token.

FUTURE DIRECTIONS
None.

c99, lex

CHANGE HISTORY
First released in Issue 2.

Issue 5
The FUTURE DIRECTIONS section is added.

Issue 6
This utility is marked as part of the C-Language Development Utilities option.
Minor changes have been added to align with the IEEE P1003.2b draft standard.
The normative text is reworded to avoid use of the term “must” for application requirements.
IEEE PASC Interpretation 1003.2 #177 is applied, changing the comment on R CURL from the |%
token to the %.

NAME
zcat — expand and concatenate data

SYNOPSIS
XSI zcat [file...]

DESCRIPTION
The zcat utility shall write to standard output the uncompressed form of files that have been compressed using the compress utility. It is the equivalent of uncompress -c. Input files are not affected.

OPTIONS
None.

OPERANDS
The following operand shall be supported:

file The pathname of a file previously processed by the compress utility. If file already has the .Z suffix specified, it is used as submitted. Otherwise, the .Z suffix is appended to the filename prior to processing.

STDIN
The standard input shall be used only if no file operands are specified, or if a file operand is ‘−’. 

INPUT FILES
Input files shall be compressed files that are in the format produced by the compress utility.

ENVIRONMENT VARIABLES
The following environment variables shall affect the execution of zcat:

LANG Provide a default value for the internationalization variables that are unset or null.
(See the Base Definitions volume of IEEE Std 1003.1-2001, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

ASYNCHRONOUS EVENTS
Default.

STDOUT
The compressed files given as input shall be written on standard output in their uncompressed form.

STDERR
The standard error shall be used only for diagnostic messages.
**OUTPUT FILES**

None.

**EXTENDED DESCRIPTION**

None.

**EXIT STATUS**

The following exit values shall be returned:

- 0  Successful completion.
- >0  An error occurred.

**CONSEQUENCES OF ERRORS**

Default.

**APPLICATION USAGE**

None.

**EXAMPLES**

None.

**RATIONALE**

None.

**FUTURE DIRECTIONS**

None.

Information Technology —
Portable Operating System Interface (POSIX®)

Rationale

Sponsor

Portable Applications Standards Committee
of the
IEEE Computer Society

and

The Open Group
Abstract

This standard defines a standard operating system interface and environment, including a command interpreter (or “shell”), and common utility programs to support applications portability at the source code level. This standard is intended to be used by both applications developers and system implementors and comprises four major components (each in an associated volume):

• General terms, concepts, and interfaces common to all volumes of this standard, including utility conventions and C-language header definitions, are included in the Base Definitions volume.

• Definitions for system service functions and subroutines, language-specific system services for the C programming language, function issues, including portability, error handling, and error recovery, are included in the System Interfaces volume.

• Definitions for a standard source code-level interface to command interpretation services (a “shell”) and common utility programs for application programs are included in the Shell and Utilities volume.

• Extended rationale that did not fit well into the rest of the document structure, which contains historical information concerning the contents of this standard and why features were included or discarded by the standard developers, is included in the Rationale (Informative) volume.

The following areas are outside the scope of this standard:

• Graphics interfaces

• Database management system interfaces

• Record I/O considerations

• Object or binary code portability

• System configuration and resource availability

This standard describes the external characteristics and facilities that are of importance to applications developers, rather than the internal construction techniques employed to achieve these capabilities. Special emphasis is placed on those functions and facilities that are needed in a wide variety of commercial applications.

Keywords

application program interface (API), argument, asynchronous, basic regular expression (BRE), batch job, batch system, built-in utility, byte, child, command language interpreter, CPU, extended regular expression (ERE), FIFO, file access control mechanism, input/output (I/O), job control, network, portable operating system interface (POSIX®), parent, shell, stream, string, synchronous, system, thread, X/Open System Interface (XSI)
The Open Group

The Open Group, a vendor and technology-neutral consortium, is committed to delivering greater business efficiency by bringing together buyers and suppliers of information technology to lower the time, cost, and risks associated with integrating new technology across the enterprise.

The Open Group’s mission is to offer all organizations concerned with open information infrastructures a forum to share knowledge, integrate open initiatives, and certify approved products and processes in a manner in which they continue to trust our impartiality.

In the global eCommerce world of today, no single economic entity can achieve independence while still ensuring interoperability. The assurance that products will interoperate with each other across differing systems and platforms is essential to the success of eCommerce and business workflow. The Open Group, with its proven testing and certification program, is the international guarantor of interoperability in the new century.

The Open Group provides opportunities to exchange information and shape the future of IT. The Open Group’s members include some of the largest and most influential organizations in the world. The flexible structure of The Open Groups membership allows for almost any organization, no matter what their size, to join and have a voice in shaping the future of the IT world.

More information is available on The Open Group web site at http://www.opengroup.org.

The Open Group has over 15 years’ experience in developing and operating certification programs and has extensive experience developing and facilitating industry adoption of test suites used to validate conformance to an open standard or specification. The Open Group portfolio of test suites includes the Westwood family of tests for this standard and the associated certification program for Version 3 of the Single UNIX Specification, as well tests for CDE, CORBA, Motif, Linux, LDAP, POSIX.1, POSIX.2, POSIX Realtime, Sockets, UNIX, XPG4, XNFS, XTI, and X11. The Open Group test tools are essential for proper development and maintenance of standards-based products, ensuring conformance of products to industry-standard APIs, applications portability, and interoperability. In-depth testing identifies defects at the earliest possible point in the development cycle, saving costs in development and quality assurance.

More information is available at http://www.opengroup.org/testing.

The Open Group publishes a wide range of technical documentation, the main part of which is focused on development of Technical and Product Standards and Guides, but which also includes white papers, technical studies, branding and testing documentation, and business titles. Full details and a catalog are available at http://www.opengroup.org/pubs.

As with all live documents, Technical Standards and Specifications require revision to align with new developments and associated international standards. To distinguish between revised specifications which are fully backwards compatible and those which are not:

- A new Version indicates there is no change to the definitive information contained in the previous publication of that title, but additions/extensions are included. As such, it replaces the previous publication.
- A new Issue indicates there is substantive change to the definitive information contained in the previous publication of that title, and there may also be additions/extensions. As such, both previous and new documents are maintained as current publications.

Readers should note that Corrigenda may apply to any publication. Corrigenda information is published at http://www.opengroup.org/corrigenda.

Full catalog and ordering information on all Open Group publications is available at http://www.opengroup.org/pubs.

Foreword

Structure of the Standard

This standard was originally developed by the Austin Group, a joint working group of members of the IEEE, members of The Open Group, and members of ISO/IEC Joint Technical Committee 1, as one of the four volumes of IEEE Std 1003.1-2001. The standard was approved by ISO and IEC and published in four parts, correlating to the original volumes.

A mapping of the parts to the volumes is shown below:

<table>
<thead>
<tr>
<th>ISO/IEC 9945 Part</th>
<th>IEEE Std 1003.1 Volume</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>9945-1</td>
<td>Base Definitions</td>
<td>Includes general terms, concepts, and interfaces common to all parts of ISO/IEC 9945, including utility conventions and C-language header definitions.</td>
</tr>
<tr>
<td>9945-2</td>
<td>System Interfaces</td>
<td>Includes definitions for system service functions and subroutines, language-specific system services for the C programming language, function issues, including portability, error handling, and error recovery.</td>
</tr>
<tr>
<td>9945-3</td>
<td>Shell and Utilities</td>
<td>Includes definitions for a standard source code-level interface to command interpretation services (a “shell”) and common utility programs for application programs.</td>
</tr>
<tr>
<td>9945-4</td>
<td>Rationale</td>
<td>Includes extended rationale that did not fit well into the rest of the document structure, containing historical information concerning the contents of ISO/IEC 9945 and why features were included or discarded by the standard developers.</td>
</tr>
</tbody>
</table>

All four parts comprise the entire standard, and are intended to be used together to accommodate significant internal referencing among them. POSIX-conforming systems are required to support all four parts.
Introduction

Note: This introduction is not part of IEEE Std 1003.1-2001, Standard for Information Technology — Portable Operating System Interface (POSIX).

This standard has been jointly developed by the IEEE and The Open Group. It is simultaneously an IEEE Standard, an ISO/IEC Standard, and an Open Group Technical Standard.

The Austin Group

This standard was developed, and is maintained, by a joint working group of members of the IEEE Portable Applications Standards Committee, members of The Open Group, and members of ISO/IEC Joint Technical Committee 1. This joint working group is known as the Austin Group. The Austin Group arose out of discussions amongst the parties which started in early 1998, leading to an initial meeting and formation of the group in September 1998. The purpose of the Austin Group has been to revise, combine, and update the following standards: ISO/IEC 9945-1, ISO/IEC 9945-2, IEEE Std 1003.1, IEEE Std 1003.2, and the Base Specifications of The Open Group Single UNIX Specification.

After two initial meetings, an agreement was signed in July 1999 between The Open Group and the Institute of Electrical and Electronics Engineers (IEEE), Inc., to formalize the project with the first draft of the revised specifications being made available at the same time. Under this agreement, The Open Group and IEEE agreed to share joint copyright of the resulting work. The Open Group has provided the chair and secretariat for the Austin Group.

The base document for the revision was The Open Group’s Base volumes of its Single UNIX Specification, Version 2. These were selected since they were a superset of the existing POSIX.1 and POSIX.2 specifications and had some organizational aspects that would benefit the audience for the new revision.

The approach to specification development has been one of “write once, adopt everywhere”, with the deliverables being a set of specifications that carry the IEEE POSIX designation, The Open Group’s Technical Standard designation, and an ISO/IEC designation. This set of specifications forms the core of the Single UNIX Specification, Version 3.

This unique development has combined both the industry-led efforts and the formal standardization activities into a single initiative, and included a wide spectrum of participants. The Austin Group continues as the maintenance body for this document.

Anyone wishing to participate in the Austin Group should contact the chair with their request. There are no fees for participation or membership. You may participate as an observer or as a contributor. You do not have to attend face-to-face meetings to participate; electronic participation is most welcome. For more information on the Austin Group and how to participate, see http://www.opengroup.org/austin.

3. The Austin Group is named after the location of the inaugural meeting held at the IBM facility in Austin, Texas in September 1998.
Introduction

Background

The developers of this standard represent a cross section of hardware manufacturers, vendors of operating systems and other software development tools, software designers, consultants, academics, authors, applications programmers, and others.

Conceptually, this standard describes a set of fundamental services needed for the efficient construction of application programs. Access to these services has been provided by defining an interface, using the C programming language, a command interpreter, and common utility programs that establish standard semantics and syntax. Since this interface enables application writers to write portable applications—it was developed with that goal in mind—it has been designated POSIX,4 an acronym for Portable Operating System Interface.

Although originated to refer to the original IEEE Std 1003.1-1988, the name POSIX more correctly refers to a family of related standards: IEEE Std 1003.n and the parts of ISO/IEC 9945. In earlier editions of the IEEE standard, the term POSIX was used as a synonym for IEEE Std 1003.1-1988. A preferred term, POSIX.1, emerged. This maintained the advantages of readability of the symbol “POSIX” without being ambiguous with the POSIX family of standards.

Audience

The intended audience for this standard is all persons concerned with an industry-wide standard operating system based on the UNIX system. This includes at least four groups of people:

1. Persons buying hardware and software systems
2. Persons managing companies that are deciding on future corporate computing directions
3. Persons implementing operating systems, and especially
4. Persons developing applications where portability is an objective

Purpose

Several principles guided the development of this standard:

• Application-Oriented

The basic goal was to promote portability of application programs across UNIX system environments by developing a clear, consistent, and unambiguous standard for the interface specification of a portable operating system based on the UNIX system documentation. This standard codifies the common, existing definition of the UNIX system.

• Interface, Not Implementation

This standard defines an interface, not an implementation. No distinction is made between library functions and system calls; both are referred to as functions. No details of the implementation of any function are given (although historical practice is sometimes indicated in the RATIONALE section). Symbolic names are given for constants (such as signals and error numbers) rather than numbers.

4. The name POSIX was suggested by Richard Stallman. It is expected to be pronounced paht-icks, as in positive, not poh-six, or other variations. The pronunciation has been published in an attempt to promulgate a standardized way of referring to a standard operating system interface.
• Source, Not Object, Portability

This standard has been written so that a program written and translated for execution on one conforming implementation may also be translated for execution on another conforming implementation. This standard does not guarantee that executable (object or binary) code will execute under a different conforming implementation than that for which it was translated, even if the underlying hardware is identical.

• The C Language

The system interfaces and header definitions are written in terms of the standard C language as specified in the ISO C standard.

• No Superuser, No System Administration

There was no intention to specify all aspects of an operating system. System administration facilities and functions are excluded from this standard, and functions usable only by the superuser have not been included. Still, an implementation of the standard interface may also implement features not in this standard. This standard is also not concerned with hardware constraints or system maintenance.

• Minimal Interface, Minimally Defined

In keeping with the historical design principles of the UNIX system, the mandatory core facilities of this standard have been kept as minimal as possible. Additional capabilities have been added as optional extensions.

• Broadly Implementable

The developers of this standard endeavored to make all specified functions implementable across a wide range of existing and potential systems, including:

1. All of the current major systems that are ultimately derived from the original UNIX system code (Version 7 or later)
2. Compatible systems that are not derived from the original UNIX system code
3. Emulations hosted on entirely different operating systems
4. Networked systems
5. Distributed systems
6. Systems running on a broad range of hardware

No direct references to this goal appear in this standard, but some results of it are mentioned in the Rationale (Informative) volume.

• Minimal Changes to Historical Implementations

When the original version of IEEE Std 1003.1 was published, there were no known historical implementations that did not have to change. However, there was a broad consensus on a set of functions, types, definitions, and concepts that formed an interface that was common to most historical implementations.

The adoption of the 1988 and 1990 IEEE system interface standards, the 1992 IEEE shell and utilities standard, the various Open Group (formerly X/Open) specifications, and the subsequent revisions and addenda to all of them have consolidated this consensus, and this revision reflects the significantly increased level of consensus arrived at since the original versions. The earlier standards and their modifications specified a number of areas where consensus had not been reached before, and these are now reflected in this revision. The authors of the original versions tried, as much as possible, to follow the principles below
when creating new specifications:

1. By standardizing an interface like one in an historical implementation; for example, directories

2. By specifying an interface that is readily implementable in terms of, and backwards-compatible with, historical implementations, such as the extended \texttt{tar} format defined in the \texttt{pax} utility

3. By specifying an interface that, when added to an historical implementation, will not conflict with it; for example, the \texttt{sigaction()} function

This revision tries to minimize the number of changes required to implementations which conform to the earlier versions of the approved standards to bring them into conformance with the current standard. Specifically, the scope of this work excluded doing any "new" work, but rather collecting into a single document what had been spread across a number of documents, and presenting it in what had been proven in practice to be a more effective way. Some changes to prior conforming implementations were unavoidable, primarily as a consequence of resolving conflicts found in prior revisions, or which became apparent when bringing the various pieces together.

However, since it references the 1999 version of the ISO C standard, and no longer supports "Common Usage C", there are a number of unavoidable changes. Applications portability is similarly affected.

This standard is specifically not a codification of a particular vendor’s product.

It should be noted that implementations will have different kinds of extensions. Some will reflect "historical usage" and will be preserved for execution of pre-existing applications. These functions should be considered "obsolete" and the standard functions used for new applications. Some extensions will represent functions beyond the scope of this standard. These need to be used with careful management to be able to adapt to future extensions of this standard and/or port to implementations that provide these services in a different manner.

- Minimal Changes to Existing Application Code

  A goal of this standard was to minimize additional work for the developers of applications. However, because every known historical implementation will have to change at least slightly to conform, some applications will have to change.

This Standard

This standard defines the Portable Operating System Interface (POSIX) requirements and consists of the following volumes:

- Base Definitions
- Shell and Utilities
- System Interfaces
- Rationale (Informative) (this volume)
This Volume

This volume is being published to assist in the process of review. It contains historical information concerning the contents of this standard and why features were included or discarded by the standard developers. It also contains notes of interest to application programmers on recommended programming practices, emphasizing the consequences of some aspects of this standard that may not be immediately apparent.

This volume is organized in parallel to the normative volumes of this standard, with a separate part for each of the three normative volumes.

Within this volume, the following terms are used:

**base standard**
- The portions of this standard that are not optional, equivalent to the definitions of classic POSIX.1 and POSIX.2.

**POSIX.0**
- Although this term is not used in the normative text of this standard, it is used in this volume to refer to IEEE Std 1003.0-1995.

**POSIX.1b**
- Although this term is not used in the normative text of this standard, it is used in this volume to refer to the elements of the POSIX Realtime Extension amendment. (This was earlier referred to as POSIX.4 during the standard development process.)

**POSIX.1c**
- Although this term is not used in the normative text of this standard, it is used in this volume to refer to the POSIX Threads Extension amendment. (This was earlier referred to as POSIX.4a during the standard development process.)

**standard developers**
- The individuals and companies in the development organizations responsible for this standard: the IEEE P1003.1 working groups, The Open Group Base working group, advised by the hundreds of individual technical experts who balloted the draft standards within the Austin Group, and the member bodies and technical experts of ISO/IEC JTC 1/SC22/WG15.

**XSI extension**
- The portions of this standard addressing the extension added for support of the Single UNIX Specification.
IEEE Std 1003.1-2001 was prepared by the Austin Group, sponsored by the Portable Applications Standards Committee of the IEEE Computer Society, The Open Group, and ISO/SC22 WG15.

The Austin Group

At the time of approval, the membership of the Austin Group was as follows:

Andrew Josey, Chair
Donald W. Cragun, Organizational Representative, IEEE PASC
Nicholas Stoughton, Organizational Representative, ISO/SC22 WG15
Mark Brown, Organizational Representative, The Open Group
Cathy Hughes, Technical Editor

The following organizational representative voted on this standard:

Andrew Josey, X/Open Company Ltd.
Participants

IEEE-SA Standards Board

When the IEEE-SA Standards Board approved IEEE Std 1003.1-2001 on 6 December 2001, it had the following membership:

Donald N. Heirman, Chair
James T. Carlo, Vice-Chair
Judith Gorman, Secretary

Satish K. Aggarwal  James H. Gurney  James W. Moore
Mark D. Bowman  Richard J. Holleman  Robert F. Munzner
Gary R. Engmann  Lowell G. Johnson  Ronald C. Petersen
Harold E. Epstein  Robert J. Kennelly  Gerald H. Peterson
H. Landis Floyd  Joseph L. Koepfinger*  John B. Posey
Jay Forster*  Peter H. Lips  Gary S. Robinson
Howard M. Frazier  L. Bruce McClung  Akio Tojo
Ruben D. Garzon  Daleep C. Mohla  Donald W. Zipse

Also included are the following non-voting IEEE-SA Standards Board liaisons:

Alan Cookson, NIST Representative
Donald R. Volzka, TAB Representative
Yvette Ho Sang, Don Messina, Savoula Amanatidis, IEEE Project Editors

* Member Emeritus
IEEE Std 1003.1-2001/Cor 1-2002 was prepared by the Austin Group, sponsored by the Portable Applications Standards Committee of the IEEE Computer Society, The Open Group, and ISO/IEC JTC 1/SC22/WG15.

The Austin Group

At the time of approval, the membership of the Austin Group was as follows:

Andrew Josey, Chair
Donald W. Cragun, Organizational Representative, IEEE PASC
Nicholas Stoughton, Organizational Representative, ISO/IEC JTC 1/SC22/WG15
Mark Brown, Organizational Representative, The Open Group
Cathy Fox, Technical Editor

Appendix A

Rationale for Base Definitions

A.1 Introduction

A.1.1 Scope

IEEE Std 1003.1-2001 is one of a family of standards known as POSIX. The family of standards extends to many topics; IEEE Std 1003.1-2001 is known as POSIX.1 and consists of both operating system interfaces and shell and utilities. IEEE Std 1003.1-2001 is technically identical to The Open Group Base Specifications, Issue 6, which comprise the core volumes of the Single UNIX Specification, Version 3.

Scope of IEEE Std 1003.1-2001

The (paraphrased) goals of this development were to produce a single common revision to the overlapping POSIX.1 and POSIX.2 standards, and the Single UNIX Specification, Version 2. As such, the scope of the revision includes the scopes of the original documents merged.

Since the revision includes merging the Base volumes of the Single UNIX Specification, many features that were previously not “adopted” into earlier revisions of POSIX.1 and POSIX.2 are now included in IEEE Std 1003.1-2001. In most cases, these additions are part of the XSI extension; in other cases the standard developers decided that now was the time to migrate these to the base standard.

The Single UNIX Specification programming environment provides a broad-based functional set of interfaces to support the porting of existing UNIX applications and the development of new applications. The environment also supports a rich set of tools for application development.

The majority of the obsolescent material from the existing POSIX.1 and POSIX.2 standards, and material marked LEGACY from The Open Group’s Base specifications, has been removed in this revision. New members of the Legacy Option Group have been added, reflecting the advance in understanding of what is required.

The following IEEE standards have been added to the base documents in this revision:

- IEEE Std 1003.1d-1999
- IEEE Std 1003.1j-2000
- IEEE Std 1003.1q-2000
- IEEE P1003.1a draft standard
- IEEE Std 1003.2d-1994
- IEEE P1003.2b draft standard
- Selected parts of IEEE Std 1003.1g-2000

Only selected parts of IEEE Std 1003.1g-2000 were included. This was because there is much duplication between the XNS, Issue 5.2 specification (another base document) and the material from IEEE Std 1003.1g-2000, the former document being aligned with the latest networking specifications for IPv6. Only the following sections of IEEE Std 1003.1g-2000 were considered for inclusion:
Introduction

Rationale for Base Definitions

• General terms related to sockets (Section 2.2.2)
• Socket concepts (Sections 5.1 through 5.3 inclusive)
• The pselect() function (Sections 6.2.2.1 and 6.2.3)
• The <sys/select.h> header (Section 6.2)

The following were requirements on IEEE Std 1003.1-2001:

• Backward-compatibility
  It was agreed that there should be no breakage of functionality in the existing base documents. This requirement was tempered by changes introduced due to interpretations and corrigenda on the base documents, and any changes introduced in the ISO/IEC 9899:1999 standard (C Language).

• Architecture and n-bit neutral
  The common standard should not make any implicit assumptions about the system architecture or size of data types; for example, previously some 32-bit implicit assumptions had crept into the standards.

• Extensibility
  It should be possible to extend the common standard without breaking backwards-compatibility. For example, the name space should be reserved and structured to avoid duplication of names between the standard and extensions to it.

POSIX.1 and the ISO C Standard

Previous revisions of POSIX.1 built upon the ISO C standard by reference only. This revision takes a different approach.

The standard developers believed it essential for a programmer to have a single complete reference place, but recognized that deference to the formal standard had to be addressed for the duplicate interface definitions between the ISO C standard and the Single UNIX Specification.

It was agreed that where an interface has a version in the ISO C standard, the DESCRIPTION section should describe the relationship to the ISO C standard and markings should be added as appropriate to show where the ISO C standard has been extended in the text.

A block of text was added to the start of each affected reference page stating whether the page is aligned with the ISO C standard or extended. Each page was parsed for additions beyond the ISO C standard (that is, including both POSIX and UNIX extensions), and these extensions are marked as CX extensions (for C Extensions).

FIPS Requirements

The Federal Information Processing Standards (FIPS) are a series of U.S. government procurement standards managed and maintained on behalf of the U.S. Department of Commerce by the National Institute of Standards and Technology (NIST).

The following restrictions have been made in this version of IEEE Std 1003.1 in order to align with FIPS 151-2 requirements:

• The implementation supports _POSIX_CHOWN_RESTRICTED.
• The limit {NGROUPS_MAX} is now greater than or equal to 8.
• The implementation supports the setting of the group ID of a file (when it is created) to that of the parent directory.
• The implementation supports _POSIX_SAVED_IDS.

• The implementation supports _POSIX_VDISABLE.

• The implementation supports _POSIX_JOB_CONTROL.

• The implementation supports _POSIX_NO_TRUNC.

• The read() function returns the number of bytes read when interrupted by a signal and does not return −1.

• The write() function returns the number of bytes written when interrupted by a signal and does not return −1.

• In the environment for the login shell, the environment variables LOGNAME and HOME are defined and have the properties described in IEEE Std 1003.1-2001.

• The value of [CHILD_MAX] is now greater than or equal to 25.

• The value of [OPEN_MAX] is now greater than or equal to 20.

• The implementation supports the functionality associated with the symbols CS7, CS8, CSTOPB, PARODD, and PARENB defined in <termios.h>.

A.1.2 Conformance

See Section A.2 (on page 9).

A.1.3 Normative References

There is no additional rationale provided for this section.

A.1.4 Terminology

The meanings specified in IEEE Std 1003.1-2001 for the words shall, should, and may are mandated by ISO/IEC directives.

In the Rationale (Informative) volume of IEEE Std 1003.1-2001, the words shall, should, and may are sometimes used to illustrate similar usages in IEEE Std 1003.1-2001. However, the rationale itself does not specify anything regarding implementations or applications.

correction document

As a practical matter, the conformance document is effectively part of the system documentation. Conformance documents are distinguished by IEEE Std 1003.1-2001 so that they can be referred to distinctly.

implementation-defined

This definition is analogous to that of the ISO C standard and, together with “undefined” and “unspecified”, provides a range of specification of freedom allowed to the interface implementor.

may

The use of may has been limited as much as possible, due both to confusion stemming from its ordinary English meaning and to objections regarding the desirability of having as few options as possible and those as clearly specified as possible.

The usage of can and may were selected to contrast optional application behavior (can) against optional implementation behavior (may).
shall

Declarative sentences are sometimes used in IEEE Std 1003.1-2001 as if they included the word *shall*, and facilities thus specified are no less required. For example, the two statements:

1. The *foo*() function shall return zero.
2. The *foo*() function returns zero.

are meant to be exactly equivalent.

should

In IEEE Std 1003.1-2001, the word *should* does not usually apply to the implementation, but rather to the application. Thus, the important words regarding implementations are *shall*, which indicates requirements, and *may*, which indicates options.

obsolescent

The term “obsolescent” means “do not use this feature in new applications”. The obsolescence concept is not an ideal solution, but was used as a method of increasing consensus: many more objections would be heard from the user community if some of these historical features were suddenly withdrawn without the grace period obsolescence implies. The phrase “may be considered for withdrawal in future revisions” implies that the result of that consideration might in fact keep those features indefinitely if the predominance of applications do not migrate away from them quickly.

legacy

The term “legacy” was added for compatibility with the Single UNIX Specification. It means “this feature is historic and optional; do not use this feature in new applications.”. It is used exclusively for XSI extensions, and includes facilities that were mandatory in previous versions of the base document but are optional in this revision. This is a way to “sunset” the usage of certain functions. Application writers should not rely on the existence of these facilities in new applications, but should follow the migration path detailed in the APPLICATION USAGE sections of the relevant pages.

The terms “legacy” and “obsolescent” are different: a feature marked LEGACY is not recommended for new work and need not be present on an implementation (if the XSI Legacy Option Group is not supported). A feature noted as obsolescent is supported by all implementations, but may be removed in a future revision; new applications should not use these features.

system documentation

The system documentation should normally describe the whole of the implementation, including any extensions provided by the implementation. Such documents normally contain information at least as detailed as the specifications in IEEE Std 1003.1-2001. Few requirements are made on the system documentation, but the term is needed to avoid a dangling pointer where the conformance document is permitted to point to the system documentation.

undefined

See implementation-defined.

unspecified

See implementation-defined.

The definitions for “unspecified” and “undefined” appear nearly identical at first examination, but are not. The term “unspecified” means that a conforming application may deal with the unspecified behavior, and it should not care what the outcome is. The term
“undefined” says that a conforming application should not do it because no definition is provided for what it does (and implicitly it would care what the outcome was if it tried it). It is important to remember, however, that if the syntax permits the statement at all, it must have some outcome in a real implementation.

Thus, the terms “undefined” and “unspecified” apply to the way the application should think about the feature. In terms of the implementation, it is always “defined”—there is always some result, even if it is an error. The implementation is free to choose the behavior it prefers.

This also implies that an implementation, or another standard, could specify or define the result in a useful fashion. The terms apply to IEEE Std 1003.1-2001 specifically.

The term “implementation-defined” implies requirements for documentation that are not required for “undefined” (or “unspecified”). Where there is no need for a conforming program to know the definition, the term “undefined” is used, even though “implementation-defined” could also have been used in this context. There could be a fourth term, specifying “this standard does not say what this does; it is acceptable to define it in an implementation, but it does not need to be documented”, and undefined would then be used very rarely for the few things for which any definition is not useful. In particular, implementation-defined is used where it is believed that certain classes of application will need to know such details to determine whether the application can be successfully ported to the implementation. Such applications are not always strictly portable, but nevertheless are common and useful; often the requirements met by the application cannot be met without dealing with the issues implied by “implementation-defined”.

In many places IEEE Std 1003.1-2001 is silent about the behavior of some possible construct. For example, a variable may be defined for a specified range of values and behaviors are described for those values; nothing is said about what happens if the variable has any other value. That kind of silence can imply an error in the standard, but it may also imply that the standard was intentionally silent and that any behavior is permitted. There is a natural tendency to infer that if the standard is silent, a behavior is prohibited. That is not the intent. Silence is intended to be equivalent to the term “unspecified”.

The term “application” is not defined in IEEE Std 1003.1-2001; it is assumed to be a part of general computer science terminology.

Three terms used within IEEE Std 1003.1-2001 overlap in meaning: “macro”, “symbolic name”, and “symbolic constant”.

**macro**

This usually describes a C preprocessor symbol, the result of the `#define` operator, with or without an argument. It may also be used to describe similar mechanisms in editors and text processors.

**symbolic name**

This can also refer to a C preprocessor symbol (without arguments), but is also used to refer to the names for characters in character sets. In addition, it is sometimes used to refer to host names and even filenames.

**symbolic constant**

This also refers to a C preprocessor symbol (also without arguments).

In most cases, the difference in semantic content is negligible to nonexistent. Readers should not attempt to read any meaning into the various usages of these terms.
A.1.5 Portability

To aid the identification of options within IEEE Std 1003.1-2001, a notation consisting of margin codes and shading is used. This is based on the notation used in previous revisions of The Open Group’s Base specifications.

The benefit of this approach is a reduction in the number of if statements within the running text, that makes the text easier to read, and also an identification to the programmer that they need to ensure that their target platforms support the underlying options. For example, if functionality is marked with THR in the margin, it will be available on all systems supporting the Threads option, but may not be available on some others.

A.1.5.1 Codes

This section includes codes for options defined in the Base Definitions volume of IEEE Std 1003.1-2001, Section 2.1.6, Options, and the following additional codes for other purposes:

CX This margin code is used to denote extensions beyond the ISO C standard. For interfaces that are duplicated between IEEE Std 1003.1-2001 and the ISO C standard, a CX introduction block describes the nature of the duplication, with any extensions appropriately CX marked and shaded.

Where an interface is added to an ISO C standard header, within the header the interface has an appropriate margin marker and shading (for example, CX, XSI, TSF, and so on) and the same marking appears on the reference page in the SYNOPSIS section. This enables a programmer to easily identify that the interface is extending an ISO C standard header.

MX This margin code is used to denote IEC 60559:1989 standard floating-point extensions.

OB This margin code is used to denote obsolescent behavior and thus flag a possible future applications portability warning.

OH The Single UNIX Specification has historically tried to reduce the number of headers an application has had to include when using a particular interface. Sometimes this was fewer than the base standard, and hence a notation is used to flag which headers are optional if you are using a system supporting the XSI extension.

XSI This code is used to denote interfaces and facilities within interfaces only required on systems supporting the XSI extension. This is introduced to support the Single UNIX Specification.

XSR This code is used to denote interfaces and facilities within interfaces only required on systems supporting STREAMS. This is introduced to support the Single UNIX Specification, although it is defined in a way so that it can stand alone from the XSI notation.

A.1.5.2 Margin Code Notation

Since some features may depend on one or more options, or require more than one option, a notation is used. Where a feature requires support of a single option, a single margin code will occur in the margin. If it depends on two options and both are required, then the codes will appear with a <space> separator. If either of two options are required, then a logical OR is denoted using the '|' symbol. If more than two codes are used, a special notation is used.
A.2 Conformance

The terms “profile” and “profiling” are used throughout this section.

A profile of a standard or standards is a codified set of option selections, such that by being conformant to a profile, particular classes of users are specifically supported.

These conformance definitions are descended from those in the ISO POSIX-1:1996 standard, but with changes for the following:

- The addition of profiling options, allowing larger profiles of options such as the XSI extension used by the Single UNIX Specification. In effect, it has profiled itself (that is, created a self-profile).
- The addition of a definition of subprofiling considerations, to allow smaller profiles of options.
- The addition of a hierarchy of super-options for XSI; these were formerly known as “Feature Groups” in the System Interfaces and Headers, Issue 5 specification.
- Options from the ISO POSIX-2:1993 standard are also now included, as IEEE Std 1003.1-2001 merges the functionality from it.

A.2.1 Implementation Conformance

These definitions allow application developers to know what to depend on in an implementation.

There is no definition of a “strictly conforming implementation”; that would be an implementation that provides only those facilities specified by POSIX.1 with no extensions whatsoever. This is because no actual operating system implementation can exist without system administration and initialization facilities that are beyond the scope of POSIX.1.

A.2.1.1 Requirements

The word “support” is used in certain instances, rather than “provide”, in order to allow an implementation that has no resident software development facilities, but that supports the execution of a Strictly Conforming POSIX.1 Application, to be a conforming implementation.

A.2.1.2 Documentation

The conformance documentation is required to use the same numbering scheme as POSIX.1 for purposes of cross-referencing. All options that an implementation chooses are reflected in <limits.h> and <unistd.h>.

Note that the use of “may” in terms of where conformance documents record where implementations may vary, implies that it is not required to describe those features identified as undefined or unspecified.

Other aspects of systems must be evaluated by purchasers for suitability. Many systems incorporate buffering facilities, maintaining updated data in volatile storage and transferring such updates to non-volatile storage asynchronously. Various exception conditions, such as a power failure or a system crash, can cause this data to be lost. The data may be associated with a file that is still open, with one that has been closed, with a directory, or with any other internal system data structures associated with permanent storage. This data can be lost, in whole or part, so that only careful inspection of file contents could determine that an update did not occur.
Also, interrelated file activities, where multiple files and/or directories are updated, or where space is allocated or released in the file system structures, can leave inconsistencies in the relationship between data in the various files and directories, or in the file system itself. Such inconsistencies can break applications that expect updates to occur in a specific sequence, so that updates in one place correspond with related updates in another place.

For example, if a user creates a file, places information in the file, and then records this action in another file, a system or power failure at this point followed by restart may result in a state in which the record of the action is permanently recorded, but the file created (or some of its information) has been lost. The consequences of this to the user may be undesirable. For a user on such a system, the only safe action may be to require the system administrator to have a policy that requires, after any system or power failure, that the entire file system must be restored from the most recent backup copy (causing all intervening work to be lost).

The characteristics of each implementation will vary in this respect and may or may not meet the requirements of a given application or user. Enforcement of such requirements is beyond the scope of POSIX.1. It is up to the purchaser to determine what facilities are provided in an implementation that affect the exposure to possible data or sequence loss, and also what underlying implementation techniques and/or facilities are provided that reduce or limit such loss or its consequences.

### A.2.1.3 POSIX Conformance

This really means conformance to the base standard; however, since this revision includes the core material of the Single UNIX Specification, the standard developers decided that it was appropriate to segment the conformance requirements into two, the former for the base standard, and the latter for the Single UNIX Specification.

Within POSIX.1 there are some symbolic constants that, if defined, indicate that a certain option is enabled. Other symbolic constants exist in POSIX.1 for other reasons.

As part of the revision some alignment has occurred of the options with the FIPS 151-2 profile on the POSIX.1-1990 standard. The following options from the POSIX.1-1990 standard are now mandatory:

- `_POSIX_JOB_CONTROL`
- `_POSIX_SAVED_IDS`
- `_POSIX_VDISABLE`

A POSIX-conformant system may support the XSI extensions of the Single UNIX Specification. This was intentional since the standard developers intend them to be upwards-compatible, so that a system conforming to the Single UNIX Specification can also conform to the base standard at the same time.

### A.2.1.4 XSI Conformance

This section is added since the revision merges in the base volumes of the Single UNIX Specification.

XSI conformance can be thought of as a profile, selecting certain options from IEEE Std 1003.1-2001.
A.2.1.5 Option Groups

The concept of “Option Groups” is introduced to IEEE Std 1003.1-2001 to allow collections of related functions or options to be grouped together. This has been used as follows: the “XSI Option Groups” have been created to allow super-options, collections of underlying options and related functions, to be collectively supported by XSI-conforming systems. These reflect the “Feature Groups” from the System Interfaces and Headers, Issue 5 specification.

The standard developers considered the matter of subprofiling and decided it was better to include an enabling mechanism rather than detailed normative requirements. A set of subprofiling options was developed and included later in this volume of IEEE Std 1003.1-2001 as an informative illustration.

Subprofiling Considerations

The goal of not simultaneously fixing maximums and minimums was to allow implementations of the base standard or standards to support multiple profiles without conflict.

The following summarizes the rules for the limit types:

<table>
<thead>
<tr>
<th>Limit Type</th>
<th>Fixed Value</th>
<th>Minimum Acceptable Value</th>
<th>Maximum Acceptable Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Standard</td>
<td>Xs</td>
<td>Ys</td>
<td>Zs</td>
</tr>
<tr>
<td>Profile</td>
<td>Xp == Xs</td>
<td>Yp &gt;= Ys</td>
<td>Zp &lt;= Zs</td>
</tr>
</tbody>
</table>

The intent is that ranges specified by limits in profiles be entirely contained within the corresponding ranges of the base standard or standards being profiled, and that the unlimited end of a range in a base standard must remain unlimited in any profile of that standard.

Thus, the fixed _POSIX_* limits are constants and must not be changed by a profile. The variable counterparts (typically without the leading _POSIX_) can be changed but still remain semantically the same; that is, they still allow implementation values to vary as long as they meet the requirements for that value (be it a minimum or maximum).

Where a profile does not provide a feature upon which a limit is based, the limit is not relevant. Applications written to that profile should be written to operate independently of the value of the limit.

An example which has previously allowed implementations to support both the base standard and two other profiles in a compatible manner follows:

Base standard (POSIX.1-1996): _POSIX_CHILD_MAX 6
Base standard: CHILD_MAX minimum maximum _POSIX_CHILD_MAX
FIPS profile/SUSv2 CHILD_MAX 25 (minimum maximum)

Another example:

Base standard (POSIX.1-1996): _POSIX_NGROUPS_MAX 0
Base standard: NGROUPS_MAX minimum maximum _POSIX_NGROUP_MAX
FIPS profile/SUSv2 NGROUPS_MAX 8

A profile may lower a minimum maximum below the equivalent _POSIX value:

Base standard: _POSIX_foo_MAX Z
Base standard: foo_MAX _POSIX_foo_MAX
profile standard: foo_MAX X (X can be less than, equal to, or greater than _POSIX_foo_MAX)
In this case an implementation conforming to the profile may not conform to the base standard, but an implementation to the base standard will conform to the profile.

A.2.1.6 Options

A.2.2 Application Conformance

These definitions guide users or adaptors of applications in determining on which implementations an application will run and how much adaptation would be required to make it run on others. These definitions are modeled after related ones in the ISO C standard.

POSIX.1 occasionally uses the expressions “portable application” or “conforming application”. As they are used, these are synonyms for any of these terms. The differences between the classes of application conformance relate to the requirements for other standards, the options supported (such as the XSI extension) or, in the case of the Conforming POSIX.1 Application Using Extensions, to implementation extensions. When one of the less explicit expressions is used, it should be apparent from the context of the discussion which of the more explicit names is appropriate.

A.2.2.1 Strictly Conforming POSIX Application

This definition is analogous to that of an ISO C standard “conforming program”. The major difference between a Strictly Conforming POSIX Application and an ISO C standard strictly conforming program is that the latter is not allowed to use features of POSIX that are not in the ISO C standard.

A.2.2.2 Conforming POSIX Application

Examples of <National Bodies> include ANSI, BSI, and AFNOR.

A.2.2.3 Conforming POSIX Application Using Extensions

Due to possible requirements for configuration or implementation characteristics in excess of the specifications in <limits.h> or related to the hardware (such as array size or file space), not every Conforming POSIX Application Using Extensions will run on every conforming implementation.

A.2.2.4 Strictly Conforming XSI Application

This is intended to be upwards-compatible with the definition of a Strictly Conforming POSIX Application, with the addition of the facilities and functionality included in the XSI extension.

A.2.2.5 Conforming XSI Application Using Extensions

Such applications may use extensions beyond the facilities defined by IEEE Std 1003.1-2001 including the XSI extension, but need to document the additional requirements.
A.2.3 Language-Dependent Services for the C Programming Language

POSIX.1 is, for historical reasons, both a specification of an operating system interface, shell and utilities, and a C binding for that specification. Efforts had been previously undertaken to generate a language-independent specification; however, that had failed, and the fact that the ISO C standard is the de facto primary language on POSIX and the UNIX system makes this a necessary and workable situation.

A.2.4 Other Language-Related Specifications

There is no additional rationale provided for this section.

A.3 Definitions

The definitions in this section are stated so that they can be used as exact substitutes for the terms in text. They should not contain requirements or cross-references to sections within IEEE Std 1003.1-2001; that is accomplished by using an informative note. In addition, the term should not be included in its own definition. Where requirements or descriptions need to be addressed but cannot be included in the definitions, due to not meeting the above criteria, these occur in the General Concepts chapter.

In this revision, the definitions have been reworked extensively to meet style requirements and to include terms from the base documents (see the Scope).

Many of these definitions are necessarily circular, and some of the terms (such as “process”) are variants of basic computing science terms that are inherently hard to define. Where some definitions are more conceptual and contain requirements, these appear in the General Concepts chapter. Those listed in this section appear in an alphabetical glossary format of terms.

Some definitions must allow extension to cover terms or facilities that are not explicitly mentioned in IEEE Std 1003.1-2001. For example, the definition of “Extended Security Controls” permits implementations beyond those defined in IEEE Std 1003.1-2001.

Some terms in the following list of notes do not appear in IEEE Std 1003.1-2001; these are marked suffixed with an asterisk (*). Many of them have been specifically excluded from IEEE Std 1003.1-2001 because they concern system administration, implementation, or other issues that are not specific to the programming interface. Those are marked with a reason, such as “implementation-defined”.

Appropriate Privileges

One of the fundamental security problems with many historical UNIX systems has been that the privilege mechanism is monolithic—a user has either no privileges or all privileges. Thus, a successful “trojan horse” attack on a privileged process defeats all security provisions. Therefore, POSIX.1 allows more granular privilege mechanisms to be defined. For many historical implementations of the UNIX system, the presence of the term “appropriate privileges” in POSIX.1 may be understood as a synonym for “superuser” (UID 0). However, other systems have emerged where this is not the case and each discrete controllable action has appropriate privileges associated with it. Because this mechanism is implementation-defined, it must be described in the conformance document. Although that description affects several parts of POSIX.1 where the term “appropriate privilege” is used, because the term “implementation-defined” only appears here, the description of the entire mechanism and its effects on these other sections belongs in this equivalent section of the conformance document. This is especially convenient for implementations with a single mechanism that applies in all areas, since it only needs to be described once.
Byte

The restriction that a byte is now exactly eight bits was a conscious decision by the standard developers. It came about due to a combination of factors, primarily the use of the type \texttt{int8_t} within the networking functions and the alignment with the ISO/IEC 9899: 1999 standard, where the \texttt{intN_t} types are now defined.

According to the ISO/IEC 9899: 1999 standard:

- The \texttt{[u]intN_t} types must be two's complement with no padding bits and no illegal values.
- All types (apart from bit fields, which are not relevant here) must occupy an integral number of bytes.
- If a type with width \( W \) occupies \( B \) bytes with \( C \) bits per byte (\( C \) is the value of \{CHAR_BIT\}), then it has \( P \) padding bits where \( P+W=B \times C \).
- Therefore, for \texttt{int8_t} \( P=0, W=8 \). Since \( B \geq 1, C \geq 8 \), the only solution is \( B=1, C=8 \).

The standard developers also felt that this was not an undue restriction for the current state-of-the-art for this version of IEEE Std 1003.1, but recognize that if industry trends continue, a wider character type may be required in the future.

Character

The term “character” is used to mean a sequence of one or more bytes representing a single graphic symbol. The deviation in the exact text of the ISO C standard definition for “byte” meets the intent of the rationale of the ISO C standard also clears up the ambiguity raised by the term “basic execution character set”. The octet-minimum requirement is a reflection of the \{CHAR_BIT\} value.

Clock Tick

The ISO C standard defines a similar interval for use by the \texttt{clock()} function. There is no requirement that these intervals be the same. In historical implementations these intervals are different.

Command

The terms “command” and “utility” are related but have distinct meanings. Command is defined as “a directive to a shell to perform a specific task”. The directive can be in the form of a single utility name (for example, \texttt{ls}), or the directive can take the form of a compound command (for example, "\texttt{ls} | \texttt{grep} name | \texttt{pr}"). A utility is a program that can be called by name from a shell. Issuing only the name of the utility to a shell is the equivalent of a one-word command. A utility may be invoked as a separate program that executes in a different process than the command language interpreter, or it may be implemented as a part of the command language interpreter. For example, the \texttt{echo} command (the directive to perform a specific task) may be implemented such that the \texttt{echo} utility (the logic that performs the task of echoing) is in a separate program; therefore, it is executed in a process that is different from the command language interpreter. Conversely, the logic that performs the \texttt{echo} utility could be built into the command language interpreter; therefore, it could execute in the same process as the command language interpreter.

The terms “tool” and “application” can be thought of as being synonymous with “utility” from the perspective of the operating system kernel. Tools, applications, and utilities historically have run, typically, in processes above the kernel level. Tools and utilities historically have been a part of the operating system non-kernel code and have performed system-related functions, such as listing directory contents, checking file systems, repairing file systems, or extracting system
status information. Applications have not generally been a part of the operating system, and they perform non-system-related functions, such as word processing, architectural design, mechanical design, workstation publishing, or financial analysis. Utilities have most frequently been provided by the operating system distributor, applications by third-party software distributors, or by the users themselves. Nevertheless, IEEE Std 1003.1-2001 does not differentiate between tools, utilities, and applications when it comes to receiving services from the system, a shell, or the standard utilities. (For example, the \texttt{xargs} utility invokes another utility; it would be of fairly limited usefulness if the users could not run their own applications in place of the standard utilities.) Utilities are not applications in the sense that they are not themselves subject to the restrictions of IEEE Std 1003.1-2001 or any other standard—there is no requirement for \texttt{grep}, \texttt{stty}, or any of the utilities defined here to be any of the classes of conforming applications.

\section*{Column Positions}

In most 1-byte character sets, such as ASCII, the concept of column positions is identical to character positions and to bytes. Therefore, it has been historically acceptable for some implementations to describe line folding or tab stops or table column alignment in terms of bytes or character positions. Other character sets pose complications, as they can have internal representations longer than one octet and they can have display characters that have different widths on the terminal screen or printer.

In IEEE Std 1003.1-2001 the term “column positions” has been defined to mean character—not byte—positions in input files (such as “column position 7 of the FORTRAN input”). Output files describe the column position in terms of the display width of the narrowest printable character in the character set, adjusted to fit the characteristics of the output device. It is very possible that \(n\) column positions will not be able to hold \(n\) characters in some character sets, unless all of those characters are of the narrowest width. It is assumed that the implementation is aware of the width of the various characters, deriving this information from the value of \texttt{LC_CTYPE}, and thus can determine how many column positions to allot for each character in those utilities where it is important.

The term “column position” was used instead of the more natural “column” because the latter is frequently used in the different contexts of columns of figures, columns of table values, and so on. Wherever confusion might result, these latter types of columns are referred to as “text columns”.

\section*{Controlling Terminal}

The question of which of possibly several special files referring to the terminal is meant is not addressed in POSIX.1. The filename \texttt{/dev/tty} is a synonym for the controlling terminal associated with a process.

\section*{Device Number*}

The concept is handled in \texttt{stat()} as \textit{ID of device}.
Direct I/O

Historically, direct I/O refers to the system bypassing intermediate buffering, but may be extended to cover implementation-defined optimizations.

Directory

The format of the directory file is implementation-defined and differs radically between System V and 4.3 BSD. However, routines (derived from 4.3 BSD) for accessing directories and certain constraints on the format of the information returned by those routines are described in the `<dirent.h>` header.

Directory Entry

Throughout IEEE Std 1003.1-2001, the term ‘link’ is used (about the `link()` function, for example) in describing the objects that point to files from directories.

Display

The Shell and Utilities volume of IEEE Std 1003.1-2001 assigns precise requirements for the terms “display” and “write”. Some historical systems have chosen to implement certain utilities without using the traditional file descriptor model. For example, the `vi` editor might employ direct screen memory updates on a personal computer, rather than a `write()` system call. An instance of user prompting might appear in a dialog box, rather than with standard error. When the Shell and Utilities volume of IEEE Std 1003.1-2001 uses the term “display”, the method of outputting to the terminal is unspecified; many historical implementations use `termcap` or `terminfo`, but this is not a requirement. The term “write” is used when the Shell and Utilities volume of IEEE Std 1003.1-2001 mandates that a file descriptor be used and that the output can be redirected. However, it is assumed that when the writing is directly to the terminal (it has not been redirected elsewhere), there is no practical way for a user or test suite to determine whether a file descriptor is being used. Therefore, the use of a file descriptor is mandated only for the redirection case and the implementation is free to use any method when the output is not redirected. The verb `write` is used almost exclusively, with the very few exceptions of those utilities where output redirection need not be supported: `tabs`, `talk`, `tput`, and `vi`.

Dot

The symbolic name `dot` is carefully used in POSIX.1 to distinguish the working directory filename from a period or a decimal point.

Dot-Dot

Historical implementations permit the use of these filenames without their special meanings. Such use precludes any meaningful use of these filenames by a Conforming POSIX.1 Application. Therefore, such use is considered an extension, the use of which makes an implementation non-conforming; see also Section A.4.11 (on page 37).
Epoch

Historically, the origin of UNIX system time was referred to as “00:00:00 GMT, January 1, 1970”. Greenwich Mean Time is actually not a term acknowledged by the international standards community; therefore, this term, “Epoch”, is used to abbreviate the reference to the actual standard, Coordinated Universal Time.

FIFO Special File

See Pipe (on page 24).

File

It is permissible for an implementation-defined file type to be non-readable or non-writable.

File Classes

These classes correspond to the historical sets of permission bits. The classes are general to allow implementations flexibility in expanding the access mechanism for more stringent security environments. Note that a process is in one and only one class, so there is no ambiguity.

Filename

At the present time, the primary responsibility for truncating filenames containing multi-byte characters must reside with the application. Some industry groups involved in internationalization believe that in the future the responsibility must reside with the kernel. For the moment, a clearer understanding of the implications of making the kernel responsible for truncation of multi-byte filenames is needed.

Character-level truncation was not adopted because there is no support in POSIX.1 that advises how the kernel distinguishes between single and multi-byte characters. Until that time, it must be incumbent upon application writers to determine where multi-byte characters must be truncated.

File System

Historically, the meaning of this term has been overloaded with two meanings: that of the complete file hierarchy, and that of a mountable subset of that hierarchy; that is, a mounted file system. POSIX.1 uses the term “file system” in the second sense, except that it is limited to the scope of a process (and a process’ root directory). This usage also clarifies the domain in which a file serial number is unique.

Graphic Character

This definition is made available for those definitions (in particular, TZ) which must exclude control characters.

Group Database

See User Database (on page 32).
Group File*
Implementation-defined; see User Database (on page 32).

Historical Implementations*
This refers to previously existing implementations of programming interfaces and operating systems that are related to the interface specified by POSIX.1.

Hosted Implementation*
This refers to a POSIX.1 implementation that is accomplished through interfaces from the POSIX.1 services to some alternate form of operating system kernel services. Note that the line between a hosted implementation and a native implementation is blurred, since most implementations will provide some services directly from the kernel and others through some indirect path. (For example, fopen() might use open(); or mkfifo() might use mknod().) There is no necessary relationship between the type of implementation and its correctness, performance, and/or reliability.

Implementation*
This term is generally used instead of its synonym, “system”, to emphasize the consequences of decisions to be made by system implementors. Perhaps if no options or extensions to POSIX.1 were allowed, this usage would not have occurred.

The term “specific implementation” is sometimes used as a synonym for “implementation”. This should not be interpreted too narrowly; both terms can represent a relatively broad group of systems. For example, a hardware vendor could market a very wide selection of systems that all used the same instruction set, with some systems desktop models and others large multi-user minicomputers. This wide range would probably share a common POSIX.1 operating system, allowing an application compiled for one to be used on any of the others; this is a [specific] implementation. However, such a wide range of machines probably has some differences between the models. Some may have different clock rates, different file systems, different resource limits, different network connections, and so on, depending on their sizes or intended usages. Even on two identical machines, the system administrators may configure them differently. Each of these different systems is known by the term “a specific instance of a specific implementation”. This term is only used in the portions of POSIX.1 dealing with runtime queries: sysconf() and pathconf().

Incomplete Pathname*
Absolute pathname has been adequately defined.

Job Control
In order to understand the job control facilities in POSIX.1 it is useful to understand how they are used by a job control-cognizant shell to create the user interface effect of job control.

While the job control facilities supplied by POSIX.1 can, in theory, support different types of interactive job control interfaces supplied by different types of shells, there was historically one particular interface that was most common when the standard was originally developed (provided by BSD C Shell).

This discussion describes that interface as a means of illustrating how the POSIX.1 job control facilities can be used.
Job control allows users to selectively stop (suspend) the execution of processes and continue (resume) their execution at a later point. The user typically employs this facility via the interactive interface jointly supplied by the terminal I/O driver and a command interpreter (shell).

The user can launch jobs (command pipelines) in either the foreground or background. When launched in the foreground, the shell waits for the job to complete before prompting for additional commands. When launched in the background, the shell does not wait, but immediately prompts for new commands.

If the user launches a job in the foreground and subsequently regrets this, the user can type the suspend character (typically set to <control>-Z), which causes the foreground job to stop and the shell to begin prompting for new commands. The stopped job can be continued by the user (via special shell commands) either as a foreground job or as a background job. Background jobs can also be moved into the foreground via shell commands.

If a background job attempts to access the login terminal (controlling terminal), it is stopped by the terminal driver and the shell is notified, which, in turn, notifies the user. (Terminal access includes read() and certain terminal control functions, and conditionally includes write().) The user can continue the stopped job in the foreground, thus allowing the terminal access to succeed in an orderly fashion. After the terminal access succeeds, the user can optionally move the job into the background via the suspend character and shell commands.

Implementing Job Control Shells

The interactive interface described previously can be accomplished using the POSIX.1 job control facilities in the following way.

The key feature necessary to provide job control is a way to group processes into jobs. This grouping is necessary in order to direct signals to a single job and also to identify which job is in the foreground. (There is at most one job that is in the foreground on any controlling terminal at a time.)

The concept of process groups is used to provide this grouping. The shell places each job in a separate process group via the setpgid() function. To do this, the setpgid() function is invoked by the shell for each process in the job. It is actually useful to invoke setpgid() twice for each process: once in the child process, after calling fork() to create the process, but before calling one of the exec family of functions to begin execution of the program, and once in the parent shell process, after calling fork() to create the child. The redundant invocation avoids a race condition by ensuring that the child process is placed into the new process group before either the parent or the child relies on this being the case. The process group ID for the job is selected by the shell to be equal to the process ID of one of the processes in the job. Some shells choose to make one process in the job the parent of the other processes in the job (if any). Other shells (for example, the C Shell) choose to make themselves the parent of all processes in the pipeline (job).

In order to support this latter case, the setpgid() function accepts a process group ID parameter since the correct process group ID cannot be inherited from the shell. The shell itself is considered to be a job and is the sole process in its own process group.

The shell also controls which job is currently in the foreground. A foreground and background job differ in two ways: the shell waits for a foreground command to complete (or stop) before continuing to read new commands, and the terminal I/O driver inhibits terminal access by background jobs (causing the processes to stop). Thus, the shell must work cooperatively with the terminal I/O driver and have a common understanding of which job is currently in the foreground. It is the user who decides which command should be currently in the foreground, and the user informs the shell via shell commands. The shell, in turn, informs the terminal I/O driver via the tcsetpgrp() function. This indicates to the terminal I/O driver the process group ID...
of the foreground process group (job). When the current foreground job either stops or terminates, the shell places itself in the foreground via `tcsetpgrp()` before prompting for additional commands. Note that when a job is created the new process group begins as a background process group. It requires an explicit act of the shell via `tcsetpgrp()` to move a process group (job) into the foreground.

When a process in a job stops or terminates, its parent (for example, the shell) receives synchronous notification by calling the `waitpid()` function with the WUNTRACED flag set. Asynchronous notification is also provided when the parent establishes a signal handler for SIGCHLD and does not specify the SA_NOCLDSTOP flag. Usually all processes in a job stop as a unit since the terminal I/O driver always sends job control stop signals to all processes in the process group.

To continue a stopped job, the shell sends the SIGCONT signal to the process group of the job. In addition, if the job is being continued in the foreground, the shell invokes `tcsetpgrp()` to place the job in the foreground before sending SIGCONT. Otherwise, the shell leaves itself in the foreground and reads additional commands.

There is additional flexibility in the POSIX.1 job control facilities that allows deviations from the typical interface. Clearing the TOSTOP terminal flag allows background jobs to perform `write()` functions without stopping. The same effect can be achieved on a per-process basis by having a process set the signal action for SIGTTOU to SIG_IGN.

Note that the terms “job” and “process group” can be used interchangeably. A login session that is not using the job control facilities can be thought of as a large collection of processes that are all in the same job (process group). Such a login session may have a partial distinction between foreground and background processes; that is, the shell may choose to wait for some processes before continuing to read new commands and may not wait for other processes. However, the terminal I/O driver will consider all these processes to be in the foreground since they are all members of the same process group.

In addition to the basic job control operations already mentioned, a job control-cognizant shell needs to perform the following actions.

When a foreground (not background) job stops, the shell must sample and remember the current terminal settings so that it can restore them later when it continues the stopped job in the foreground (via the `tcgetattr()` and `tcsetattr()` functions).

Because a shell itself can be spawned from a shell, it must take special action to ensure that subshells interact well with their parent shells.

A subshell can be spawned to perform an interactive function (prompting the terminal for commands) or a non-interactive function (reading commands from a file). When operating non-interactively, the job control shell will refrain from performing the job control-specific actions described above. It will behave as a shell that does not support job control. For example, all jobs will be left in the same process group as the shell, which itself remains in the process group established for it by its parent. This allows the shell and its children to be treated as a single job by a parent shell, and they can be affected as a unit by terminal keyboard signals.

An interactive subshell can be spawned from another job control-cognizant shell in either the foreground or background. (For example, from the C Shell, the user can execute the command, `csh &`.) Before the subshell activates job control by calling `setpgid()` to place itself in its own process group and `tcsetpgrp()` to place its new process group in the foreground, it needs to ensure that it has already been placed in the foreground by its parent. (Otherwise, there could be multiple job control shells that simultaneously attempt to control mediation of the terminal.) To determine this, the shell retrieves its own process group via `getpgid()` and the process group of the current foreground job via `tcgetpgrp()`. If these are not equal, the shell sends SIGTTIN to
its own process group, causing itself to stop. When continued later by its parent, the shell
repeats the process group check. When the process groups finally match, the shell is in the
foreground and it can proceed to take control. After this point, the shell ignores all the job
control stop signals so that it does not inadvertently stop itself.

Implementing Job Control Applications

Most applications do not need to be aware of job control signals and operations; the intuitively
correct behavior happens by default. However, sometimes an application can inadvertently
interfere with normal job control processing, or an application may choose to overtly effect job
control in cooperation with normal shell procedures.

An application can inadvertently subvert job control processing by “blindly” altering the
handling of signals. A common application error is to learn how many signals the system
supports and to ignore or catch them all. Such an application makes the assumption that it does
not know what this signal is, but knows the right handling action for it. The system may
initialize the handling of job control stop signals so that they are being ignored. This allows
shells that do not support job control to inherit and propagate these settings and hence to be
immune to stop signals. A job control shell will set the handling to the default action and
propagate this, allowing processes to stop. In doing so, the job control shell is taking
responsibility for restarting the stopped applications. If an application wishes to catch the stop
signals itself, it should first determine their inherited handling states. If a stop signal is being
ignored, the application should continue to ignore it. This is directly analogous to the
recommended handling of SIGINT described in the referenced UNIX Programmer’s Manual.

If an application is reading the terminal and has disabled the interpretation of special characters
(by clearing the ISIG flag), the terminal I/O driver will not send SIGTSTP when the suspend
character is typed. Such an application can simulate the effect of the suspend character by
recognizing it and sending SIGTSTP to its process group as the terminal driver would have
done. Note that the signal is sent to the process group, not just to the application itself; this
ensures that other processes in the job also stop. (Note also that other processes in the job could
be children, siblings, or even ancestors.) Applications should not assume that the suspend
character is <control>-Z (or any particular value); they should retrieve the current setting at
startup.

Implementing Job Control Systems

The intent in adding 4.2 BSD-style job control functionality was to adopt the necessary 4.2 BSD
programmatic interface with only minimal changes to resolve syntactic or semantic conflicts
with System V or to close recognized security holes. The goal was to maximize the ease of
providing both conforming implementations and Conforming POSIX.1 Applications.

It is only useful for a process to be affected by job control signals if it is the descendant of a job
control shell. Otherwise, there will be nothing that continues the stopped process.

POSIX.1 does not specify how controlling terminal access is affected by a user logging out (that
is, by a controlling process terminating). 4.2 BSD uses the vhangup() function to prevent any
access to the controlling terminal through file descriptors opened prior to logout. System V does
not prevent controlling terminal access through file descriptors opened prior to logout (except
for the case of the special file, /dev/tty). Some implementations choose to make processes
immune from job control after logout (that is, such processes are always treated as if in the
foreground); other implementations continue to enforce foreground/background checks after
logout. Therefore, a Conforming POSIX.1 Application should not attempt to access the
controlling terminal after logout since such access is unreliable. If an implementation chooses to
deny access to a controlling terminal after its controlling process exits, POSIX.1 requires a certain
type of behavior (see Controlling Terminal (on page 15)).
Kernel*
See System Call* (on page 30).

Library Routine*
See System Call* (on page 30).

Logical Device*
Implementation-defined.

Map
The definition of map is included to clarify the usage of mapped pages in the description of the behavior of process memory locking.

Memory-Resident
The term “memory-resident” is historically understood to mean that the so-called resident pages are actually present in the physical memory of the computer system and are immune from swapping, paging, copy-on-write faults, and so on. This is the actual intent of IEEE Std 1003.1-2001 in the process memory locking section for implementations where this is logical. But for some implementations—primarily mainframes—actually locking pages into primary storage is not advantageous to other system objectives, such as maximizing throughput. For such implementations, memory locking is a “hint” to the implementation that the application wishes to avoid situations that would cause long latencies in accessing memory. Furthermore, there are other implementation-defined issues with minimizing memory access latencies that “memory residency” does not address—such as MMU reload faults. The definition attempts to accommodate various implementations while allowing conforming applications to specify to the implementation that they want or need the best memory access times that the implementation can provide.

Memory Object*
The term “memory object” usually implies shared memory. If the object is the same as a filename in the file system name space of the implementation, it is expected that the data written into the memory object be preserved on disk. A memory object may also apply to a physical device on an implementation. In this case, writes to the memory object are sent to the controller for the device and reads result in control registers being returned.

Mount Point*
The directory on which a “mounted file system” is mounted. This term, like mount() and umount(), was not included because it was implementation-defined.

Mounted File System*
See File System (on page 17).
Name

There are no explicit limits in IEEE Std 1003.1-2001 on the sizes of names, words (see the
definition of word in the Base Definitions volume of IEEE Std 1003.1-2001), lines, or other
objects. However, other implicit limits do apply: shell script lines produced by many of the
standard utilities cannot exceed \[\text{LINE\_MAX}\] and the sum of exported variables comes under
the \[\text{ARG\_MAX}\] limit. Historical shells dynamically allocate memory for names and words and
parse incoming lines a character at a time. Lines cannot have an arbitrary \[\text{LINE\_MAX}\] limit
because of historical practice, such as makefiles, where make removes the <newline>s associated
with the commands for a target and presents the shell with one very long line. The text on
INPUT FILES in the Shell and Utilities volume of IEEE Std 1003.1-2001, Section 1.11, Utility
Description Defaults does allow a shell to run out of memory, but it cannot have arbitrary
programming limits.

Native Implementation*

This refers to an implementation of POSIX.1 that interfaces directly to an operating system
kernel; see also hosted implementation. A similar concept is a native UNIX system, which would
be a kernel derived from one of the original UNIX system products.

Nice Value

This definition is not intended to suggest that all processes in a system have priorities that are
comparable. Scheduling policy extensions, such as adding realtime priorities, make the notion of
a single underlying priority for all scheduling policies problematic. Some implementations may
implement the features related to nice to affect all processes on the system, others to affect just
the general time-sharing activities implied by IEEE Std 1003.1-2001, and others may have no
effect at all. Because of the use of “implementation-defined” in nice and renice, a wide range of
implementation strategies is possible.

Open File Description

An “open file description”, as it is currently named, describes how a file is being accessed. What
is currently called a “file descriptor” is actually just an identifier or “handle”; it does not actually
describe anything.

The following alternate names were discussed:

- For “open file description”:
  “open instance”, “file access description”, “open file information”, and “file access
  information”.

- For “file descriptor”:
  “file handle”, “file number” (cf., fileno()). Some historical implementations use the term “file
  table entry”.

Orphaned Process Group

Historical implementations have a concept of an orphaned process, which is a process whose
parent process has exited. When job control is in use, it is necessary to prevent processes from
being stopped in response to interactions with the terminal after they no longer are controlled by
a job control-cognizant program. Because signals generated by the terminal are sent to a process
group and not to individual processes, and because a signal may be provoked by a process that
is not orphaned, but sent to another process that is orphaned, it is necessary to define an
orphaned process group. The definition assumes that a process group will be manipulated as a
group and that the job control-cognizant process controlling the group is outside of the group.
and is the parent of at least one process in the group (so that state changes may be reported via 
waitpid()). Therefore, a group is considered to be controlled as long as at least one process in the 
group has a parent that is outside of the process group, but within the session.

This definition of orphaned process groups ensures that a session leader’s process group is 
always considered to be orphaned, and thus it is prevented from stopping in response to 
terminal signals.

Page

The term “page” is defined to support the description of the behavior of memory mapping for 
shared memory and memory mapped files, and the description of the behavior of process 
memory locking. It is not intended to imply that shared memory/file mapping and memory 
locking are applicable only to “paged” architectures. For the purposes of IEEE Std 1003.1-2001, 
whatever the granularity on which an architecture supports mapping or locking, this is 
considered to be a “page”. If an architecture cannot support the memory mapping or locking 
functions specified by IEEE Std 1003.1-2001 on any granularity, then these options will not be 
implemented on the architecture.

Passwd File*

Implementation-defined; see User Database (on page 32).

Parent Directory

There may be more than one directory entry pointing to a given directory in some 
implementations. The wording here identifies that exactly one of those is the parent directory. In 
pathname resolution, dot-dot is identified as the way that the unique directory is identified. 
(That is, the parent directory is the one to which dot-dot points.) In the case of a remote file 
system, if the same file system is mounted several times, it would appear as if they were distinct 
file systems (with interesting synchronization properties).

Pipe

It proved convenient to define a pipe as a special case of a FIFO, even though historically the 
latter was not introduced until System III and does not exist at all in 4.3 BSD.

Portable Filename Character Set

The encoding of this character set is not specified—specifically, ASCII is not required. But the 
implementation must provide a unique character code for each of the printable graphics 
specified by POSIX.1; see also Section A.4.6 (on page 34).

Situations where characters beyond the portable filename character set (or historically ASCII or 
the ISO/IEC 646:1991 standard) would be used (in a context where the portable filename 
character set or the ISO/IEC 646:1991 standard is required by POSIX.1) are expected to be 
common. Although such a situation renders the use technically non-compliant, mutual 
agreement among the users of an extended character set will make such use portable between 
those users. Such a mutual agreement could be formalized as an optional extension to POSIX.1. 
(Making it required would eliminate too many possible systems, as even those systems using the 
ISO/IEC 646:1991 standard as a base character set extend their character sets for Western 
Europe and the rest of the world in different ways.)

Nothing in POSIX.1 is intended to preclude the use of extended characters where interchange is 
not required or where mutual agreement is obtained. It has been suggested that in several places 
“should” be used instead of “shall”. Because (in the worst case) use of any character beyond the
portable filename character set would render the program or data not portable to all possible systems, no extensions are permitted in this context.

**Regular File**

POSIX.1 does not intend to preclude the addition of structuring data (for example, record lengths) in the file, as long as such data is not visible to an application that uses the features described in POSIX.1.

**Root Directory**

This definition permits the operation of `chroot()`, even though that function is not in POSIX.1; see also Section A.4.5 (on page 33).

**Root File System**

Implementation-defined.

**Root of a File System**

Implementation-defined; see **Mount Point** (on page 22).

**Signal**

The definition implies a double meaning for the term. Although a signal is an event, common usage implies that a signal is an identifier of the class of event.

**Superuser**

This concept, with great historical significance to UNIX system users, has been replaced with the notion of appropriate privileges.

**Supplementary Group ID**

The POSIX.1-1990 standard is inconsistent in its treatment of supplementary groups. The definition of supplementary group ID explicitly permits the effective group ID to be included in the set, but wording in the description of the `setuid()` and `setgid()` functions states: “Any supplementary group IDs of the calling process remain unchanged by these function calls”. In the case of `setgid()` this contradicts that definition. In addition, some felt that the unspecified behavior in the definition of supplementary group IDs adds unnecessary portability problems. The standard developers considered several solutions to this problem:

1. Reword the description of `setgid()` to permit it to change the supplementary group IDs to reflect the new effective group ID. A problem with this is that it adds more “may”s to the wording and does not address the portability problems of this optional behavior.

2. Mandate the inclusion of the effective group ID in the supplementary set (giving `[NGROUPS_MAX]` a minimum value of 1). This is the behavior of 4.4 BSD. In that system, the effective group ID is the first element of the array of supplementary group IDs (there is no separate copy stored, and changes to the effective group ID are made only in the supplementary group set). By convention, the initial value of the effective group ID is duplicated elsewhere in the array so that the initial value is not lost when executing a set-group-ID program.

3. Change the definition of supplementary group ID to exclude the effective group ID and specify that the effective group ID does not change the set of supplementary group IDs. This is the behavior of 4.2 BSD, 4.3 BSD, and System V Release 4.
4. Change the definition of supplementary group ID to exclude the effective group ID, and require that `getgroups()` return the union of the effective group ID and the supplementary group IDs.

5. Change the definition of `NGROUPS_MAX` to be one more than the number of supplementary group IDs, so it continues to be the number of values returned by `getgroups()` and existing applications continue to work. This alternative is effectively the same as the second (and might actually have the same implementation).

The standard developers decided to permit either 2 or 3. The effective group ID is orthogonal to the set of supplementary group IDs, and it is implementation-defined whether `getgroups()` returns this. If the effective group ID is returned with the set of supplementary group IDs, then all changes to the effective group ID affect the supplementary group set returned by `getgroups()`. It is permissible to eliminate duplicates from the list returned by `getgroups()`. However, if a group ID is contained in the set of supplementary group IDs, setting the group ID to that value and then to a different value should not remove that value from the supplementary group IDs.

The definition of supplementary group IDs has been changed to not include the effective group ID. This simplifies permanent rationale and makes the relevant functions easier to understand. The `getgroups()` function has been modified so that it can, on an implementation-defined basis, return the effective group ID. By making this change, functions that modify the effective group ID do not need to discuss adding to the supplementary group list; the only view into the supplementary group list that the application writer has is through the `getgroups()` function.

**Symbolic Link**

Many implementations associate no attributes, including ownership with symbolic links. Security experts encouraged consideration for defining these attributes as optional. Consideration was given to changing `utime()` to allow modification of the times for a symbolic link, or as an alternative adding an `lutime()` interface. Modifications to `chown()` were also considered: allow changing symbolic link ownership or alternatively adding `lchown()`. As a result of alignment with the Single UNIX Specification, the `lchown()` function is included as part of the XSI extension and XSI-conformant systems may support an owner and a group associated with a symbolic link. There was no consensus to define further attributes for symbolic links, and for systems not supporting the XSI extension only the file type bits in the `st_mode` member and the `st_size` member of the `stat` structure are required to be applicable to symbolic links.

Historical implementations were followed when determining which interfaces should apply to symbolic links. Interfaces that historically followed symbolic links include `chmod()`, `link()`, and `utime()`. Interfaces that historically do not follow symbolic links include `chown()`, `lstat()`, `readlink()`, `rename()`, `remove()`, `rmdir()`, and `unlink()`. IEEE Std 1003.1-2001 deviates from historical practice only in the case of `chown()`. Because there is no requirement for systems not supporting the XSI extension that there is an association of ownership with symbolic links, there was no interface in the base standard to change ownership. In addition, other implementations of symbolic links have modified `chown()` to follow symbolic links.

In the case of symbolic links, IEEE Std 1003.1-2001 states that a trailing slash is considered to be the final component of a pathname rather than the pathname component that preceded it. This is the behavior of historical implementations. For example, for `/a/b` and `/a/b/`, if `/a/b` is a symbolic link to a directory, then `/a/b` refers to the symbolic link, and `/a/b/` is the same as `/a/b/`, which is the directory to which the symbolic link points.

For multi-level security purposes, it is possible to have the link read mode govern permission for the `readlink()` function. It is also possible that the read permissions of the directory containing the link be used for this purpose. Implementations may choose to use either of these methods; however, this is not current practice and neither method is specified.
Several reasons were advanced for requiring that when a symbolic link is used as the source argument to the `link()` function, the resulting link will apply to the file named by the contents of the symbolic link rather than to the symbolic link itself. This is the case in historical implementations. This action was preferred, as it supported the traditional idea of persistence with respect to the target of a hard link. This decision is appropriate in light of a previous decision not to require association of attributes with symbolic links, thereby allowing implementations which do not use inodes. Opposition centered on the lack of symmetry on the part of the `link()` and `unlink()` function pair with respect to symbolic links.

Because a symbolic link and its referenced object coexist in the file system name space, confusion can arise in distinguishing between the link itself and the referenced object. Historically, utilities and system calls have adopted their own link following conventions in a somewhat *ad hoc* fashion. Rules for a uniform approach are outlined here, although historical practice has been adhered to as much as was possible. To promote consistent system use, user-written utilities are encouraged to follow these same rules.

Symbolic links are handled either by operating on the link itself, or by operating on the object referenced by the link. In the latter case, an application or system call is said to ‘follow’ the link. Symbolic links may reference other symbolic links, in which case links are dereferenced until an object that is not a symbolic link is found, a symbolic link that references a file that does not exist is found, or a loop is detected. (Current implementations do not detect loops, but have a limit on the number of symbolic links that they will dereference before declaring it an error.)

There are four domains for which default symbolic link policy is established in a system. In almost all cases, there are utility options that override this default behavior. The four domains are as follows:

1. Symbolic links specified to system calls that take filename arguments
2. Symbolic links specified as command line filename arguments to utilities that are not performing a traversal of a file hierarchy
3. Symbolic links referencing files not of type directory, specified to utilities that are performing a traversal of a file hierarchy
4. Symbolic links referencing files of type directory, specified to utilities that are performing a traversal of a file hierarchy

**First Domain**

The first domain is considered in earlier rationale.

**Second Domain**

The reason this category is restricted to utilities that are not traversing the file hierarchy is that some standard utilities take an option that specifies a hierarchical traversal, but by default operate on the arguments themselves. Generally, users specifying the option for a file hierarchy traversal wish to operate on a single, physical hierarchy, and therefore symbolic links, which may reference files outside of the hierarchy, are ignored. For example, `chown owner file` is a different operation from the same command with the `−R` option specified. In this example, the behavior of the command `chown owner file` is described here, while the behavior of the command `chown −R owner file` is described in the third and fourth domains.

The general rule is that the utilities in this category follow symbolic links named as arguments.

Exceptions in the second domain are:

- The `mv` and `rm` utilities do not follow symbolic links named as arguments, but respectively attempt to rename or delete them.
The `ls` utility is also an exception to this rule. For compatibility with historical systems, when the `−R` option is not specified, the `ls` utility follows symbolic links named as arguments if the `−L` option is specified or if the `−F`, `−d`, or `−l` options are not specified. (If the `−L` option is specified, `ls` always follows symbolic links; it is the only utility where the `−L` option affects its behavior even though a tree walk is not being performed.)

All other standard utilities, when not traversing a file hierarchy, always follow symbolic links named as arguments.

Historical practice is that the `−h` option is specified if standard utilities are to act upon symbolic links instead of upon their targets. Examples of commands that have historically had a `−h` option for this purpose are the `chgrp`, `chown`, `file`, and `test` utilities.

### Third Domain

The third domain is symbolic links, referencing files not of type directory, specified to utilities that are performing a traversal of a file hierarchy. (This includes symbolic links specified as command line filename arguments or encountered during the traversal.)

The intention of the Shell and Utilities volume of IEEE Std 1003.1-2001 is that the operation that the utility is performing is applied to the symbolic link itself, if that operation is applicable to symbolic links. The reason that the operation is not required is that symbolic links in some implementations do not have such attributes as a file owner, and therefore the `chown` operation would be meaningless. If symbolic links on the system have an owner, it is the intention that the utility `chown` cause the owner of the symbolic link to change. If symbolic links do not have an owner, the symbolic link should be ignored. Specifically, by default, no change should be made to the file referenced by the symbolic link.

### Fourth Domain

The fourth domain is symbolic links referencing files of type directory, specified to utilities that are performing a traversal of a file hierarchy. (This includes symbolic links specified as command line filename arguments or encountered during the traversal.)

Most standard utilities do not, by default, indirect into the file hierarchy referenced by the symbolic link. (The Shell and Utilities volume of IEEE Std 1003.1-2001 uses the informal term “physical walk” to describe this case. The case where the utility does indirect through the symbolic link is termed a “logical walk”.)

There are three reasons for the default to be a physical walk:

1. With very few exceptions, a physical walk has been the historical default on UNIX systems supporting symbolic links. Because some utilities (that is, `rm`) must default to a physical walk, regardless, changing historical practice in this regard would be confusing to users and needlessly incompatible.

2. For systems where symbolic links have the historical file attributes (that is, `owner`, `group`, `mode`), defaulting to a logical traversal would require the addition of a new option to the commands to modify the attributes of the link itself. This is painful and more complex than the alternatives.

3. There is a security issue with defaulting to a logical walk. Historically, the command `chown −R user file` has been safe for the superuser because `setuid` and `setgid` bits were lost when the ownership of the file was changed. If the walk were logical, changing ownership would no longer be safe because a user might have inserted a symbolic link pointing to any file in the tree. Again, this would necessitate the addition of an option to the commands doing hierarchy traversal to not indirect through the symbolic links, and historical scripts doing recursive walks would instantly become security problems. While this is mostly an
issue for system administrators, it is preferable to not have different defaults for different classes of users.

However, the standard developers agreed to leave it unspecified to achieve consensus.

As consistently as possible, users may cause standard utilities performing a file hierarchy traversal to follow any symbolic links named on the command line, regardless of the type of file they reference, by specifying the \(-H\) (for half logical) option. This option is intended to make the command line name space look like the logical name space.

As consistently as possible, users may cause standard utilities performing a file hierarchy traversal to follow any symbolic links named on the command line as well as any symbolic links encountered during the traversal, regardless of the type of file they reference, by specifying the \(-L\) (for logical) option. This option is intended to make the entire name space look like the logical name space.

For consistency, implementors are encouraged to use the \(-P\) (for "physical") flag to specify the physical walk in utilities that do logical walks by default for whatever reason. The only standard utilities that require the \(-P\) option are \(cd\) and \(pwd\); see the note below.

When one or more of the \(-H\), \(-L\), and \(-P\) flags can be specified, the last one specified determines the behavior of the utility. This permits users to alias commands so that the default behavior is a logical walk and then override that behavior on the command line.

Exceptions in the Third and Fourth Domains

The \(ls\) and \(rm\) utilities are exceptions to these rules. The \(rm\) utility never follows symbolic links and does not support the \(-H\), \(-L\), or \(-P\) options. Some historical versions of \(ls\) always followed symbolic links given on the command line whether the \(-L\) option was specified or not. Historical versions of \(ls\) did not support the \(-H\) option. In IEEE Std 1003.1-2001, unless one of the \(-H\) or \(-L\) options is specified, the \(ls\) utility only follows symbolic links to directories that are given as operands. The \(ls\) utility does not support the \(-P\) option.

The Shell and Utilities volume of IEEE Std 1003.1-2001 requires that the standard utilities \(ls\), \(find\), and \(pax\) detect infinite loops when doing logical walks; that is, a directory, or more commonly a symbolic link, that refers to an ancestor in the current file hierarchy. If the file system itself is corrupted, causing the infinite loop, it may be impossible to recover. Because \(find\) and \(ls\) are often used in system administration and security applications, they should attempt to recover and continue as best as they can. The \(pax\) utility should terminate because the archive it was creating is by definition corrupted. Other, less vital, utilities should probably simply terminate as well. Implementations are strongly encouraged to detect infinite loops in all utilities.

Historical practice is shown in Table A-1 (on page 30). The heading \textit{SVID3} stands for the Third Edition of the System V Interface Definition.

Historically, several shells have had built-in versions of the \(pwd\) utility. In some of these shells, \(pwd\) reported the physical path, and in others, the logical path. Implementations of the shell corresponding to IEEE Std 1003.1-2001 must report the logical path by default. Earlier versions of IEEE Std 1003.1-2001 did not require the \(pwd\) utility to be a built-in utility. Now that \(pwd\) is required to set an environment variable in the current shell execution environment, it must be a built-in utility.

The \(cd\) command is required, by default, to treat the filename dot-dot logically. Implementors are required to support the \(-P\) flag in \(cd\) so that users can have their current environment handled physically. In 4.3 BSD, \(chgrp\) during tree traversal changed the group of the symbolic link, not the target. Symbolic links in 4.4 BSD do not have \textit{owner}, \textit{group}, \textit{mode}, or other standard UNIX system file attributes.

Synchronously-Generated Signal

Those signals that may be generated synchronously include SIGABRT, SIGBUS, SIGILL, SIGFPE, SIGPIPE, and SIGSEGV.

Any signal sent via the `raise()` function or a `kill()` function targeting the current process is also considered synchronous.

System Call*

The distinction between a “system call” and a “library routine” is an implementation detail that may differ between implementations and has thus been excluded from POSIX.1.

See “Interface, Not Implementation” in Introduction (on page xiii).
System Reboot

A “system reboot” is an event initiated by an unspecified circumstance that causes all processes (other than special system processes) to be terminated in an implementation-defined manner, after which any changes to the state and contents of files created or written to by a Conforming POSIX.1 Application prior to the event are implementation-defined.

Synchronized I/O Data (and File) Integrity Completion

These terms specify that for synchronized read operations, pending writes must be successfully completed before the read operation can complete. This is motivated by two circumstances. Firstly, when synchronizing processes can access the same file, but not share common buffers (such as for a remote file system), this requirement permits the reading process to guarantee that it can read data written remotely. Secondly, having data written synchronously is insufficient to guarantee the order with respect to a subsequent write by a reading process, and thus this extra read semantic is necessary.

Text File

The term “text file” does not prevent the inclusion of control or other non-printable characters (other than NUL). Therefore, standard utilities that list text files as inputs or outputs are either able to process the special characters or they explicitly describe their limitations within their individual descriptions. The definition of “text file” has caused controversy. The only difference between text and binary files is that text files have lines of less than {LINE_MAX} bytes, with no NUL characters, each terminated by a <newline>. The definition allows a file with a single <newline>, but not a totally empty file, to be called a text file. If a file ends with an incomplete line it is not strictly a text file by this definition. The <newline> referred to in IEEE Std 1003.1-2001 is not some generic line separator, but a single character; files created on systems where they use multiple characters for ends of lines are not portable to all conforming systems without some translation process unspecified by IEEE Std 1003.1-2001.

Thread

IEEE Std 1003.1-2001 defines a thread to be a flow of control within a process. Each thread has a minimal amount of private state; most of the state associated with a process is shared among all of the threads in the process. While most multi-thread extensions to POSIX have taken this approach, others have made different decisions.

Note: The choice to put threads within a process does not constrain implementations to implement threads in that manner. However, all functions have to behave as though threads share the indicated state information with the process from which they were created.

Threads need to share resources in order to cooperate. Memory has to be widely shared between threads in order for the threads to cooperate at a fine level of granularity. Threads keep data structures and the locks protecting those data structures in shared memory. For a data structure to be usefully shared between threads, such structures should not refer to any data that can only be interpreted meaningfully by a single thread. Thus, any system resources that might be referred to in data structures need to be shared between all threads. File descriptors, pathnames, and pointers to stack variables are all things that programmers want to share between their threads. Thus, the file descriptor table, the root directory, the current working directory, and the address space have to be shared.

Library implementations are possible as long as the effective behavior is as if system services invoked by one thread do not suspend other threads. This may be difficult for some library implementations on systems that do not provide asynchronous facilities.
See Section B.2.9 (on page 150) for additional rationale.

Thread ID
See Section B.2.9.2 (on page 166) for additional rationale.

Thread-Safe Function
All functions required by IEEE Std 1003.1-2001 need to be thread-safe; see Section A.4.16 (on page 40) and Section B.2.9.1 (on page 163) for additional rationale.

User Database
There are no references in IEEE Std 1003.1-2001 to a “passwd file” or a “group file”, and there is no requirement that the group or passwd databases be kept in files containing editable text. Many large timesharing systems use passwd databases that are hashed for speed. Certain security classifications prohibit certain information in the passwd database from being publicly readable.

The term “encoded” is used instead of “encrypted” in order to avoid the implementation connotations (such as reversibility or use of a particular algorithm) of the latter term.

The getgrent(), setgrent(), endgrent(), getpwent(), setpwent(), and endpwent() functions are not included as part of the base standard because they provide a linear database search capability that is not generally useful (the getpwuid(), getpwnam(), getgrgid(), and getgrnam() functions are provided for keyed lookup) and because in certain distributed systems, especially those with different authentication domains, it may not be possible or desirable to provide an application with the ability to browse the system databases indiscriminately. They are provided on XSI-conformant systems due to their historical usage by many existing applications.

A change from historical implementations is that the structures used by these functions have fields of the types gid_t and uid_t, which are required to be defined in the <sys/types.h> header. IEEE Std 1003.1-2001 requires implementations to ensure that these types are defined by inclusion of <grp.h> and <pwd.h>, respectively, without imposing any name space pollution or errors from redefinition of types.

IEEE Std 1003.1-2001 is silent about the content of the strings containing user or group names. These could be digit strings. IEEE Std 1003.1-2001 is also silent as to whether such digit strings bear any relationship to the corresponding (numeric) user or group ID.

Database Access
The thread-safe versions of the user and group database access functions return values in user-supplied buffers instead of possibly using static data areas that may be overwritten by each call.

Virtual Processor*
The term “virtual processor” was chosen as a neutral term describing all kernel-level schedulable entities, such as processes, Mach tasks, or lightweight processes. Implementing threads using multiple processes as virtual processors, or implementing multiplexed threads above a virtual processor layer, should be possible, provided some mechanism has also been implemented for sharing state between processes or virtual processors. Many systems may also wish to provide implementations of threads on systems providing “shared processes” or “variable-weight processes”. It was felt that exposing such implementation details would severely limit the type of systems upon which the threads interface could be supported and prevent certain types of valid implementations. It was also determined that a virtual processor interface was out of the scope of the Rationale (Informative) volume of IEEE Std 1003.1-2001.
XSI

This is introduced to allow IEEE Std 1003.1-2001 to be adopted as an IEEE standard and an Open Group Technical Standard, serving both the POSIX and the Single UNIX Specification in a core set of volumes.

The term “XSI” has been used for 10 years in connection with the XPG series and the first and second versions of the base volumes of the Single UNIX Specification. The XSI margin code was introduced to denote the extended or more restrictive semantics beyond POSIX that are applicable to UNIX systems.

A.4 General Concepts

A.4.1 Concurrent Execution

There is no additional rationale provided for this section.

A.4.2 Directory Protection

There is no additional rationale provided for this section.

A.4.3 Extended Security Controls

Allowing an implementation to define extended security controls enables the use of IEEE Std 1003.1-2001 in environments that require different or more rigorous security than that provided in POSIX.1. Extensions are allowed in two areas: privilege and file access permissions. The semantics of these areas have been defined to permit extensions with reasonable, but not exact, compatibility with all existing practices. For example, the elimination of the superuser definition precludes identifying a process as privileged or not by virtue of its effective user ID.

A.4.4 File Access Permissions

A process should not try to anticipate the result of an attempt to access data by \textit{a priori} use of these rules. Rather, it should make the attempt to access data and examine the return value (and possibly \textit{errno} as well), or use \texttt{access()}\texttt{.} An implementation may include other security mechanisms in addition to those specified in POSIX.1, and an access attempt may fail because of those additional mechanisms, even though it would succeed according to the rules given in this section. (For example, the user’s security level might be lower than that of the object of the access attempt.) The supplementary group IDs provide another reason for a process to not attempt to anticipate the result of an access attempt.

A.4.5 File Hierarchy

Though the file hierarchy is commonly regarded to be a tree, POSIX.1 does not define it as such for three reasons:

1. Links may join branches.
2. In some network implementations, there may be no single absolute root directory; see \textit{pathname resolution}.
3. With symbolic links, the file system need not be a tree or even a directed acyclic graph.
Historically, certain filenames have been reserved. This list includes core, /etc/passwd, and so on. Conforming applications should avoid these.

Most historical implementations prohibit case folding in filenames; that is, treating uppercase and lowercase alphabetic characters as identical. However, some consider case folding desirable:

- For user convenience
- For ease-of-implementation of the POSIX.1 interface as a hosted system on some popular operating systems

Variants, such as maintaining case distinctions in filenames, but ignoring them in comparisons, have been suggested. Methods of allowing escaped characters of the case opposite the default have been proposed.

Many reasons have been expressed for not allowing case folding, including:

- No solid evidence has been produced as to whether case-sensitivity or case-insensitivity is more convenient for users.
- Making case-insensitivity a POSIX.1 implementation option would be worse than either having it or not having it, because:
  - More confusion would be caused among users.
  - Application developers would have to account for both cases in their code.
  - POSIX.1 implementors would still have other problems with native file systems, such as short or otherwise constrained filenames or pathnames, and the lack of hierarchical directory structure.
- Case folding is not easily defined in many European languages, both because many of them use characters outside the US ASCII alphabetic set, and because:
  - In Spanish, the digraph "ll" is considered to be a single letter, the capitalized form of which may be either "Ll" or "LL", depending on context.
  - In French, the capitalized form of a letter with an accent may or may not retain the accent, depending on the country in which it is written.
  - In German, the sharp ess may be represented as a single character resembling a Greek beta (β) in lowercase, but as the digraph "SS" in uppercase.
  - In Greek, there are several lowercase forms of some letters; the one to use depends on its position in the word. Arabic has similar rules.
- Many East Asian languages, including Japanese, Chinese, and Korean, do not distinguish case and are sometimes encoded in character sets that use more than one byte per character.
- Multiple character codes may be used on the same machine simultaneously. There are several ISO character sets for European alphabets. In Japan, several Japanese character codes are commonly used together, sometimes even in filenames; this is evidently also the case in China. To handle case insensitivity, the kernel would have to at least be able to distinguish for which character sets the concept made sense.
- The file system implementation historically deals only with bytes, not with characters, except for slash and the null byte.
- The purpose of POSIX.1 is to standardize the common, existing definition, not to change it. Mandating case-insensitivity would make all historical implementations non-standard.
• Not only the interface, but also application programs would need to change, counter to the purpose of having minimal changes to existing application code.

• At least one of the original developers of the UNIX system has expressed objection in the strongest terms to either requiring case-insensitivity or making it an option, mostly on the basis that POSIX.1 should not hinder portability of application programs across related implementations in order to allow compatibility with unrelated operating systems.

Two proposals were entertained regarding case folding in filenames:

1. Remove all wording that previously permitted case folding.

   Rationale Case folding is inconsistent with portable filename character set definition and filename definition (all characters except slash and null). No known implementations allowing all characters except slash and null also do case folding.

2. Change “though this practice is not recommended:” to “although this practice is strongly discouraged.”

   Rationale If case folding must be included in POSIX.1, the wording should be stronger to discourage the practice.

The consensus selected the first proposal. Otherwise, a conforming application would have to assume that case folding would occur when it was not wanted, but that it would not occur when it was wanted.

A.4.7 File Times Update

This section reflects the actions of historical implementations. The times are not updated immediately, but are only marked for update by the functions. An implementation may update these times immediately.

The accuracy of the time update values is intentionally left unspecified so that systems can control the bandwidth of a possible covert channel.

The wording was carefully chosen to make it clear that there is no requirement that the conformance document contain information that might incidentally affect file update times. Any function that performs pathname resolution might update several st_atime fields. Functions such as getpwnam() and getgrnam() might update the st_atime field of some specific file or files. It is intended that these are not required to be documented in the conformance document, but they should appear in the system documentation.

A.4.8 Host and Network Byte Order

There is no additional rationale provided for this section.

A.4.9 Measurement of Execution Time

The methods used to measure the execution time of processes and threads, and the precision of these measurements, may vary considerably depending on the software architecture of the implementation, and on the underlying hardware. Implementations can also make tradeoffs between the scheduling overhead and the precision of the execution time measurements. IEEE Std 1003.1-2001 does not impose any requirement on the accuracy of the execution time; it instead specifies that the measurement mechanism and its precision are implementation-defined.
A.4.10 Memory Synchronization

In older multi-processors, access to memory by the processors was strictly multiplexed. This meant that a processor executing program code interrogates or modifies memory in the order specified by the code and that all the memory operation of all the processors in the system appear to happen in some global order, though the operation histories of different processors are interleaved arbitrarily. The memory operations of such machines are said to be sequentially consistent. In this environment, threads can synchronize using ordinary memory operations. For example, a producer thread and a consumer thread can synchronize access to a circular data buffer as follows:

```c
int rdptr = 0;
int wrptr = 0;
data_t buf[BUFSIZE];

Thread 1:
    while (work_to_do) {
        int next;
        buf[wrptr] = produce();
        next = (wrptr + 1) % BUFSIZE;
        while (rdptr == next)
            ;
        wrptr = next;
    }

Thread 2:
    while (work_to_do) {
        while (rdptr == wrptr)
            ;
        consume(buf[rdptr]);
        rdptr = (rdptr + 1) % BUFSIZE;
    }
```

In modern multi-processors, these conditions are relaxed to achieve greater performance. If one processor stores values in location A and then location B, then other processors loading data from location B and then location A may see the new value of B but the old value of A. The memory operations of such machines are said to be weakly ordered. On these machines, the circular buffer technique shown in the example will fail because the consumer may see the new value of `wrptr` but the old value of the data in the buffer. In such machines, synchronization can only be achieved through the use of special instructions that enforce an order on memory operations. Most high-level language compilers only generate ordinary memory operations to take advantage of the increased performance. They usually cannot determine when memory operation order is important and generate the special ordering instructions. Instead, they rely on the programmer to use synchronization primitives correctly to ensure that modifications to a location in memory are ordered with respect to modifications and/or access to the same location in other threads. Access to read-only data need not be synchronized. The resulting program is said to be data race-free.

Synchronization is still important even when accessing a single primitive variable (for example, an integer). On machines where the integer may not be aligned to the bus data width or be larger than the data width, a single memory load may require multiple memory cycles. This means that it may be possible for some parts of the integer to have an old value while other parts have a newer value. On some processor architectures this cannot happen, but portable programs cannot rely on this.
In summary, a portable multi-threaded program, or a multi-process program that shares writable memory between processes, has to use the synchronization primitives to synchronize data access. It cannot rely on modifications to memory being observed by other threads in the order written in the application or even on modification of a single variable being seen atomically.

Conforming applications may only use the functions listed to synchronize threads of control with respect to memory access. There are many other candidates for functions that might also be used. Examples are: signal sending and reception, or pipe writing and reading. In general, any function that allows one thread of control to wait for an action caused by another thread of control is a candidate. IEEE Std 1003.1-2001 does not require these additional functions to synchronize memory access since this would imply the following:

1. All these functions would have to be recognized by advanced compilation systems so that memory operations and calls to these functions are not reordered by optimization.
2. All these functions would potentially have to have memory synchronization instructions added, depending on the particular machine.
3. The additional functions complicate the model of how memory is synchronized and make automatic data race detection techniques impractical.

Formal definitions of the memory model were rejected as unreadable by the vast majority of programmers. In addition, most of the formal work in the literature has concentrated on the memory as provided by the hardware as opposed to the application programmer through the compiler and runtime system. It was believed that a simple statement intuitive to most programmers would be most effective. IEEE Std 1003.1-2001 defines functions that can be used to synchronize access to memory, but it leaves open exactly how one relates those functions to the semantics of each function as specified elsewhere in IEEE Std 1003.1-2001. IEEE Std 1003.1-2001 also does not make a formal specification of the partial ordering in time that the functions can impose, as that is implied in the description of the semantics of each function. It simply states that the programmer has to ensure that modifications do not occur “simultaneously” with other access to a memory location.

IEEE Std 1003.1-2001/Cor 1-2002, item XBD/TC1/D6/4 is applied, adding a new paragraph beneath the table of functions: “The pthread_once() function shall synchronize memory for the first call in each thread for a given pthread_once_t object.”.

A.4.11 Pathname Resolution

It is necessary to differentiate between the definition of pathname and the concept of pathname resolution with respect to the handling of trailing slashes. By specifying the behavior here, it is not possible to provide an implementation that is conforming but extends all interfaces that handle pathnames to also handle strings that are not legal pathnames (because they have trailing slashes).

Pathnames that end with one or more trailing slash characters must refer to directory paths. Previous versions of IEEE Std 1003.1-2001 were not specific about the distinction between trailing slashes on files and directories, and both were permitted.

Two types of implementation have been prevalent; those that ignored trailing slash characters on all pathnames regardless, and those that permitted them only on existing directories. IEEE Std 1003.1-2001 requires that a pathname with a trailing slash character be treated as if it had a trailing " / . " everywhere.

Note that this change does not break any conforming applications; since there were two different types of implementation, no application could have portably depended on either
behavior. This change does however require some implementations to be altered to remain compliant. Substantial discussion over a three-year period has shown that the benefits to application developers outweighs the disadvantages for some vendors.

On a historical note, some early applications automatically appended a ‘/’ to every path. Rather than fix the applications, the system implementation was modified to accept this behavior by ignoring any trailing slash.

Each directory has exactly one parent directory which is represented by the name dot-dot in the first directory. No other directory, regardless of linkages established by symbolic links, is considered the parent directory by IEEE Std 1003.1-2001.

There are two general categories of interfaces involving pathname resolution: those that follow the symbolic link, and those that do not. There are several exceptions to this rule; for example, open(path,O_CREAT|O_EXCL) will fail when path names a symbolic link. However, in all other situations, the open() function will follow the link.

What the filename dot-dot refers to relative to the root directory is implementation-defined. In Version 7 it refers to the root directory itself; this is the behavior mentioned in IEEE Std 1003.1-2001. In some networked systems the construction /../hostname/ is used to refer to the root directory of another host, and POSIX.1 permits this behavior.

Other networked systems use the construct /hostname for the same purpose; that is, a double initial slash is used. There is a potential problem with existing applications that create full pathnames by taking a trunk and a relative pathname and making them into a single string separated by ‘/’, because they can accidentally create networked pathnames when the trunk is ‘/’. This practice is not prohibited because such applications can be made to conform by simply changing to use ”/“ as a separator instead of ‘/’:

- If the trunk is ‘/’, the full pathname will begin with ”/“ (the initial ‘/’ and the separator ”/“). This is the same as ‘/’, which is what is desired. (This is the general case of making a relative pathname into an absolute one by prefixing with ”/“ instead of ‘/’.)
- If the trunk is ”/A”, the result is ”/A/...”; since non-leading sequences of two or more slashes are treated as a single slash, this is equivalent to the desired ”/A/...”.
- If the trunk is ”/A”, the implementation-defined semantics will apply. (The multiple slash rule would apply.)

Application developers should avoid generating pathnames that start with ”/“. Implementations are strongly encouraged to avoid using this special interpretation since a number of applications currently do not follow this practice and may inadvertently generate ”/...”.

The term “root directory” is only defined in POSIX.1 relative to the process. In some implementations, there may be no absolute root directory. The initialization of the root directory of a process is implementation-defined.
A.4.12  Process ID Reuse
There is no additional rationale provided for this section.

A.4.13  Scheduling Policy
There is no additional rationale provided for this section.

A.4.14  Seconds Since the Epoch
Coordinated Universal Time (UTC) includes leap seconds. However, in POSIX time (seconds since the Epoch), leap seconds are ignored (not applied) to provide an easy and compatible method of computing time differences. Broken-down POSIX time is therefore not necessarily UTC, despite its appearance.

As of September 2000, 24 leap seconds had been added to UTC since the Epoch, 1 January, 1970. Historically, one leap second is added every 15 months on average, so this offset can be expected to grow steadily with time.

Most systems' notion of "time" is that of a continuously increasing value, so this value should increase even during leap seconds. However, not only do most systems not keep track of leap seconds, but most systems are probably not synchronized to any standard time reference. Therefore, it is inappropriate to require that a time represented as seconds since the Epoch precisely represent the number of seconds between the referenced time and the Epoch.

It is sufficient to require that applications be allowed to treat this time as if it represented the number of seconds between the referenced time and the Epoch. It is the responsibility of the vendor of the system, and the administrator of the system, to ensure that this value represents the number of seconds between the referenced time and the Epoch as closely as necessary for the application being run on that system.

It is important that the interpretation of time names and seconds since the Epoch values be consistent across conforming systems; that is, it is important that all conforming systems interpret "536 457 999 seconds since the Epoch" as 59 seconds, 59 minutes, 23 hours 31 December 1986, regardless of the accuracy of the system's idea of the current time. The expression is given to ensure a consistent interpretation, not to attempt to specify the calendar. The relationship between tm_yday and the day of week, day of month, and month is in accordance with the Gregorian calendar, and so is not specified in POSIX.1.

Consistent interpretation of seconds since the Epoch can be critical to certain types of distributed applications that rely on such timestamps to synchronize events. The accrual of leap seconds in a time standard is not predictable. The number of leap seconds since the Epoch will likely increase. POSIX.1 is more concerned about the synchronization of time between applications of astronomically short duration.

Note that tm_yday is zero-based, not one-based, so the day number in the example above is 364. Note also that the division is an integer division (discarding remainder) as in the C language.

Note also that the meaning of gmtime(), localtime(), and mktime() is specified in terms of this expression. However, the ISO C standard computes tm_yday from tm_mday, tm_mon, and tm_year in mktime(). Because it is stated as a (bidirectional) relationship, not a function, and because the conversion between month-day-year and day-of-year dates is presumed well known and is also a relationship, this is not a problem.

Implementations that implement time_t as a signed 32-bit integer will overflow in 2 038. The data size for time_t is as per the ISO C standard definition, which is implementation-defined.
The topic of whether seconds since the Epoch should account for leap seconds has been debated on a number of occasions, and each time consensus was reached (with acknowledged dissent each time) that the majority of users are best served by treating all days identically. (That is, the majority of applications were judged to assume a single length—as measured in seconds since the Epoch—for all days. Thus, leap seconds are not applied to seconds since the Epoch.) Those applications which do care about leap seconds can determine how to handle them in whatever way those applications feel is best. This was particularly emphasized because there was disagreement about what the best way of handling leap seconds might be. It is a practical impossibility to mandate that a conforming implementation must have a fixed relationship to any particular official clock (consider isolated systems, or systems performing "reruns" by setting the clock to some arbitrary time).

Note that as a practical consequence of this, the length of a second as measured by some external standard is not specified. This unspecified second is nominally equal to an International System (SI) second in duration. Applications must be matched to a system that provides the particular handling of external time in the way required by the application.

A.4.15 Semaphore

There is no additional rationale provided for this section.

A.4.16 Thread-Safety

Where the interface of a function required by IEEE Std 1003.1-2001 precludes thread-safety, an alternate thread-safe form is provided. The names of these thread-safe forms are the same as the non-thread-safe forms with the addition of the suffix "_r". The suffix "_r" is historical, where the 'r' stood for "reentrant".

In some cases, thread-safety is provided by restricting the arguments to an existing function.

A.4.17 Tracing

Refer to Section B.2.11 (on page 179).

A.4.19 Treatment of NaN Arguments for Mathematical Functions

There is no additional rationale provided for this section.

A.4.20 Utility

There is no additional rationale provided for this section.
A.4.21 Variable Assignment

There is no additional rationale provided for this section.

A.5 File Format Notation

The notation for spaces allows some flexibility for application output. Note that an empty character position in format represents one or more <blank>s on the output (not white space, which can include <newline>s). Therefore, another utility that reads that output as its input must be prepared to parse the data using scanf(), awk, and so on. The ‘∆’ character is used when exactly one <space> is output.

The treatment of integers and spaces is different from the printf() function in that they can be surrounded with <blank>s. This was done so that, given a format such as:

"%d\n",<foo>  

the implementation could use a printf() call such as:

printf("%6d\n", foo);

and still conform. This notation is thus somewhat like scanf() in addition to printf().

The printf() function was chosen as a model because most of the standard developers were familiar with it. One difference from the C function printf() is that the 1 and h conversion specifier characters are not used. As expressed by the Shell and Utilities volume of IEEE Std 1003.1-2001, there is no differentiation between decimal values for type int, type long, or type short. The conversion specifications %d or %i should be interpreted as an arbitrary length sequence of digits. Also, no distinction is made between single precision and double precision numbers (float or double in C). These are simply referred to as floating-point numbers.

Many of the output descriptions in the Shell and Utilities volume of IEEE Std 1003.1-2001 use the term ‘line’, such as:

"%s", <input line>

Since the definition of line includes the trailing <newline> already, there is no need to include a ‘\n’ in the format; a double <newline> would otherwise result.

A.6 Character Set

A.6.1 Portable Character Set

The portable character set is listed in full so there is no dependency on the ISO/IEC 646:1991 standard (or historically ASCII) encoded character set, although the set is identical to the characters defined in the International Reference version of the ISO/IEC 646:1991 standard.

IEEE Std 1003.1-2001 poses no requirement that multiple character sets or codesets be supported, leaving this as a marketing differentiation for implementors. Although multiple charmap files are supported, it is the responsibility of the implementation to provide the file(s); if only one is provided, only that one will be accessible using the localedef –f option.

The statement about invariance in codesets for the portable character set is worded to avoid precluding implementations where multiple incompatible codesets are available (for instance, ASCII and EBCDIC). The standard utilities cannot be expected to produce predictable results if they access portable characters that vary on the same implementation.
Not all character sets need include the portable character set, but each locale must include it. For example, a Japanese-based locale might be supported by a mixture of character sets: JIS X 0201 Roman (a Japanese version of the ISO/IEC 646:1991 standard), JIS X 0208, and JIS X 0201 Katakana. Not all of these character sets include the portable characters, but at least one does (JIS X 0201 Roman).

A.6.2 Character Encoding

Encoding mechanisms based on single shifts, such as the EUC encoding used in some Asian and other countries, can be supported via the current charmap mechanism. With single-shift encoding, each character is preceded by a shift code (SS2 or SS3). A complete EUC code, consisting of the portable character set (G0) and up to three additional character sets (G1, G2, G3), can be described using the current charmap mechanism; the encoding for each character in additional character sets G2 and G3 must then include their single-shift code. Other mechanisms to support locales based on encoding mechanisms such as locking shift are not addressed by this volume of IEEE Std 1003.1-2001.

A.6.3 C Language Wide-Character Codes

There is no additional rationale provided for this section.

A.6.4 Character Set Description File

IEEE PASC Interpretation 1003.2 #196 is applied, removing three lines of text dealing with ranges of symbolic names using position constant values which had been erroneously included in the final IEEE P1003.2b draft standard.

A.6.4.1 State-Dependent Character Encodings

A requirement was considered that would force utilities to eliminate any redundant locking shifts, but this was left as a quality of implementation issue.

This change satisfies the following requirement from the ISO POSIX-2:1993 standard, Annex H.1:

The support of state-dependent (shift encoding) character sets should be addressed fully. See descriptions of these in the Base Definitions volume of IEEE Std 1003.1-2001, Section 6.2, Character Encoding. If such character encodings are supported, it is expected that this will impact the Base Definitions volume of IEEE Std 1003.1-2001, Section 6.2, Character Encoding, the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 7, Locale, the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 9, Regular Expressions, and the comm, cut, diff, grep, head, join, paste, and tail utilities.

The character set description file provides:

- The capability to describe character set attributes (such as collation order or character classes) independent of character set encoding, and using only the characters in the portable character set. This makes it possible to create generic localedef source files for all codesets that share the portable character set (such as the ISO 8859 family or IBM Extended ASCII).

- Standardized symbolic names for all characters in the portable character set, making it possible to refer to any such character regardless of encoding.

Implementations are free to choose their own symbolic names, as long as the names identified by the Base Definitions volume of IEEE Std 1003.1-2001 are also defined; this provides support for already existing "character names".
The names selected for the members of the portable character set follow the ISO/IEC 8859-1:1998 standard and the ISO/IEC 10646-1:2000 standard. However, several commonly used UNIX system names occur as synonyms in the list:

- The historical UNIX system names are used for control characters.
- The word “slash” is given in addition to “solidus”.
- The word “backslash” is given in addition to “reverse-solidus”.
- The word “hyphen” is given in addition to “hyphen-minus”.
- The word “period” is given in addition to “full-stop”.
- For digits, the word “digit” is eliminated.
- For letters, the words “Latin Capital Letter” and “Latin Small Letter” are eliminated.
- The words “left brace” and “right brace” are given in addition to “left-curly-bracket” and “right-curly-bracket”.
- The names of the digits are preferred over the numbers to avoid possible confusion between ‘0’ and ‘O’, and between ‘1’ and ‘l’ (one and the letter ell).

The names for the control characters in the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 6, Character Set were taken from the ISO/IEC 4873:1991 standard.

The charmap file was introduced to resolve problems with the portability of, especially, localedef sources. IEEE Std 1003.1-2001 assumes that the portable character set is constant across all locales, but does not prohibit implementations from supporting two incompatible codings, such as both ASCII and EBCDIC. Such dual-support implementations should have all charmaps and localedef sources encoded using one portable character set, in effect cross-compiling for the other environment. Naturally, charmaps (and localedef sources) are only portable without transformation between systems using the same encodings for the portable character set. They can, however, be transformed between two sets using only a subset of the actual characters (the portable character set). However, the particular coded character set used for an application or an implementation does not necessarily imply different characteristics or collation; on the contrary, these attributes should in many cases be identical, regardless of codeset. The charmap provides the capability to define a common locale definition for multiple codesets (the same localedef source can be used for codesets with different extended characters; the ability in the charmap to define empty names allows for characters missing in certain codesets).

The <escape_char> declaration was added at the request of the international community to ease the creation of portable charmap files on terminals not implementing the default backslash escape. The <comment_char> declaration was added at the request of the international community to eliminate the potential confusion between the number sign and the pound sign.

The octal number notation with no leading zero required was selected to match those of awk and tr and is consistent with that used by localedef. To avoid confusion between an octal constant and the back-references used in localedef source, the octal, hexadecimal, and decimal constants must contain at least two digits. As single-digit constants are relatively rare, this should not impose any significant hardship. Provision is made for more digits to account for systems in which the byte size is larger than 8 bits. For example, a Unicode (ISO/IEC 10646-1:2000 standard) system that has defined 16-bit bytes may require six octal, four hexadecimal, and five decimal digits.

The decimal notation is supported because some newer international standards define character values in decimal, rather than in the old column/row notation.
The charmap identifies the coded character sets supported by an implementation. At least one charmap must be provided, but no implementation is required to provide more than one. Likewise, implementations can allow users to generate new charmaps (for instance, for a new version of the ISO 8859 family of coded character sets), but does not have to do so. If users are allowed to create new charmaps, the system documentation describes the rules that apply (for instance, “only coded character sets that are supersets of the ISO/IEC 646: 1991 standard IRV, no multi-byte characters”).

This addition of the WIDTH specification satisfies the following requirement from the ISO POSIX-2: 1993 standard, Annex H.1:

1723 The definition of column position relies on the implementation’s knowledge of the integral width of the characters. The charmap or LC_CTYPE locale definitions should be enhanced to allow application specification of these widths.

1724 The character “width” information was first considered for inclusion under LC_CTYPE but was moved because it is more closely associated with the information in the charmap than information in the locale source (cultural conventions information). Concerns were raised that formalizing this type of information is moving the locale source definition from the codeset-independent entity that it was designed to be to a repository of codeset-specific information. A similar issue occurred with the <code_set_name>, <mb_cur_max>, and <mb_cur_min> information, which was resolved to reside in the charmap definition.

1726 The width definition was added to the IEEE P1003.2b draft standard with the intent that the wcswidth() and/or wcswidth() functions (currently specified in the System Interfaces volume of IEEE Std 1003.1-2001) be the mechanism to retrieve the character width information.

A.7 Locale

A.7.1 General

The description of locales is based on work performed in the UniForum Technical Committee, Subcommittee on Internationalization. Wherever appropriate, keywords are taken from the ISO C standard or the X/Open Portability Guide.

The value used to specify a locale with environment variables is the name specified as the name operand to the localedef utility when the locale was created. This provides a verifiable method to create and invoke a locale.

The “object” definitions need not be portable, as long as “source” definitions are. Strictly speaking, source definitions are portable only between implementations using the same character set(s). Such source definitions, if they use symbolic names only, easily can be ported between systems using different codesets, as long as the characters in the portable character set (see the Base Definitions volume of IEEE Std 1003.1-2001, Section 6.1, Portable Character Set) have common values between the codesets; this is frequently the case in historical implementations. Of source, this requires that the symbolic names used for characters outside the portable character set be identical between character sets. The definition of symbolic names for characters is outside the scope of IEEE Std 1003.1-2001, but is certainly within the scope of other standards organizations.

Applications can select the desired locale by invoking the setlocale() function (or equivalent) with the appropriate value. If the function is invoked with an empty string, the value of the corresponding environment variable is used. If the environment variable is not set or is set to the empty string, the implementation sets the appropriate environment as defined in the Base
A.7.2 POSIX Locale

The POSIX locale is equal to the C locale. To avoid being classified as a C-language function, the name has been changed to the POSIX locale; the environment variable value can be either "POSIX" or, for historical reasons, "C".

The POSIX definitions mirror the historical UNIX system behavior.

The use of symbolic names for characters in the tables does not imply that the POSIX locale must be described using symbolic character names, but merely that it may be advantageous to do so.

A.7.3 Locale Definition

The decision to separate the file format from the localedef utility description was only partially editorial. Implementations may provide other interfaces than localedef. Requirements on "the utility", mostly concerning error messages, are described in this way because they are meant to affect the other interfaces implementations may provide as well as localedef.

The text about POSIX2_LOCALEDEF does not mean that internationalization is optional; only that the functionality of the localedef utility is. REs, for instance, must still be able to recognize, for example, character class expressions such as "[:alpha:]". A possible analogy is with an applications development environment; while all conforming implementations must be capable of executing applications, not all need to have the development environment installed.

The assumption is that the capability to modify the behavior of utilities (and applications) via locale settings must be supported. If the localedef utility is not present, then the only choice is to select an existing (presumably implementation-documented) locale. An implementation could, for example, choose to support only the POSIX locale, which would in effect limit the amount of changes from historical implementations quite drastically. The localedef utility is still required, but would always terminate with an exit code indicating that no locale could be created. Supported locales must be documented using the syntax defined in this chapter. (This ensures that users can accurately determine what capabilities are provided. If the implementation decides to provide additional capabilities to the ones in this chapter, that is already provided for.)

If the option is present (that is, locales can be created), then the localedef utility must be capable of creating locales based on the syntax and rules defined in this chapter. This does not mean that the implementation cannot also provide alternate means for creating locales.

The octal, decimal, and hexadecimal notations are the same employed by the charmap facility (see the Base Definitions volume of IEEE Std 1003.1-2001, Section 6.4, Character Set Description File). To avoid confusion between an octal constant and a back-reference, the octal, hexadecimal, and decimal constants must contain at least two digits. As single-digit constants are relatively rare, this should not impose any significant hardship. Provision is made for more digits to account for systems in which the byte size is larger than 8 bits. For example, a Unicode (see the ISO/IEC 10646-1:2000 standard) system that has defined 16-bit bytes may require six octal, four hexadecimal, and five decimal digits. As with the charmap file, multi-byte characters are described in the locale definition file using "big-endian" notation for reasons of portability. There is no requirement that the internal representation in the computer memory be in this same order.

One of the guidelines used for the development of this volume of IEEE Std 1003.1-2001 is that characters outside the invariant part of the ISO/IEC 646:1991 standard should not be used in portable specifications. The backslash character is not in the invariant part; the number sign is, but with multiple representations: as a number sign, and as a pound sign. As far as general
usage of these symbols, they are covered by the “grandfather clause”, but for newly defined interfaces, the WG15 POSIX working group has requested that POSIX provide alternate representations. Consequently, while the default escape character remains the backslash and the default comment character is the number sign, implementations are required to recognize alternative representations, identified in the applicable source file via the <escape_char> and <comment_char> keywords.

A.7.3.1 LC_CTYPE

The LC_CTYPE category is primarily used to define the encoding-independent aspects of a character set, such as character classification. In addition, certain encoding-dependent characteristics are also defined for an application via the LC_CTYPE category. IEEE Std 1003.1-2001 does not mandate that the encoding used in the locale is the same as the one used by the application because an implementation may decide that it is advantageous to define locales in a system-wide encoding rather than having multiple, logically identical locales in different encodings, and to convert from the application encoding to the system-wide encoding on usage. Other implementations could require encoding-dependent locales.

In either case, the LC_CTYPE attributes that are directly dependent on the encoding, such as <mb_cur_max> and the display width of characters, are not user-specifiable in a locale source and are consequently not defined as keywords.

Implementations may define additional keywords or extend the LC_CTYPE mechanism to allow application-defined keywords.

The text “The ellipsis specification shall only be valid within a single encoded character set” is present because it is possible to have a locale supported by multiple character encodings, as explained in the rationale for the Base Definitions volume of IEEE Std 1003.1-2001, Section 6.1, Portable Character Set. An example given there is of a possible Japanese-based locale supported by a mixture of the character sets JIS X 0201 Roman, JIS X 0208, and JIS X 0201 Katakana. Attempting to express a range of characters across these sets is not logical and the implementation is free to reject such attempts.

As the LC_CTYPE character classes are based on the ISO C standard character class definition, the category does not support multi-character elements. For instance, the German character <sharp-s> is traditionally classified as a lowercase letter. There is no corresponding uppercase letter; in proper capitalization of German text, the <sharp-s> will be replaced by “SS”; that is, by two characters. This kind of conversion is outside the scope of the toupper and tolower keywords.

Where IEEE Std 1003.1-2001 specifies that only certain characters can be specified, as for the keywords digit andxdigit, the specified characters must be from the portable character set, as shown. As an example, only the Arabic digits 0 through 9 are acceptable as digits.

The character classes digit, xdigit, lower, upper, and space have a set of automatically included characters. These only need to be specified if the character values (that is, encoding) differs from the implementation default values. It is not possible to define a locale without these automatically included characters unless some implementation extension is used to prevent their inclusion. Such a definition would not be a proper superset of the C locale, and thus, it might not be possible for the standard utilities to be implemented as programs conforming to the ISO C standard.

The definition of character class digit requires that only ten characters—the ones defining digits—can be specified; alternate digits (for example, Hindi or Kanji) cannot be specified here. However, the encoding may vary if an implementation supports more than one encoding.
The definition of character class \texttt{xdigit} requires that the characters included in character class \texttt{digit} are included here also and allows for different symbols for the hexadecimal digits 10 through 15.

The inclusion of the charclass keyword satisfies the following requirement from the ISO POSIX-2: 1993 standard, Annex H.1:

(3) The LC_CTYPE (2.5.2.1) locale definition should be enhanced to allow user-specified additional character classes, similar in concept to the ISO C standard Multibyte Support Extension (MSE) \texttt{iswctype} function.

This keyword was previously included in The Open Group specifications and is now mandated in the Shell and Utilities volume of IEEE Std 1003.1-2001.

The symbolic constant {CHARCLASS_NAME_MAX} was also adopted from The Open Group specifications. Applications portability is enhanced by the use of symbolic constants.

\textbf{A.7.3.2} \texttt{LC_COLLATE}

The rules governing collation depend to some extent on the use. At least five different levels of increasingly complex collation rules can be distinguished:

1. \textit{Byte/machine code order}: This is the historical collation order in the UNIX system and many proprietary operating systems. Collation is here performed character by character, without any regard to context. The primary virtue is that it usually is quite fast and also completely deterministic; it works well when the native machine collation sequence matches the user expectations.

2. \textit{Character order}: On this level, collation is also performed character by character, without regard to context. The order between characters is, however, not determined by the code values, but on the expectations by the user of the ‘’correct’’ order between characters. In addition, such a (simple) collation order can specify that certain characters collate equally (for example, uppercase and lowercase letters).

3. \textit{String ordering}: On this level, entire strings are compared based on relatively straightforward rules. Several ‘’passes’’ may be required to determine the order between two strings. Characters may be ignored in some passes, but not in others; the strings may be compared in different directions; and simple string substitutions may be performed before strings are compared. This level is best described as ‘’dictionary’’ ordering; it is based on the spelling, not the pronunciation, or meaning, of the words.

4. \textit{Text search ordering}: This is a further refinement of the previous level, best described as ‘’telephone book ordering’’; some common homonyms (words spelled differently but with the same pronunciation) are collated together; numbers are collated as if they were spelled out, and so on.

5. \textit{Semantic-level ordering}: Words and strings are collated based on their meaning; entire words (such as “the”) are eliminated; the ordering is not deterministic. This usually requires special software and is highly dependent on the intended use.

While the historical collation order formally is at level 1, for the English language it corresponds roughly to elements at level 2. The user expects to see the output from the \texttt{ls} utility sorted very much as it would be in a dictionary. While telephone book ordering would be an optimal goal for standard collation, this was ruled out as the order would be language-dependent. Furthermore, a requirement was that the order must be determined solely from the text string and the collation rules; no external information (for example, ‘’pronunciation dictionaries’’) could be required.
As a result, the goal for the collation support is at level 3. This also matches the requirements for the Canadian collation order, as well as other, known collation requirements for alphabetic scripts. It specifically rules out collation based on pronunciation rules or based on semantic analysis of the text.

The syntax for the LC_COLLATE category source meets the requirements for level 3 and has been verified to produce the correct result with examples based on French, Canadian, and Danish collation order. Because it supports multi-character collating elements, it is also capable of supporting collation in codesets where a character is expressed using non-spacing characters followed by the base character (such as the ISO/IEC 6937:1994 standard).

The directives that can be specified in an operand to the order_start keyword are based on the requirements specified in several proposed standards and in customary use. The following is a rephrasing of rules defined for "lexical ordering in English and French" by the Canadian Standards Association (the text in square brackets is rephrased):

- Once special characters [punctuation] have been removed from original strings, the ordering is determined by scanning forwards (left to right) [disregarding case and diacriticals].
- In case of equivalence, special characters are once again removed from original strings and the ordering is determined by scanning backwards (starting from the rightmost character of the string and back), character by character [disregarding case but considering diacriticals].
- In case of repeated equivalence, special characters are removed again from original strings and the ordering is determined by scanning forwards, character by character [considering both case and diacriticals].
- If there is still an ordering equivalence after the first three rules have been applied, then only special characters and the position they occupy in the string are considered to determine ordering. The string that has a special character in the lowest position comes first. If two strings have a special character in the same position, the character [with the lowest collation value] comes first. In case of equality, the other special characters are considered until there is a difference or until all special characters have been exhausted.

It is estimated that this part of IEEE Std 1003.1-2001 covers the requirements for all European languages, and no particular problems are anticipated with Slavic or Middle East character sets.

The Far East (particularly Japanese/Chinese) collations are often based on contextual information and pronunciation rules (the same ideogram can have different meanings and different pronunciations). Such collation, in general, falls outside the desired goal of IEEE Std 1003.1-2001. There are, however, several other collation rules (stroke/radical or "most common pronunciation") that can be supported with the mechanism described here.

The character order is defined by the order in which characters and elements are specified between the order_start and order_end keywords. Weights assigned to the characters and elements define the collation sequence; in the absence of weights, the character order is also the collation sequence.

The position keyword provides the capability to consider, in a compare, the relative position of characters not subject to IGNORE. As an example, consider the two strings "o-ring" and "or-ing". Assuming the hyphen is subject to IGNORE on the first pass, the two strings compare equal, and the position of the hyphen is immaterial. On second pass, all characters except the hyphen are subject to IGNORE, and in the normal case the two strings would again compare equal. By taking position into account, the first collates before the second.
The currency symbol does not appear in LC_MONETARY because it is not defined in the C locale of the ISO C standard.

The ISO C standard limits the size of decimal points and thousands delimiters to single-byte values. In locales based on multi-byte coded character sets, this cannot be enforced; IEEE Std 1003.1-2001 does not prohibit such characters, but makes the behavior unspecified (in the text “In contexts where other standards . . .”).

The grouping specification is based on, but not identical to, the ISO C standard. The −1 indicates that no further grouping is performed; the equivalent of {CHAR_MAX} in the ISO C standard.

The text “the value is not available in the locale” is taken from the ISO C standard and is used instead of the “unspecified” text in early proposals. There is no implication that omitting these keywords or assigning them values of " " or −1 produces unspecified results; such omissions or assignments eliminate the effects described for the keyword or produce zero-length strings, as appropriate.

The locale definition is an extension of the ISO C standard localeconv() specification. In particular, rules on how currency_symbol is treated are extended to also cover int_curr_symbol, and p_set_by_space and n_sep_by_space have been augmented with the value 2, which places a <space> between the sign and the symbol (if they are adjacent; otherwise, it should be treated as a 0). The following table shows the result of various combinations:

<table>
<thead>
<tr>
<th>p_cs_precedes</th>
<th>p_sign_posn</th>
<th>p_sep_by_space</th>
<th>Formatted Value</th>
<th>ISO C String</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0</td>
<td>2</td>
<td>($1.25)</td>
<td>($1.25)</td>
</tr>
<tr>
<td></td>
<td>1</td>
<td>1</td>
<td>+$1.25</td>
<td>+$1.25</td>
</tr>
<tr>
<td></td>
<td>2</td>
<td>2</td>
<td>$1.25</td>
<td>$1.25+</td>
</tr>
<tr>
<td></td>
<td>3</td>
<td>3</td>
<td>+$1.25</td>
<td>+$1.25+</td>
</tr>
<tr>
<td></td>
<td>4</td>
<td>4</td>
<td>$+1.25</td>
<td>$+1.25</td>
</tr>
<tr>
<td>0</td>
<td>0</td>
<td>2</td>
<td>(1.25 $)</td>
<td>(1.25 $)</td>
</tr>
<tr>
<td></td>
<td>1</td>
<td>1</td>
<td>+1.25 $</td>
<td>+1.25 $</td>
</tr>
<tr>
<td></td>
<td>2</td>
<td>2</td>
<td>1.25$</td>
<td>1.25$+</td>
</tr>
<tr>
<td></td>
<td>3</td>
<td>3</td>
<td>1.25+ $</td>
<td>1.25+ $</td>
</tr>
<tr>
<td></td>
<td>4</td>
<td>4</td>
<td>1.25$</td>
<td>1.25$+</td>
</tr>
</tbody>
</table>

The following is an example of the interpretation of the mon_grouping keyword. Assuming that the value to be formatted is 123 456 789 and the mon_thousands_sep is "", then the following table shows the result. The third column shows the equivalent string in the ISO C standard that would be used by the localeconv() function to accommodate this grouping.

<table>
<thead>
<tr>
<th>mon_grouping</th>
<th>Formatted Value</th>
<th>ISO C String</th>
</tr>
</thead>
<tbody>
<tr>
<td>3;−1</td>
<td>123456789</td>
<td>&quot;\3\177&quot;</td>
</tr>
<tr>
<td>3</td>
<td>123'456'789</td>
<td>&quot;\3&quot;</td>
</tr>
<tr>
<td>3;2;−1</td>
<td>123'4'56'789</td>
<td>&quot;\3\2\177&quot;</td>
</tr>
<tr>
<td>3;2</td>
<td>123'4'56'789</td>
<td>&quot;\3\2&quot;</td>
</tr>
<tr>
<td>−1</td>
<td>123456789</td>
<td>&quot;\177&quot;</td>
</tr>
</tbody>
</table>

In these examples, the octal value of {CHAR_MAX} is 177.

IEEE Std 1003.1-2001/Cor 1-2002, item XBD/TC1/D6/6 adds a correction that permits the Euro currency symbol and addresses extensibility. The correction is stated using the term “should” intentionally, in order to make this a recommendation rather than a restriction on implementations. This allows for flexibility in implementations on how they handle future
currency symbol additions.

IEEE Std 1003.1-2001/Cor 1-2002, tem XBD/TC1/D6/5 is applied, adding the int_[np]_* values to the POSIX locale definition of LC_MONETARY.

A.7.3.4 LC_NUMERIC

See the rationale for LC_MONETARY for a description of the behavior of grouping.

A.7.3.5 LC_TIME

Although certain of the conversion specifications in the POSIX locale (such as the name of the month) are shown with initial capital letters, this need not be the case in other locales. Programs using these conversion specifications may need to adjust the capitalization if the output is going to be used at the beginning of a sentence.

The LC_TIME descriptions of abday, day, mon, and abmon imply a Gregorian style calendar (7-day weeks, 12-month years, leap years, and so on). Formatting time strings for other types of calendars is outside the scope of IEEE Std 1003.1-2001.

While the ISO 8601:2000 standard numbers the weekdays starting with Monday, historical practice is to use the Sunday as the first day. Rather than change the order and introduce potential confusion, the days must be specified beginning with Sunday; previous references to “first day” have been removed. Note also that the Shell and Utilities volume of IEEE Std 1003.1-2001 date utility supports numbering compliant with the ISO 8601:2000 standard.

As specified under date in the Shell and Utilities volume of IEEE Std 1003.1-2001 and strftime() in the System Interfaces volume of IEEE Std 1003.1-2001, the conversion specifications corresponding to the optional keywords consist of a modifier followed by a traditional conversion specification (for instance, %Ex). If the optional keywords are not supported by the implementation or are unspecified for the current locale, these modified conversion specifications are treated as the traditional conversion specifications. For example, assume the following keywords:

```
alt_digits "0th";"1st";"2nd";"3rd";"4th";"5th";\n6th";"7th";"8th";"9th";"10th"
```

```
d_fmt "The %Od day of %B in %Y"
```

On July 4th 1776, the %x conversion specifications would result in "The 4th day of July in 1776", while on July 14th 1789 it would result in "The 14 day of July in 1789". It can be noted that the above example is for illustrative purposes only; the %O modifier is primarily intended to provide for Kanji or Hindi digits in date formats.

The following is an example for Japan that supports the current plus last three Emperors and reverts to Western style numbering for years prior to the Meiji era. The example also allows for the custom of using a special name for the first year of an era instead of using 1. (The examples substitute romaji where kanji should be used.)
Assuming that the current date is September 21, 1991, a request to \texttt{date} or \texttt{strftime()} would yield the following results:

\begin{verbatim}
%Ec - Heisei3nen9gatsu21nichi (Sat) 14:39:26
%Ex - Heisei
%Ey - 3
%EY - Heisei3nen
\end{verbatim}

Example era definitions for the Republic of China:

\begin{verbatim}
era "+:2:1913/01/01:+*:ChungHwaMingGuo:%EC%EyNen";
"+:1:1912/1/1:1912/12/31:ChungHwaMingGuo:%ECYuenNen";
"+:1:1911/12/31:-*:MingChien:%EC%EyNen"
\end{verbatim}

Example definitions for the Christian Era:

\begin{verbatim}
era "+:1:0001/01/01:+*:AD:%EC %Ey";
"+:1:-0001/12/31:-*:BC:%Ey %EC"
\end{verbatim}

\section*{A.7.3.6 \texttt{LC\_MESSAGES}}

The \texttt{yesstr} and \texttt{nostr} locale keywords and the YESSTR and NOSTR \texttt{langinfo} items were formerly used to match user affirmative and negative responses. In IEEE Std 1003.1-2001, the \texttt{yesexpr}, \texttt{noexpr}, YESEXPR, and NOEXPR extended regular expressions have replaced them. Applications should use the general locale-based messaging facilities to issue prompting messages which include sample desired responses.

\section*{A.7.4 Locale Definition Grammar}

There is no additional rationale provided for this section.

\subsection*{A.7.4.1 Locale Lexical Conventions}

There is no additional rationale provided for this section.

\subsection*{A.7.4.2 Locale Grammar}

There is no additional rationale provided for this section.
A.7.5 Locale Definition Example

The following is an example of a locale definition file that could be used as input to the localedef utility. It assumes that the utility is executed with the −f option, naming a charmap file with (at least) the following content:

```
CHARMAP
<space> \x20
<dollar> \x24
<A> \101
<a> \141
<A-acute> \346
<a-acute> \365
<A-grave> \300
<a-grave> \366
<b> \142
<C> \103
<c> \143
<c-cedilla> \347
<d> \x64
<H> \110
<h> \150
<eszet> \xb7
<s> \x73
<z> \x7a
END CHARMAP
```

It should not be taken as complete or to represent any actual locale, but only to illustrate the syntax.

```
# LC_CTYPE
lower <a>;<b>;<c>;<c-cedilla>;<d>;...;<z>
upper A;B;C;Ç;...;Z
space \x20;\x09;\x0a;\x0b;\x0c;\x0d
blank \040;\011
toupper (<a>,<A>);(<b>,B);(<c>,C);(<Ç>,Ç);(<d>,D);(<z>,Z)
END LC_CTYPE
```

```
# The following example of collation is based on
# Canadian standard Z243.4.1-1999, "Canadian Alphanumeric
# Ordering Standard for Character Sets of CSA Z234.4 Standard".
# (Other parts of this example locale definition file do not
# purport to relate to Canada, or to any other real culture.)
# The proposed standard defines a 4-weight collation, such that
# in the first pass, characters are compared without regard to
# case or accents; in the second pass, backwards-compare without
# regard to case; in the third pass, forwards-compare without
# regard to diacriticals. In the 3 first passes, non-alphabetic
# characters are ignored; in the fourth pass, only special
# characters are considered, such that "The string that has a
# special character in the lowest position comes first. If two
strings have a special character in the same position, the
collation value of the special character determines ordering.

# Only a subset of the character set is used here; mostly to
# illustrate the set-up.

# Further collating-symbols follow.

# Properly, the standard does not include any multi-character
# collating elements; the one below is added for completeness.

# Collating symbols are specified first in the sequence to allocate
# basic collation values to them, lower than that of any character.

# Further collating symbols are given a basic collating value here.

# Here follow special characters.

# Here follow the regular characters.
As an example, the strings "Bach" and "bach" could be encoded (for compare purposes) as:

```
"Bach" <b>;<a>;<ch>;<LOW_VALUE>;<NO_ACCENT>;<NO_ACCENT>;\n"<LOWER-CASE>;<UPPER-CASE>\n"bach" <b>;<a>;<ch>;<LOW_VALUE>;<NO_ACCENT>;<NO_ACCENT>;\n"<LOWER-CASE>;<NULL>
```

The two strings are equal in pass 1 and 2, but differ in pass 3.

Further characters follow.

```
UNDEFINED IGNORE;IGNORE;IGNORE;IGNORE
```

```
order_end
```

```
END LC_COLLATE
```

```
LC_MONETARY
```

```
int_curr_symbol "USD "
currency_symbol "$"
mon_decimal_point ",."
mon_grouping 3;0
positive_sign ""
negative_sign "." p_cs_precedes 1
n_sign_posn 0
```

```
END LC_MONETARY
```

```
LC_NUMERIC
```

```
copy "US_en.ASCII"
```

```
END LC_NUMERIC
```

```
# LC_TIME
```

### A.8 Environment Variables

#### A.8.1 Environment Variable Definition

The variable `environ` is not intended to be declared in any header, but rather to be declared by the user for accessing the array of strings that is the environment. This is the traditional usage of the symbol. Putting it into a header could break some programs that use the symbol for their own purposes.

The decision to restrict conforming systems to the use of digits, uppercase letters, and underscores for environment variable names allows applications to use lowercase letters in their environment variable names without conflicting with any conforming system.

In addition to the obvious conflict with the shell syntax for positional parameter substitution, some historical applications (including some shells) exclude names with leading digits from the environment.

#### A.8.2 Internationalization Variables

The text about locale implies that any utilities written in standard C and conforming to IEEE Std 1003.1-2001 must issue the following call:

```c
setlocale(LC_ALL, "")
```

If this were omitted, the ISO C standard specifies that the C locale would be used.

If any of the environment variables are invalid, it makes sense to default to an implementation-defined, consistent locale environment. It is more confusing for a user to have partial settings occur in case of a mistake. All utilities would then behave in one language/cultural environment. Furthermore, it provides a way of forcing the whole environment to be the implementation-defined default. Disastrous results could occur if a pipeline of utilities partially uses the environment variables in different ways. In this case, it would be appropriate for utilities that use `LANG` and related variables to exit with an error if any of the variables are
invalid. For example, users typing individual commands at a terminal might want `date` to work if
`LC_MONETARY` is invalid as long as `LC_TIME` is valid. Since these are conflicting reasonable
alternatives, IEEE Std 1003.1-2001 leaves the results unspecified if the locale environment
variables would not produce a complete locale matching the specification of the user.

The locale settings of individual categories cannot be truly independent and still guarantee
correct results. For example, when collating two strings, characters must first be extracted from
each string (governed by `LC_CTYPE`) before being mapped to collating elements (governed by
`LC_COLLATE`) for comparison. That is, if `LC_CTYPE` is causing parsing according to the rules of
a large, multi-byte code set (potentially returning 20,000 or more distinct character codeset
values), but `LC_COLLATE` is set to handle only an 8-bit codeset with 256 distinct characters,
meaningful results are obviously impossible.

The `LC_MESSAGES` variable affects the language of messages generated by the standard
utilities.

The description of the environment variable names starting with the characters “LC_”
acknowledges the fact that the interfaces presented may be extended as new international
functionality is required. In the ISO C standard, names preceded by “LC_” are reserved in the
name space for future categories.

To avoid name clashes, new categories and environment variables are divided into two
classifications: “implementation-independent” and “implementation-defined”.

Implementation-independent names will have the following format:

```
LC_NAME
```

where `NAME` is the name of the new category and environment variable. Capital letters must be
used for implementation-independent names.

Implementation-defined names must be in lowercase letters, as below:

```
LC_name
```

### A.8.3 Other Environment Variables

## COLUMNS, LINES

The default values for the number of column positions, `COLUMNS`, and screen height, `LINES`,
are unspecified because historical implementations use different methods to determine values
corresponding to the size of the screen in which the utility is run. This size is typically known to
the implementation through the value of `TERM`, or by more elaborate methods such as
extensions to the `stty` utility or knowledge of how the user is dynamically resizing windows on a
bit-mapped display terminal. Users should not need to set these variables in the environment
unless there is a specific reason to override the default behavior of the implementation, such as
to display data in an area arbitrarily smaller than the terminal or window. Values for these
variables that are not decimal integers greater than zero are implicitly undefined values; it is
unnecessary to enumerate all of the possible values outside of the acceptable set.
LOGNAME

In most implementations, the value of such a variable is easily forged, so security-critical applications should rely on other means of determining user identity. LOGNAME is required to be constructed from the portable filename character set for reasons of interchange. No diagnostic condition is specified for violating this rule, and no requirement for enforcement exists. The intent of the requirement is that if extended characters are used, the “guarantee” of portability implied by a standard is void.

PATH

Many historical implementations of the Bourne shell do not interpret a trailing colon to represent the current working directory and are thus non-conforming. The C Shell and the KornShell conform to IEEE Std 1003.1-2001 on this point. The usual name of dot may also be used to refer to the current working directory.

Many implementations historically have used a default value of /bin and /usr/bin for the PATH variable. IEEE Std 1003.1-2001 does not mandate this default path be identical to that retrieved from getconf _CS_PATH because it is likely that the standardized utilities may be provided in another directory separate from the directories used by some historical applications.

SHELL

The SHELL variable names the preferred shell of the user; it is a guide to applications. There is no direct requirement that that shell conform to IEEE Std 1003.1-2001; that decision should rest with the user. It is the intention of the standard developers that alternative shells be permitted, if the user chooses to develop or acquire one. An operating system that builds its shell into the “kernel” in such a manner that alternative shells would be impossible does not conform to the spirit of IEEE Std 1003.1-2001.

TZ

The quoted form of the timezone variable allows timezone names of the form UTC+1 (or any name that contains the character plus (‘+’), the character minus (‘−’), or digits), which may be appropriate for countries that do not have an official timezone name. It would be coded as <UTC+1>+1<UTC+2>, which would cause std to have a value of UTC+1 and dst a value of UTC+2, each with a length of 5 characters. This does not appear to conflict with any existing usage. The characters ‘<’ and ‘>’ were chosen for quoting because they are easier to parse visually than a quoting character that does not provide some sense of bracketing (and in a string like this, such bracketing is helpful). They were also chosen because they do not need special treatment when assigning to the TZ variable. Users are often confused by embedding quotes in a string. Because ‘<’ and ‘>’ are meaningful to the shell, the whole string would have to be quoted, but that is easily explained. (Parentheses would have presented the same problems.) Although the ‘>’ symbol could have been permitted in the string by either escaping it or doubling it, it seemed of little value to require that. This could be provided as an extension if there was a need. Timezone names of this new form lead to a requirement that the value of _POSIX_TZNAME_MAX change from 3 to 6.

Since the TZ environment variable is usually inherited by all applications started by a user after the value of the TZ environment variable is changed and since many applications run using the C or POSIX locale, using characters that are not in the portable character set in the std and dst fields could cause unexpected results.

The format of the TZ environment variable is changed in Issue 6 to allow for the quoted form, as defined in previous versions of the ISO POSIX-1 standard.
IEEE Std 1003.1-2001/Cor 1-2002, item XBD/TC1/D6/7 is applied, adding the `ctime_r()` and `localtime_r()` functions to the list of functions that use the `TZ` environment variable.

A.9 Regular Expressions

Rather than repeating the description of REs for each utility supporting REs, the standard developers preferred a common, comprehensive description of regular expressions in one place. The most common behavior is described here, and exceptions or extensions to this are documented for the respective utilities, as appropriate.

The BRE corresponds to the `ed` or historical `grep` type, and the ERE corresponds to the historical `egrep` type (now `grep −E`).

The text is based on the `ed` description and substantially modified, primarily to aid developers and others in the understanding of the capabilities and limitations of REs. Much of this was influenced by internationalization requirements.

It should be noted that the definitions in this section do not cover the `tr` utility; the `tr` syntax does not employ REs.

The specification of REs is particularly important to internationalization because pattern matching operations are very basic operations in business and other operations. The syntax and rules of REs are intended to be as intuitive as possible to make them easy to understand and use. The historical rules and behavior do not provide that capability to non-English language users, and do not provide the necessary support for commonly used characters and language constructs. It was necessary to provide extensions to the historical RE syntax and rules to accommodate other languages.

As they are limited to bracket expressions, the rationale for these modifications is in the Base Definitions volume of IEEE Std 1003.1-2001, Section 9.3.5, RE Bracket Expression.

A.9.1 Regular Expression Definitions

It is possible to determine what strings correspond to subexpressions by recursively applying the leftmost longest rule to each subexpression, but only with the proviso that the overall match is leftmost longest. For example, matching "\(\{ac*\}\)c*d\[ac\]*\1" against `acdacaaa` matches `acdacaaa` (with \1=a); simply matching the longest match for "\(ac*\)" would yield \1=ac, but the overall match would be smaller (acdac). Conceptually, the implementation must examine every possible match and among those that yield the leftmost longest total matches, pick the one that does the longest match for the leftmost subexpression, and so on. Note that this means that matching by subexpressions is context-dependent: a subexpression within a larger RE may match a different string from the one it would match as an independent RE, and two instances of the same subexpression within the same larger RE may match different lengths even in similar sequences of characters. For example, in the ERE "(a.*b)(a.*b)", the two identical subexpressions would match four and six characters, respectively, of `acchacccecb`.

The definition of single character has been expanded to include also collating elements consisting of two or more characters; this expansion is applicable only when a bracket expression is included in the BRE or ERE. An example of such a collating element may be the Dutch `ij`, which collates as a ‘y’. In some encodings, a ligature “i with j” exists as a character and would represent a single-character collating element. In another encoding, no such ligature exists, and the two-character sequence `ij` is defined as a multi-character collating element. Outside brackets, the `ij` is treated as a two-character RE and matches the same characters in a string. Historically, a bracket expression only matched a single character. The ISO POSIX-2:1993 standard required bracket expressions like "[^[:lower:]]" to match multi-character collating...
elements such as "ij". However, this requirement led to behavior that many users did not expect and that could not feasibly be mimicked in user code, and it was rarely if ever implemented correctly. The current standard leaves it unspecified whether a bracket expression matches a multi-character collating element, allowing both historical and ISO POSIX-2:1993 standard implementations to conform.

Also, in the current standard, it is unspecified whether character class expressions like "[:lower:]" can include multi-character collating elements like "ij"; hence "[[[:lower:]]]" can match "ij", and "[^[:lower:]]" can fail to match "ij". Common practice is for a character class expression to match a collating element if it matches the collating element’s first character.

A.9.2 Regular Expression General Requirements

The definition of which sequence is matched when several are possible is based on the leftmost-longest rule historically used by deterministic recognizers. This rule is easier to define and describe, and arguably more useful, than the first-match rule historically used by non-deterministic recognizers. It is thought that dependencies on the choice of rule are rare; carefully contrived examples are needed to demonstrate the difference.

A formal expression of the leftmost-longest rule is:

The search is performed as if all possible suffixes of the string were tested for a prefix matching the pattern; the longest suffix containing a matching prefix is chosen, and the longest possible matching prefix of the chosen suffix is identified as the matching sequence.

Historically, most RE implementations only match lines, not strings. However, that is more an effect of the usage than of an inherent feature of REs themselves. Consequently, IEEE Std 1003.1-2001 does not regard <newline>s as special; they are ordinary characters, and both a period and a non-matching list can match them. Those utilities (like grep) that do not allow <newline>s to match are responsible for eliminating any <newline> from strings before matching against the RE. The regcomp() function, however, can provide support for such processing without violating the rules of this section.

Some implementations of egrep have had very limited flexibility in handling complex EREs. IEEE Std 1003.1-2001 does not attempt to define the complexity of a BRE or ERE, but does place a lower limit on it—any RE must be handled, as long as it can be expressed in 256 bytes or less. (Of course, this does not place an upper limit on the implementation.) There are historical programs using a non-deterministic-recognizer implementation that should have no difficulty with this limit. It is possible that a good approach would be to attempt to use the faster, but more limited, deterministic recognizer for simple expressions and to fall back on the non-deterministic recognizer for those expressions requiring it. Non-deterministic implementations must be careful to observe the rules on which match is chosen; the longest match, not the first match, starting at a given character is used.

The term “invalid” highlights a difference between this section and some others: IEEE Std 1003.1-2001 frequently avoids mandating of errors for syntax violations because they can be used by implementors to trigger extensions. However, the authors of the internationalization features of REs wanted to mandate errors for certain conditions to identify usage problems or non-portable constructs. These are identified within this rationale as appropriate. The remaining syntax violations have been left implicitly or explicitly undefined. For example, the BRE construct "\{1, 2, 3\}" does not comply with the grammar. A conforming application cannot rely on it producing an error nor matching the literal characters "\{1, 2, 3\}".
The term “undefined” was used in favor of “unspecified” because many of the situations are considered errors on some implementations, and the standard developers considered that consistency throughout the section was preferable to mixing undefined and unspecified.

A.9.3 Basic Regular Expressions

There is no additional rationale provided for this section.

A.9.3.1 BREs Matching a Single Character or Collating Element

There is no additional rationale provided for this section.

A.9.3.2 BRE Ordinary Characters

There is no additional rationale provided for this section.

A.9.3.3 BRE Special Characters

There is no additional rationale provided for this section.

A.9.3.4 Periods in BREs

There is no additional rationale provided for this section.

A.9.3.5 RE Bracket Expression

Range expressions are, historically, an integral part of REs. However, the requirements of “natural language behavior” and portability do conflict. In the POSIX locale, ranges must be treated according to the collating sequence and include such characters that fall within the range based on that collating sequence, regardless of character values. In other locales, ranges have unspecified behavior.

Some historical implementations allow range expressions where the ending range point of one range is also the starting point of the next (for instance, " [a–m–o] "). This behavior should not be permitted, but to avoid breaking historical implementations, it is now undefined whether it is a valid expression and how it should be interpreted.

Current practice in awk and lex is to accept escape sequences in bracket expressions as per the Base Definitions volume of IEEE Std 1003.1-2001, Table 5-1, Escape Sequences and Associated Actions, while the normal ERE behavior is to regard such a sequence as consisting of two characters. Allowing the awk/lex behavior in EREs would change the normal behavior in an unacceptable way; it is expected that awk and lex will decode escape sequences in EREs before passing them to regcomp() or comparable routines. Each utility describes the escape sequences it accepts as an exception to the rules in this section; the list is not the same, for historical reasons.

As noted previously, the new syntax and rules have been added to accommodate other languages than English. The remainder of this section describes the rationale for these modifications.

In the POSIX locale, a regular expression that starts with a range expression matches a set of strings that are contiguously sorted, but this is not necessarily true in other locales. For example, a French locale might have the following behavior:

```
$ ls
alpha Alpha estimé ESTIMÉ été eurêka
$ ls [a-e]*
alpha Alpha estimé eurêka
```
Such disagreements between matching and contiguous sorting are unavoidable because POSIX sorting cannot be implemented in terms of a deterministic finite-state automaton (DFA), but range expressions by design are implementable in terms of DFAs.

Historical implementations used native character order to interpret range expressions. The ISO POSIX-2: 1993 standard instead required collating element order (CEO): the order that collating elements were specified between the `order_start` and `order_end` keywords in the `LC_COLLATE` category of the current locale. CEO had some advantages in portability over the native character order, but it also had some disadvantages:

- CEO could not feasibly be mimicked in user code, leading to inconsistencies between POSIX matchers and matchers in popular user programs like Emacs, `ksh`, and Perl.
- CEO caused range expressions to match accented and capitalized letters contrary to many users' expectations. For example, "[a-e]" typically matched both 'É' and 'â' but neither 'Á' nor 'é'.
- CEO was not consistent across implementations. In practice, CEO was often less portable than native character order. For example, it was common for the CEOs of two implementation-supplied locales to disagree, even if both locales were named "da_DK".

Because of these problems, some implementations of regular expressions continued to use native character order. Others used the collation sequence, which is more consistent with sorting than either CEO or native order, but which departs further from the traditional POSIX semantics because it generally requires "[a-e]" to match either 'A' or 'E' but not both. As a result of this kind of implementation variation, programmers who wanted to write portable regular expressions could not rely on the ISO POSIX-2: 1993 standard guarantees in practice.

While revising the standard, lengthy consideration was given to proposals to attack this problem by adding an API for querying the CEO to allow user-mode matchers, but none of these proposals had implementation experience and none achieved consensus. Leaving the standard alone was also considered, but rejected due to the problems described above.

The current standard leaves unspecified the behavior of a range expression outside the POSIX locale. This makes it clearer that conforming applications should avoid range expressions outside the POSIX locale, and it allows implementations and compatible user-mode matchers to interpret range expressions using native order, CEO, collation sequence, or other, more advanced techniques. The concerns which led to this change were raised in IEEE PASC interpretation 1003.2 #43 and others, and related to ambiguities in the specification of how multi-character collating elements should be handled in range expressions. These ambiguities had led to multiple interpretations of the specification, in conflicting ways, which led to varying implementations. As noted above, efforts were made to resolve the differences, but no solution has been found that would be specific enough to allow for portable software while not invalidating existing implementations.

The standard developers recognize that collating elements are important, such elements being common in several European languages; for example, 'ch' or '11' in traditional Spanish; 'aa' in several Scandinavian languages. Existing internationalized implementations have processed, and continue to process, these elements in range expressions. Efforts are expected to continue in the future to find a way to define the behavior of these elements precisely and portably.

The ISO POSIX-2:1993 standard required "[b-a]" to be an invalid expression in the POSIX locale, but this requirement has been relaxed in this version of the standard so that "[b-a]" can instead be treated as a valid expression that does not match any string.
A.9.3.6 BREs Matching Multiple Characters

The limit of nine back-references to subexpressions in the RE is based on the use of a single-digit identifier; increasing this to multiple digits would break historical applications. This does not imply that only nine subexpressions are allowed in REs. The following is a valid BRE with ten subexpressions:

```
((ab)*c)*d)/(ef)*((gh)*{2})(ij)*((kl)*((mn)*((op)*((qr)*
```

The standard developers regarded the common historical behavior, which supported "\n*", but not "\n{min,max}"", "\((...)\)*", or "\((...)\){min,max}"", as a non-intentional result of a specific implementation, and they supported both duplication and interval expressions following subexpressions and back-references.

The changes to the processing of the back-reference expression remove an unspecified or ambiguous behavior in the Shell and Utilities volume of IEEE Std 1003.1-2001, aligning it with the requirements specified for the `regcomp()` expression, and is the result of PASC Interpretation 1003.2-92 #43 submitted for the ISO POSIX-2:1993 standard.

A.9.3.7 BRE Precedence

There is no additional rationale provided for this section.

A.9.3.8 BRE Expression Anchoring

Often, the dollar sign is viewed as matching the ending `<newline>` in text files. This is not strictly true; the `<newline>` is typically eliminated from the strings to be matched, and the dollar sign matches the terminating null character.

The ability of `^`, `$`, and `*` to be non-special in certain circumstances may be confusing to some programmers, but this situation was changed only in a minor way from historical practice to avoid breaking many historical scripts. Some consideration was given to making the use of the anchoring characters undefined if not escaped and not at the beginning or end of strings. This would cause a number of historical BREs, such as `"2^10"`, `"$HOME"`, and `"$1.35"`, that relied on the characters being treated literally, to become invalid.

However, one relatively uncommon case was changed to allow an extension used on some implementations. Historically, the BREs `"^foo"` and `"\(^foo\)"` did not match the same string, despite the general rule that subexpressions and entire BREs match the same strings. To increase consensus, IEEE Std 1003.1-2001 has allowed an extension on some implementations to treat these two cases in the same way by declaring that anchoring may occur at the beginning or end of a subexpression. Therefore, portable BREs that require a literal circumflex at the beginning or a dollar sign at the end of a subexpression must escape them. Note that a BRE such as `"a\(^bc\)"` will either match `"a^bc"` or nothing on different systems under the rules.

ERE anchoring has been different from BRE anchoring in all historical systems. An unescaped anchor character has never matched its literal counterpart outside a bracket expression. Some implementations treated `"foo$bar"` as a valid expression that never matched anything; others treated it as invalid. IEEE Std 1003.1-2001 mandates the former, valid unmatched behavior.

Some implementations have extended the BRE syntax to add alternation. For example, the subexpression `"\{foo\}\|bar\}` would match either `"foo"` at the end of the string or `"bar"` anywhere. The extension is triggered by the use of the undefined `"\"` sequence. Because the BRE is undefined for portable scripts, the extending system is free to make other assumptions, such that the `'$'` represents the end-of-line anchor in the middle of a subexpression. If it were not for the extension, the `'$'` would match a literal dollar sign under the rules.
A.9.4 Extended Regular Expressions

As with BREs, the standard developers decided to make the interpretation of escaped ordinary characters undefined.

The right parenthesis is not listed as an ERE special character because it is only special in the context of a preceding left parenthesis. If found without a preceding left parenthesis, the right parenthesis has no special meaning.

The interval expression, \"\{m,n\}\", has been added to EREs. Historically, the interval expression has only been supported in some ERE implementations. The standard developers estimated that the addition of interval expressions to EREs would not decrease consensus and would also make BREs more of a subset of EREs than in many historical implementations.

It was suggested that, in addition to interval expressions, back-references (\'\n\') should also be added to EREs. This was rejected by the standard developers as likely to decrease consensus.

In historical implementations, multiple duplication symbols are usually interpreted from left to right and treated as additive. As an example, \"a+a+b\" matches zero or more instances of \'a\' followed by \'b\'. In IEEE Std 1003.1-2001, multiple duplication symbols are undefined; that is, they cannot be relied upon for conforming applications. One reason for this is to provide some scope for future enhancements.

The precedence of operations differs between EREs and those in lex; in lex, for historical reasons, interval expressions have a lower precedence than concatenation.

A.9.4.1 EREs Matching a Single Character or Collating Element

There is no additional rationale provided for this section.

A.9.4.2 ERE Ordinary Characters

There is no additional rationale provided for this section.

A.9.4.3 ERE Special Characters

There is no additional rationale provided for this section.

A.9.4.4 Periods in EREs

There is no additional rationale provided for this section.

A.9.4.5 ERE Bracket Expression

There is no additional rationale provided for this section.

A.9.4.6 EREs Matching Multiple Characters

There is no additional rationale provided for this section.

A.9.4.7 ERE Alternation

There is no additional rationale provided for this section.
A.9.4.8 ERE Precedence

There is no additional rationale provided for this section.

A.9.4.9 ERE Expression Anchoring

There is no additional rationale provided for this section.

A.9.5 Regular Expression Grammar

The grammars are intended to represent the range of acceptable syntaxes available to conforming applications. There are instances in the text where undefined constructs are described; as explained previously, these allow implementation extensions. There is no intended requirement that an implementation extension must somehow fit into the grammars shown here.

The BRE grammar does not permit L_ANCHOR or R_ANCHOR inside "\( " and "\) " (which implies that ‘^’ and ‘$’ are ordinary characters). This reflects the semantic limits on the application, as noted in the Base Definitions volume of IEEE Std 1003.1-2001, Section 9.3.8, BRE Expression Anchoring. Implementations are permitted to extend the language to interpret ‘^’ and ‘$’ as anchors in these locations, and as such, conforming applications cannot use unescaped ‘^’ and ‘$’ in positions inside "\( " and "\) " that might be interpreted as anchors.

The ERE grammar does not permit several constructs that the Base Definitions volume of IEEE Std 1003.1-2001, Section 9.4.2, ERE Ordinary Characters and the Base Definitions volume of IEEE Std 1003.1-2001, Section 9.4.3, ERE Special Characters specify as having undefined results:

- ORD_CHAR preceded by ‘\’
- ERE_dupl_symbol(s) appearing first in an ERE, or immediately following ‘|’ , ‘^’, or ‘(‘
- ‘{’ not part of a valid ERE_dupl_symbol
- ‘|’ appearing first or last in an ERE, or immediately following ‘|’ or ‘(‘, or immediately preceding ‘)’

Implementations are permitted to extend the language to allow these. Conforming applications cannot use such constructs.

A.9.5.1 BRE/ERE Grammar Lexical Conventions

There is no additional rationale provided for this section.

A.9.5.2 RE and Bracket Expression Grammar

The removal of the Back_open_paren Back_close_paren option from the nondupl_RE specification is the result of PASC Interpretation 1003.2-92 #43 submitted for the ISO POSIX-2:1993 standard. Although the grammar required support for null subexpressions, this section does not describe the meaning of, and historical practice did not support, this construct.

A.9.5.3 ERE Grammar

There is no additional rationale provided for this section.
A.10 Directory Structure and Devices

A.10.1 Directory Structure and Files

A description of the historical /usr/tmp was omitted, removing any concept of differences in emphasis between the / and /usr directories. The descriptions of /bin, /usr/bin, /lib, and /usr/lib were omitted because they are not useful for applications. In an early draft, a distinction was made between system and application directory usage, but this was not found to be useful.

The directories / and /dev are included because the notion of a hierarchical directory structure is key to other information presented elsewhere in IEEE Std 1003.1-2001. In early drafts, it was argued that special devices and temporary files could conceivably be handled without a directory structure on some implementations. For example, the system could treat the characters "/tmp" as a special token that would store files using some non-POSIX file system structure. This notion was rejected by the standard developers, who required that all the files in this section be implemented via POSIX file systems.

The /tmp directory is retained in IEEE Std 1003.1-2001 to accommodate historical applications that assume its availability. Implementations are encouraged to provide suitable directory names in the environment variable TMPDIR and applications are encouraged to use the contents of TMPDIR for creating temporary files.

The standard files /dev/null and /dev/tty are required to be both readable and writable to allow applications to have the intended historical access to these files.

The standard file /dev/console has been added for alignment with the Single UNIX Specification.

A.10.2 Output Devices and Terminal Types

There is no additional rationale provided for this section.

A.11 General Terminal Interface

If the implementation does not support this interface on any device types, it should behave as if it were being used on a device that is not a terminal device (in most cases errno will be set to [ENOTTY] on return from functions defined by this interface). This is based on the fact that many applications are written to run both interactively and in some non-interactive mode, and they adapt themselves at runtime. Requiring that they all be modified to test an environment variable to determine whether they should try to adapt is unnecessary. On a system that provides no general terminal interface, providing all the entry points as stubs that return [ENOTTY] (or an equivalent, as appropriate) has the same effect and requires no changes to the application.

Although the needs of both interface implementors and application developers were addressed throughout IEEE Std 1003.1-2001, this section pays more attention to the needs of the latter. This is because, while many aspects of the programming interface can be hidden from the user by the application developer, the terminal interface is usually a large part of the user interface. Although to some extent the application developer can build missing features or work around inappropriate ones, the difficulties of doing that are greater in the terminal interface than elsewhere. For example, efficiency prohibits the average program from interpreting every character passing through it in order to simulate character erase, line kill, and so on. These functions should usually be done by the operating system, possibly at the interrupt level.

The tc*() functions were introduced as a way of avoiding the problems inherent in the traditional ioctl() function and in variants of it that were proposed. For example, tcsetattr() is
specified in place of the use of the TCSETA \texttt{ioctl()} command function. This allows specification of all the arguments in a manner consistent with the ISO C standard unlike the varying third argument of \texttt{ioctl()}, which is sometimes a pointer (to any of many different types) and sometimes an \texttt{int}.

The advantages of this new method include:

- It allows strict type checking.
- The direction of transfer of control data is explicit.
- Portable capabilities are clearly identified.
- The need for a general interface routine is avoided.
- Size of the argument is well-defined (there is only one type).

The disadvantages include:

- No historical implementation used the new method.
- There are many small routines instead of one general-purpose one.
- The historical parallel with \texttt{fcntl()} is broken.

The issue of modem control was excluded from IEEE Std 1003.1-2001 on the grounds that:

- It was concerned with setting and control of hardware timers.
- The appropriate timers and settings vary widely internationally.
- Feedback from European computer manufacturers indicated that this facility was not consistent with European needs and that specification of such a facility was not a requirement for portability.

\section*{A.11.1 Interface Characteristics}

\subsection*{A.11.1.1 Opening a Terminal Device File}

There is no additional rationale provided for this section.

\subsection*{A.11.1.2 Process Groups}

There is a potential race when the members of the foreground process group on a terminal leave that process group, either by exit or by changing process groups. After the last process exits the process group, but before the foreground process group ID of the terminal is changed (usually by a job control shell), it would be possible for a new process to be created with its process ID equal to the terminal's foreground process group ID. That process might then become the process group leader and accidentally be placed into the foreground on a terminal that was not necessarily its controlling terminal. As a result of this problem, the controlling terminal is defined to not have a foreground process group during this time.

The cases where a controlling terminal has no foreground process group occur when all processes in the foreground process group either terminate and are waited for or join other process groups via \texttt{setpgid()} or \texttt{setsid()}. If the process group leader terminates, this is the first case described; if it leaves the process group via \texttt{setpgid()}, this is the second case described (a process group leader cannot successfully call \texttt{setsid()}). When one of those cases causes a controlling terminal to have no foreground process group, it has two visible effects on applications. The first is the value returned by \texttt{tcgetpgrp()}. The second (which occurs only in the case where the process group leader terminates) is the sending of signals in response to special input characters. The intent of IEEE Std 1003.1-2001 is that no process group be wrongly
identified as the foreground process group by \texttt{tcgetpgrp()} or unintentionally receive signals because of placement into the foreground.

In 4.3 BSD, the old process group ID continues to be used to identify the foreground process group and is returned by the function equivalent to \texttt{tcgetpgrp()}. In that implementation it is possible for a newly created process to be assigned the same value as a process ID and then form a new process group with the same value as a process group ID. The result is that the new process group would receive signals from this terminal for no apparent reason, and IEEE Std 1003.1-2001 precludes this by forbidding a process group from entering the foreground in this way. It would be more direct to place part of the requirement made by the last sentence under \texttt{fork()}, but there is no convenient way for that section to refer to the value that \texttt{tcgetpgrp()} returns, since in this case there is no process group and thus no process group ID.

One possibility for a conforming implementation is to behave similarly to 4.3 BSD, but to prevent this reuse of the ID, probably in the implementation of \texttt{fork()}, as long as it is in use by the terminal.

Another possibility is to recognize when the last process stops using the terminal’s foreground process group ID, which is when the process group lifetime ends, and to change the terminal’s foreground process group ID to a reserved value that is never used as a process ID or process group ID. (See the definition of \textit{process group lifetime} in the definitions section.) The process ID can then be reserved until the terminal has another foreground process group.

The 4.3 BSD implementation permits the leader (and only member) of the foreground process group to leave the process group by calling the equivalent of \texttt{setpgid()} and to later return, expecting to return to the foreground. There are no known application needs for this behavior, and IEEE Std 1003.1-2001 neither requires nor forbids it (except that it is forbidden for session leaders) by leaving it unspecified.

\textbf{A.11.1.3 The Controlling Terminal}

IEEE Std 1003.1-2001 does not specify a mechanism by which to allocate a controlling terminal. This is normally done by a system utility (such as \texttt{getty}) and is considered an administrative feature outside the scope of IEEE Std 1003.1-2001.

Historical implementations allocate controlling terminals on certain \texttt{open()} calls. Since \texttt{open()} is part of POSIX.1, its behavior had to be dealt with. The traditional behavior is not required because it is not very straightforward or flexible for either implementations or applications. However, because of its prevalence, it was not practical to disallow this behavior either. Thus, a mechanism was standardized to ensure portable, predictable behavior in \texttt{open()}.

Some historical implementations deallocate a controlling terminal on the last system-wide close. This behavior in neither required nor prohibited. Even on implementations that do provide this behavior, applications generally cannot depend on it due to its system-wide nature.

\textbf{A.11.1.4 Terminal Access Control}

The access controls described in this section apply only to a process that is accessing its controlling terminal. A process accessing a terminal that is not its controlling terminal is effectively treated the same as a member of the foreground process group. While this may seem unintuitive, note that these controls are for the purpose of job control, not security, and job control relates only to a process’ controlling terminal. Normal file access permissions handle security.

If the process calling \texttt{read()} or \texttt{write()} is in a background process group that is orphaned, it is not desirable to stop the process group, as it is no longer under the control of a job control shell that could put it into the foreground again. Accordingly, calls to \texttt{read()} or \texttt{write()} functions by such
processes receive an immediate error return. This is different from 4.2 BSD, which kills orphaned processes that receive terminal stop signals.

The foreground/background/orphaned process group check performed by the terminal driver must be repeatedly performed until the calling process moves into the foreground or until the process group of the calling process becomes orphaned. That is, when the terminal driver determines that the calling process is in the background and should receive a job control signal, it sends the appropriate signal (SIGTTIN or SIGTTOU) to every process in the process group of the calling process and then it allows the calling process to immediately receive the signal. The latter is typically performed by blocking the process so that the signal is immediately noticed. Note, however, that after the process finishes receiving the signal and control is returned to the driver, the terminal driver must re-execute the foreground/background/orphaned process group check. The process may still be in the background, either because it was continued in the background by a job control shell, or because it caught the signal and did nothing.

The terminal driver repeatedly performs the foreground/background/orphaned process group checks whenever a process is about to access the terminal. In the case of write() or the control tc* functions, the check is performed at the entry of the function. In the case of read(), the check is performed not only at the entry of the function, but also after blocking the process to wait for input characters (if necessary). That is, once the driver has determined that the process calling the read() function is in the foreground, it attempts to retrieve characters from the input queue. If the queue is empty, it blocks the process waiting for characters. When characters are available and control is returned to the driver, the terminal driver must return to the repeated foreground/background/orphaned process group check again. The process may have moved from the foreground to the background while it was blocked waiting for input characters.

A.11.1.5 Input Processing and Reading Data

There is no additional rationale provided for this section.

A.11.1.6 Canonical Mode Input Processing

The term ‘‘character’’ is intended here. ERASE should erase the last character, not the last byte. In the case of multi-byte characters, these two may be different.

4.3 BSD has a WERASE character that erases the last ‘‘word’’ typed (but not any preceding <blank>s or <tab>s). A word is defined as a sequence of non-<blank>s, with <tab>s counted as <blank>s. Like ERASE, WERASE does not erase beyond the beginning of the line. This WERASE feature has not been specified in POSIX.1 because it is difficult to define in the international environment. It is only useful for languages where words are delimited by <blank>s. In some ideographic languages, such as Japanese and Chinese, words are not delimited at all. The WERASE character should presumably go back to the beginning of a sentence in those cases; practically, this means it would not be used much for those languages.

It should be noted that there is a possible inherent deadlock if the application and implementation conflict on the value of [MAX_CANON]. With ICANON set (if IXOFF is enabled) and more than {MAX_CANON} characters transmitted without a <linefeed>, transmission will be stopped, the <linefeed> (or <carriage-return> when ICRLF is set) will never arrive, and the read() will never be satisfied.

An application should not set IXOFF if it is using canonical mode unless it knows that (even in the face of a transmission error) the conditions described previously cannot be met or unless it is prepared to deal with the possible deadlock in some other way, such as timeouts.

It should also be noted that this can be made to happen in non-canonical mode if the trigger value for sending IXOFF is less than VMIN and VTIME is zero.
A.11.1.7 Non-Canonical Mode Input Processing

Some points to note about MIN and TIME:

1. The interactions of MIN and TIME are not symmetric. For example, when MIN>0 and TIME=0, TIME has no effect. However, in the opposite case where MIN=0 and TIME>0, both MIN and TIME play a role in that MIN is satisfied with the receipt of a single character.

2. Also note that in case A (MIN>0, TIME>0), TIME represents an inter-character timer, while in case C (MIN=0, TIME>0), TIME represents a read timer.

These two points highlight the dual purpose of the MIN/TIME feature. Cases A and B, where MIN>0, exist to handle burst-mode activity (for example, file transfer programs) where a program would like to process at least MIN characters at a time. In case A, the inter-character timer is activated by a user as a safety measure; in case B, it is turned off.

Cases C and D exist to handle single-character timed transfers. These cases are readily adaptable to screen-based applications that need to know if a character is present in the input queue before refreshing the screen. In case C, the read is timed; in case D, it is not.

Another important note is that MIN is always just a minimum. It does not denote a record length. That is, if a program does a read of 20 bytes, MIN is 10, and 25 characters are present, 20 characters are returned to the user. In the special case of MIN=0, this still applies: if more than one character is available, they all will be returned immediately.

A.11.1.8 Writing Data and Output Processing

There is no additional rationale provided for this section.

A.11.1.9 Special Characters

There is no additional rationale provided for this section.

A.11.1.10 Modem Disconnect

There is no additional rationale provided for this section.

A.11.1.11 Closing a Terminal Device File

IEEE Std 1003.1-2001 does not specify that a close() on a terminal device file include the equivalent of a call to tcflow(fd,TCOON).

An implementation that discards output at the time close() is called after reporting the return value to the write() call that data was written does not conform with IEEE Std 1003.1-2001. An application has functions such as tcdrain(), tcflush(), and tcflow() available to obtain the detailed behavior it requires with respect to flushing of output.

At the time of the last close on a terminal device, an application relinquishes any ability to exert flow control via tcflow().
A.11.2 Parameters that Can be Set

A.11.2.1 The termios Structure

This structure is part of an interface that, in general, retains the historic grouping of flags. Although a more optimal structure for implementations may be possible, the degree of change to applications would be significantly larger.

A.11.2.2 Input Modes

Some historical implementations treated a long break as multiple events, as many as one per character time. The wording in POSIX.1 explicitly prohibits this.

Although the ISTRIP flag is normally superfluous with today’s terminal hardware and software, it is historically supported. Therefore, applications may be using ISTRIP, and there is no technical problem with supporting this flag. Also, applications may wish to receive only 7-bit input bytes and may not be connected directly to the hardware terminal device (for example, when a connection traverses a network).

Also, there is no requirement in general that the terminal device ensures that high-order bits beyond the specified character size are cleared. ISTRIP provides this function for 7-bit characters, which are common.

In dealing with multi-byte characters, the consequences of a parity error in such a character, or in an escape sequence affecting the current character set, are beyond the scope of POSIX.1 and are best dealt with by the application processing the multi-byte characters.

A.11.2.3 Output Modes

POSIX.1 does not describe postprocessing of output to a terminal or detailed control of that from a conforming application. (That is, translation of <newline> to <carriage-return> followed by <linefeed> or <tab> processing.) There is nothing that a conforming application should do to its output for a terminal because that would require knowledge of the operation of the terminal. It is the responsibility of the operating system to provide postprocessing appropriate to the output device, whether it is a terminal or some other type of device.

Extensions to POSIX.1 to control the type of postprocessing already exist and are expected to continue into the future. The control of these features is primarily to adjust the interface between the system and the terminal device so the output appears on the display correctly. This should be set up before use by any application.

In general, both the input and output modes should not be set absolutely, but rather modified from the inherited state.

A.11.2.4 Control Modes

This section could be misread that the symbol “CSIZE” is a title in the termios c_cflag field. Although it does serve that function, it is also a required symbol, as a literal reading of POSIX.1 (and the caveats about typography) would indicate.

A.11.2.5 Local Modes

Non-canonical mode is provided to allow fast bursts of input to be read efficiently while still allowing single-character input.

The ECHONL function historically has been in many implementations. Since there seems to be no technical problem with supporting ECHONL, it is included in POSIX.1 to increase consensus.
The alternate behavior possible when ECHOK or ECHOE are specified with ICANON is permitted as a compromise depending on what the actual terminal hardware can do. Erasing characters and lines is preferred, but is not always possible.

A.11.2.6 Special Control Characters

Permitting VMIN and VTIME to overlap with VEOF and VEOL was a compromise for historical implementations. Only when backwards-compatibility of object code is a serious concern to an implementor should an implementation continue this practice. Correct applications that work with the overlap (at the source level) should also work if it is not present, but not the reverse.

A.12 Utility Conventions

A.12.1 Utility Argument Syntax

The standard developers considered that recent trends toward diluting the SYNOPSIS sections of historical reference pages to the equivalent of:

```
command [options][operands]
```

were a disservice to the reader. Therefore, considerable effort was placed into rigorous definitions of all the command line arguments and their interrelationships. The relationships depicted in the synopses are normative parts of IEEE Std 1003.1-2001; this information is sometimes repeated in textual form, but that is only for clarity within context.

The use of “undefined” for conflicting argument usage and for repeated usage of the same option is meant to prevent conforming applications from using conflicting arguments or repeated options unless specifically allowed (as is the case with ls, which allows simultaneous, repeated use of the –C, –l, and –I options). Many historical implementations will tolerate this usage, choosing either the first or the last applicable argument. This tolerance can continue, but conforming applications cannot rely upon it. (Other implementations may choose to print usage messages instead.)

The use of “undefined” for conflicting argument usage also allows an implementation to make reasonable extensions to utilities where the implementor considers mutually-exclusive options according to IEEE Std 1003.1-2001 to have a sensible meaning and result.

IEEE Std 1003.1-2001 does not define the result of a command when an option-argument or operand is not followed by ellipses and the application specifies more than one of that option-argument or operand. This allows an implementation to define valid (although non-standard) behavior for the utility when more than one such option or operand is specified.

The following table summarizes the requirements for option-arguments:

<table>
<thead>
<tr>
<th>SYNOPSIS Shows:</th>
<th>Conforming application uses:</th>
<th>System supports:</th>
<th>Non-conforming applications may use:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>–a arg</td>
<td>–a arg</td>
<td>–a arg and –aarg</td>
</tr>
<tr>
<td></td>
<td>–c [arg]</td>
<td>–c[arg]</td>
<td>–carg or –c</td>
</tr>
</tbody>
</table>

Allowing <blank>s after an option (that is, placing an option and its option-argument into separate argument strings) when IEEE Std 1003.1-2001 does not require it encourages portability of users, while still preserving backwards-compatibility of scripts. Inserting <blank>s between
the option and the option-argument is preferred; however, historical usage has not been
consistent in this area; therefore, <blank>s are required to be handled by all implementations,
but implementations are also allowed to handle the historical syntax. Another justification for
selecting the multiple-argument method was that the single-argument case is inherently
ambiguous when the option-argument can legitimately be a null string.

IEEE Std 1003.1-2001 explicitly states that digits are permitted as operands and option-
arguments. The lower and upper bounds for the values of the numbers used for operands and
option-arguments were derived from the ISO C standard values for [LONG_MIN] and
[LONG_MAX]. The requirement on the standard utilities is that numbers in the specified range
do not cause a syntax error, although the specification of a number need not be semantically
correct for a particular operand or option-argument of a utility. For example, the specification of:

```
dd obs=3000000000
```

would yield undefined behavior for the application and could be a syntax error because the
number 3 000 000 000 is outside of the range −2 147 483 647 to +2 147 483 647. On the other hand:

```
dd obs=2000000000
```

may cause some error, such as “blocksize too large”, rather than a syntax error.

### A.12.2 Utility Syntax Guidelines

This section is based on the rules listed in the SVID. It was included for two reasons:

1. The individual utility descriptions in the Shell and Utilities volume of
   IEEE Std 1003.1-2001, Chapter 4, Utilities needed a set of common (although not universal)
   actions on which they could anchor their descriptions of option and operand syntax. Most
   of the standard utilities actually do use these guidelines, and many of their historical
   implementations use the `getopt()` function for their parsing. Therefore, it was simpler to
cite the rules and merely identify exceptions.

2. Writers of conforming applications need suggested guidelines if the POSIX community is
   to avoid the chaos of historical UNIX system command syntax.

It is recommended that all future utilities and applications use these guidelines to enhance “user
portability”. The fact that some historical utilities could not be changed (to avoid breaking
historical applications) should not deter this future goal.

The voluntary nature of the guidelines is highlighted by repeated uses of the word *should*
throughout. This usage should not be misinterpreted to imply that utilities that claim
conformance in their OPTIONS sections do not always conform.

Guidelines 1 and 2 are offered as guidance for locales using Latin alphabets. No
recommendations are made by IEEE Std 1003.1-2001 concerning utility naming in other locales.

In the Shell and Utilities volume of IEEE Std 1003.1-2001, Section 2.9.1, Simple Commands, it is
further stated that a command used in the Shell Command Language cannot be named with a
trailing colon.

Guideline 3 was changed to allow alphanumeric characters (letters and digits) from the character
set to allow compatibility with historical usage. Historical practice allows the use of digits
wherever practical, and there are no portability issues that would prohibit the use of digits. In
fact, from an internationalization viewpoint, digits (being non-language-dependent) are
preferable over letters (a −2 is intuitively self-explanatory to any user, while in the −f *filename* the
letter ‘f’ is a mnemonic aid only to speakers of Latin-based languages where “filename”
happens to translate to a word that begins with ‘f’. Since guideline 3 still retains the word
“single”, multi-digit options are not allowed. Instances of historical utilities that used them have
been marked obsolescent, with the numbers being changed from option names to option-
arguments.

It was difficult to achieve a satisfactory solution to the problem of name space in option
characters. When the standard developers desired to extend the historical cc utility to accept
ISO C standard programs, they found that all of the portable alphabet was already in use by
various vendors. Thus, they had to devise a new name, c89 (now superseded by c99), rather than
something like cc −X. There were suggestions that implementors be restricted to providing
extensions through various means (such as using a plus sign as the option delimiter or using
option characters outside the alphanumeric set) that would reserve all of the remaining
alphanumeric characters for future POSIX standards. These approaches were resisted because they
lacked the historical style of UNIX systems. Furthermore, if a vendor-provided option
should become commonly used in the industry, it would be a candidate for standardization. It
would be desirable to standardize such a feature using historical practice for the syntax (the
semantics can be standardized with any syntax). This would not be possible if the syntax was
one reserved for the vendor. However, since the standardization process may lead to minor
changes in the semantics, it may prove to be better for a vendor to use a syntax that will not be
affected by standardization.

Guideline 8 includes the concept of comma-separated lists in a single argument. It is up to the
utility to parse such a list itself because getopt() just returns the single string. This situation was
retained so that certain historical utilities would not violate the guidelines. Applications
preparing for international use should be aware of an occasional problem with comma-
separated lists: in some locales, the comma is used as the radix character. Thus, if an application
is preparing operands for a utility that expects a comma-separated list, it should avoid
generating non-integer values through one of the means that is influenced by setting the
LC_NUMERIC variable (such as awk, bc, printf, or printf()).

Applications calling any utility with a first operand starting with '−' should usually specify −−,
as indicated by Guideline 10, to mark the end of the options. This is true even if the SYNOPSIS in
the Shell and Utilities volume of IEEE Std 1003.1-2001 does not specify any options;
implementations may provide options as extensions to the Shell and Utilities volume of
IEEE Std 1003.1-2001. The standard utilities that do not support Guideline 10 indicate that fact in
the OPTIONS section of the utility description.

Guideline 11 was modified to clarify that the order of different options should not matter
relative to one another. However, the order of repeated options that also have option-arguments
may be significant; therefore, such options are required to be interpreted in the order that they
are specified. The make utility is an instance of a historical utility that uses repeated options in
which the order is significant. Multiple files are specified by giving multiple instances of the −f
option; for example:

    make −f common_header −f specific_rules target

Guideline 13 does not imply that all of the standard utilities automatically accept the operand
'−' to mean standard input or output, nor does it specify the actions of the utility upon
encountering multiple '−' operands. It simply says that, by default, '−' operands are not used
for other purposes in the file reading or writing (but not when using stat(), unlink(), touch, and
so on) utilities. All information concerning actual treatment of the '−' operand is found in the
individual utility sections.

An area of concern was that as implementations mature, implementation-defined utilities and
implementation-defined utility options will result. The idea was expressed that there needed to
be a standard way, say an environment variable or some such mechanism, to identify
implementation-defined utilities separately from standard utilities that may have the same
name. It was decided that there already exist several ways of dealing with this situation and that
it is outside of the scope to attempt to standardize in the area of non-standard items. A method that exists on some historical implementations is the use of the so-called /local/bin or /usr/local/bin directory to separate local or additional copies or versions of utilities. Another method that is also used is to isolate utilities into completely separate domains. Still another method to ensure that the desired utility is being used is to request the utility by its full pathname. There are many approaches to this situation; the examples given above serve to illustrate that there is more than one.

A.13 Headers

A.13.1 Format of Entries

Each header reference page has a common layout of sections describing the interface. This layout is similar to the manual page or “man” page format shipped with most UNIX systems, and each header has sections describing the SYNOPSIS and DESCRIPTION. These are the two sections that relate to conformance.

Additional sections are informative, and add considerable information for the application developer. APPLICATION USAGE sections provide additional caveats, issues, and recommendations to the developer. RATIONALE sections give additional information on the decisions made in defining the interface.

FUTURE DIRECTIONS sections act as pointers to related work that may impact the interface in the future, and often cautions the developer to architect the code to account for a change in this area. Note that a future directions statement should not be taken as a commitment to adopt a feature or interface in the future.

The CHANGE HISTORY section describes when the interface was introduced, and how it has changed.

Option labels and margin markings in the page can be useful in guiding the application developer.
Rationale (Informative)

Part B:
System Interfaces

The Open Group
The Institute of Electrical and Electronics Engineers, Inc.
Appendix B

Rationale for System Interfaces

B.1 Introduction

B.1.1 Scope
Refer to Section A.1.1 (on page 3).

B.1.2 Conformance
Refer to Section A.2 (on page 9).

B.1.3 Normative References
There is no additional rationale provided for this section.

B.1.4 Change History
The change history is provided as an informative section, to track changes from previous issues of IEEE Std 1003.1-2001.

The following sections describe changes made to the System Interfaces volume of IEEE Std 1003.1-2001 since Issue 5 of the base document. The CHANGE HISTORY section for each entry details the technical changes that have been made to that entry from Issue 5. Changes between earlier issues of the base document and Issue 5 are not included.

The change history between Issue 5 and Issue 6 also lists the changes since the ISO POSIX-1:1996 standard.

Changes from Issue 5 to Issue 6 (IEEE Std 1003.1-2001)
The following list summarizes the major changes that were made in the System Interfaces volume of IEEE Std 1003.1-2001 from Issue 5 to Issue 6:

- This volume of IEEE Std 1003.1-2001 is extensively revised so that it can be both an IEEE POSIX Standard and an Open Group Technical Standard.
- The POSIX System Interfaces requirements incorporate support of FIPS 151-2.
- The POSIX System Interfaces requirements are updated to align with some features of the Single UNIX Specification.
- A RATIONALE section is added to each reference page.
- Networking interfaces from the XNS, Issue 5.2 specification are incorporated.
- IEEE Std 1003.1d-1999 is incorporated.
- IEEE Std 1003.1j-2000 is incorporated.
- IEEE Std 1003.1q-2000 is incorporated.
- IEEE P1003.1a draft standard is incorporated.
Introduction

• Existing functionality is aligned with the ISO/IEC 9899:1999 standard.

• New functionality from the ISO/IEC 9899:1999 standard is incorporated.

• IEEE PASC Interpretations are applied.

• The Open Group corrigenda and resolutions are applied.

New Features in Issue 6

The functions first introduced in Issue 6 (over the Issue 5 Base document) are listed in the table below:

<table>
<thead>

**B.1.5 Terminology**

Refer to Section A.1.4 (on page 5).

**B.1.6 Definitions**

Refer to Section A.3 (on page 13).

**B.1.7 Relationship to Other Formal Standards**

There is no additional rationale provided for this section.

**B.1.8 Portability**

Refer to Section A.1.5 (on page 8).

**B.1.8.1 Codes**

Refer to Section A.1.5.1 (on page 8).

**B.1.9 Format of Entries**

Each system interface reference page has a common layout of sections describing the interface. This layout is similar to the manual page or “man” page format shipped with most UNIX systems, and each header has sections describing the SYNOPSIS, DESCRIPTION, RETURN VALUE, and ERRORS. These are the four sections that relate to conformance.

Additional sections are informative, and add considerable information for the application developer. EXAMPLES sections provide example usage. APPLICATION USAGE sections provide additional caveats, issues, and recommendations to the developer. RATIONALE sections give additional information on the decisions made in defining the interface.

FUTURE DIRECTIONS sections act as pointers to related work that may impact the interface in the future, and often cautions the developer to architect the code to account for a change in this area. Note that a future directions statement should not be taken as a commitment to adopt a feature or interface in the future.

The CHANGE HISTORY section describes when the interface was introduced, and how it has changed.
Option labels and margin markings in the page can be useful in guiding the application
developer.

**B.2 General Information**

**B.2.1 Use and Implementation of Functions**

The information concerning the use of functions was adapted from a description in the ISO C
standard. Here is an example of how an application program can protect itself from functions
that may or may not be macros, rather than true functions:

The `atoi()` function may be used in any of several ways:

- By use of its associated header (possibly generating a macro expansion):

```c
#include <stdlib.h>
/* ... */
i = atoi(str);
```

- By use of its associated header (assuredly generating a true function call):

```c
#include <stdlib.h>
#undef atoi
/* ... */
i = atoi(str);
```

or:

```c
#include <stdlib.h>
/* ... */
i = (atoi)(str);
```

- By explicit declaration:

```c
extern int atoi (const char *);
/* ... */
i = atoi(str);
```

- By implicit declaration:

```c
/* ... */
i = atoi(str);
```

(Assuming no function prototype is in scope. This is not allowed by the ISO C standard for
functions with variable arguments; furthermore, parameter type conversion “widening” is
subject to different rules in this case.)

Note that the ISO C standard reserves names starting with ‘_’ for the compiler. Therefore, the
compiler could, for example, implement an intrinsic, built-in function `asm_builtin_atoi()`, which
it recognized and expanded into inline assembly code. Then, in `<stdlib.h>`, there could be the
following:

```c
#define atoi(X) _asm_builtin_atoi(X)
```

The user’s “normal” call to `atoi()` would then be expanded inline, but the implementor would
also be required to provide a callable function named `atoi()` for use when the application
requires it; for example, if its address is to be stored in a function pointer variable.
B.2.2 The Compilation Environment

B.2.2.1 POSIX.1 Symbols

This and the following section address the issue of “name space pollution”. The ISO C standard requires that the name space beyond what it reserves not be altered except by explicit action of the application writer. This section defines the actions to add the POSIX.1 symbols for those headers where both the ISO C standard and POSIX.1 need to define symbols, and also where the XSI extension extends the base standard.

When headers are used to provide symbols, there is a potential for introducing symbols that the application writer cannot predict. Ideally, each header should only contain one set of symbols, but this is not practical for historical reasons. Thus, the concept of feature test macros is included. Two feature test macros are explicitly defined by IEEE Std 1003.1-2001; it is expected that future revisions may add to this.

Note: Feature test macros allow an application to announce to the implementation its desire to have certain symbols and prototypes exposed. They should not be confused with the version test macros and constants for options in <unistd.h> which are the implementation’s way of announcing functionality to the application.

It is further intended that these feature test macros apply only to the headers specified by IEEE Std 1003.1-2001. Implementations are expressly permitted to make visible symbols not specified by IEEE Std 1003.1-2001, within both POSIX.1 and other headers, under the control of feature test macros that are not defined by IEEE Std 1003.1-2001.

The _POSIX_C_SOURCE Feature Test Macro

Since _POSIX_SOURCE specified by the POSIX.1-1990 standard did not have a value associated with it, the _POSIX_C_SOURCE macro replaces it, allowing an application to inform the system of the revision of the standard to which it conforms. This symbol will allow implementations to support various revisions of IEEE Std 1003.1-2001 simultaneously. For instance, when either _POSIX_SOURCE is defined or _POSIX_C_SOURCE is defined as 1, the system should make visible the same name space as permitted and required by the POSIX.1-1990 standard. When _POSIX_C_SOURCE is defined, the state of _POSIX_SOURCE is completely irrelevant.

It is expected that C bindings to future POSIX standards will define new values for _POSIX_C_SOURCE, with each new value reserving the name space for that new standard, plus all earlier POSIX standards.

The _XOPEN_SOURCE Feature Test Macro

The feature test macro _XOPEN_SOURCE is provided as the announcement mechanism for the application that it requires functionality from the Single UNIX Specification. _XOPEN_SOURCE must be defined to the value 600 before the inclusion of any header to enable the functionality in the Single UNIX Specification. Its definition subsumes the use of _POSIX_SOURCE and _POSIX_C_SOURCE.

An extract of code from a conforming application, that appears before any #include statements, is given below:

#define _XOPEN_SOURCE 600 /* Single UNIX Specification, Version 3 */
#include ...

Note that the definition of _XOPEN_SOURCE with the value 600 makes the definition of _POSIX_C_SOURCE redundant and it can safely be omitted.
The reservation of identifiers is paraphrased from the ISO C standard. The text is included because it needs to be part of IEEE Std 1003.1-2001, regardless of possible changes in future versions of the ISO C standard.

These identifiers may be used by implementations, particularly for feature test macros. Implementations should not use feature test macro names that might be reasonably used by a standard.

Including headers more than once is a reasonably common practice, and it should be carried forward from the ISO C standard. More significantly, having definitions in more than one header is explicitly permitted. Where the potential declaration is “benign” (the same definition twice) the declaration can be repeated, if that is permitted by the compiler. (This is usually true of macros, for example.) In those situations where a repetition is not benign (for example, typedef), conditional compilation must be used. The situation actually occurs both within the ISO C standard and within POSIX.1: time_t should be in <sys/types.h>, and the ISO C standard mandates that it be in <time.h>.

The area of name space pollution versus additions to structures is difficult because of the macro structure of C. The following discussion summarizes all the various problems with and objections to the issue.

Note the phrase “user-defined macro’. Users are not permitted to define macro names (or any other name) beginning with "_[A-Z_]". Thus, the conflict cannot occur for symbols reserved to the vendor’s name space, and the permission to add fields automatically applies, without qualification, to those symbols.

1. Data structures (and unions) need to be defined in headers by implementations to meet certain requirements of POSIX.1 and the ISO C standard.

2. The structures defined by POSIX.1 are typically minimal, and any practical implementation would wish to add fields to these structures either to hold additional related information or for backwards-compatibility (or both). Future standards (and de facto standards) would also wish to add to these structures. Issues of field alignment make it impractical (at least in the general case) to simply omit fields when they are not defined by the particular standard involved.

The dirent structure is an example of such a minimal structure (although one could argue about whether the other fields need visible names). The st_rdev field of most implementations’ stat structure is a common example where extension is needed and where a conflict could occur.

3. Fields in structures are in an independent name space, so the addition of such fields presents no problem to the C language itself in that such names cannot interact with identically named user symbols because access is qualified by the specific structure name.

4. There is an exception to this: macro processing is done at a lexical level. Thus, symbols added to a structure might be recognized as user-provided macro names at the location where the structure is declared. This only can occur if the user-provided name is declared as a macro before the header declaring the structure is included. The user’s use of the name after the declaration cannot interfere with the structure because the symbol is hidden and only accessible through access to the structure. Presumably, the user would not declare such a macro if there was an intention to use that field name.

5. Macros from the same or a related header might use the additional fields in the structure, and those field names might also collide with user macros. Although this is a less frequent occurrence, since macros are expanded at the point of use, no constraint on the order of use...
of names can apply.

6. An “obvious” solution of using names in the reserved name space and then redefining them as macros when they should be visible does not work because this has the effect of exporting the symbol into the general name space. For example, given a (hypothetical) system-provided header `<h.h>`, and two parts of a C program in `a.c` and `b.c`, in header `<h.h>`:

   ```c
   struct foo {
       int __i;
   }
   #ifdef _FEATURE_TEST
   #define i __i;
   #endif
   ```

   In file `a.c`:

   ```c
   #include h.h
   extern int i;
   ...  
   ```

   In file `b.c`:

   ```c
   extern int i;
   ...  
   ```

   The symbol that the user thinks of as `i` in both files has an external name of `__i` in `a.c`; the same symbol `i` in `b.c` has an external name `i` (ignoring any hidden manipulations the compiler might perform on the names). This would cause a mysterious name resolution problem when `a.o` and `b.o` are linked.

   Simply avoiding definition then causes alignment problems in the structure.

   A structure of the form:

   ```c
   struct foo {
       union {
           int __i;
       #ifdef _FEATURE_TEST
            int i;
        #endif
       } __ii;
   }
   ```

   does not work because the name of the logical field `i` is `__ii.i`, and introduction of a macro to restore the logical name immediately reintroduces the problem discussed previously (although its manifestation might be more immediate because a syntax error would result if a recursive macro did not cause it to fail first).
7. A more workable solution would be to declare the structure:

```c
struct foo {
    #ifdef _FEATURE_TEST
        int i;
    #else
        int __i;
    #endif
}
```

However, if a macro (particularly one required by a standard) is to be defined that uses this field, two must be defined: one that uses \( i \), the other that uses \( __i \). If more than one additional field is used in a macro and they are conditional on distinct combinations of features, the complexity goes up as \( 2^n \).

All this leaves a difficult situation: vendors must provide very complex headers to deal with what is conceptually simple and safe—adding a field to a structure. It is the possibility of user-provided macros with the same name that makes this difficult.

Several alternatives were proposed that involved constraining the user’s access to part of the name space available to the user (as specified by the ISO C standard). In some cases, this was only until all the headers had been included. There were two proposals discussed that failed to achieve consensus:

1. Limiting it for the whole program.
2. Restricting the use of identifiers containing only uppercase letters until after all system headers had been included. It was also pointed out that because macros might wish to access fields of a structure (and macro expansion occurs totally at point of use) restricting names in this way would not protect the macro expansion, and thus the solution was inadequate.

It was finally decided that reservation of symbols would occur, but as constrained.

The current wording also allows the addition of fields to a structure, but requires that user macros of the same name not interfere. This allows vendors to do one of the following:

- Not create the situation (do not extend the structures with user-accessible names or use the solution in (7) above)
- Extend their compilers to allow some way of adding names to structures and macros safely

There are at least two ways that the compiler might be extended: add new preprocessor directives that turn off and on macro expansion for certain symbols (without changing the value of the macro) and a function or lexical operation that suppresses expansion of a word. The latter seems more flexible, particularly because it addresses the problem in macros as well as in declarations.

The following seems to be a possible implementation extension to the C language that will do this: any token that during macro expansion is found to be preceded by three ‘#’ symbols shall not be further expanded in exactly the same way as described for macros that expand to their own name as in Section 3.8.3.4 of the ISO C standard. A vendor may also wish to implement this as an operation that is lexically a function, which might be implemented as:

```c
#define __safe_name(x) ###x
```

Using a function notation would insulate vendors from changes in standards until such a functionality is standardized (if ever). Standardization of such a function would be valuable because it would then permit third parties to take advantage of it portably in software they may
The symbols that are “explicitly permitted, but not required by IEEE Std 1003.1-2001” include those classified below. (That is, the symbols classified below might, but are not required to, be present when _POSIX_C_SOURCE is defined to have the value 200112L.)

- Symbols in `<limits.h>` and `<unistd.h>` that are defined to indicate support for options or limits that are constant at compile-time
- Symbols in the name space reserved for the implementation by the ISO C standard
- Symbols in a name space reserved for a particular type of extension (for example, type names ending with `_t` in `<sys/types.h>`)
- Additional members of structures or unions whose names do not reduce the name space reserved for applications

Since both implementations and future revisions of IEEE Std 1003.1 and other POSIX standards may use symbols in the reserved spaces described in these tables, there is a potential for name space clashes. To avoid future name space clashes when adding symbols, implementations should not use the posix_, POSIX_, or _POSIX_ prefixes.

IEEE Std 1003.1-2001/Cor 1-2002, item XSH/TC1/D6/2 is applied, deleting the entries POSIX_, _POSIX_, and posix_ from the column of allowed name space prefixes for use by an implementation in the first table. The presence of these prefixes was contradicting later text which states that: “The prefixes posix_, POSIX_, and _POSIX are reserved for use by Shell and Utilities volume of IEEE Std 1003.1-2001, Chapter 2, Shell Command Language and other POSIX standards. Implementations may add symbols to the headers shown in the following table, provided the identifiers ... do not use the reserved prefixes posix_, POSIX_, or _POSIX.”.

IEEE Std 1003.1-2001/Cor 1-2002, item XSH/TC1/D6/3 is applied, correcting the reserved macro prefix from: “PRI[a-z], SCN[a-z]” to: “PRI[Xa-z], SCN[Xa-z]” in the second table. The change was needed since the ISO C standard allows implementations to define macros of the form PRI or SCN followed by any lowercase letter or ‘X’ in `<inttypes.h>`. (The ISO/IEC 9899: 1999 standard, Subclause 7.26.4.)

IEEE Std 1003.1-2001/Cor 1-2002, item XSH/TC1/D6/4 is applied, adding a new section listing reserved names for the `<stdint.h>` header. This change is for alignment with the ISO C standard.

**B.2.3 Error Numbers**

It was the consensus of the standard developers that to allow the conformance document to state that an error occurs and under what conditions, but to disallow a statement that it never occurs, does not make sense. It could be implied by the current wording that this is allowed, but to reduce the possibility of future interpretation requests, it is better to make an explicit statement.

The ISO C standard requires that `errno` be an assignable lvalue. Originally, the definition in POSIX.1 was stricter than that in the ISO C standard, `extern int errno`, in order to support historical usage. In a multi-threaded environment, implementing `errno` as a global variable results in non-deterministic results when accessed. It is required, however, that `errno` work as a per-thread error reporting mechanism. In order to do this, a separate `errno` value has to be maintained for each thread. The following section discusses the various alternative solutions that were considered.

In order to avoid this problem altogether for new functions, these functions avoid using `errno` and, instead, return the error number directly as the function return value; a return value of zero indicates that no error was detected.
For any function that can return errors, the function return value is not used for any purpose other than for reporting errors. Even when the output of the function is scalar, it is passed through a function argument. While it might have been possible to allow some scalar outputs to be coded as negative function return values and mixed in with positive error status returns, this was rejected—using the return value for a mixed purpose was judged to be of limited use and error prone.

Checking the value of *errno* alone is not sufficient to determine the existence or type of an error, since it is not required that a successful function call clear *errno*. The variable *errno* should only be examined when the return value of a function indicates that the value of *errno* is meaningful. In that case, the function is required to set the variable to something other than zero.

The variable *errno* is never set to zero by any function call; to do so would contradict the ISO C standard.

POSIX.1 requires (in the ERRORS sections of function descriptions) certain error values to be set in certain conditions because many existing applications depend on them. Some error numbers, such as [EFAULT], are entirely implementation-defined and are noted as such in their description in the ERRORS section. This section otherwise allows wide latitude to the implementation in handling error reporting.

Some of the ERRORS sections in IEEE Std 1003.1-2001 have two subsections. The first:

"The function shall fail if:"

could be called the "mandatory" section.

The second:

"The function may fail if:"

could be informally known as the "optional" section.

Attempting to infer the quality of an implementation based on whether it detects optional error conditions is not useful.

Following each one-word symbolic name for an error, there is a description of the error. The rationale for some of the symbolic names follows:

**[ECANCELED]** This spelling was chosen as being more common.

**[EFAULT]** Most historical implementations do not catch an error and set *errno* when an invalid address is given to the functions *wait()*, *time()*, or *times()*. Some implementations cannot reliably detect an invalid address. And most systems that detect invalid addresses will do so only for a system call, not for a library routine.

**[EFTYPE]** This error code was proposed in earlier proposals as "Inappropriate operation for file type", meaning that the operation requested is not appropriate for the file specified in the function call. This code was proposed, although the same idea was covered by [ENOTTY], because the connotations of the name would be misleading. It was pointed out that the *fcntl()* function uses the error code [EINVAL] for this notion, and hence all instances of [EFTYPE] were changed to this code.

**[EINTR]** POSIX.1 prohibits conforming implementations from restarting interrupted system calls of conforming applications unless the SA_RESTART flag is in effect for the signal. However, it does not require that [EINTR] be returned when another legitimate value may be substituted; for example, a partial transfer count when *read()* or *write()* are interrupted. This is only given when
the signal-catching function returns normally as opposed to returns by mechanisms like longjmp() or siglongjmp().

[ELOOP] In specifying conditions under which implementations would generate this error, the following goals were considered:

- To ensure that actual loops are detected, including loops that result from symbolic links across distributed file systems.
- To ensure that during pathname resolution an application can rely on the ability to follow at least [SYMLOOP_MAX] symbolic links in the absence of a loop.
- To allow implementations to provide the capability of traversing more than [SYMLOOP_MAX] symbolic links in the absence of a loop.
- To allow implementations to detect loops and generate the error prior to encountering [SYMLOOP_MAX] symbolic links.

[ENAMETOOLONG] When a symbolic link is encountered during pathname resolution, the contents of that symbolic link are used to create a new pathname. The standard developers intended to allow, but not require, that implementations enforce the restriction of [PATH_MAX] on the result of this pathname substitution.

[ENOMEM] The term “main memory” is not used in POSIX.1 because it is implementation-defined.

[ENOTSUP] This error code is to be used when an implementation chooses to implement the required functionality of IEEE Std 1003.1-2001 but does not support optional facilities defined by IEEE Std 1003.1-2001. The return of [ENOSYS] is to be taken to indicate that the function of the interface is not supported at all; the function will always fail with this error code.

[ENOTTY] The symbolic name for this error is derived from a time when device control was done by ioctl() and that operation was only permitted on a terminal interface. The term “TTY” is derived from “teletypewriter”, the devices to which this error originally applied.

[E_OVERFLOW] Most of the uses of this error code are related to large file support. Typically, these cases occur on systems which support multiple programming environments with different sizes for off_t, but they may also occur in connection with remote file systems.

In addition, when different programming environments have different widths for types such as int and uid_t, several functions may encounter a condition where a value in a particular environment is too wide to be represented. In that case, this error should be raised. For example, suppose the currently running process has 64-bit int, and file descriptor 9 223 372 036 854 775 807 is open and does not have the close-on-exec flag set. If the process then uses exec() to exec a file compiled in a programming environment with 32-bit int, the call to exec() can fail with errno set to [EOVERFLOW]. A similar failure can occur with exec() if any of the user IDs or any of the group IDs to be assigned to the new process image are out of range for the executed file’s programming environment.
Note, however, that this condition cannot occur for functions that are explicitly described as always being successful, such as `getpid()`.

This condition normally generates the signal SIGPIPE; the error is returned if the signal does not terminate the process.

In historical implementations, attempting to `unlink()` or `rmdir()` a mount point would generate an [EBUSY] error. An implementation could be envisioned where such an operation could be performed without error. In this case, if either the directory entry or the actual data structures reside on a read-only file system, [EROFS] is the appropriate error to generate. (For example, changing the link count of a file on a read-only file system could not be done, as is required by `unlink()`, and thus an error should be reported.)

Three error numbers, [EDOM], [EILSEQ], and [ERANGE], were added to this section primarily for consistency with the ISO C standard.

Alternative Solutions for Per-Thread `errno`

The usual implementation of `errno` as a single global variable does not work in a multi-threaded environment. In such an environment, a thread may make a POSIX.1 call and get a −1 error return, but before that thread can check the value of `errno`, another thread might have made a second POSIX.1 call that also set `errno`. This behavior is unacceptable in robust programs. There were a number of alternatives that were considered for handling the `errno` problem:

- Implement `errno` as a per-thread integer variable.
- Implement `errno` as a service that can access the per-thread error number.
- Change all POSIX.1 calls to accept an extra status argument and avoid setting `errno`.
- Change all POSIX.1 calls to raise a language exception.

The first option offers the highest level of compatibility with existing practice but requires special support in the linker, compiler, and/or virtual memory system to support the new concept of thread private variables. When compared with current practice, the third and fourth options are much cleaner, more efficient, and encourage a more robust programming style, but they require new versions of all of the POSIX.1 functions that might detect an error. The second option offers compatibility with existing code that uses the `<errno.h>` header to define the `errno` symbol. In this option, `errno` may be a macro defined:

```c
#define errno (*__errno())
extern int *__errno();
```

This option may be implemented as a per-thread variable whereby an `errno` field is allocated in the user space object representing a thread, and whereby the function `__errno()` makes a system call to determine the location of its user space object and returns the address of the `errno` field of that object. Another implementation, one that avoids calling the kernel, involves allocating stacks in chunks. The stack allocator keeps a side table indexed by chunk number containing a pointer to the thread object that uses that chunk. The `__errno()` function then looks at the stack pointer, determines the chunk number, and uses that as an index into the chunk table to find its thread object and thus its private value of `errno`. On most architectures, this can be done in four to five instructions. Some compilers may wish to implement `__errno()` inline to improve performance.
Disallowing Return of the [EINTR] Error Code

Many blocking interfaces defined by IEEE Std 1003.1-2001 may return [EINTR] if interrupted during their execution by a signal handler. Blocking interfaces introduced under the Threads option do not have this property. Instead, they require that the interface appear to be atomic with respect to interruption. In particular, clients of blocking interfaces need not handle any possible [EINTR] return as a special case since it will never occur. If it is necessary to restart operations or complete incomplete operations following the execution of a signal handler, this is handled by the implementation, rather than by the application.

Requiring applications to handle [EINTR] errors on blocking interfaces has been shown to be a frequent source of often unreproducible bugs, and it adds no compelling value to the available functionality. Thus, blocking interfaces introduced for use by multi-threaded programs do not use this paradigm. In particular, in none of the functions flockfile(), pthread_cond_timedwait(), pthread_cond_wait(), pthread_join(), pthread_mutex_lock(), and sigwait() did providing [EINTR] returns add value, or even particularly make sense. Thus, these functions do not provide for an [EINTR] return, even when interrupted by a signal handler. The same arguments can be applied to sem_wait(), sem_trywait(), sigwaitinfo(), and sigtimedwait(), but implementations are permitted to return [EINTR] error codes for these functions for compatibility with earlier versions of IEEE Std 1003.1. Applications cannot rely on calls to these functions returning [EINTR] error codes when signals are delivered to the calling thread, but they should allow for the possibility.

B.2.3.1 Additional Error Numbers

The ISO C standard defines the name space for implementations to add additional error numbers.

B.2.4 Signal Concepts

Historical implementations of signals, using the signal() function, have shortcomings that make them unreliable for many application uses. Because of this, a new signal mechanism, based very closely on the one of 4.2 BSD and 4.3 BSD, was added to POSIX.1.

Signal Names

The restriction on the actual type used for sigset_t is intended to guarantee that these objects can always be assigned, have their address taken, and be passed as parameters by value. It is not intended that this type be a structure including pointers to other data structures, as that could impact the portability of applications performing such operations. A reasonable implementation could be a structure containing an array of some integer type.

The signals described in IEEE Std 1003.1-2001 must have unique values so that they may be named as parameters of case statements in the body of a C-language switch clause. However, implementation-defined signals may have values that overlap with each other or with signals specified in IEEE Std 1003.1-2001. An example of this is SIGABRT, which traditionally overlaps some other signal, such as SIGIOT.

SIGKILL, SIGTERM, SIGUSR1, and SIGUSR2 are ordinarily generated only through the explicit use of the kill() function, although some implementations generate SIGKILL under extraordinary circumstances. SIGTERM is traditionally the default signal sent by the kill command.

The signals SIGBUS, SIGEMT, SIGIOT, SIGTRAP, and SIGSYS were omitted from POSIX.1 because their behavior is implementation-defined and could not be adequately categorized. Conforming implementations may deliver these signals, but must document the circumstances
under which they are delivered and note any restrictions concerning their delivery. The signals SIGFPE, SIGILL, and SIGSEGV are similar in that they also generally result only from programming errors. They were included in POSIX.1 because they do indicate three relatively well-categorized conditions. They are all defined by the ISO C standard and thus would have to be defined by any system with an ISO C standard binding, even if not explicitly included in POSIX.1.

There is very little that a Conforming POSIX.1 Application can do by catching, ignoring, or masking any of the signals SIGILL, SIGTRAP, SIGIOT, SIGEMT, SIGBUS, SIGSEGV, SIGSYS, or SIGFPE. They will generally be generated by the system only in cases of programming errors. While it may be desirable for some robust code (for example, a library routine) to be able to detect and recover from programming errors in other code, these signals are not nearly sufficient for that purpose. One portable use that does exist for these signals is that a command interpreter can recognize them as the cause of a process’ termination (with `wait()`) and print an appropriate message. The mnemonic tags for these signals are derived from their PDP-11 origin.

The signals SIGSTOP, SIGTSTP, SIGTTIN, SIGTTOU, and SIGCONT are provided for job control and are unchanged from 4.2 BSD. The signal SIGCHLD is also typically used by job control shells to detect children that have terminated or, as in 4.2 BSD, stopped.

Some implementations, including System V, have a signal named SIGCLD, which is similar to SIGCHLD in 4.2 BSD. POSIX.1 permits implementations to have a single signal with both names. POSIX.1 carefully specifies ways in which conforming applications can avoid the semantic differences between the two different implementations. The name SIGCHLD was chosen for POSIX.1 because most current application usages of it can remain unchanged in conforming applications. SIGCLD in System V has more cases of semantics that POSIX.1 does not specify, and thus applications using it are more likely to require changes in addition to the name change.

The signals SIGUSR1 and SIGUSR2 are commonly used by applications for notification of exceptional behavior and are described as “reserved as application-defined” so that such use is not prohibited. Implementations should not generate SIGUSR1 or SIGUSR2, except when explicitly requested by `kill()`. It is recommended that libraries not use these two signals, as such use in libraries could interfere with their use by applications calling the libraries. If such use is unavoidable, it should be documented. It is prudent for non-portable libraries to use non-standard signals to avoid conflicts with use of standard signals by portable libraries.

There is no portable way for an application to catch or ignore non-standard signals. Some implementations define the range of signal numbers, so applications can install signal-catching functions for all of them. Unfortunately, implementation-defined signals often cause problems when caught or ignored by applications that do not understand the reason for the signal. While the desire exists for an application to be more robust by handling all possible signals (even those only generated by `kill()`), no existing mechanism was found to be sufficiently portable to include in POSIX.1. The value of such a mechanism, if included, would be diminished given that SIGKILL would still not be catchable.

A number of new signal numbers are reserved for applications because the two user signals defined by POSIX.1 are insufficient for many real-time applications. A range of signal numbers is specified, rather than an enumeration of additional reserved signal names, because different applications and application profiles will require a different number of application signals. It is not desirable to burden all application domains and therefore all implementations with the maximum number of signals required by all possible applications. Note that in this context, signal numbers are essentially different signal priorities.

The relatively small number of required additional signals, `_POSIX_RTSIG_MAX`, was chosen so as not to require an unreasonably large signal mask/set. While this number of signals defined
in POSIX.1 will fit in a single 32-bit word signal mask, it is recognized that most existing implementations define many more signals than are specified in POSIX.1 and, in fact, many implementations have already exceeded 32 signals (including the “null signal”). Support of \[\_POSIX\_RTSIG\_MAX\] additional signals may push some implementation over the single 32-bit word line, but is unlikely to push any implementations that are already over that line beyond the 64-signal line.

B.2.4.1 Signal Generation and Delivery

The terms defined in this section are not used consistently in documentation of historical systems. Each signal can be considered to have a lifetime beginning with generation and ending with delivery or acceptance. The POSIX.1 definition of “delivery” does not exclude ignored signals; this is considered a more consistent definition. This revised text in several parts of IEEE Std 1003.1-2001 clarifies the distinct semantics of asynchronous signal delivery and synchronous signal acceptance. The previous wording attempted to categorize both under the term “delivery”, which led to conflicts over whether the effects of asynchronous signal delivery applied to synchronous signal acceptance.

Signals generated for a process are delivered to only one thread. Thus, if more than one thread is eligible to receive a signal, one has to be chosen. The choice of threads is left entirely up to the implementation both to allow the widest possible range of conforming implementations and to give implementations the freedom to deliver the signal to the “easiest possible” thread should there be differences in ease of delivery between different threads.

Note that should multiple delivery among cooperating threads be required by an application, this can be trivially constructed out of the provided single-delivery semantics. The construction of a \texttt{sigwait\_multiple(\() \) function that accomplishes this goal is presented with the rationale for \texttt{sigwaitinfo(\).}

Implementations should deliver unblocked signals as soon after they are generated as possible. However, it is difficult for POSIX.1 to make specific requirements about this, beyond those in \texttt{kill(\) and sigprocmask(\). Even on systems with prompt delivery, scheduling of higher priority processes is always likely to cause delays.

In general, the interval between the generation and delivery of unblocked signals cannot be detected by an application. Thus, references to pending signals generally apply to blocked, pending signals. An implementation registers a signal as pending on the process when no thread has the signal unblocked and there are no threads blocked in a \texttt{sigwait(\) function for that signal.}

Thereafter, the implementation delivers the signal to the first thread that unblocks the signal or calls a \texttt{sigwait(\) function on a signal set containing this signal rather than choosing the recipient thread at the time the signal is sent.

In the 4.3 BSD system, signals that are blocked and set to SIG\_IGN are discarded immediately upon generation. For a signal that is ignored as its default action, if the action is SIG\_DFL and the signal is blocked, a generated signal remains pending. In the 4.1 BSD system and in System V Release 3 (two other implementations that support a somewhat similar signal mechanism), all ignored blocked signals remain pending if generated. Because it is not normally useful for an application to simultaneously ignore and block the same signal, it was unnecessary for POSIX.1 to specify behavior that would invalidate any of the historical implementations.

There is one case in some historical implementations where an unblocked, pending signal does not remain pending until it is delivered. In the System V implementation of \texttt{signal(\), pending signals are discarded when the action is set to SIG\_DFL or a signal-catching routine (as well as to SIG\_IGN). Except in the case of setting SIGCHLD to SIG\_DFL, implementations that do this do not conform completely to POSIX.1. Some earlier proposals for POSIX.1 explicitly stated this, but these statements were redundant due to the requirement that functions defined by POSIX.1
not change attributes of processes defined by POSIX.1 except as explicitly stated.

POSIX.1 specifically states that the order in which multiple, simultaneously pending signals are delivered is unspecified. This order has not been explicitly specified in historical implementations, but has remained quite consistent and been known to those familiar with the implementations. Thus, there have been cases where applications (usually system utilities) have been written with explicit or implicit dependencies on this order. Implementors and others porting existing applications may need to be aware of such dependencies.

When there are multiple pending signals that are not blocked, implementations should arrange for the delivery of all signals at once, if possible. Some implementations stack calls to all pending signal-catching routines, making it appear that each signal-catcher was interrupted by the next signal. In this case, the implementation should ensure that this stacking of signals does not violate the semantics of the signal masks established by `sigaction()`.

Other implementations process at most one signal when the operating system is entered, with remaining signals saved for later delivery. Although this practice is widespread, this behavior is neither standardized nor endorsed. In either case, implementations should attempt to deliver signals associated with the current state of the process (for example, SIGFPE) before other signals, if possible.

In 4.2 BSD and 4.3 BSD, it is not permissible to ignore or explicitly block SIGCONT, because if blocking or ignoring this signal prevented it from continuing a stopped process, such a process could never be continued (only killed by SIGKILL). However, 4.2 BSD and 4.3 BSD do block SIGCONT during execution of its signal-catching function when it is caught, creating exactly this problem. A proposal was considered to disallow catching SIGCONT in addition to ignoring and blocking it, but this limitation led to objections. The consensus was to require that SIGCONT always continue a stopped process when generated. This removed the need to disallow ignoring or explicit blocking of the signal; note that SIG_IGN and SIG_DFL are equivalent for SIGCONT.

### B.2.4.2 Realtime Signal Generation and Delivery

The Realtime Signals Extension option to POSIX.1 signal generation and delivery behavior is required for the following reasons:

- The `sigevent` structure is used by other POSIX.1 functions that result in asynchronous event notifications to specify the notification mechanism to use and other information needed by the notification mechanism. IEEE Std 1003.1-2001 defines only three symbolic values for the notification mechanism:
  - SIGEV_NONE is used to indicate that no notification is required when the event occurs. This is useful for applications that use asynchronous I/O with polling for completion.
  - SIGEV_SIGNAL indicates that a signal is generated when the event occurs.
  - SIGEV_THREAD provides for “callback functions” for asynchronous notifications done by a function call within the context of a new thread. This provides a multi-threaded process with a more natural means of notification than signals.

The primary difficulty with previous notification approaches has been to specify the environment of the notification routine.

- One approach is to limit the notification routine to call only functions permitted in a signal handler. While the list of permissible functions is clearly stated, this is overly restrictive.

- A second approach is to define a new list of functions or classes of functions that are explicitly permitted or not permitted. This would give a programmer more lists to deal with, which would be awkward.

---

Part B: System Interfaces — Copyright © 2001-2003, IEEE and The Open Group. All rights reserved.
The third approach is to define completely the environment for execution of the notification function. A clear definition of an execution environment for notification is provided by executing the notification function in the environment of a newly created thread.

Implementations may support additional notification mechanisms by defining new values for `sigev_notify`.

For a notification type of SIGEV_SIGNAL, the other members of the `sigevent` structure defined by IEEE Std 1003.1-2001 specify the realtime signal—that is, the signal number and application-defined value that differentiates between occurrences of signals with the same number—that will be generated when the event occurs. The structure is defined in `<signal.h>`, even though the structure is not directly used by any of the signal functions, because it is part of the signals interface used by the POSIX.1b "client functions". When the client functions include `<signal.h>` to define the signal names, the `sigevent` structure will also be defined.

An application-defined value passed to the signal handler is used to differentiate between different "events" instead of requiring that the application use different signal numbers for several reasons:

- Realtime applications potentially handle a very large number of different events. Requiring that implementations support a correspondingly large number of distinct signal numbers will adversely impact the performance of signal delivery because the signal masks to be manipulated on entry and exit to the handlers will become large.

- Event notifications are prioritized by signal number (the rationale for this is explained in the following paragraphs) and the use of different signal numbers to differentiate between the different event notifications overloads the signal number more than has already been done. It also requires that the application writer make arbitrary assignments of priority to events that are logically of equal priority.

A union is defined for the application-defined value so that either an integer constant or a pointer can be portably passed to the signal-catching function. On some architectures a pointer cannot be cast to an `int` and vice versa.

Use of a structure here with an explicit notification type discriminant rather than explicit parameters to realtime functions, or embedded in other realtime structures, provides for future extensions to IEEE Std 1003.1-2001. Additional, perhaps more efficient, notification mechanisms can be supported for existing realtime function interfaces, such as timers and asynchronous I/O, by extending the `sigevent` structure appropriately. The existing realtime function interfaces will not have to be modified to use any such new notification mechanism.

The revised text concerning the SIGEV_SIGNAL value makes consistent the semantics of the members of the `sigevent` structure, particularly in the definitions of `lio_listio()` and `aio_fsync()`. For uniformity, other revisions cause this specification to be referred to rather than inaccurately duplicated in the descriptions of functions and structures using the `sigevent` structure. The revised wording does not relax the requirement that the signal number be in the range SIGRTMIN to SIGRTMAX to guarantee queuing and passing of the application value, since that requirement is still implied by the signal names.

- IEEE Std 1003.1-2001 is intentionally vague on whether "non-realtime" signal-generating mechanisms can result in a `siginfo_t` being supplied to the handler on delivery. In one existing implementation, a `siginfo_t` is posted on signal generation, even though the implementation does not support queuing of multiple occurrences of a signal. It is not the intent of IEEE Std 1003.1-2001 to preclude this, independent of the mandate to define signals that do support queuing. Any interpretation that appears to preclude this is a mistake in the
Signals handled by realtime signal handlers might be generated by functions or conditions that do not allow the specification of an application-defined value and do not queue. IEEE Std 1003.1-2001 specifies the si_code member of the siginfo_t structure used in existing practice and defines additional codes so that applications can detect whether an application-defined value is present or not. The code SI_USER for kill()-generated signals is adopted from existing practice.

The sigaction() sa_flags value SA_SIGINFO tells the implementation that the signal-catching function expects two additional arguments. When the flag is not set, a single argument, the signal number, is passed as specified by IEEE Std 1003.1-2001. Although IEEE Std 1003.1-2001 does not explicitly allow the info argument to the handler function to be NULL, this is existing practice. This provides for compatibility with programs whose signal-catching functions are not prepared to accept the additional arguments. IEEE Std 1003.1-2001 is explicitly unspecified as to whether signals actually queue when SA_SIGINFO is not set for a signal, as there appear to be no benefits to applications in specifying one behavior or another. One existing implementation queues a siginfo_t on each signal generation, unless the signal is already pending, in which case the implementation discards the new siginfo_t; that is, the queue length is never greater than one. This implementation only examines SA_SIGINFO on signal delivery, discarding the queued siginfo_t if its delivery was not requested.

IEEE Std 1003.1-2001 specifies several new values for the si_code member of the siginfo_t structure. In existing practice, a si_code value of less than or equal to zero indicates that the signal was generated by a process via the kill() function. In existing practice, values of si_code that provide additional information for implementation-generated signals, such as SIGFPE or SIGSEGV, are all positive. Thus, if implementations define the new constants specified in IEEE Std 1003.1-2001 to be negative numbers, programs written to use existing practice will not break. IEEE Std 1003.1-2001 chose not to attempt to specify existing practice values of si_code other than SI_USER both because it was deemed beyond the scope of IEEE Std 1003.1-2001 and because many of the values in existing practice appear to be platform and implementation-defined. But, IEEE Std 1003.1-2001 does specify that if an implementation—for example, one that does not have existing practice in this area—chooses to define additional values for si_code, these values have to be different from the values of the symbols specified by IEEE Std 1003.1-2001. This will allow conforming applications to differentiate between signals generated by one of the POSIX.1b asynchronous events and those generated by other implementation events in a manner compatible with existing practice.

The unique values of si_code for the POSIX.1b asynchronous events have implications for implementations of, for example, asynchronous I/O or message passing in user space library code. Such an implementation will be required to provide a hidden interface to the signal generation mechanism that allows the library to specify the standard values of si_code.

Existing practice also defines additional members of siginfo_t, such as the process ID and user ID of the sending process for kill()-generated signals. These members were deemed not necessary to meet the requirements of realtime applications and are not specified by IEEE Std 1003.1-2001. Neither are they precluded.

The third argument to the signal-catching function, context, is left undefined by IEEE Std 1003.1-2001, but is specified in the interface because it matches existing practice for the SA_SIGINFO flag. It was considered undesirable to require a separate implementation for SA_SIGINFO for POSIX conformance on implementations that already support the two additional parameters.
• The requirement to deliver lower numbered signals in the range SIGRTMIN to SIGRTMAX first, when multiple unblocked signals are pending, results from several considerations:

— A method is required to prioritize event notifications. The signal number was chosen instead of, for instance, associating a separate priority with each request, because an implementation has to check pending signals at various points and select one for delivery when more than one is pending. Specifying a selection order is the minimal additional semantic that will achieve prioritized delivery. If a separate priority were to be associated with queued signals, it would be necessary for an implementation to search all non-empty, non-blocked signal queues and select from among them the pending signal with the highest priority. This would significantly increase the cost of and decrease the determinism of signal delivery.

— Given the specified selection of the lowest numeric unblocked pending signal, preemptive priority signal delivery can be achieved using signal numbers and signal masks by ensuring that the sa_mask for each signal number blocks all signals with a higher numeric value.

For realtime applications that want to use only the newly defined realtime signal numbers without interference from the standard signals, this can be achieved by blocking all of the standard signals in the thread signal mask and in the sa_mask installed by the signal action for the realtime signal handlers.

IEEE Std 1003.1-2001 explicitly leaves unspecified the ordering of signals outside of the range of realtime signals and the ordering of signals within this range with respect to those outside the range. It was believed that this would unduly constrain implementations or standards in the future definition of new signals.

B.2.4.3 Signal Actions

Early proposals mentioned SIGCONT as a second exception to the rule that signals are not delivered to stopped processes until continued. Because IEEE Std 1003.1-2001 now specifies that SIGCONT causes the stopped process to continue when it is generated, delivery of SIGCONT is not prevented because a process is stopped, even without an explicit exception to this rule.

Ignoring a signal by setting the action to SIG_IGN (or SIG_DFL for signals whose default action is to ignore) is not the same as installing a signal-catching function that simply returns. Invoking such a function will interrupt certain system functions that block processes (for example, wait(), sigsuspend(), pause(), read(), write()) while ignoring a signal has no such effect on the process.

Historical implementations discard pending signals when the action is set to SIG_IGN. However, they do not always do the same when the action is set to SIG_DFL and the default action is to ignore the signal. IEEE Std 1003.1-2001 requires this for the sake of consistency and also for completeness, since the only signal this applies to is SIGCHLD, and IEEE Std 1003.1-2001 disallows setting its action to SIG_IGN.

Some implementations (System V, for example) assign different semantics for SIGCLD depending on whether the action is set to SIG_IGN or SIG_DFL. Since POSIX.1 requires that the default action for SIGCHLD be to ignore the signal, applications should always set the action to SIG_DFL in order to avoid SIGCHLD.

Whether or not an implementation allows SIG_IGN as a SIGCHLD disposition to be inherited across a call to one of the exec family of functions or posix_spawn() is explicitly left as unspecified. This change was made as a result of IEEE PASC Interpretation 1003.1 #132, and permits the implementation to decide between the following alternatives:
• Unconditionally leave SIGCHLD set to SIG_IGN, in which case the implementation would not allow applications that assume inheritance of SIG_DFL to conform to IEEE Std 1003.1-2001 without change. The implementation would, however, retain an ability to control applications that create child processes but never call on the wait family of functions, potentially filling up the process table.

• Unconditionally reset SIGCHLD to SIG_DFL, in which case the implementation would allow applications that assume inheritance of SIG_DFL to conform. The implementation would, however, lose an ability to control applications that spawn child processes but never reap them.

• Provide some mechanism, not specified in IEEE Std 1003.1-2001, to control inherited SIGCHLD dispositions.

Some implementations (System V, for example) will deliver a SIGCHLD signal immediately when a process establishes a signal-catching function for SIGCHLD when that process has a child that has already terminated. Other implementations, such as 4.3 BSD, do not generate a new SIGCHLD signal in this way. In general, a process should not attempt to alter the signal action for the SIGCHLD signal while it has any outstanding children. However, it is not always possible for a process to avoid this; for example, shells sometimes start up processes in pipelines with other processes from the pipeline as children. Processes that cannot ensure that they have no children when altering the signal action for SIGCHLD thus need to be prepared for, but not depend on, generation of an immediate SIGCHLD signal.

The default action of the stop signals (SIGSTOP, SIGTSTP, SIGTTIN, SIGTTOU) is to stop a process that is executing. If a stop signal is delivered to a process that is already stopped, it has no effect. In fact, if a stop signal is generated for a stopped process whose signal mask blocks the signal, the signal will never be delivered to the process since the process must receive a SIGCONT, which discards all pending stop signals, in order to continue executing.

The SIGCONT signal continues a stopped process even if SIGCONT is blocked (or ignored). However, if a signal-catching routine has been established for SIGCONT, it will not be entered until SIGCONT is unblocked.

If a process in an orphaned process group stops, it is no longer under the control of a job control shell and would not normally ever be continued. Because of this, orphaned processes that receive terminal-related stop signals (SIGTSTP, SIGTTIN, SIGTTOU, but not SIGSTOP) must not be allowed to stop. The goal is to prevent stopped processes from languishing forever. (As SIGSTOP is sent only via kill(), it is assumed that the process or user sending a SIGSTOP can send a SIGCONT when desired.) Instead, the system must discard the stop signal. As an extension, it may also deliver another signal in its place. 4.3 BSD sends a SIGKILL, which is overly effective because SIGKILL is not catchable. Another possible choice is SIGHUP. 4.3 BSD also does this for orphaned processes (processes whose parent has terminated) rather than for members of orphaned process groups; this is less desirable because job control shells manage process groups. POSIX.1 also prevents SIGTTIN and SIGTTOU signals from being generated for processes in orphaned process groups as a direct result of activity on a terminal, preventing infinite loops when read() and write() calls generate signals that are discarded; see Section A.11.1.4 (on page 67). A similar restriction on the generation of SIGTSTP was considered, but that would be unnecessary and more difficult to implement due to its asynchronous nature.

Although POSIX.1 requires that signal-catching functions be called with only one argument, there is nothing to prevent conforming implementations from extending POSIX.1 to pass additional arguments, as long as Strictly Conforming POSIX.1 Applications continue to compile and execute correctly. Most historical implementations do, in fact, pass additional, signal-specific arguments to certain signal-catching routines.
There was a proposal to change the declared type of the signal handler to:

void func (int sig, ...);

The usage of ellipses ("...") is ISO C standard syntax to indicate a variable number of arguments. Its use was intended to allow the implementation to pass additional information to the signal handler in a standard manner.

Unfortunately, this construct would require all signal handlers to be defined with this syntax because the ISO C standard allows implementations to use a different parameter passing mechanism for variable parameter lists than for non-variable parameter lists. Thus, all existing signal handlers in all existing applications would have to be changed to use the variable syntax in order to be standard and portable. This is in conflict with the goal of Minimal Changes to Existing Application Code.

When terminating a process from a signal-catching function, processes should be aware of any interpretation that their parent may make of the status returned by wait() or waitpid(). In particular, a signal-catching function should not call exit(0) or _exit(0) unless it wants to indicate successful termination. A non-zero argument to exit() or _exit() can be used to indicate unsuccessful termination. Alternatively, the process can use kill() to send itself a fatal signal (first ensuring that the signal is set to the default action and not blocked). See also the RATIONALE section of the _exit() function.

The behavior of unsafe functions, as defined by this section, is undefined when they are invoked from signal-catching functions in certain circumstances. The behavior of reentrant functions, as defined by this section, is as specified by POSIX.1, regardless of invocation from a signal-catching function. This is the only intended meaning of the statement that reentrant functions may be used in signal-catching functions without restriction. Applications must still consider all effects of such functions on such things as data structures, files, and process state. In particular, application writers need to consider the restrictions on interactions when interrupting sleep() (see sleep()) and interactions among multiple handles for a file description. The fact that any specific function is listed as reentrant does not necessarily mean that invocation of that function from a signal-catching function is recommended.

In order to prevent errors arising from interrupting non-reentrant function calls, applications should protect calls to these functions either by blocking the appropriate signals or through the use of some programmatic semaphore. POSIX.1 does not address the more general problem of synchronizing access to shared data structures. Note in particular that even the "safe" functions may modify the global variable errno; the signal-catching function may want to save and restore its value. The same principles apply to the reentrancy of application routines and asynchronous data access.

Note that longjmp() and siglongjmp() are not in the list of reentrant functions. This is because the code executing after longjmp() or siglongjmp() can call any unsafe functions with the same danger as calling those unsafe functions directly from the signal handler. Applications that use longjmp() or siglongjmp() out of signal handlers require rigorous protection in order to be portable. Many of the other functions that are excluded from the list are traditionally implemented using either the C language malloc() or free() functions or the ISO C standard I/O library, both of which traditionally use data structures in a non-reentrant manner. Because any combination of different functions using a common data structure can cause reentrancy problems, POSIX.1 does not define the behavior when any unsafe function is called in a signal handler that interrupts any unsafe function.

The only realtime extension to signal actions is the addition of the additional parameters to the signal-catching function. This extension has been explained and motivated in the previous section. In making this extension, though, developers of POSIX.1b ran into issues relating to
function prototypes. In response to input from the POSIX.1 standard developers, members were
added to the `sigaction` structure to specify function prototypes for the newer signal-catching
function specified by POSIX.1b. These members follow changes that are being made to POSIX.1.
Note that IEEE Std 1003.1-2001 explicitly states that these fields may overlap so that a union can
be defined. This enabled existing implementations of POSIX.1 to maintain binary-compatibility
when these extensions were added.

The `siginfo_t` structure was adopted for passing the application-defined value to match existing
practice, but the existing practice has no provision for an application-defined value, so this was
added. Note that POSIX normally reserves the ‘‘_t’’ type designation for opaque types. The
`siginfo_t` structure breaks with this convention to follow existing practice and thus promote
portability. Standardization of the existing practice for the other members of this structure may
be addressed in the future.

Although it is not explicitly visible to applications, there are additional semantics for signal
actions implied by queued signals and their interaction with other POSIX.1b realtime functions.
Specifically:

- It is not necessary to queue signals whose action is SIG_IGN.
- For implementations that support POSIX.1b timers, some interaction with the timer functions
  at signal delivery is implied to manage the timer overrun count.

IEEE Std 1003.1-2001/Cor 1-2002, item XSH/TC1/D6/5 is applied, reordering the RTS shaded
text under the third and fourth paragraphs of the SIG_DFL description. This corrects an earlier
editorial error in this section.

IEEE Std 1003.1-2001/Cor 1-2002, item XSH/TC1/D6/6 is applied, adding the `abort()` function
to the list of async-cancel-safe functions.

B.2.4.4 Signal Effects on Other Functions

The most common behavior of an interrupted function after a signal-catching function returns is
for the interrupted function to give an [EINTR] error unless the SA_RESTART flag is in effect for
the signal. However, there are a number of specific exceptions, including `sleep()` and certain
situations with `read()` and `write()`.

The historical implementations of many functions defined by IEEE Std 1003.1-2001 are not
interruptible, but delay delivery of signals generated during their execution until after they
complete. This is never a problem for functions that are guaranteed to complete in a short
(imperceptible to a human) period of time. It is normally those functions that can suspend a
process indefinitely or for long periods of time (for example, `wait()`, `pause()`, `sigsuspend()`, `sleep()
`, or `read()`/`write()` on a slow device like a terminal) that are interruptible. This permits
applications to respond to interactive signals or to set timeouts on calls to most such functions
with `alarm()`. Therefore, implementations should generally make such functions (including ones
defined as extensions) interruptible.

Functions not mentioned explicitly as interruptible may be so on some implementations,
possibly as an extension where the function gives an [EINTR] error. There are several functions
(for example, `getpid()`, `getuid()`) that are specified as never returning an error, which can thus
never be extended in this way.

If a signal-catching function returns while the SA_RESTART flag is in effect, an interrupted
function is restarted at the point it was interrupted. Conforming applications cannot make
assumptions about the internal behavior of interrupted functions, even if the functions are
async-signal-safe. For example, suppose the `read()` function is interrupted with SA_RESTART in
effect, the signal-catching function closes the file descriptor being read from and returns, and the

read() function is then restarted; in this case the application cannot assume that the read() function will give an [EBADF] error, since read() might have checked the file descriptor for validity before being interrupted.

B.2.5 Standard I/O Streams

B.2.5.1 Interaction of File Descriptors and Standard I/O Streams

There is no additional rationale provided for this section.

B.2.5.2 Stream Orientation and Encoding Rules

There is no additional rationale provided for this section.

B.2.6 STREAMS

STREAMS are introduced into IEEE Std 1003.1-2001 as part of the alignment with the Single UNIX Specification, but marked as an option in recognition that not all systems may wish to implement the facility. The option within IEEE Std 1003.1-2001 is denoted by the XSR margin marker. The standard developers made this option independent of the XSI option.

STREAMS are a method of implementing network services and other character-based input/output mechanisms, with the STREAM being a full-duplex connection between a process and a device. STREAMS provides direct access to protocol modules, and optional protocol modules can be interposed between the process-end of the STREAM and the device-driver at the device-end of the STREAM. Pipes can be implemented using the STREAMS mechanism, so they can provide process-to-process as well as process-to-device communications.

This section introduces STREAMS I/O, the message types used to control them, an overview of the priority mechanism, and the interfaces used to access them.

B.2.6.1 Accessing STREAMS

There is no additional rationale provided for this section.

B.2.7 XSI Interprocess Communication

There are two forms of IPC supported as options in IEEE Std 1003.1-2001. The traditional System V IPC routines derived from the SVID—that is, the msg*( ), sem*( ), and shm*( ) interfaces—are mandatory on XSI-conformant systems. Thus, all XSI-conformant systems provide the same mechanisms for manipulating messages, shared memory, and semaphores.

In addition, the POSIX Realtime Extension provides an alternate set of routines for those systems supporting the appropriate options.

The application writer is presented with a choice: the System V interfaces or the POSIX interfaces (loosely derived from the Berkeley interfaces). The XSI profile prefers the System V interfaces, but the POSIX interfaces may be more suitable for realtime or other performance-sensitive applications.
B.2.7.1 IPC General Information

General information that is shared by all three mechanisms is described in this section. The common permissions mechanism is briefly introduced, describing the mode bits, and how they are used to determine whether or not a process has access to read or write/alter the appropriate instance of one of the IPC mechanisms. All other relevant information is contained in the reference pages themselves.

The semaphore type of IPC allows processes to communicate through the exchange of semaphore values. A semaphore is a positive integer. Since many applications require the use of more than one semaphore, XSI-conformant systems have the ability to create sets or arrays of semaphores.

Calls to support semaphores include:

- semctl(), semget(), semop()

Semaphore sets are created by using the semget() function.

The message type of IPC allows processes to communicate through the exchange of data stored in buffers. This data is transmitted between processes in discrete portions known as messages.

Calls to support message queues include:

- msgctl(), msgget(), msgrcv(), msgsnd()

The shared memory type of IPC allows two or more processes to share memory and consequently the data contained therein. This is done by allowing processes to set up access to a common memory address space. This sharing of memory provides a fast means of exchange of data between processes.

Calls to support shared memory include:

- shmt(), shmdt(), shmget()

The ftok() interface is also provided.

B.2.8 Realtime

Advisory Information

POSIX.1b contains an Informative Annex with proposed interfaces for “realtime files”. These interfaces could determine groups of the exact parameters required to do “direct I/O” or “extents”. These interfaces were objected to by a significant portion of the balloting group as too complex. A conforming application had little chance of correctly navigating the large parameter space to match its desires to the system. In addition, they only applied to a new type of file (realtime files) and they told the implementation exactly what to do as opposed to advising the implementation on application behavior and letting it optimize for the system the (portable) application was running on. For example, it was not clear how a system that had a disk array should set its parameters.

There seemed to be several overall goals:

- Optimizing sequential access
- Optimizing caching behavior
- Optimizing I/O data transfer
- Preallocation
The advisory interfaces, `posix_fadvise()` and `posix_madvise()`, satisfy the first two goals. The POSIX_FADV_SEQUENTIAL and POSIX_MADV_SEQUENTIAL advice tells the implementation to expect serial access. Typically the system will prefetch the next several serial accesses in order to overlap I/O. It may also free previously accessed serial data if memory is tight. If the application is not doing serial access it can use POSIX_FADV_WILLNEED and POSIX_MADV_WILLNEED to accomplish I/O overlap, as required. When the application advises POSIX_FADV_RANDOM or POSIX_MADV_RANDOM behavior, the implementation usually tries to fetch a minimum amount of data with each request and it does not expect much locality. POSIX_FADV_DONTNEED and POSIX_MADV_DONTNEED allow the system to free up caching resources as the data will not be required in the near future.

POSIX_FADV_NOREUSE tells the system that caching the specified data is not optimal. For file I/O, the transfer should go directly to the user buffer instead of being cached internally by the implementation. To portably perform direct disk I/O on all systems, the application must perform its I/O transfers according to the following rules:

1. The user buffer should be aligned according to the [POSIX_REC_XFER_ALIGN] `pathconf()` variable.
2. The number of bytes transferred in an I/O operation should be a multiple of the [POSIX_ALLOC_SIZE_MIN] `pathconf()` variable.
3. The offset into the file at the start of an I/O operation should be a multiple of the [POSIX_ALLOC_SIZE_MIN] `pathconf()` variable.
4. The application should ensure that all threads which open a given file specify POSIX_FADV_NOREUSE to be sure that there is no unexpected interaction between threads using buffered I/O and threads using direct I/O to the same file.

In some cases, a user buffer must be properly aligned in order to be transferred directly to/from the device. The [POSIX_REC_XFER_ALIGN] `pathconf()` variable tells the application the proper alignment.

The preallocation goal is met by the space control function, `posix_fallocate()`. The application can use `posix_fallocate()` to guarantee no [ENOSPC] errors and to improve performance by prepaying any overhead required for block allocation.

Implementations may use information conveyed by a previous `posix_fadvise()` call to influence the manner in which allocation is performed. For example, if an application did the following calls:

```c
fd = open("file");
posix_fadvise(fd, offset, len, POSIX_FADV_SEQUENTIAL);
posix_fallocate(fd, len, size);
```

an implementation might allocate the file contiguously on disk.

Finally, the `pathconf()` variables [POSIX_REC_MIN_XFER_SIZE], [POSIX_REC_MAX_XFER_SIZE], and [POSIX_REC_INCR_XFER_SIZE] tell the application a range of transfer sizes that are recommended for best I/O performance.

Where bounded response time is required, the vendor can supply the appropriate settings of the advisories to achieve a guaranteed performance level.

The interfaces meet the goals while allowing applications using regular files to take advantage of performance optimizations. The interfaces tell the implementation expected application behavior which the implementation can use to optimize performance on a particular system with a particular dynamic load.
The `posix_memalign()` function was added to allow for the allocation of specifically aligned buffers; for example, for `{POSIX_REC_XFER_ALIGN}`.

The working group also considered the alternative of adding a function which would return an aligned pointer to memory within a user-supplied buffer. This was not considered to be the best method, because it potentially wastes large amounts of memory when buffers need to be aligned on large alignment boundaries.

**Message Passing**

This section provides the rationale for the definition of the message passing interface in IEEE Std 1003.1-2001. This is presented in terms of the objectives, models, and requirements imposed upon this interface.

- **Objectives**

  Many applications, including both realtime and database applications, require a means of passing arbitrary amounts of data between cooperating processes comprising the overall application on one or more processors. Many conventional interfaces for interprocess communication are insufficient for realtime applications in that efficient and deterministic data passing methods cannot be implemented. This has prompted the definition of message passing interfaces providing these facilities:

  - Open a message queue.
  - Send a message to a message queue.
  - Receive a message from a queue, either synchronously or asynchronously.
  - Alter message queue attributes for flow and resource control.

  It is assumed that an application may consist of multiple cooperating processes and that these processes may wish to communicate and coordinate their activities. The message passing facility described in IEEE Std 1003.1-2001 allows processes to communicate through system-wide queues. These message queues are accessed through names that may be pathnames. A message queue can be opened for use by multiple sending and/or multiple receiving processes.

- **Background on Embedded Applications**

  Interprocess communication utilizing message passing is a key facility for the construction of deterministic, high-performance realtime applications. The facility is present in all realtime systems and is the framework upon which the application is constructed. The performance of the facility is usually a direct indication of the performance of the resulting application.

  Realtime applications, especially for embedded systems, are typically designed around the performance constraints imposed by the message passing mechanisms. Applications for embedded systems are typically very tightly constrained. Application writers expect to design and control the entire system. In order to minimize system costs, the writer will attempt to use all resources to their utmost and minimize the requirement to add additional memory or processors.

  The embedded applications usually share address spaces and only a simple message passing mechanism is required. The application can readily access common data incurring only mutual-exclusion overheads. The models desired are the simplest possible with the application building higher-level facilities only when needed.
The following requirements determined the features of the message passing facilities defined in IEEE Std 1003.1-2001:

— Naming of Message Queues

The mechanism for gaining access to a message queue is a pathname evaluated in a context that is allowed to be a file system name space, or it can be independent of any file system. This is a specific attempt to allow implementations based on either method in order to address both embedded systems and to also allow implementation in larger systems.

The interface of `mq_open()` is defined to allow but not require the access control and name conflicts resulting from utilizing a file system for name resolution. All required behavior is specified for the access control case. Yet a conforming implementation, such as an embedded system kernel, may define that there are no distinctions between users and may define that all processes have all access privileges.

— Embedded System Naming

Embedded systems need to be able to utilize independent name spaces for accessing the various system objects. They typically do not have a file system, precluding its utilization as a common name resolution mechanism. The modularity of an embedded system limits the connections between separate mechanisms that can be allowed.

Embedded systems typically do not have any access protection. Since the system does not support the mixing of applications from different areas, and usually does not even have the concept of an authorization entity, access control is not useful.

— Large System Naming

On systems with more functionality, the name resolution must support the ability to use the file system as the name resolution mechanism/object storage medium and to have control over access to the objects. Utilizing the pathname space can result in further errors when the names conflict with other objects.

— Fixed Size of Messages

The interfaces impose a fixed upper bound on the size of messages that can be sent to a specific message queue. The size is set on an individual queue basis and cannot be changed dynamically.

The purpose of the fixed size is to increase the ability of the system to optimize the implementation of `mq_send()` and `mq_receive()`. With fixed sizes of messages and fixed numbers of messages, specific message blocks can be pre-allocated. This eliminates a significant amount of checking for errors and boundary conditions. Additionally, an implementation can optimize data copying to maximize performance. Finally, with a restricted range of message sizes, an implementation is better able to provide deterministic operations.

— Prioritization of Messages

Message prioritization allows the application to determine the order in which messages are received. Prioritization of messages is a key facility that is provided by most realtime kernels and is heavily utilized by the applications. The major purpose of having priorities in message queues is to avoid priority inversions in the message system, where a high-priority message is delayed behind one or more lower-priority messages. This allows the applications to be designed so that they do not need to be interrupted in order to change...
the flow of control when exceptional conditions occur. The prioritization does add
additional overhead to the message operations in those cases it is actually used but a
clever implementation can optimize for the FIFO case to make that more efficient.

Asynchronous Notification

The interface supports the ability to have a task asynchronously notified of the
availability of a message on the queue. The purpose of this facility is to allow the task to
perform other functions and yet still be notified that a message has become available on
the queue.

To understand the requirement for this function, it is useful to understand two models of
application design: a single task performing multiple functions and multiple tasks
performing a single function. Each of these models has advantages.

Asynchronous notification is required to build the model of a single task performing
multiple operations. This model typically results from either the expectation that
interruption is less expensive than utilizing a separate task or from the growth of the
application to include additional functions.

Semaphores

Semaphores are a high-performance process synchronization mechanism. Semaphores are
named by null-terminated strings of characters.

A semaphore is created using the `sem_init()` function or the `sem_open()` function with the
O_CREAT flag set in `oflag`.

To use a semaphore, a process has to first initialize the semaphore or inherit an open descriptor
for the semaphore via `fork()`.

A semaphore preserves its state when the last reference is closed. For example, if a semaphore
has a value of 13 when the last reference is closed, it will have a value of 13 when it is next
opened.

When a semaphore is created, an initial state for the semaphore has to be provided. This value is
a non-negative integer. Negative values are not possible since they indicate the presence of
blocked processes. The persistence of any of these objects across a system crash or a system
reboot is undefined. Conforming applications must not depend on any sort of persistence across
a system reboot or a system crash.

• Models and Requirements

A realtime system requires synchronization and communication between the processes
comprising the overall application. An efficient and reliable synchronization mechanism has
to be provided in a realtime system that will allow more than one schedulable process
mutually-exclusive access to the same resource. This synchronization mechanism has to
allow for the optimal implementation of synchronization or systems implementors will
define other, more cost-effective methods.

At issue are the methods whereby multiple processes (tasks) can be designed and
implemented to work together in order to perform a single function. This requires
interprocess communication and synchronization. A semaphore mechanism is the lowest
level of synchronization that can be provided by an operating system.

A semaphore is defined as an object that has an integral value and a set of blocked processes
associated with it. If the value is positive or zero, then the set of blocked processes is empty;
otherwise, the size of the set is equal to the absolute value of the semaphore value. The value
of the semaphore can be incremented or decremented by any process with access to the
A semaphore may be used to guard access to any resource accessible by more than one schedulable task in the system. It is a global entity and not associated with any particular process. As such, a method of obtaining access to the semaphore has to be provided by the operating system. A process that wants access to a critical resource (section) has to wait on the semaphore that guards that resource. When the semaphore is locked on behalf of a process, it knows that it can utilize the resource without interference by any other cooperating process in the system. When the process finishes its operation on the resource, leaving it in a well-defined state, it posts the semaphore, indicating that some other process may now obtain the resource associated with that semaphore.

In this section, mutexes and condition variables are specified as the synchronization mechanisms between threads.

These primitives are typically used for synchronizing threads that share memory in a single process. However, this section provides an option allowing the use of these synchronization interfaces and objects between processes that share memory, regardless of the method for sharing memory.

Much experience with semaphores shows that there are two distinct uses of synchronization: locking, which is typically of short duration; and waiting, which is typically of long or unbounded duration. These distinct usages map directly onto mutexes and condition variables, respectively.

Semaphores are provided in IEEE Std 1003.1-2001 primarily to provide a means of synchronization for processes; these processes may or may not share memory. Mutexes and condition variables are specified as synchronization mechanisms between threads; these threads always share (some) memory. Both are synchronization paradigms that have been in widespread use for a number of years. Each set of primitives is particularly well matched to certain problems.

With respect to binary semaphores, experience has shown that condition variables and mutexes are easier to use for many synchronization problems than binary semaphores. The primary reason for this is the explicit appearance of a Boolean predicate that specifies when the condition wait is satisfied. This Boolean predicate terminates a loop, including the call to \texttt{pthread\_cond\_wait(\)}. As a result, extra wakeups are benign since the predicate governs whether the thread will actually proceed past the condition wait. With stateful primitives, such as binary semaphores, the wakeup in itself typically means that the wait is satisfied. The burden of ensuring correctness for such waits is thus placed on all signalers of the semaphore rather than on an \textit{explicitly coded} Boolean predicate located at the condition wait. Experience has shown that the latter creates a major improvement in safety and ease-of-use.

Counting semaphores are well matched to dealing with producer/consumer problems, including those that might exist between threads of different processes, or between a signal handler and a thread. In the former case, there may be little or no memory shared by the processes; in the latter case, one is not communicating between co-equal threads, but between a thread and an interrupt-like entity. It is for these reasons that IEEE Std 1003.1-2001 allows semaphores to be used by threads.

Mutexes and condition variables have been effectively used with and without priority inheritance, priority ceiling, and other attributes to synchronize threads that share memory. The efficiency of their implementation is comparable to or better than that of other synchronization primitives that are sometimes harder to use (for example, binary
semaphores). Furthermore, there is at least one known implementation of Ada tasking that uses these primitives. Mutexes and condition variables together constitute an appropriate, sufficient, and complete set of inter-thread synchronization primitives.

Efficient multi-threaded applications require high-performance synchronization primitives. Considerations of efficiency and generality require a small set of primitives upon which more sophisticated synchronization functions can be built.

- Standardization Issues

It is possible to implement very high-performance semaphores using test-and-set instructions on shared memory locations. The library routines that implement such a high-performance interface have to properly ensure that a `sem_wait()` or `sem_trywait()` operation that cannot be performed will issue a blocking semaphore system call or properly report the condition to the application. The same interface to the application program would be provided by a high-performance implementation.

### B.2.8.1 Realtime Signals

#### Realtime Signals Extension

This portion of the rationale presents models, requirements, and standardization issues relevant to the Realtime Signals Extension. This extension provides the capability required to support reliable, deterministic, asynchronous notification of events. While a new mechanism, unencumbered by the historical usage and semantics of POSIX.1 signals, might allow for a more efficient implementation, the application requirements for event notification can be met with a small number of extensions to signals. Therefore, a minimal set of extensions to signals to support the application requirements is specified.

The realtime signal extensions specified in this section are used by other realtime functions requiring asynchronous notification:

- Models

  The model supported is one of multiple cooperating processes, each of which handles multiple asynchronous external events. Events represent occurrences that are generated as the result of some activity in the system. Examples of occurrences that can constitute an event include:

  - Completion of an asynchronous I/O request
  - Expiration of a POSIX.1b timer
  - Arrival of an interprocess message
  - Generation of a user-defined event

  Processing of these events may occur synchronously via polling for event notifications or asynchronously via a software interrupt mechanism. Existing practice for this model is well established for traditional proprietary realtime operating systems, realtime executives, and realtime extended POSIX-like systems.

  A contrasting model is that of “cooperating sequential processes” where each process handles a single priority of events via polling. Each process blocks while waiting for events, and each process depends on the preemptive, priority-based process scheduling mechanism to arbitrate between events of different priority that need to be processed concurrently. Existing practice for this model is also well established for small realtime executives that typically execute in an unprotected physical address space, but it is just emerging in the
context of a fuller function operating system with multiple virtual address spaces.

It could be argued that the cooperating sequential process model, and the facilities supported by the POSIX Threads Extension obviate a software interrupt model. But, even with the cooperating sequential process model, the need has been recognized for a software interrupt model to handle exceptional conditions and process aborting, so the mechanism must be supported in any case. Furthermore, it is not the purview of IEEE Std 1003.1-2001 to attempt to convince realtime practitioners that their current application models based on software interrupts are “broken” and should be replaced by the cooperating sequential process model. Rather, it is the charter of IEEE Std 1003.1-2001 to provide standard extensions to mechanisms that support existing realtime practice.

• Requirements

This section discusses the following realtime application requirements for asynchronous event notification:

— Reliable delivery of asynchronous event notification

The events notification mechanism guarantees delivery of an event notification. Asynchronous operations (such as asynchronous I/O and timers) that complete significantly after they are invoked have to guarantee that delivery of the event notification can occur at the time of completion.

— Prioritized handling of asynchronous event notifications

The events notification mechanism supports the assigning of a user function as an event notification handler. Furthermore, the mechanism supports the preemption of an event handler function by a higher priority event notification and supports the selection of the highest priority pending event notification when multiple notifications (of different priority) are pending simultaneously.

The model here is based on hardware interrupts. Asynchronous event handling allows the application to ensure that time-critical events are immediately processed when delivered, without the indeterminism of being at a random location within a polling loop. Use of handler priority allows the specification of how handlers are interrupted by other higher priority handlers.

— Differentiation between multiple occurrences of event notifications of the same type

The events notification mechanism passes an application-defined value to the event handler function. This value can be used for a variety of purposes, such as enabling the application to identify which of several possible events of the same type (for example, timer expirations) has occurred.

— Polled reception of asynchronous event notifications

The events notification mechanism supports blocking and non-blocking polls for asynchronous event notification.

The polled mode of operation is often preferred over the interrupt mode by those practitioners accustomed to this model. Providing support for this model facilitates the porting of applications based on this model to POSIX.1b conforming systems.

— Deterministic response to asynchronous event notifications

The events notification mechanism does not preclude implementations that provide deterministic event dispatch latency and minimizes the number of system calls needed to use the event facilities during realtime processing.
Rationale for Extension

POSIX.1 signals have many of the characteristics necessary to support the asynchronous handling of event notifications, and the Realtime Signals Extension addresses the following deficiencies in the POSIX.1 signal mechanism:

- Signals do not support reliable delivery of event notification. Subsequent occurrences of a pending signal are not guaranteed to be delivered.
- Signals do not support prioritized delivery of event notifications. The order of signal delivery when multiple unblocked signals are pending is undefined.
- Signals do not support the differentiation between multiple signals of the same type.

B.2.8.2 Asynchronous I/O

Many applications need to interact with the I/O subsystem in an asynchronous manner. The asynchronous I/O mechanism provides the ability to overlap application processing and I/O operations initiated by the application. The asynchronous I/O mechanism allows a single process to perform I/O simultaneously to a single file multiple times or to multiple files multiple times.

Overview

Asynchronous I/O operations proceed in logical parallel with the processing done by the application after the asynchronous I/O has been initiated. Other than this difference, asynchronous I/O behaves similarly to normal I/O using `read()`, `write()`, `lseek()`, and `fsync()`. The effect of issuing an asynchronous I/O request is as if a separate thread of execution were to perform atomically the implied `lseek()` operation, if any, and then the requested I/O operation (either `read()`, `write()`, or `fsync()`). There is no seek implied with a call to `aio_fsync()`. Concurrent asynchronous operations and synchronous operations applied to the same file update the file as if the I/O operations had proceeded serially.

When asynchronous I/O completes, a signal can be delivered to the application to indicate the completion of the I/O. This signal can be used to indicate that buffers and control blocks used for asynchronous I/O can be reused. Signal delivery is not required for an asynchronous operation and may be turned off on a per-operation basis by the application. Signals may also be synchronously polled using `aio_suspend()`, `sigtimedwait()`, or `sigwaitinfo()`.

Normal I/O has a return value and an error status associated with it. Asynchronous I/O returns a value and an error status when the operation is first submitted, but that only relates to whether the operation was successfully queued up for servicing. The I/O operation itself also has a return status and an error value. To allow the application to retrieve the return status and the error value, functions are provided that, given the address of an asynchronous I/O control block, yield the return and error status associated with the operation. Until an asynchronous I/O operation is done, its error status is `[EINPROGRESS]`. Thus, an application can poll for completion of an asynchronous I/O operation by waiting for the error status to become equal to a value other than `[EINPROGRESS]`. The return status of an asynchronous I/O operation is undefined so long as the error status is equal to `[EINPROGRESS]`.

Storage for asynchronous operation return and error status may be limited. Submission of asynchronous I/O operations may fail if this storage is exceeded. When an application retrieves the return status of a given asynchronous operation, therefore, any system-maintained storage used for this status and the error status may be reclaimed for use by other asynchronous operations.
Asynchronous I/O can be performed on file descriptors that have been enabled for POSIX.1b synchronized I/O. In this case, the I/O operation still occurs asynchronously, as defined herein; however, the asynchronous operation I/O in this case is not completed until the I/O has reached either the state of synchronized I/O data integrity completion or synchronized I/O file integrity completion, depending on the sort of synchronized I/O that is enabled on the file descriptor.

Models

Three models illustrate the use of asynchronous I/O: a journalization model, a data acquisition model, and a model of the use of asynchronous I/O in supercomputing applications.

- Journalization Model
  Many realtime applications perform low-priority journalizing functions. Journalizing requires that logging records be queued for output without blocking the initiating process.

- Data Acquisition Model
  A data acquisition process may also serve as a model. The process has two or more channels delivering intermittent data that must be read within a certain time. The process issues one asynchronous read on each channel. When one of the channels needs data collection, the process reads the data and posts it through an asynchronous write to secondary memory for future processing.

- Supercomputing Model
  The supercomputing community has used asynchronous I/O much like that specified in POSIX.1 for many years. This community requires the ability to perform multiple I/O operations to multiple devices with a minimal number of entries to “the system”; each entry to “the system” provokes a major delay in operations when compared to the normal progress made by the application. This existing practice motivated the use of combined _lseek() and read() or write() calls, as well as the _lio_flistio() call. Another common practice is to disable signal notification for I/O completion, and simply poll for I/O completion at some interval by which the I/O should be completed. Likewise, interfaces like _aio_cancel() have been in successful commercial use for many years. Note also that an underlying implementation of asynchronous I/O will require the ability, at least internally, to cancel outstanding asynchronous I/O, at least when the process exits. (Consider an asynchronous read from a terminal, when the process intends to exit immediately.)

Requirements

Asynchronous input and output for realtime implementations have these requirements:

- The ability to queue multiple asynchronous read and write operations to a single open instance. Both sequential and random access should be supported.
- The ability to queue asynchronous read and write operations to multiple open instances.
- The ability to obtain completion status information by polling and/or asynchronous event notification.
- Asynchronous event notification on asynchronous I/O completion is optional.
- It has to be possible for the application to associate the event with the _aiochp for the operation that generated the event.
- The ability to cancel queued requests.
- The ability to wait upon asynchronous I/O completion in conjunction with other types of events.
• The ability to accept an `aio_read()` and an `aio_cancel()` for a device that accepts a `read()`, and
the ability to accept an `aio_write()` and an `aio_cancel()` for a device that accepts a `write()`. This
does not imply that the operation is asynchronous.

Standardization Issues
The following issues are addressed by the standardization of asynchronous I/O:

• Rationale for New Interface
Non-blocking I/O does not satisfy the needs of either realtime or high-performance
computing models; these models require that a process overlap program execution and I/O
processing. Realtime applications will often make use of direct I/O to or from the address
space of the process, or require synchronized (unbuffered) I/O; they also require the ability
to overlap this I/O with other computation. In addition, asynchronous I/O allows an
application to keep a device busy at all times, possibly achieving greater throughput.
Supercomputing and database architectures will often have specialized hardware that can
provide true asynchrony underlying the logical asynchrony provided by this interface. In
addition, asynchronous I/O should be supported by all types of files and devices in the same
manner.

• Effect of Buffering
If asynchronous I/O is performed on a file that is buffered prior to being actually written to
the device, it is possible that asynchronous I/O will offer no performance advantage over
normal I/O; the cycles stolen to perform the asynchronous I/O will be taken away from the
running process and the I/O will occur at interrupt time. This potential lack of gain in
performance in no way obviates the need for asynchronous I/O by realtime applications,
which very often will use specialized hardware support, multiple processors, and/or
unbuffered, synchronized I/O.

B.2.8.3 Memory Management
All memory management and shared memory definitions are located in the `<sys/mman.h>`
header. This is for alignment with historical practice.

IEEE Std 1003.1-2001/Cor 1-2002, item XSH/TC1/D6/7 is applied, correcting the shading and
margin markers in the introduction to Section 2.8.3.1.

Memory Locking Functions
This portion of the rationale presents models, requirements, and standardization issues relevant
to process memory locking.

• Models
Realtime systems that conform to IEEE Std 1003.1-2001 are expected (and desired) to be
supported on systems with demand-paged virtual memory management, non-paged
swapping memory management, and physical memory systems with no memory
management hardware. The general case, however, is the demand-paged, virtual memory
system with each POSIX process running in a virtual address space. Note that this includes
architectures where each process resides in its own virtual address space and architectures
where the address space of each process is only a portion of a larger global virtual address
space.

The concept of memory locking is introduced to eliminate the indeterminacy introduced by
paging and swapping, and to support an upper bound on the time required to access the
memory mapped into the address space of a process. Ideally, this upper bound will be the
same as the time required for the processor to access ‘‘main memory’’, including any address translation and cache miss overheads. But some implementations—primarily on mainframes—will not actually force locked pages to be loaded and held resident in main memory. Rather, they will handle locked pages so that accesses to these pages will meet the performance metrics for locked process memory in the implementation. Also, although it is not, for example, the intention that this interface, as specified, be used to lock process memory into ‘‘cache’’, it is conceivable that an implementation could support a large static RAM memory and define this as ‘‘main memory’’ and use a large[r] dynamic RAM as ‘‘backing store’’. These interfaces could then be interpreted as supporting the locking of process memory into the static RAM. Support for multiple levels of backing store would require extensions to these interfaces.

Implementations may also use memory locking to guarantee a fixed translation between virtual and physical addresses where such is beneficial to improving determinancy for direct-to/from-process input/output. IEEE Std 1003.1-2001 does not guarantee to the application that the virtual-to-physical address translations, if such exist, are fixed, because such behavior would not be implementable on all architectures on which implementations of IEEE Std 1003.1-2001 are expected. But IEEE Std 1003.1-2001 does mandate that an implementation define, for the benefit of potential users, whether or not locking guarantees fixed translations.

Memory locking is defined with respect to the address space of a process. Only the pages mapped into the address space of a process may be locked by the process, and when the pages are no longer mapped into the address space—for whatever reason—the locks established with respect to that address space are removed. Shared memory areas warrant special mention, as they may be mapped into more than one address space or mapped more than once into the address space of a process; locks may be established on pages within these areas with respect to several of these mappings. In such a case, the lock state of the underlying physical pages is the logical OR of the lock state with respect to each of the mappings. Only when all such locks have been removed are the shared pages considered unlocked.

In recognition of the page granularity of Memory Management Units (MMU), and in order to support locking of ranges of address space, memory locking is defined in terms of ‘‘page’’ granularity. That is, for the interfaces that support an address and size specification for the region to be locked, the address must be on a page boundary, and all pages mapped by the specified range are locked, if valid. This means that the length is implicitly rounded up to a multiple of the page size. The page size is implementation-defined and is available to applications as a compile-time symbolic constant or at runtime via sysconf().

A ‘‘real memory’’ POSIX.1b implementation that has no MMU could elect not to support these interfaces, returning [ENOSYS]. But an application could easily interpret this as meaning that the implementation would unconditionally page or swap the application when such is not the case. It is the intention of IEEE Std 1003.1-2001 that such a system could define these interfaces as ‘‘NO-OPs’’, returning success without actually performing any function except for mandated argument checking.

• Requirements

For realtime applications, memory locking is generally considered to be required as part of application initialization. This locking is performed after an application has been loaded (that is, exec’d) and the program remains locked for its entire lifetime. But to support applications that undergo major mode changes where, in one mode, locking is required, but in another it is not, the specified interfaces allow repeated locking and unlocking of memory within the lifetime of a process.
When a realtime application locks its address space, it should not be necessary for the application to then "touch" all of the pages in the address space to guarantee that they are resident or else suffer potential paging delays the first time the page is referenced. Thus, IEEE Std 1003.1-2001 requires that the pages locked by the specified interfaces be resident when the locking functions return successfully.

Many architectures support system-managed stacks that grow automatically when the current extent of the stack is exceeded. A realtime application has a requirement to be able to "preallocate" sufficient stack space and lock it down so that it will not suffer page faults to grow the stack during critical realtime operation. There was no consensus on a portable way to specify how much stack space is needed, so IEEE Std 1003.1-2001 supports no specific interface for preallocating stack space. But an application can portably lock down a specific amount of stack space by specifying MCL_FUTURE in a call to mlockall() and then calling a dummy function that declares an automatic array of the desired size.

Memory locking for realtime applications is also generally considered to be an "all or nothing" proposition. That is, the entire process, or none, is locked down. But, for applications that have well-defined sections that need to be locked and others that do not, IEEE Std 1003.1-2001 supports an optional set of interfaces to lock or unlock a range of process addresses. Reasons for locking down a specific range include:

— An asynchronous event handler function that must respond to external events in a deterministic manner such that page faults cannot be tolerated

— An input/output "buffer" area that is the target for direct-to-process I/O, and the overhead of implicit locking and unlocking for each I/O call cannot be tolerated

Finally, locking is generally viewed as an "application-wide" function. That is, the application is globally aware of which regions are locked and which are not over time. This is in contrast to a function that is used temporarily within a "third party" library routine whose function is unknown to the application, and therefore must have no "side effects". The specified interfaces, therefore, do not support "lock stacking" or "lock nesting" within a process. But, for pages that are shared between processes or mapped more than once into a process address space, “lock stacking” is essentially mandated by the requirement that unlocking of pages that are mapped by more than one process or more than once by the same process does not affect locks established on the other mappings.

There was some support for "lock stacking" so that locking could be transparently used in functions or opaque modules. But the consensus was not to burden all implementations with lock stacking (and reference counting), and an implementation option was proposed. There were strong objections to the option because applications would have to support both options in order to remain portable. The consensus was to eliminate lock stacking altogether, primarily through overwhelming support for the System V "m[un]lock[all]" interface on which IEEE Std 1003.1-2001 is now based.

Locks are not inherited across fork()s because some implementations implement fork() by creating new address spaces for the child. In such an implementation, requiring locks to be inherited would lead to new situations in which a fork would fail due to the inability of the system to lock sufficient memory to lock both the parent and the child. The consensus was that there was no benefit to such inheritance. Note that this does not mean that locks are removed when, for instance, a thread is created in the same address space.

Similarly, locks are not inherited across exec because some implementations implement exec by unmapping all of the pages in the address space (which, by definition, removes the locks on these pages), and maps in pages of the exec'd image. In such an implementation, requiring locks to be inherited would lead to new situations in which exec would fail. Reporting this...
failure would be very cumbersome to detect in time to report to the calling process, and no
appropriate mechanism exists for informing the exec’d process of its status.

It was determined that, if the newly loaded application required locking, it was the
responsibility of that application to establish the locks. This is also in keeping with the
general view that it is the responsibility of the application to be aware of all locks that are
established.

There was one request to allow (not mandate) locks to be inherited across fork(), and a
request for a flag, MCL_INHERIT, that would specify inheritance of memory locks across
execs. Given the difficulties raised by this and the general lack of support for the feature in
IEEE Std 1003.1-2001, it was not added. IEEE Std 1003.1-2001 does not preclude an
implementation from providing this feature for administrative purposes, such as a “run”
command that will lock down and execute a specified application. Additionally, the rationale
for the objection equated fork() with creating a thread in the address space. IEEE Std 1003.1-2001
does not mandate releasing locks when creating additional threads in
an existing process.

• Standardization Issues

One goal of IEEE Std 1003.1-2001 is to define a set of primitives that provide the necessary
functionality for realtime applications, with consideration for the needs of other application
domains where such were identified, which is based to the extent possible on existing
industry practice.

The Memory Locking option is required by many realtime applications to tune performance.
Such a facility is accomplished by placing constraints on the virtual memory system to limit
paging of time of the process or of critical sections of the process. This facility should not be
used by most non-realtime applications.

Optional features provided in IEEE Std 1003.1-2001 allow applications to lock selected
address ranges with the caveat that the process is responsible for being aware of the page
granularity of locking and the unnested nature of the locks.

Mapped Files Functions

The Memory Mapped Files option provides a mechanism that allows a process to access files by
directly incorporating file data into its address space. Once a file is “mapped” into a process
address space, the data can be manipulated by instructions as memory. The use of mapped files
can significantly reduce I/O data movement since file data does not have to be copied into
process data buffers as in read() and write(). If more than one process maps a file, its contents
are shared among them. This provides a low overhead mechanism by which processes can
synchronize and communicate.

• Historical Perspective

Realtime applications have historically been implemented using a collection of cooperating
processes or tasks. In early systems, these processes ran on bare hardware (that is, without an
operating system) with no memory relocation or protection. The application paradigms that
arose from this environment involve the sharing of data between the processes.

When realtime systems were implemented on top of vendor-supplied operating systems, the
paradigm or performance benefits of direct access to data by multiple processes was still
deemed necessary. As a result, operating systems that claim to support realtime applications
must support the shared memory paradigm.

Additionally, a number of realtime systems provide the ability to map specific sections of the
physical address space into the address space of a process. This ability is required if an
application is to obtain direct access to memory locations that have specific properties (for example, refresh buffers or display devices, dual ported memory locations, DMA target locations). The use of this ability is common enough to warrant some degree of standardization of its interface. This ability overlaps the general paradigm of shared memory in that, in both instances, common global objects are made addressable by individual processes or tasks.

Finally, a number of systems also provide the ability to map process addresses to files. This provides both a general means of sharing persistent objects, and using files in a manner that optimizes memory and swapping space usage.

Simple shared memory is clearly a special case of the more general file mapping capability. In addition, there is relatively widespread agreement and implementation of the file mapping interface. In these systems, many different types of objects can be mapped (for example, files, memory, devices, and so on) using the same mapping interfaces. This approach both minimizes interface proliferation and maximizes the generality of programs using the mapping interfaces.

- Memory Mapped Files Usage

A memory object can be concurrently mapped into the address space of one or more processes. The \texttt{mmap()} and \texttt{munmap()} functions allow a process to manipulate their address space by mapping portions of memory objects into it and removing them from it. When multiple processes map the same memory object, they can share access to the underlying data. Implementations may restrict the size and alignment of mappings to be on page-size boundaries. The page size, in bytes, is the value of the system-configurable variable \texttt{PAGESIZE}, typically accessed by calling \texttt{sysconf()} with a \texttt{name} argument of \_SC_PAGESIZE. If an implementation has no restrictions on size or alignment, it may specify a 1-byte page size.

To map memory, a process first opens a memory object. The \texttt{ftruncate()} function can be used to contract or extend the size of the memory object even when the object is currently mapped. If the memory object is extended, the contents of the extended areas are zeros.

After opening a memory object, the application maps the object into its address space using the \texttt{mmap()} function call. Once a mapping has been established, it remains mapped until unmapped with \texttt{munmap()}, even if the memory object is closed. The \texttt{mprotect()} function can be used to change the memory protections initially established by \texttt{mmap()}.

A \texttt{close()} of the file descriptor, while invalidating the file descriptor itself, does not unmap any mappings established for the memory object. The address space, including all mapped regions, is inherited on \texttt{fork()}. The entire address space is unmapped on process termination or by successful calls to any of the \texttt{exec} family of functions.

The \texttt{msync()} function is used to force mapped file data to permanent storage.

- Effects on Other Functions

When the Memory Mapped Files option is supported, the operation of the \texttt{open()}, \texttt{creat()}, and \texttt{unlink()} functions are a natural result of using the file system name space to map the global names for memory objects.

The \texttt{ftruncate()} function can be used to set the length of a sharable memory object.

The meaning of \texttt{stat()} fields other than the size and protection information is undefined on implementations where memory objects are not implemented using regular files. When regular files are used, the times reflect when the implementation updated the file image of the data, not when a process updated the data in memory.
The operations of `fdopen()`, `write()`, `read()`, and `lseek()` were made unspecified for objects opened with `shm_open()`, so that implementations that did not implement memory objects as regular files would not have to support the operation of these functions on shared memory objects.

The behavior of memory objects with respect to `close()`, `dup()`, `dup2()`, `open()`, `close()`, `fork()`, `_exit()`, and the `exec` family of functions is the same as the behavior of the existing practice of the `mmap()` function.

A memory object can still be referenced after a close. That is, any mappings made to the file are still in effect, and reads and writes that are made to those mappings are still valid and are shared with other processes that have the same mapping. Likewise, the memory object can still be used if any references remain after its name(s) have been deleted. Any references that remain after a close must not appear to the application as file descriptors.

This is existing practice for `mmap()` and `close()`. In addition, there are already mappings present (text, data, stack) that do not have open file descriptors. The text mapping in particular is considered a reference to the file containing the text. The desire was to treat all mappings by the process uniformly. Also, many modern implementations use `mmap()` to implement shared libraries, and it would not be desirable to keep file descriptors for each of the many libraries an application can use. It was felt there were many other existing programs that used this behavior to free a file descriptor, and thus IEEE Std 1003.1-2001 could not forbid it and still claim to be using existing practice.

For implementations that implement memory objects using memory only, memory objects will retain the memory allocated to the file after the last close and will use that same memory on the next open. Note that closing the memory object is not the same as deleting the name, since the memory object is still defined in the memory object name space.

The locks of `fcntl()` do not block any read or write operation, including read or write access to shared memory or mapped files. In addition, implementations that only support shared memory objects should not be required to implement record locks. The reference to `fcntl()` is added to make this point explicitly. The other `fcntl()` commands are useful with shared memory objects.

The size of pages that mapping hardware may be able to support may be a configurable value, or it may change based on hardware implementations. The addition of the `_SC_PAGESIZE` parameter to the `sysconf()` function is provided for determining the mapping page size at runtime.

**Shared Memory Functions**

Implementations may support the Shared Memory Objects option without supporting a general Memory Mapped Files option. Shared memory objects are named regions of storage that may be independent of the file system and can be mapped into the address space of one or more processes to allow them to share the associated memory.

- **Requirements**

  Shared memory is used to share data among several processes, each potentially running at different priority levels, responding to different inputs, or performing separate tasks. Shared memory is not just simply providing common access to data, it is providing the fastest possible communication between the processes. With one memory write operation, a process can pass information to as many processes as have the memory region mapped.

  As a result, shared memory provides a mechanism that can be used for all other interprocess communication facilities. It may also be used by an application for implementing more
sophisticated mechanisms than semaphores and message queues.

The need for a shared memory interface is obvious for virtual memory systems, where the operating system is directly preventing processes from accessing each other's data. However, in unprotected systems, such as those found in some embedded controllers, a shared memory interface is needed to provide a portable mechanism to allocate a region of memory to be shared and then to communicate the address of that region to other processes.

This, then, provides the minimum functionality that a shared memory interface must have in order to support realtime applications: to allocate and name an object to be mapped into memory for potential sharing (open() or shm_open()), and to make the memory object available within the address space of a process (mmap()). To complete the interface, a mechanism to release the claim of a process on a shared memory object (munmap()) is also needed, as well as a mechanism for deleting the name of a sharable object that was previously created (unlink() or shm_unlink()).

After a mapping has been established, an implementation should not have to provide services to maintain that mapping. All memory writes into that area will appear immediately in the memory mapping of that region by any other processes.

Thus, requirements include:

— Support creation of sharable memory objects and the mapping of these objects into the address space of a process.

— Sharable memory objects should be accessed by global names accessible from all processes.

— Support the mapping of specific sections of physical address space (such as a memory mapped device) into the address space of a process. This should not be done by the process specifying the actual address, but again by an implementation-defined global name (such as a special device name) dedicated to this purpose.

— Support the mapping of discrete portions of these memory objects.

— Support for minimum hardware configurations that contain no physical media on which to store shared memory contents permanently.

— The ability to preallocate the entire shared memory region so that minimum hardware configurations without virtual memory support can guarantee contiguous space.

— The maximizing of performance by not requiring functionality that would require implementation interaction above creating the shared memory area and returning the mapping.

Note that the above requirements do not preclude:

— The sharable memory object from being implemented using actual files on an actual file system.

— The global name that is accessible from all processes being restricted to a file system area that is dedicated to handling shared memory.

— An implementation not providing implementation-defined global names for the purpose of physical address mapping.

— Shared Memory Objects Usage

If the Shared Memory Objects option is supported, a shared memory object may be created, or opened if it already exists, with the shm_open() function. If the shared memory object is created, it has a length of zero. The ftruncate() function can be used to set the size of the
shared memory object after creation. The `shm_unlink()` function removes the name for a shared memory object created by `shm_open()`.

- **Shared Memory Overview**

  The shared memory facility defined by IEEE Std 1003.1-2001 usually results in memory locations being added to the address space of the process. The implementation returns the address of the new space to the application by means of a pointer. This works well in languages like C. However, in languages without pointer types it will not work. In the bindings for such a language, either a special COMMON section will need to be defined (which is unlikely), or the binding will have to allow existing structures to be mapped. The implementation will likely have to place restrictions on the size and alignment of such structures or will have to map a suitable region of the address space of the process into the memory object, and thus into other processes. These are issues for that particular language binding. For IEEE Std 1003.1-2001, however, the practice will not be forbidden, merely undefined.

  Two potentially different name spaces are used for naming objects that may be mapped into process address spaces. When the Memory Mapped Files option is supported, files may be accessed via `open()`; when the Shared Memory Objects option is supported, sharable memory objects that might not be files may be accessed via the `shm_open()` function. These options are not mutually-exclusive.

  Some implementations supporting the Shared Memory Objects option may choose to implement the shared memory object name space as part of the file system name space. There are several reasons for this:

  — It allows applications to prevent name conflicts by use of the directory structure.

  — It uses an existing mechanism for accessing global objects and prevents the creation of a new mechanism for naming global objects.

  In such implementations, memory objects can be implemented using regular files, if that is what the implementation chooses. The `shm_open()` function can be implemented as an `open()` call in a fixed directory followed by a call to `fcntl()` to set FD_CLOEXEC. The `shm_unlink()` function can be implemented as an `unlink()` call.

  On the other hand, it is also expected that small embedded systems that support the Shared Memory Objects option may wish to implement shared memory without having any file systems present. In this case, the implementations may choose to use a simple string valued name space for shared memory regions. The `shm_open()` function permits either type of implementation.

  Some implementations have hardware that supports protection of mapped data from certain classes of access and some do not. Systems that supply this functionality can support the Memory Protection option.

  Some implementations restrict size, alignment, and protections to be on page-size boundaries. If an implementation has no restrictions on size or alignment, it may specify a 1-byte page size. Applications on implementations that do support larger pages must be cognizant of the page size since this is the alignment and protection boundary.

  Simple embedded implementations may have a 1-byte page size and only support the Shared Memory Objects option. This provides simple shared memory between processes without requiring mapping hardware.

  IEEE Std 1003.1-2001 specifically allows a memory object to remain referenced after a close because that is existing practice for the `mmap()` function.
Typed Memory Functions

Implementations may support the Typed Memory Objects option without supporting either the Shared Memory option or the Memory Mapped Files option. Typed memory objects are pools of specialized storage, different from the main memory resource normally used by a processor to hold code and data, that can be mapped into the address space of one or more processes.

- Model

Realtime systems conforming to one of the POSIX.13 realtime profiles are expected (and desired) to be supported on systems with more than one type or pool of memory (for example, SRAM, DRAM, ROM, EPROM, EEPROM), where each type or pool of memory may be accessible by one or more processors via one or more busses (ports). Memory mapped files, shared memory objects, and the language-specific storage allocation operators (malloc() for the ISO C standard, new for ISO Ada) fail to provide application program interfaces versatile enough to allow applications to control their utilization of such diverse memory resources. The typed memory interfaces posix_typed_mem_open(), posix_mem_offset(), posix_typed_mem_get_info(), mmap(), and munmap() defined herein support the model of typed memory described below.

For purposes of this model, a system comprises several processors (for example, P₁ and P₂), several physical memory pools (for example, M₁, M₂, M₃, M₄, M₅, and M₆), and several busses or "ports" (for example, B₁, B₂, B₃, and B₄) interconnecting the various processors and memory pools in some system-specific way. Notice that some memory pools may be contained in others (for example, M₂a and M₂b are contained in M₂).

Figure B-1 shows an example of such a model. In a system like this, an application should be able to perform the following operations:

---

Figure B-1  Example of a System with Typed Memory

---

Typed Memory Allocation

An application should be able to allocate memory dynamically from the desired pool using the desired bus, and map it into a process’ address space. For example, processor P₁ can allocate some portion of memory pool M₁ through port B₁, treating all unmapped subareas of M₁ as a heap-storage resource from which memory may be allocated. This portion of memory is mapped into the process’ address space, and subsequently deallocated when unmapped from all processes.
— Using the Same Storage Region from Different Busses

An application process with a mapped region of storage that is accessed from one bus should be able to map that same storage area at another address (subject to page size restrictions detailed in `mmap()`), to allow it to be accessed from another bus. For example, processor \( P_1 \) may wish to access the same region of memory pool \( M_{2b} \) both through ports \( B_1 \) and \( B_2 \).

— Sharing Typed Memory Regions

Several application processes running on the same or different processors may wish to share a particular region of a typed memory pool. Each process or processor may wish to access this region through different buses. For example, processor \( P_1 \) may want to share a region of memory pool \( M_4 \) with processor \( P_2 \), and they may be required to use buses \( B_2 \) and \( B_3 \) respectively, to minimize bus contention. A problem arises here when a process allocates and maps a portion of fragmented memory and then wants to share this region of memory with another process, either in the same processor or different processors. The solution adopted is to allow the first process to find out the memory map (offsets and lengths) of all the different fragments of memory that were mapped into its address space, by repeatedly calling `posix_mem_offset()`. Then, this process can pass the offsets and lengths obtained to the second process, which can then map the same memory fragments into its address space.

— Contiguous Allocation

The problem of finding the memory map of the different fragments of the memory pool that were mapped into logically contiguous addresses of a given process can be solved by requesting contiguous allocation. For example, a process in \( P_1 \) can allocate 10 Kbytes of physically contiguous memory from \( M_3-B_1 \) and obtain the offset (within pool \( M_3 \)) of this block of memory. Then, it can pass this offset (and the length) to a process in \( P_2 \) using some interprocess communication mechanism. The second process can map the same block of memory by using the offset transferred and specifying \( M_3-B_2 \).

— Unallocated Mapping

Any subarea of a memory pool that is mapped to a process, either as the result of an allocation request or an explicit mapping, is normally unavailable for allocation. Special processes such as debuggers, however, may need to map large areas of a typed memory pool, yet leave those areas available for allocation.

Typed memory allocation and mapping has to coexist with storage allocation operators like `malloc()`, but systems are free to choose how to implement this coexistence. For example, it may be system configuration-dependent if all available system memory is made part of one of the typed memory pools or if some part will be restricted to conventional allocation operators. Equally system configuration-dependent may be the availability of operators like `malloc()` to allocate storage from certain typed memory pools. It is not excluded to configure a system such that a given named pool, \( P_1 \), is in turn split into non-overlapping named subpools. For example, \( M_1-B_1, M_2-B_1, \) and \( M_3-B_1 \) could also be accessed as one common pool \( M_{123-B_1} \). A call to `malloc()` on \( P_1 \) could work on such a larger pool while full optimization of memory usage by \( P_1 \) would require typed memory allocation at the subpool level.

• Existing Practice

OS-9 provides for the naming (numbering) and prioritization of memory types by a system administrator. It then provides APIs to request memory allocation of typed (colored) memory by number, and to generate a bus address from a mapped memory address (translate). When requesting colored memory, the user can specify type 0 to signify allocation...
from the first available type in priority order.

HP-RT presents interfaces to map different kinds of storage regions that are visible through a VME bus, although it does not provide allocation operations. It also provides functions to perform address translation between VME addresses and virtual addresses. It represents a VME-bus unique solution to the general problem.

The PSOS approach is similar (that is, based on a pre-established mapping of bus address ranges to specific memories) with a concept of segments and regions (regions dynamically allocated from a heap which is a special segment). Therefore, PSOS does not fully address the general allocation problem either. PSOS does not have a “process”-based model, but more of a “thread”-only-based model of multi-tasking. So mapping to a process address space is not an issue.

QNX uses the System V approach of opening specially named devices (shared memory segments) and using `mmap()` to then gain access from the process. They do not address allocation directly, but once typed shared memory can be mapped, an “allocation manager” process could be written to handle requests for allocation.

The System V approach also included allocation, implemented by opening yet other special “devices” which allocate, rather than appearing as a whole memory object.

The Orkid realtime kernel interface definition has operations to manage memory “regions” and “pools”, which are areas of memory that may reflect the differing physical nature of the memory. Operations to allocate memory from these regions and pools are also provided.

- **Requirements**

  Existing practice in SVID-derived UNIX systems relies on functionality similar to `mmap()` and its related interfaces to achieve mapping and allocation of typed memory. However, the issue of sharing typed memory (allocated or mapped) and the complication of multiple ports are not addressed in any consistent way by existing UNIX system practice. Part of this functionality is existing practice in specialized realtime operating systems. In order to solidify the capabilities implied by the model above, the following requirements are imposed on the interface:

  — **Identification of Typed Memory Pools and Ports**

    All processes (running in all processors) in the system are able to identify a particular (system configured) typed memory pool accessed through a particular (system configured) port by a name. That name is a member of a name space common to all these processes, but need not be the same name space as that containing ordinary filenames. The association between memory pools/ports and corresponding names is typically established when the system is configured. The “open” operation for typed memory objects should be distinct from the `open()` function, for consistency with other similar services, but implementable on top of `open()`. This implies that the handle for a typed memory object will be a file descriptor.

  — **Allocation and Mapping of Typed Memory**

    Once a typed memory object has been identified by a process, it is possible to both map user-selected subareas of that object into process address space and to map system-selected (that is, dynamically allocated) subareas of that object, with user-specified length, into process address space. It is also possible to determine the maximum length of memory allocation that may be requested from a given typed memory object.
Sharing Typed Memory

Two or more processes are able to share portions of typed memory, either user-selected or dynamically allocated. This requirement applies also to dynamically allocated regions of memory that are composed of several non-contiguous pieces.

Contiguous Allocation

For dynamic allocation, it is the user’s option whether the system is required to allocate a contiguous subarea within the typed memory object, or whether it is permitted to allocate discontiguous fragments which appear contiguous in the process mapping. Contiguous allocation simplifies the process of sharing allocated typed memory, while discontiguous allocation allows for potentially better recovery of deallocated typed memory.

Accessing Typed Memory Through Different Ports

Once a subarea of a typed memory object has been mapped, it is possible to determine the location and length corresponding to a user-selected portion of that object within the memory pool. This location and length can then be used to remap that portion of memory for access from another port. If the referenced portion of typed memory was allocated discontiguously, the length thus determined may be shorter than anticipated, and the user code must adapt to the value returned.

Deallocation

When a previously mapped subarea of typed memory is no longer mapped by any process in the system—as a result of a call or calls to `munmap()`—that subarea becomes potentially reusable for dynamic allocation; actual reuse of the subarea is a function of the dynamic typed memory allocation policy.

Unallocated Mapping

It must be possible to map user-selected subareas of a typed memory object without marking that subarea as unavailable for allocation. This option is not the default behavior, and requires appropriate privilege.

Scenario

The following scenario will serve to clarify the use of the typed memory interfaces.

Process A running on P₁ (see Figure B-1 (on page 122)) wants to allocate some memory from memory pool M₂, and it wants to share this portion of memory with process B running on P₂. Since P₂ only has access to the lower part of M₂, both processes will use the memory pool named M₂b, which is the part of M₂ that is accessible both from P₁ and P₂. The operations that both processes need to perform are shown below:

Allocating Typed Memory

Process A calls `posix_typed_mem_open()` with the name `/typed.m2b-b1` and a `tflag` of `POSIX_TYPED_MEM_ALLOCATE` to get a file descriptor usable for allocating from pool M₂b accessed through port B₁. It then calls `mmap()` with this file descriptor requesting a length of 4,096 bytes. The system allocates two discontiguous blocks of sizes 1,024 and 3,072 bytes within M₂b. The `mmap()` function returns a pointer to a 4,096-byte array in process A’s logical address space, mapping the allocated blocks contiguously. Process A can then utilize the array, and store data in it.

Determining the Location of the Allocated Blocks

Process A can determine the lengths and offsets (relative to M₂b) of the two blocks allocated, by using the following procedure: First, process A calls `posix_mem_offset()` with
the address of the first element of the array and length 4096. Upon return, the offset and
length (1024 bytes) of the first block are returned. A second call to \texttt{posix_mem_offset()} is
then made using the address of the first element of the array plus 1024 (the length of the
first block), and a new length of 4096–1024. If there were more fragments allocated, this
procedure could have been continued within a loop until the offsets and lengths of all the
blocks were obtained. Notice that this relatively complex procedure can be avoided if
contiguous allocation is requested (by opening the typed memory object with the \texttt{tflag}
\texttt{POSIX_TYPED_MEM_ALLOCATE_CONTIG}).

— Sharing Data Across Processes

Process A passes the two offset values and lengths obtained from the \texttt{posix_mem_offset()}
calls to process B running on \texttt{P_2} via some form of interprocess communication. Process B
can gain access to process A’s data by calling \texttt{posix_typed_mem_open()} with the name
\texttt{/typed.m2b-b2} and a \texttt{tflag} of zero, then using two \texttt{mmap()} calls on the resulting file
descriptor to map the two subareas of that typed memory object to its own address space.

- Rationale for no \texttt{mem_alloc()} and \texttt{mem_free()}

The standard developers had originally proposed a pair of new flags to \texttt{mmap()} which, when
applied to a typed memory object descriptor, would cause \texttt{mmap()} to allocate dynamically
from an unallocated and unmapped area of the typed memory object.Deallocation was
similarly accomplished through the use of \texttt{munmap()}. This was rejected by the ballot group
because it excessively complicated the (already rather complex) \texttt{mmap()} interface and
introduced semantics useful only for typed memory, to a function which must also map
shared memory and files. They felt that a memory allocator should be built on top of \texttt{mmap()}
instead of being incorporated within the same interface, much as the ISO C standard libraries
build \texttt{malloc()} on top of the virtual memory mapping functions \texttt{brk()} and \texttt{sbrk()}. This would
eliminate the complicated semantics involved with unmapping only part of an allocated
block of typed memory.

To attempt to achieve ballot group consensus, typed memory allocation and deallocation was
first migrated from \texttt{mmap()} and \texttt{munmap()} to a pair of complementary functions modeled on
the ISO C standard \texttt{malloc()} and \texttt{free()}. The \texttt{mem_alloc()} function specified explicitly the
typed memory object (typed memory pool/access port) from which allocation takes place,
unlike \texttt{malloc()} where the memory pool and port are unspecified. The \texttt{mem_free()} function
handled deallocation. These new semantics still met all of the requirements detailed above
without modifying the behavior of \texttt{mmap()} except to allow it to map specified areas of typed
memory objects. An implementation would have been free to implement \texttt{mem_alloc()} and
\texttt{mem_free()} over \texttt{mmap()}, through \texttt{mmap()}, or independently but cooperating with \texttt{mmap()}.

The ballot group was queried to see if this was an acceptable alternative, and while there was
some agreement that it achieved the goal of removing the complicated semantics of
allocation from the \texttt{mmap()} interface, several balloters realized that it just created two
additional functions that behaved, in great part, like \texttt{mmap()}. These balloters proposed an
alternative which has been implemented here in place of a separate \texttt{mem_alloc()} and
\texttt{mem_free()}. This alternative is based on four specific suggestions:

1. The \texttt{posix_typed_mem_open()} function should provide a flag which specifies “allocate
on \texttt{mmap()}” (otherwise, \texttt{mmap()} just maps the underlying object). This allows things
roughly similar to \texttt{/dev/zero versus /dev/swap}. Two such flags have been implemented,
one of which forces contiguous allocation.

2. The \texttt{posix_mem_offset()} function is acceptable because it can be applied usefully to
mapped objects in general. It should return the file descriptor of the underlying object.
3. The `mem_get_info()` function in an earlier draft should be renamed `posix_typed_mem_get_info()` because it is not generally applicable to memory objects. It should probably return the file descriptor’s allocation attribute. The renaming of the function has been implemented, but having it return a piece of information which is readily known by an application without this function has been rejected. Its whole purpose is to query the typed memory object for attributes that are not user-specified, but determined by the implementation.

4. There should be no separate `mem_alloc()` or `mem_free()` functions. Instead, using `mmap()` on a typed memory object opened with an “allocate on `mmap()`” flag should be used to force allocation. These are precisely the semantics defined in the current draft.

- Rationale for no Typed Memory Access Management

The working group had originally defined an additional interface (and an additional kind of object: typed memory master) to establish and dissolve mappings to typed memory on behalf of devices or processors which were independent of the operating system and had no inherent capability to directly establish mappings on their own. This was to have provided functionality similar to device driver interfaces such as `physio()` and their underlying bus-specific interfaces (for example, `mballoc()`) which serve to set up and break down DMA pathways, and derive mapped addresses for use by hardware devices and processor cards.

The ballot group felt that this was beyond the scope of POSIX.1 and its amendments. Furthermore, the removal of interrupt handling interfaces from a preceding amendment (the IEEE Std 1003.1d-1999) during its balloting process renders these typed memory access management interfaces an incomplete solution to portable device management from a user process; it would be possible to initiate a device transfer to/from typed memory, but impossible to handle the transfer-complete interrupt in a portable way.

To achieve ballot group consensus, all references to typed memory access management capabilities were removed. The concept of portable interfaces from a device driver to both operating system and hardware is being addressed by the Uniform Driver Interface (UDI) industry forum, with formal standardization deferred until proof of concept and industry-wide acceptance and implementation.

B.2.8.4 Process Scheduling

IEEE PASC Interpretation 1003.1 #96 has been applied, adding the `pthread_setschedprio()` function. This was added since previously there was no way for a thread to lower its own priority without going to the tail of the threads list for its new priority. This capability is necessary to bound the duration of priority inversion encountered by a thread.

The following portion of the rationale presents models, requirements, and standardization issues relevant to process scheduling; see also Section B.2.9.4 (on page 167).

In an operating system supporting multiple concurrent processes, the system determines the order in which processes execute to meet implementation-defined goals. For time-sharing systems, the goal is to enhance system throughput and promote fairness; the application is provided with little or no control over this sequencing function. While this is acceptable and desirable behavior in a time-sharing system, it is inappropriate in a realtime system; realtime applications must specifically control the execution sequence of their concurrent processes in order to meet externally defined response requirements.

In IEEE Std 1003.1-2001, the control over process sequencing is provided using a concept of scheduling policies. These policies, described in detail in this section, define the behavior of the system whenever processor resources are to be allocated to competing processes. Only the behavior of the policy is defined; conforming implementations are free to use any mechanism...
desired to achieve the described behavior.

- **Models**

In an operating system supporting multiple concurrent processes, the system determines the order in which processes execute and might force long-running processes to yield to other processes at certain intervals. Typically, the scheduling code is executed whenever an event occurs that might alter the process to be executed next.

The simplest scheduling strategy is a “first-in, first-out” (FIFO) dispatcher. Whenever a process becomes runnable, it is placed on the end of a ready list. The process at the front of the ready list is executed until it exits or becomes blocked, at which point it is removed from the list. This scheduling technique is also known as “run-to-completion” or “run-to-block”.

A natural extension to this scheduling technique is the assignment of a “non-migrating priority” to each process. This policy differs from strict FIFO scheduling in only one respect: whenever a process becomes runnable, it is placed at the end of the list of processes runnable at that priority level. When selecting a process to run, the system always selects the first process from the highest priority queue with a runnable process. Thus, when a process becomes unblocked, it will preempt a running process of lower priority without otherwise altering the ready list. Further, if a process elects to alter its priority, it is removed from the ready list and reinserted, using its new priority, according to the policy above.

While the above policy might be considered unfriendly in a time-sharing environment in which multiple users require more balanced resource allocation, it could be ideal in a realtime environment for several reasons. The most important of these is that it is deterministic: the highest-priority process is always run and, among processes of equal priority, the process that has been runnable for the longest time is executed first. Because of this determinism, cooperating processes can implement more complex scheduling simply by altering their priority. For instance, if processes at a single priority were to reschedule themselves at fixed time intervals, a time-slice policy would result.

In a dedicated operating system in which all processes are well-behaved realtime applications, non-migrating priority scheduling is sufficient. However, many existing implementations provide for more complex scheduling policies.

IEEE Std 1003.1-2001 specifies a linear scheduling model. In this model, every process in the system has a priority. The system scheduler always dispatches a process that has the highest (generally the most time-critical) priority among all runnable processes in the system. As long as there is only one such process, the dispatching policy is trivial. When multiple processes of equal priority are eligible to run, they are ordered according to a strict run-to-completion (FIFO) policy.

The priority is represented as a positive integer and is inherited from the parent process. For processes running under a fixed priority scheduling policy, the priority is never altered except by an explicit function call.

It was determined arbitrarily that larger integers correspond to “higher priorities”.

Certain implementations might impose restrictions on the priority ranges to which processes can be assigned. There also can be restrictions on the set of policies to which processes can be set.

- **Requirements**

Realtime processes require that scheduling be fast and deterministic, and that it guarantees to preempt lower priority processes.
Thus, given the linear scheduling model, realtime processes require that they be run at a priority that is higher than other processes. Within this framework, realtime processes are free to yield execution resources to each other in a completely portable and implementation-defined manner.

As there is a generally perceived requirement for processes at the same priority level to share processor resources more equitably, provisions are made by providing a scheduling policy (that is, SCHED_RR) intended to provide a timeslice-like facility.

**Note:** The following topics assume that low numeric priority implies low scheduling criticality and vice versa.

- **Rationale for New Interface**

  Realtime applications need to be able to determine when processes will run in relation to each other. It must be possible to guarantee that a critical process will run whenever it is runnable; that is, whenever it wants to for as long as it needs. SCHED_FIFO satisfies this requirement. Additionally, SCHED_RR was defined to meet a realtime requirement for a well-defined time-sharing policy for processes at the same priority.

  It would be possible to use the BSD `setpriority()` and `getpriority()` functions by redefining the meaning of the “nice” parameter according to the scheduling policy currently in use by the process. The System V `nice()` interface was felt to be undesirable for realtime because it specifies an adjustment to the “nice” value, rather than setting it to an explicit value. Realtime applications will usually want to set priority to an explicit value. Also, System V `nice()` does not allow for changing the priority of another process.

  With the POSIX.1b interfaces, the traditional “nice” value does not affect the SCHED_FIFO or SCHED_RR scheduling policies. If a “nice” value is supported, it is implementation-defined whether it affects the SCHED_OTHER policy.

  An important aspect of IEEE Std 1003.1-2001 is the explicit description of the queuing and preemption rules. It is critical, to achieve deterministic scheduling, that such rules be stated clearly in IEEE Std 1003.1-2001.

  IEEE Std 1003.1-2001 does not address the interaction between priority and swapping. The issues involved with swapping and virtual memory paging are extremely implementation-defined and would be nearly impossible to standardize at this point. The proposed scheduling paradigm, however, fully describes the scheduling behavior of runnable processes, of which one criterion is that the working set be resident in memory. Assuming the existence of a portable interface for locking portions of a process in memory, paging behavior need not affect the scheduling of realtime processes.

  IEEE Std 1003.1-2001 also does not address the priorities of “system” processes. In general, these processes should always execute in low-priority ranges to avoid conflict with other realtime processes. Implementations should document the priority ranges in which system processes run.

  The default scheduling policy is not defined. The effect of I/O interrupts and other system processing activities is not defined. The temporary lending of priority from one process to another (such as for the purposes of affecting freeing resources) by the system is not addressed. Preemption of resources is not addressed. Restrictions on the ability of a process to affect other processes beyond a certain level (influence levels) is not addressed.

  The rationale used to justify the simple time-quantum scheduler is that it is common practice to depend upon this type of scheduling to ensure “fair” distribution of processor resources among portions of the application that must interoperate in a serial fashion. Note that IEEE Std 1003.1-2001 is silent with respect to the setting of this time quantum, or whether it is
a system-wide value or a per-process value, although it appears that the prevailing realtime practice is for it to be a system-wide value.

In a system with \( N \) processes at a given priority, all processor-bound, in which the time quantum is equal for all processes at a specific priority level, the following assumptions are made of such a scheduling policy:

1. A time quantum \( Q \) exists and the current process will own control of the processor for at least a duration of \( Q \) and will have the processor for a duration of \( Q \).

2. The \( N \)th process at that priority will control a processor within a duration of \((N-1) \times Q\).

These assumptions are necessary to provide equal access to the processor and bounded response from the application.

The assumptions hold for the described scheduling policy only if no system overhead, such as interrupt servicing, is present. If the interrupt servicing load is non-zero, then one of the two assumptions becomes fallacious, based upon how \( Q \) is measured by the system.

If \( Q \) is measured by clock time, then the assumption that the process obtains a duration \( Q \) processor time is false if interrupt overhead exists. Indeed, a scenario can be constructed with \( N \) processes in which a single process undergoes complete processor starvation if a peripheral device, such as an analog-to-digital converter, generates significant interrupt activity periodically with a period of \( N \times Q \).

If \( Q \) is measured as actual processor time, then the assumption that the \( N \)th process runs in within the duration \((N-1) \times Q\) is false.

It should be noted that SCHED_FIFO suffers from interrupt-based delay as well. However, for SCHED_FIFO, the implied response of the system is ‘as soon as possible’, so that the interrupt load for this case is a vendor selection and not a compliance issue.

With this in mind, it is necessary either to complete the definition by including bounds on the interrupt load, or to modify the assumptions that can be made about the scheduling policy.

Since the motivation of inclusion of the policy is common usage, and since current applications do not enjoy the luxury of bounded interrupt load, item (2) above is sufficient to express existing application needs and is less restrictive in the standard definition. No difference in interface is necessary.

In an implementation in which the time quantum is equal for all processes at a specific priority, our assumptions can then be restated as:

— A time quantum \( Q \) exists, and a processor-bound process will be rescheduled after a duration of, at most, \( Q \). Time quantum \( Q \) may be defined in either wall clock time or execution time.

— In general, the \( N \)th process of a priority level should wait no longer than \((N-1) \times Q\) time to execute, assuming no processes exist at higher priority levels.

— No process should wait indefinitely.

For implementations supporting per-process time quanta, these assumptions can be readily extended.
Sporadic Server Scheduling Policy

The sporadic server is a mechanism defined for scheduling aperiodic activities in time-critical realtime systems. This mechanism reserves a certain bounded amount of execution capacity for processing aperiodic events at a high priority level. Any aperiodic events that cannot be processed within the bounded amount of execution capacity are executed in the background at a low priority level. Thus, a certain amount of execution capacity can be guaranteed to be available for processing periodic tasks, even under burst conditions in the arrival of aperiodic processing requests (that is, a large number of requests in a short time interval). The sporadic server also simplifies the schedulability analysis of the realtime system, because it allows aperiodic processes or threads to be treated as if they were periodic. The sporadic server was first described by Sprunt, et al.

The key concept of the sporadic server is to provide and limit a certain amount of computation capacity for processing aperiodic events at their assigned normal priority, during a time interval called the "replenishment period". Once the entity controlled by the sporadic server mechanism is initialized with its period and execution-time budget attributes, it preserves its execution capacity until an aperiodic request arrives. The request will be serviced (if there are no higher priority activities pending) as long as there is execution capacity left. If the request is completed, the actual execution time used to service it is subtracted from the capacity, and a replenishment of this amount of execution time is scheduled to happen one replenishment period after the arrival of the aperiodic request. If the request is not completed, because there is no execution capacity left, then the aperiodic process or thread is assigned a lower background priority. For each portion of consumed execution capacity the execution time used is replenished after one replenishment period. At the time of replenishment, if the sporadic server was executing at a background priority level, its priority is elevated to the normal level. Other similar replenishment policies have been defined, but the one presented here represents a compromise between efficiency and implementation complexity.

The interface that appears in this section defines a new scheduling policy for threads and processes that behaves according to the rules of the sporadic server mechanism. Scheduling attributes are defined and functions are provided to allow the user to set and get the parameters that control the scheduling behavior of this mechanism, namely the normal and low priority, the replenishment period, the maximum number of pending replenishment operations, and the initial execution-time budget.

- Scheduling Aperiodic Activities

Virtually all realtime applications are required to process aperiodic activities. In many cases, there are tight timing constraints that the response to the aperiodic events must meet. Usual timing requirements imposed on the response to these events are:

- The effects of an aperiodic activity on the response time of lower priority activities must be controllable and predictable.
- The system must provide the fastest possible response time to aperiodic events.
- It must be possible to take advantage of all the available processing bandwidth not needed by time-critical activities to enhance average-case response times to aperiodic events.

Traditional methods for scheduling aperiodic activities are background processing, polling tasks, and direct event execution:

- Background processing consists of assigning a very low priority to the processing of aperiodic events. It utilizes all the available bandwidth in the system that has not been consumed by higher priority threads. However, it is very difficult, or impossible, to meet...
requirements on average-case response time, because the aperiodic entity has to wait for
the execution of all other entities which have higher priority.

— Polling consists of creating a periodic process or thread for servicing aperiodic requests.
At regular intervals, the polling entity is started and its services accumulated pending
aperiodic requests. If no aperiodic requests are pending, the polling entity suspends itself
until its next period. Polling allows the aperiodic requests to be processed at a higher
priority level. However, worst and average-case response times of polling entities are a
direct function of the polling period, and there is execution overhead for each polling
period, even if no event has arrived. If the deadline of the aperiodic activity is short
compared to the inter-arrival time, the polling frequency must be increased to guarantee
meeting the deadline. For this case, the increase in frequency can dramatically reduce the
efficiency of the system and, therefore, its capacity to meet all deadlines. Yet, polling
represents a good way to handle a large class of practical problems because it preserves
system predictability, and because the amortized overhead drops as load increases.

— Direct event execution consists of executing the aperiodic events at a high fixed-priority
level. Typically, the aperiodic event is processed by an interrupt service routine as soon as
it arrives. This technique provides predictable response times for aperiodic events, but
makes the response times of all lower priority activities completely unpredictable under
burst arrival conditions. Therefore, if the density of aperiodic event arrivals is
unbounded, it may be a dangerous technique for time-critical systems. Yet, for those cases
in which the physics of the system imposes a bound on the event arrival rate, it is
probably the most efficient technique.

— The sporadic server scheduling algorithm combines the predictability of the polling
approach with the short response times of the direct event execution. Thus, it allows
systems to meet an important class of application requirements that cannot be met by
using the traditional approaches. Multiple sporadic servers with different attributes can
be applied to the scheduling of multiple classes of aperiodic events, each with different
kinds of timing requirements, such as individual deadlines, average response times, and
so on. It also has many other interesting applications for realtime, such as scheduling
producer/consumer tasks in time-critical systems, limiting the effects of faults on the
estimation of task execution-time requirements, and so on.

• Existing Practice

The sporadic server has been used in different kinds of applications, including military
avionics, robot control systems, industrial automation systems, and so on. There are
examples of many systems that cannot be successfully scheduled using the classic
approaches, such as direct event execution, or polling, and are schedulable using a sporadic
server scheduler. The sporadic server algorithm itself can successfully schedule all systems
scheduled with direct event execution or polling.

The sporadic server scheduling policy has been implemented as a commercial product in the
run-time system of the Veridix Ada compiler. There are also many applications that have
used a much less efficient application-level sporadic server. These realtime applications
would benefit from a sporadic server scheduler implemented at the scheduler level.

• Library-Level versus Kernel-Level Implementation

The sporadic server interface described in this section requires the sporadic server policy to
be implemented at the same level as the scheduler. This means that the process sporadic
server must be implemented at the kernel level and the thread sporadic server policy
implemented at the same level as the thread scheduler; that is, kernel or library level.
In an earlier interface for the sporadic server, this mechanism was implementable at a different level than the scheduler. This feature allowed the implementor to choose between an efficient scheduler-level implementation, or a simpler user or library-level implementation. However, the working group considered that this interface made the use of sporadic servers more complex, and that library-level implementations would lack some of the important functionality of the sporadic server, namely the limitation of the actual execution time of aperiodic activities. The working group also felt that the interface described in this chapter does not preclude library-level implementations of threads intended to provide efficient low-overhead scheduling for those threads that are not scheduled under the sporadic server policy.

- Range of Scheduling Priorities

Each of the scheduling policies supported in IEEE Std 1003.1-2001 has an associated range of priorities. The priority ranges for each policy might or might not overlap with the priority ranges of other policies. For time-critical realtime applications it is usual for periodic and aperiodic activities to be scheduled together in the same processor. Periodic activities will usually be scheduled using the SCHED_FIFO scheduling policy, while aperiodic activities may be scheduled using SCHED_SPORADIC. Since the application developer will require complete control over the relative priorities of these activities in order to meet his timing requirements, it would be desirable for the priority ranges of SCHED_FIFO and SCHED_SPORADIC to overlap completely. Therefore, although IEEE Std 1003.1-2001 does not require any particular relationship between the different priority ranges, it is recommended that these two ranges should coincide.

- Dynamically Setting the Sporadic Server Policy

Several members of the working group requested that implementations should not be required to support dynamically setting the sporadic server scheduling policy for a thread. The reason is that this policy may have a high overhead for library-level implementations of threads, and if threads are allowed to dynamically set this policy, this overhead can be experienced even if the thread does not use that policy. By disallowing the dynamic setting of the sporadic server scheduling policy, these implementations can accomplish efficient scheduling for threads using other policies. If a strictly conforming application needs to use the sporadic server policy, and is therefore willing to pay the overhead, it must set this policy at the time of thread creation.

- Limitation of the Number of Pending Replenishments

The number of simultaneously pending replenishment operations must be limited for each sporadic server for two reasons: an unlimited number of replenishment operations would need an unlimited number of system resources to store all the pending replenishment operations; on the other hand, in some implementations each replenishment operation will represent a source of priority inversion (just for the duration of the replenishment operation) and thus, the maximum amount of replenishments must be bounded to guarantee bounded response times. The way in which the number of replenishments is bounded is by lowering the priority of the sporadic server to sched_ss_low_priority when the number of pending replenishments has reached its limit. In this way, no new replenishments are scheduled until the number of pending replenishments decreases.

In the sporadic server scheduling policy defined in IEEE Std 1003.1-2001, the application can specify the maximum number of pending replenishment operations for a single sporadic server, by setting the value of the sched_ss_max_repl scheduling parameter. This value must be between one and SS_REPL_MAX, which is a maximum limit imposed by the implementation. The limit SS_REPL_MAX must be greater than or equal to _POSIX_SS_REPL_MAX, which is defined to be four in IEEE Std 1003.1-2001. The minimum
limit of four was chosen so that an application can at least guarantee that four different aperiodic events can be processed during each interval of length equal to the replenishment period.

B.2.8.5 Clocks and Timers

- Clocks

IEEE Std 1003.1-2001 and the ISO C standard both define functions for obtaining system time. Implicit behind these functions is a mechanism for measuring passage of time. This specification makes this mechanism explicit and calls it a clock. The CLOCK_REALTIME clock required by IEEE Std 1003.1-2001 is a higher resolution version of the clock that maintains POSIX.1 system time. This is a “system-wide” clock, in that it is visible to all processes and, were it possible for multiple processes to all read the clock at the same time, they would see the same value.

An extensible interface was defined, with the ability for implementations to define additional clocks. This was done because of the observation that many realtime platforms support multiple clocks, and it was desired to fit this model within the standard interface. But implementation-defined clocks need not represent actual hardware devices, nor are they necessarily system-wide.

- Timers

Two timer types are required for a system to support realtime applications:

1. One-shot

A one-shot timer is a timer that is armed with an initial expiration time, either relative to the current time or at an absolute time (based on some timing base, such as time in seconds and nanoseconds since the Epoch). The timer expires once and then is disarmed. With the specified facilities, this is accomplished by setting the it_value member of the value argument to the desired expiration time and the it_interval member to zero.

2. Periodic

A periodic timer is a timer that is armed with an initial expiration time, again either relative or absolute, and a repetition interval. When the initial expiration occurs, the timer is reloaded with the repetition interval and continues counting. With the specified facilities, this is accomplished by setting the it_value member of the value argument to the desired initial expiration time and the it_interval member to the desired repetition interval.

For both of these types of timers, the time of the initial timer expiration can be specified in two ways:

1. Relative (to the current time)

2. Absolute

- Examples of Using Realtime Timers

In the diagrams below, S indicates a program schedule, R shows a schedule method request, and E suggests an internal operating system event.

- Periodic Timer: Data Logging

During an experiment, it might be necessary to log realtime data periodically to an internal buffer or to a mass storage device. With a periodic scheduling method, a logging
module can be started automatically at fixed time intervals to log the data.

Program schedule is requested every 10 seconds.

---+---+---+---+---+---+---+---+---+---+---+--->
R S S S S S S S S S S S
5 10 15 20 25 30 35 40 45 50 55

[Time (in Seconds)]

To achieve this type of scheduling using the specified facilities, one would allocate a per-process timer based on clock ID CLOCK_REALTIME. Then the timer would be armed via a call to `timer_settime()` with the TIMER_ABSTIME flag reset, and with an initial expiration value and a repetition interval of 10 seconds.

--- One-shot Timer (Relative Time): Device Initialization

In an emission test environment, large sample bags are used to capture the exhaust from a vehicle. The exhaust is purged from these bags before each and every test. With a one-shot timer, a module could initiate the purge function and then suspend itself for a predetermined period of time while the sample bags are prepared.

Program schedule requested 20 seconds after call is issued.

---+---+---+---+---+---+---+---+---+---+---+--->
R S S S S S S S S S S S
5 10 15 20 25 30 35 40 45 50 55

[Time (in Seconds)]

To achieve this type of scheduling using the specified facilities, one would allocate a per-process timer based on clock ID CLOCK_REALTIME. Then the timer would be armed via a call to `timer_settime()` with the TIMER_ABSTIME flag reset, and with an initial expiration value of 20 seconds and a repetition interval of zero.

Note that if the program wishes merely to suspend itself for the specified interval, it could more easily use `nanosleep()`.

--- One-shot Timer (Absolute Time): Data Transmission

The results from an experiment are often moved to a different system within a network for postprocessing or archiving. With an absolute one-shot timer, a module that moves data from a test-cell computer to a host computer can be automatically scheduled on a daily basis.

Program schedule requested for 2:30 a.m.

---+---+---+---+---+---+---+---+---+---+---+--->
R S S S S S S S S S S S
23:00 23:30 24:00 00:30 01:00 01:30 02:00 02:30 03:00

[Time of Day]

To achieve this type of scheduling using the specified facilities, a per-process timer would be allocated based on clock ID CLOCK_REALTIME. Then the timer would be armed via a call to `timer_settime()` with the TIMER_ABSTIME flag set, and an initial expiration value equal to 2:30 a.m. of the next day.

--- Periodic Timer (Relative Time): Signal Stabilization

Some measurement devices, such as emission analyzers, do not respond instantaneously to an introduced sample. With a periodic timer with a relative initial expiration time, a
module that introduces a sample and records the average response could suspend itself for a predetermined period of time while the signal is stabilized and then sample at a fixed rate.

Program schedule requested 15 seconds after call is issued and every 2 seconds thereafter.

---+---+---+---+---+---+---+---+---+---+---+---
   5 10 15 20 25 30 35 40 45 50 55
[Time (in Seconds)]

To achieve this type of scheduling using the specified facilities, one would allocate a per-process timer based on clock ID CLOCK_REALTIME. Then the timer would be armed via a call to `timer_settime()` with TIMER_ABSTIME flag reset, and with an initial expiration value of 15 seconds and a repetition interval of 2 seconds.

— Periodic Timer (Absolute Time): Work Shift-related Processing

Resource utilization data is useful when time to perform experiments is being scheduled at a facility. With a periodic timer with an absolute initial expiration time, a module can be scheduled at the beginning of a work shift to gather resource utilization data throughout the shift. This data can be used to allocate resources effectively to minimize bottlenecks and delays and maximize facility throughput.

Program schedule requested for 2:00 a.m. and every 15 minutes thereafter.

---+---+---+---+---+---+---+---+---+---+---+---
 23:00 23:30 24:00 00:30 01:00 01:30 02:00 02:30 03:00
[Time of Day]

To achieve this type of scheduling using the specified facilities, one would allocate a per-process timer based on clock ID CLOCK_REALTIME. Then the timer would be armed via a call to `timer_settime()` with TIMER_ABSTIME flag set, and with an initial expiration value equal to 2:00 a.m. and a repetition interval equal to 15 minutes.

• Relationship of Timers to Clocks

The relationship between clocks and timers armed with an absolute time is straightforward: a timer expiration signal is requested when the associated clock reaches or exceeds the specified time. The relationship between clocks and timers armed with a relative time (an interval) is less obvious, but not unintuitive. In this case, a timer expiration signal is requested when the specified interval, as measured by the associated clock, has passed. For the required CLOCK_REALTIME clock, this allows timer expiration signals to be requested at specified ‘wall clock’ times (absolute), or when a specified interval of ‘realtime’ has passed (relative). For an implementation-defined clock—say, a process virtual time clock—timer expirations could be requested when the process has used a specified total amount of virtual time (absolute), or when it has used a specified additional amount of virtual time (relative).

The interfaces also allow flexibility in the implementation of the functions. For example, an implementation could convert all absolute times to intervals by subtracting the clock value at the time of the call from the requested expiration time and “counting down” at the supported resolution. Or it could convert all relative times to absolute expiration time by adding in the clock value at the time of the call and comparing the clock value to the expiration time at the supported resolution. Or it might even choose to maintain absolute times as absolute and compare them to the clock value at the supported resolution for absolute timers, and maintain relative times as intervals and count them down at the
resolution supported for relative timers. The choice will be driven by efficiency considerations and the underlying hardware or software clock implementation.

- Data Definitions for Clocks and Timers

IEEE Std 1003.1-2001 uses a time representation capable of supporting nanosecond resolution timers for the following reasons:

- To enable IEEE Std 1003.1-2001 to represent those computer systems already using nanosecond or submicrosecond resolution clocks.

- To accommodate those per-process timers that might need nanoseconds to specify an absolute value of system-wide clocks, even though the resolution of the per-process timer may only be milliseconds, or vice versa.

- Because the number of nanoseconds in a second can be represented in 32 bits.

Time values are represented in the timespec structure. The tv_sec member is of type time_t so that this member is compatible with time values used by POSIX.1 functions and the ISO C standard. The tv_nsec member is a signed long in order to simplify and clarify code that decrements or finds differences of time values. Note that because 1 billion (number of nanoseconds per second) is less than half of the value representable by a signed 32-bit value, it is always possible to add two valid fractional seconds represented as integral nanoseconds without overflowing the signed 32-bit value.

A maximum allowable resolution for the CLOCK_REALTIME clock of 20 ms (1/50 seconds) was chosen to allow line frequency clocks in European countries to be conforming. 60 Hz clocks in the U.S. will also be conforming, as will finer granularity clocks, although a Strictly Conforming Application cannot assume a granularity of less than 20 ms (1/50 seconds).

The minimum allowable maximum time allowed for the CLOCK_REALTIME clock and the function nanosleep(), and timers created with clock_id=CLOCK_REALTIME, is determined by the fact that the tv_sec member is of type time_t.

IEEE Std 1003.1-2001 specifies that timer expirations must not be delivered early, and nanosleep() must not return early due to quantization error. IEEE Std 1003.1-2001 discusses the various implementations of alarm() in the rationale and states that implementations that do not allow alarm signals to occur early are the most appropriate, but refrained from mandating this behavior. Because of the importance of predictability to realtime applications, IEEE Std 1003.1-2001 takes a stronger stance.

The developers of IEEE Std 1003.1-2001 considered using a time representation that differs from POSIX.1b in the second 32 bit of the 64-bit value. Whereas POSIX.1b defines this field as a fractional second in nanoseconds, the other methodology defines this as a binary fraction of one second, with the radix point assumed before the most significant bit.

POSIX.1b is a software, source-level standard and most of the benefits of the alternate representation are enjoyed by hardware implementations of clocks and algorithms. It was felt that mandating this format for POSIX.1b clocks and timers would unnecessarily burden the application writer with writing, possibly non-portable, multiple precision arithmetic packages to perform conversion between binary fractions and integral units such as nanoseconds, milliseconds, and so on.
Rationale for the Monotonic Clock

For those applications that use time services to achieve realtime behavior, changing the value of the clock on which these services rely may cause erroneous timing behavior. For these applications, it is necessary to have a monotonic clock which cannot run backwards, and which has a maximum clock jump that is required to be documented by the implementation. Additionally, it is desirable (but not required by IEEE Std 1003.1-2001) that the monotonic clock increases its value uniformly. This clock should not be affected by changes to the system time; for example, to synchronize the clock with an external source or to account for leap seconds. Such changes would cause errors in the measurement of time intervals for those time services that use the absolute value of the clock.

One could argue that by defining the behavior of time services when the value of a clock is changed, deterministic realtime behavior can be achieved. For example, one could specify that relative time services should be unaffected by changes in the value of a clock. However, there are time services that are based upon an absolute time, but that are essentially intended as relative time services. For example, `pthread_cond_timedwait()` uses an absolute time to allow it to wake up after the required interval despite spurious wakeups. Although sometimes the `pthread_cond_timedwait()` timeouts are absolute in nature, there are many occasions in which they are relative, and their absolute value is determined from the current time plus a relative time interval. In this latter case, if the clock changes while the thread is waiting, the wait interval will not be the expected length. If a `pthread_cond_timedwait()` function were created that would take a relative time, it would not solve the problem because to retain the intended ‘‘deadline’’ a thread would need to compensate for latency due to the spurious wakeup, and preemption between wakeup and the next wait.

The solution is to create a new monotonic clock, whose value does not change except for the regular ticking of the clock, and use this clock for implementing the various relative timeouts that appear in the different POSIX interfaces, as well as allow `pthread_cond_timedwait()` to choose this new clock for its timeout. A new `clock_nanosleep()` function is created to allow an application to take advantage of this newly defined clock. Notice that the monotonic clock may be implemented using the same hardware clock as the system clock.

Relative timeouts for `sigtimedwait()` and `aio_suspend()` have been redefined to use the monotonic clock, if present. The `alarm()` function has not been redefined, because the same effect but with better resolution can be achieved by creating a timer (for which the appropriate clock may be chosen).

The `pthread_cond_timedwait()` function has been treated in a different way, compared to other functions with absolute timeouts, because it is used to wait for an event, and thus it may have a deadline, while the other timeouts are generally used as an error recovery mechanism, and for them the use of the monotonic clock is not so important. Since the desired timeout for the `pthread_cond_timedwait()` function may either be a relative interval or an absolute time of day deadline, a new initialization attribute has been created for condition variables to specify the clock that is used for measuring the timeout in a call to `pthread_cond_timedwait()`. In this way, if a relative timeout is desired, the monotonic clock will be used; if an absolute deadline is required instead, the CLOCK_REALTIME or another appropriate clock may be used. This capability has not been added to other functions with absolute timeouts because for those functions the expected use of the timeout is mostly to prevent errors, and not so often to meet precise deadlines. As a consequence, the complexity of adding this capability is not justified by its perceived application usage.

The `nanosleep()` function has not been modified with the introduction of the monotonic clock. Instead, a new `clock_nanosleep()` function has been created, in which the desired clock may be specified in the function call.
• History of Resolution Issues

Due to the shift from relative to absolute timeouts in IEEE Std 1003.1d-1999, the amendments to the `sem_timedwait()`, `pthread_mutex_timedlock()`, `mq_timedreceive()`, and `mq_timedsend()` functions of that standard have been removed. Those amendments specified that CLOCK_MONOTONIC would be used for the (relative) timeouts if the Monotonic Clock option was supported.

Having these functions continue to be tied solely to CLOCK_MONOTONIC would not work. Since the absolute value of a time value obtained from CLOCK_MONOTONIC is unspecified, under the absolute timeouts interface, applications would behave differently depending on whether the Monotonic Clock option was supported or not (because the absolute value of the clock would have different meanings in either case).

Two options were considered:

1. Leave the current behavior unchanged, which specifies the CLOCK_REALTIME clock for these (absolute) timeouts, to allow portability of applications between implementations supporting or not the Monotonic Clock option.

2. Modify these functions in the way that `pthread_cond_timedwait()` was modified to allow a choice of clock, so that an application could use CLOCK_REALTIME when it is trying to achieve an absolute timeout and CLOCK_MONOTONIC when it is trying to achieve a relative timeout.

It was decided that the features of CLOCK_MONOTONIC are not as critical to these functions as they are to `pthread_cond_timedwait()`. The `pthread_cond_timedwait()` function is given a relative timeout; the timeout may represent a deadline for an event. When these functions are given relative timeouts, the timeouts are typically for error recovery purposes and need not be so precise.

Therefore, it was decided that these functions should be tied to CLOCK_REALTIME and not complicated by being given a choice of clock.

Execution Time Monitoring

• Introduction

The main goals of the execution time monitoring facilities defined in this chapter are to measure the execution time of processes and threads and to allow an application to establish CPU time limits for these entities.

The analysis phase of time-critical realtime systems often relies on the measurement of execution times of individual threads or processes to determine whether the timing requirements will be met. Also, performance analysis techniques for soft deadline realtime systems rely heavily on the determination of these execution times. The execution time monitoring functions provide application developers with the ability to measure these execution times online and open the possibility of dynamic execution-time analysis and system reconfiguration, if required.

The second goal of allowing an application to establish execution time limits for individual processes or threads and detecting when they overrun allows program robustness to be increased by enabling online checking of the execution times.

If errors are detected—possibly because of erroneous program constructs, the existence of errors in the analysis phase, or a burst of event arrivals—online detection and recovery is possible in a portable way. This feature can be extremely important for many time-critical applications. Other applications require trapping CPU-time errors as a normal way to exit an
algorithm; for instance, some realtime artificial intelligence applications trigger a number of
independent inference processes of varying accuracy and speed, limit how long they can run,
and pick the best answer available when time runs out. In many periodic systems, overrun
processes are simply restarted in the next resource period, after necessary end-of-period
actions have been taken. This allows algorithms that are inherently data-dependent to be
made predictable.

The interface that appears in this chapter defines a new type of clock, the CPU-time clock,
which measures execution time. Each process or thread can invoke the clock and timer
functions defined in POSIX.1 to use them. Functions are also provided to access the CPU-
time clock of other processes or threads to enable remote monitoring of these clocks.
Monitoring of threads of other processes is not supported, since these threads are not visible
from outside of their own process with the interfaces defined in POSIX.1.

• Execution Time Monitoring Interface

The clock and timer interface defined in POSIX.1 historically only defined one clock, which
measures wall-clock time. The requirements for measuring execution time of processes and
threads, and setting limits to their execution time by detecting when they overrun, can be
accomplished with that interface if a new kind of clock is defined. These new clocks measure
execution time, and one is associated with each process and with each thread. The clock
functions currently defined in POSIX.1 can be used to read and set these CPU-time clocks,
and timers can be created using these clocks as their timing base. These timers can then be
used to send a signal when some specified execution time has been exceeded. The CPU-time
clocks of each process or thread can be accessed by using the symbols
CLOCK_PROCESS_CPUTIME_ID or CLOCK_THREAD_CPUTIME_ID.

The clock and timer interface defined in POSIX.1 and extended with the new kind of CPU-
time clock would only allow processes or threads to access their own CPU-time clocks.
However, many realtime systems require the possibility of monitoring the execution time of
processes or threads from independent monitoring entities. In order to allow applications to
construct independent monitoring entities that do not require cooperation from or
modification of the monitored entities, two functions have been added: clock_getcpuclockid(),
for accessing CPU-time clocks of other processes, and pthread_getcpuclockid(), for accessing
CPU-time clocks of other threads. These functions return the clock identifier associated with
the process or thread specified in the call. These clock IDs can then be used in the rest of the
clock function calls.

The clocks accessed through these functions could also be used as a timing base for the
creation of timers, thereby allowing independent monitoring entities to limit the CPU time
consumed by other entities. However, this possibility would imply additional complexity
and overhead because of the need to maintain a timer queue for each process or thread, to
store the different expiration times associated with timers created by different processes or
threads. The working group decided this additional overhead was not justified by
application requirements. Therefore, creation of timers attached to the CPU-time clocks of
other processes or threads has been specified as implementation-defined.

• Overhead Considerations

The measurement of execution time may introduce additional overhead in the thread
scheduling, because of the need to keep track of the time consumed by each of these entities.
In library-level implementations of threads, the efficiency of scheduling could be somehow
compromised because of the need to make a kernel call, at each context switch, to read the
process CPU-time clock. Consequently, a thread creation attribute called cpu-clock-
requirement was defined, to allow threads to disconnect their respective CPU-time clocks.
However, the Ballot Group considered that this attribute itself introduced some overhead,
and that in current implementations it was not worth the effort. Therefore, the attribute was
deleted, and thus thread CPU-time clocks are required for all threads if the Thread CPU-Time
Clocks option is supported.

- Accuracy of CPU-Time Clocks

The mechanism used to measure the execution time of processes and threads is specified in
IEEE Std 1003.1-2001 as implementation-defined. The reason for this is that both the
underlying hardware and the implementation architecture have a very strong influence on
the accuracy achievable for measuring CPU time. For some implementations, the
specification of strict accuracy requirements would represent very large overheads, or even
the impossibility of being implemented.

Since the mechanism for measuring execution time is implementation-defined, realtime
applications will be able to take advantage of accurate implementations using a portable
interface. Of course, strictly conforming applications cannot rely on any particular degree of
accuracy, in the same way as they cannot rely on a very accurate measurement of wall clock
time. There will always exist applications whose accuracy or efficiency requirements on the
implementation are more rigid than the values defined in IEEE Std 1003.1-2001 or any other
standard.

In any case, there is a minimum set of characteristics that realtime applications would expect
from most implementations. One such characteristic is that the sum of all the execution times
of all the threads in a process equals the process execution time, when no CPU-time clocks
are disabled. This need not always be the case because implementations may differ in how
they account for time during context switches. Another characteristic is that the sum of the
execution times of all processes in a system equals the number of processors, multiplied by
the elapsed time, assuming that no processor is idle during that elapsed time. However, in
some implementations it might not be possible to relate CPU time to elapsed time. For
example, in a heterogeneous multi-processor system in which each processor runs at a
different speed, an implementation may choose to define each “second” of CPU time to be a
certain number of “cycles” that a CPU has executed.

- Existing Practice

Measuring and limiting the execution time of each concurrent activity are common features
of most industrial implementations of realtime systems. Almost all critical realtime systems
are currently built upon a cyclic executive. With this approach, a regular timer interrupt kicks
off the next sequence of computations. It also checks that the current sequence has
completed. If it has not, then some error recovery action can be undertaken (or at least an
overrun is avoided). Current software engineering principles and the increasing complexity
of software are driving application developers to implement these systems on multi-
threaded or multi-process operating systems. Therefore, if a POSIX operating system is to be
used for this type of application, then it must offer the same level of protection.

Execution time clocks are also common in most UNIX implementations, although these
clocks usually have requirements different from those of realtime applications. The POSIX.1
times() function supports the measurement of the execution time of the calling process, and
its terminated child processes. This execution time is measured in clock ticks and is supplied
as two different values with the user and system execution times, respectively. BSD supports
the function getrusage(), which allows the calling process to get information about the
resources used by itself and/or all of its terminated child processes. The resource usage
includes user and system CPU time. Some UNIX systems have options to specify high
resolution (up to one microsecond) CPU-time clocks using the times() or the getrusage()
The `times()` and `getrusage()` interfaces do not meet important realtime requirements, such as the possibility of monitoring execution time from a different process or thread, or the possibility of detecting an execution time overrun. The latter requirement is supported in some UNIX implementations that are able to send a signal when the execution time of a process has exceeded some specified value. For example, BSD defines the functions `getitimer()` and `setitimer()`, which can operate either on a realtime clock (wall-clock), or on virtual-time or profile-time clocks which measure CPU time in two different ways. These functions do not support access to the execution time of other processes.

IBM's MVS operating system supports per-process and per-thread execution time clocks. It also supports limiting the execution time of a given process.

Given all this existing practice, the working group considered that the POSIX.1 clocks and timers interface was appropriate to meet most of the requirements that realtime applications have for execution time clocks. Functions were added to get the CPU time clock IDs, and to allow/disallow the thread CPU-time clocks (in order to preserve the efficiency of some implementations of threads).

**Clock Constants**

The definition of the manifest constants `CLOCK_PROCESS_CPUTIME_ID` and `CLOCK_THREAD_CPUTIME_ID` allows processes or threads, respectively, to access their own execution-time clocks. However, given a process or thread, access to its own execution-time clock is also possible if the clock ID of this clock is obtained through a call to `clock_getcpuclockid()` or `pthread_getcpuclockid()`. Therefore, these constants are not necessary and could be deleted to make the interface simpler. Their existence saves one system call in the first access to the CPU-time clock of each process or thread. The working group considered this issue and decided to leave the constants in IEEE Std 1003.1-2001 because they are closer to the POSIX.1b use of clock identifiers.

**Library Implementations of Threads**

In library implementations of threads, kernel entities and library threads can coexist. In this case, if the CPU-time clocks are supported, most of the clock and timer functions will need to have two implementations: one in the thread library, and one in the system calls library. The main difference between these two implementations is that the thread library implementation will have to deal with clocks and timers that reside in the thread space, while the kernel implementation will operate on timers and clocks that reside in kernel space. In the library implementation, if the clock ID refers to a clock that resides in the kernel, a kernel call will have to be made. The correct version of the function can be chosen by specifying the appropriate order for the libraries during the link process.

**History of Resolution Issues: Deletion of the enable Attribute**

In early proposals, consideration was given to inclusion of an attribute called `enable` for CPU-time clocks. This would allow implementations to avoid the overhead of measuring execution time for those processes or threads for which this measurement was not required. However, this is unnecessary since processes are already required to measure execution time by the POSIX.1 `times()` function. Consequently, the `enable` attribute is not present.
Rationale for System Interfaces

Rationale Relating to Timeouts

• Requirements for Timeouts

Realtime systems which must operate reliably over extended periods without human intervention are characteristic in embedded applications such as avionics, machine control, and space exploration, as well as more mundane applications such as cable TV, security systems, and plant automation. A multi-tasking paradigm, in which many independent and/or cooperating software functions relinquish the processor(s) while waiting for a specific stimulus, resource, condition, or operation completion, is very useful in producing well engineered programs for such systems. For such systems to be robust and fault-tolerant, expected occurrences that are unduly delayed or that never occur must be detected so that appropriate recovery actions may be taken. This is difficult if there is no way for a task to regain control of a processor once it has relinquished control (blocked) awaiting an occurrence which, perhaps because of corrupted code, hardware malfunction, or latent software bugs, will not happen when expected. Therefore, the common practice in realtime operating systems is to provide a capability to time out such blocking services. Although there are several methods to achieve this already defined by POSIX, none are as reliable or efficient as initiating a timeout simultaneously with initiating a blocking service. This is especially critical in hard-realtime embedded systems because the processors typically have little time reserve, and allowed fault recovery times are measured in milliseconds rather than seconds.

The working group largely agreed that such timeouts were necessary and ought to become part of IEEE Std 1003.1-2001, particularly vendors of realtime operating systems whose customers had already expressed a strong need for timeouts. There was some resistance to inclusion of timeouts in IEEE Std 1003.1-2001 because the desired effect, fault tolerance, could, in theory, be achieved using existing facilities and alternative software designs, but there was no compelling evidence that realtime system designers would embrace such designs at the sacrifice of performance and/or simplicity.

• Which Services should be Timed Out?

Originally, the working group considered the prospect of providing timeouts on all blocking services, including those currently existing in POSIX.1, POSIX.1b, and POSIX.1c, and future interfaces to be defined by other working groups, as sort of a general policy. This was rather quickly rejected because of the scope of such a change, and the fact that many of those services would not normally be used in a realtime context. More traditional timesharing solutions to timeout would suffice for most of the POSIX.1 interfaces, while others had asynchronous alternatives which, while more complex to utilize, would be adequate for some realtime and all non-realtime applications.

The list of potential candidates for timeouts was narrowed to the following for further consideration:

— POSIX.1b
  — sem_wait()
  — mq_receive()
  — mq_send()
  — lio_listio()
  — aio_suspend()
  — sigwait() (timeout already implemented by sigtimedwait())
— POSIX.1c
  — pthread_mutex_lock()
  — pthread_join()
  — pthread_cond_wait() (timeout already implemented by pthread_cond_timedwait())
— POSIX.1
  — read()
  — write()

After further review by the working group, the lio_listio(), read(), and write() functions (all forms of blocking synchronous I/O) were eliminated from the list because of the following:

— Asynchronous alternatives exist
— Timeouts can be implemented, albeit non-portably, in device drivers
— A strong desire not to introduce modifications to POSIX.1 interfaces

The working group ultimately rejected pthread_join() since both that interface and a timed variant of that interface are non-minimal and may be implemented as a function. See below for a library implementation of pthread_join().

Thus, there was a consensus among the working group members to add timeouts to 4 of the remaining 5 functions (the timeout for aio_suspend() was ultimately added directly to POSIX.1b, while the others were added by POSIX.1d). However, pthread_mutex_lock() remained contentious.

Many feel that pthread_mutex_lock() falls into the same class as the other functions; that is, it is desirable to time out a mutex lock because a mutex may fail to be unlocked due to errant or corrupted code in a critical section (looping or branching outside of the unlock code), and therefore is equally in need of a reliable, simple, and efficient timeout. In fact, since mutexes are intended to guard small critical sections, most pthread_mutex_lock() calls would be expected to obtain the lock without blocking nor utilizing any kernel service, even in implementations of threads with global contention scope; the timeout alternative need only be considered after it is determined that the thread must block.

Those opposed to timing out mutexes feel that the very simplicity of the mutex is compromised by adding a timeout semantic, and that to do so is senseless. They claim that if a timed mutex is really deemed useful by a particular application, then it can be constructed from the facilities already in POSIX.1b and POSIX.1c. The following two C-language library implementations of mutex locking with timeout represent the solutions offered (in both implementations, the timeout parameter is specified as absolute time, not relative time as in the proposed POSIX.1c interfaces).
• Spinlock Implementation

```c
#include <pthread.h>
#include <time.h>
#include <errno.h>

int pthread_mutex_timedlock(pthread_mutex_t *mutex,
     const struct timespec *timeout)
{
    struct timespec timenow;

    while (pthread_mutex_trylock(mutex) == EBUSY)
    {
        clock_gettime(CLOCK_REALTIME, &timenow);
        if (timespec_cmp(&timenow,timeout) >= 0)
        {
            return ETIMEDOUT;
        }
        pthread_yield();
    }
    return 0;
}
```

The Spinlock implementation is generally unsuitable for any application using priority-based
thread scheduling policies such as SCHED_FIFO or SCHED_RR, since the mutex could
currently be held by a thread of lower priority within the same allocation domain, but since
the waiting thread never blocks, only threads of equal or higher priority will ever run, and
the mutex cannot be unlocked. Setting priority inheritance or priority ceiling protocol on the
mutex does not solve this problem, since the priority of a mutex owning thread is only
boosted if higher priority threads are blocked waiting for the mutex; clearly not the case for
this spinlock.

• Condition Wait Implementation

```c
#include <pthread.h>
#include <time.h>
#include <errno.h>

struct timed_mutex
{
    int locked;
    pthread_mutex_t mutex;
    pthread_cond_t cond;
};
typedef struct timed_mutex timed_mutex_t;

int timed_mutex_lock(timed_mutex_t *tm,
    const struct timespec *timeout)
{
    int timedout=FALSE;
    int error_status;
    pthread_mutex_lock(&tm->mutex);
    while (tm->locked && !timedout)
    {
        if ((error_status=pthread_cond_timedwait(&tm->cond,
```
The Condition Wait implementation effectively substitutes the `pthread_cond_timedwait()` function (which is currently timed out) for the desired `pthread_mutex_timedlock()`. Since waits on condition variables currently do not include protocols which avoid priority inversion, this method is generally unsuitable for realtime applications because it does not provide the same priority inversion protection as the untimed `pthread_mutex_lock()`. Also, for any given implementations of the current mutex and condition variable primitives, this library implementation has a performance cost at least 2.5 times that of the untimed `pthread_mutex_lock()` even in the case where the timed mutex is readily locked without blocking (the interfaces required for this case are shown in bold). Even in uniprocessors or where assignment is atomic, at least an additional `pthread_cond_signal()` is required. `pthread_mutex_timedlock()` could be implemented at effectively no performance penalty in this case because the timeout parameters need only be considered after it is determined that the mutex cannot be locked immediately.

Thus it has not yet been shown that the full semantics of mutex locking with timeout can be efficiently and reliably achieved using existing interfaces. Even if the existence of an acceptable library implementation were proven, it is difficult to justify why the interface itself should not be made portable, especially considering approval for the other four timeouts.
• Rationale for Library Implementation of `pthread_timedjoin()`

Library implementation of `pthread_timedjoin()`:

```c
/*
* Construct a thread variety entirely from existing functions
* with which a join can be done, allowing the join to time out.
*/
#include <pthread.h>
#include <time.h>

struct timed_thread {
    pthread_t t;
    pthread_mutex_t m;
    int exiting;
    pthread_cond_t exit_c;
    void *(*start_routine)(void *arg);
    void *arg;
    void *status;
};

typedef struct timed_thread *timed_thread_t;
static pthread_key_t timed_thread_key;
static pthread_once_t timed_thread_once = PTHREAD_ONCE_INIT;

static void timed_thread_init()
{
    pthread_key_create(&timed_thread_key, NULL);
}

static void *timed_thread_start_routine(void *args)
/*
* Routine to establish thread-specific data value and run the actual
* thread start routine which was supplied to timed_thread_create().
*/
{
    timed_thread_t tt = (timed_thread_t) args;
    pthread_once(&timed_thread_once, timed_thread_init);
    pthread_setspecific(timed_thread_key, (void *)tt);
    timed_thread_exit((tt->start_routine)(tt->arg));
}

int timed_thread_create(timed_thread_t ttp, const pthread_attr_t *attr,
    void *(*start_routine)(void *, void *), void *arg)
/*
* Allocate a thread which can be used with timed_thread_join().
*/
{
    timed_thread_t tt;
    int result;
    tt = (timed_thread_t) malloc(sizeof(struct timed_thread));
    pthread_mutex_init(&tt->m,NULL);
    tt->exiting = FALSE;
    pthread_cond_init(&tt->exit_c,NULL);
```
General Information Rationale for System Interfaces

```c
6167     tt->start_routine = start_routine;
6168     tt->arg = arg;
6169     tt->status = NULL;
6170     if ((result = pthread_create(&tt->t, attr,
6171         timed_thread_start_routine, (void *)tt)) != 0) {
6172         free(tt);
6173         return result;
6174     }
6175     pthread_detach(tt->t);
6176     ttp = tt;
6177     return 0;
6178 }
6179
6180 int timed_thread_join(timed_thread_t tt,
6181 struct timespec *timeout,
6182     void **status)
6183 {
6184     int result;
6185     pthread_mutex_lock(&tt->m);
6186     result = 0;
6187     /*
6188     * Wait until the thread announces that it is exiting,
6189     * or until timeout.
6190     */
6191     while (result == 0 && ! tt->exiting) {
6192         result = pthread_cond_timedwait(&tt->exit_c, &tt->m, timeout);
6193     }
6194     pthread_mutex_unlock(&tt->m);
6195     if (result == 0 && tt->exiting) {
6196         *status = tt->status;
6197         free((void *)tt);
6198         return result;
6199     }
6200     return result;
6201 }
6202
6203 void timed_thread_exit(void *status)
6204 {
6205     timed_thread_t tt;
6206     void *specific;
6207     if ((specific=pthread_getspecific(timed_thread_key)) == NULL){
6208         /*
6209         * Handle cases which won’t happen with correct usage.
6210         */
6211         pthread_exit( NULL);
6212     }
6213     tt = (timed_thread_t) specific;
6214     pthread_mutex_lock(&tt->m);
6215     /*
6216     * Tell a joiner that we’re exiting.
6217     */
6218 }
```
tt->status = status;
process_lock = TRUE;
pthread_cond_signal(&tt->exit_c);
pthread_mutex_unlock(&tt->m);
/*
 * Call pthread exit() to call destructors and really
 * exit the thread.
 */
pthread_exit(NULL);
}

The pthread_join() C-language example shown above demonstrates that it is possible, using
existing pthread facilities, to construct a variety of thread which allows for joining such a
thread, but which allows the join operation to time out. It does this by using a
pthread_cond_timedwait() to wait for the thread to exit. A timed_thread_t descriptor structure
is used to pass parameters from the creating thread to the created thread, and from the
exiting thread to the joining thread. This implementation is roughly equivalent to what a
normal pthread_join() implementation would do, with the single change being that
pthread_cond_timedwait() is used in place of a simple pthread_cond_wait().

Since it is possible to implement such a facility entirely from existing pthread interfaces, and
with roughly equal efficiency and complexity to an implementation which would be
provided directly by a pthreads implementation, it was the consensus of the working group
members that any pthread_timedjoin() facility would be unnecessary, and should not be
provided.

**Form of the Timeout Interfaces**

The working group considered a number of alternative ways to add timeouts to blocking
services. At first, a system interface which would specify a one-shot or persistent timeout to
be applied to subsequent blocking services invoked by the calling process or thread was
considered because it allowed all blocking services to be timed out in a uniform manner with
a single additional interface; this was rather quickly rejected because it could easily result in
the wrong services being timed out.

It was suggested that a timeout value might be specified as an attribute of the object
(semaphore, mutex, message queue, and so on), but there was no consensus on this, either on
a case-by-case basis or for all timeouts.

Looking at the two existing timeouts for blocking services indicates that the working group
members favor a separate interface for the timed version of a function. However,
pthread_cond_timedwait() utilizes an absolute timeout value while sigtimedwait() uses a
relative timeout value. The working group members agreed that relative timeout values are
appropriate where the timeout mechanism’s primary use was to deal with an unexpected or
error situation, but they are inappropriate when the timeout must expire at a particular time,
or before a specific deadline. For the timeouts being introduced in IEEE Std 1003.1-2001, the
working group considered allowing both relative and absolute timeouts as is done with
POSIX.1b timers, but ultimately favored the simpler absolute timeout form.

An absolute time measure can be easily implemented on top of an interface that specifies
relative time, by reading the clock, calculating the difference between the current time and
the desired wake-up time, and issuing a relative timeout call. But there is a race condition
with this approach because the thread could be preempted after reading the clock, but before
making the timed-out call; in this case, the thread would be awakened later than it should
and, thus, if the wake-up time represented a deadline, it would miss it.
There is also a race condition when trying to build a relative timeout on top of an interface that specifies absolute timeouts. In this case, the clock would have to be read to calculate the absolute wake-up time as the sum of the current time plus the relative timeout interval. In this case, if the thread is preempted after reading the clock but before making the timed-out call, the thread would be awakened earlier than desired.

But the race condition with the absolute timeouts interface is not as bad as the one that happens with the relative timeout interface, because there are simple workarounds. For the absolute timeouts interface, if the timing requirement is a deadline, the deadline can still be met because the thread woke up earlier than the deadline. If the timeout is just used as an error recovery mechanism, the precision of timing is not really important. If the timing requirement is that between actions A and B a minimum interval of time must elapse, the absolute timeout interface can be safely used by reading the clock after action A has been started. It could be argued that, since the call with the absolute timeout is atomic from the application point of view, it is not possible to read the clock after action A, if this action is part of the timed-out call. But looking at the nature of the calls for which timeouts are specified (locking a mutex, waiting for a semaphore, waiting for a message, or waiting until there is space in a message queue), the timeouts that an application would build on these actions would not be triggered by these actions themselves, but by some other external action. For example, if waiting for a message to arrive to a message queue, and waiting for at least 20 milliseconds, this time interval would start to be counted from some event that would trigger both the action that produces the message, as well as the action that waits for the message to arrive, and not by the wait-for-message operation itself. In this case, the workaround proposed above could be used.

For these reasons, the absolute timeout is preferred over the relative timeout interface.

### B.2.9 Threads

Threads will normally be more expensive than subroutines (or functions, routines, and so on) if specialized hardware support is not provided. Nevertheless, threads should be sufficiently efficient to encourage their use as a medium to fine-grained structuring mechanism for parallelism in an application. Structuring an application using threads then allows it to take immediate advantage of any underlying parallelism available in the host environment. This means implementors are encouraged to optimize for fast execution at the possible expense of efficient utilization of storage. For example, a common thread creation technique is to cache appropriate thread data structures. That is, rather than releasing system resources, the implementation retains these resources and reuses them when the program next asks to create a new thread. If this reuse of thread resources is to be possible, there has to be very little unique state associated with each thread, because any such state has to be reset when the thread is reused.

#### Thread Creation Attributes

Attributes objects are provided for threads, mutexes, and condition variables as a mechanism to support probable future standardization in these areas without requiring that the interface itself be changed.

Attributes objects provide clean isolation of the configurable aspects of threads. For example, “stack size” is an important attribute of a thread, but it cannot be expressed portably. When porting a threaded program, stack sizes often need to be adjusted. The use of attributes objects can help by allowing the changes to be isolated in a single place, rather than being spread across every instance of thread creation.
Attributes objects can be used to set up classes of threads with similar attributes; for example, “threads with large stacks and high priority” or “threads with minimal stacks”. These classes can be defined in a single place and then referenced wherever threads need to be created. Changes to “class” decisions become straightforward, and detailed analysis of each pthread_create() call is not required.

The attributes objects are defined as opaque types as an aid to extensibility. If these objects had been specified as structures, adding new attributes would force recompilation of all multi-threaded programs when the attributes objects are extended; this might not be possible if different program components were supplied by different vendors.

Additionally, opaque attributes objects present opportunities for improving performance. Argument validity can be checked once when attributes are set, rather than each time a thread is created. Implementations will often need to cache kernel objects that are expensive to create. Opaque attributes objects provide an efficient mechanism to detect when cached objects become invalid due to attribute changes.

Because assignment is not necessarily defined on a given opaque type, implementation-defined default values cannot be defined in a portable way. The solution to this problem is to allow attribute objects to be initialized dynamically by attributes object initialization functions, so that default values can be supplied automatically by the implementation.

The following proposal was provided as a suggested alternative to the supplied attributes:

1. Maintain the style of passing a parameter formed by the bitwise-inclusive OR of flags to the initialization routines (pthread_create(), pthread_mutex_init(), pthread_cond_init()). The parameter containing the flags should be an opaque type for extensibility. If no flags are set in the parameter, then the objects are created with default characteristics. An implementation may specify implementation-defined flag values and associated behavior.

2. If further specialization of mutexes and condition variables is necessary, implementations may specify additional procedures that operate on the pthread_mutex_t and pthread_cond_t objects (instead of on attributes objects).

The difficulties with this solution are:

1. A bitmask is not opaque if bits have to be set into bit-vector attributes objects using explicitly-coded bitwise-inclusive OR operations. If the set of options exceeds an int, application programmers need to know the location of each bit. If bits are set or read by encapsulation (that is, get*() or set*() functions), then the bitmask is merely an implementation of attributes objects as currently defined and should not be exposed to the programmer.

2. Many attributes are not Boolean or very small integral values. For example, scheduling policy may be placed in 3 bits or 4 bits, but priority requires 5 bits or more, thereby taking up at least 8 bits out of a possible 16 bits on machines with 16-bit integers. Because of this, the bitmask can only reasonably control whether particular attributes are set or not, and it cannot serve as the repository of the value itself. The value needs to be specified as a function parameter (which is non-extensible), or by setting a structure field (which is non-opaque), or by get*() and set*() functions (making the bitmask a redundant addition to the attributes objects).

Stack size is defined as an optional attribute because the very notion of a stack is inherently machine-dependent. Some implementations may not be able to change the size of the stack, for example, and others may not need to because stack pages may be discontiguous and can be allocated and released on demand.
The attribute mechanism has been designed in large measure for extensibility. Future extensions to the attribute mechanism or to any attributes object defined in IEEE Std 1003.1-2001 have to be done with care so as not to affect binary-compatibility.

Attribute objects, even if allocated by means of dynamic allocation functions such as `malloc()`, may have their size fixed at compile time. This means, for example, a `pthread_create()` in an implementation with extensions to the `pthread_attr_t` cannot look beyond the area that the binary application assumes is valid. This suggests that implementations should maintain a size field in the attributes object, as well as possibly version information, if extensions in different directions (possibly by different vendors) are to be accommodated.

**Thread Implementation Models**

There are various thread implementation models. At one end of the spectrum is the “library-thread model”. In such a model, the threads of a process are not visible to the operating system kernel, and the threads are not kernel-scheduled entities. The process is the only kernel-scheduled entity. The process is scheduled onto the processor by the kernel according to the scheduling attributes of the process. The threads are scheduled onto the single kernel-scheduled entity (the process) by the runtime library according to the scheduling attributes of the threads.

A problem with this model is that it constrains concurrency. Since there is only one kernel-scheduled entity (namely, the process), only one thread per process can execute at a time. If the thread that is executing blocks on I/O, then the whole process blocks.

At the other end of the spectrum is the “kernel-thread model”. In this model, all threads are visible to the operating system kernel. Thus, all threads are kernel-scheduled entities, and all threads can concurrently execute. The threads are scheduled onto processors by the kernel according to the scheduling attributes of the threads. The drawback to this model is that the creation and management of the threads entails operating system calls, as opposed to subroutine calls, which makes kernel threads heavier weight than library threads.

Hybrids of these two models are common. A hybrid model offers the speed of library threads and the concurrency of kernel threads. In hybrid models, a process has some (relatively small) number of kernel scheduled entities associated with it. It also has a potentially much larger number of library threads associated with it. Some library threads may be bound to kernel-scheduled entities, while the other library threads are multiplexed onto the remaining kernel-scheduled entities. There are two levels of thread scheduling:

1. The runtime library manages the scheduling of (unbound) library threads onto kernel-scheduled entities.
2. The kernel manages the scheduling of kernel-scheduled entities onto processors.

For this reason, a hybrid model is referred to as a two-level threads scheduling model. In this model, the process can have multiple concurrently executing threads; specifically, it can have as many concurrently executing threads as it has kernel-scheduled entities.

**Thread-Specific Data**

Many applications require that a certain amount of context be maintained on a per-thread basis across procedure calls. A common example is a multi-threaded library routine that allocates resources from a common pool and maintains an active resource list for each thread. The thread-specific data interface provided to meet these needs may be viewed as a two-dimensional array of values with keys serving as the row index and thread IDs as the column index (although the implementation need not work this way).
Rationale for System Interfaces

General Information

• Models

Three possible thread-specific data models were considered:

1. No Explicit Support

A standard thread-specific data interface is not strictly necessary to support applications that require per-thread context. One could, for example, provide a hash function that converted a *pthread_t* into an integer value that could then be used to index into a global array of per-thread data pointers. This hash function, in conjunction with *pthread_self()*, would be all the interface required to support a mechanism of this sort. Unfortunately, this technique is cumbersome. It can lead to duplicated code as each set of cooperating modules implements their own per-thread data management schemes.

2. Single (*void*) Pointer

Another technique would be to provide a single word of per-thread storage and a pair of functions to fetch and store the value of this word. The word could then hold a pointer to a block of per-thread memory. The allocation, partitioning, and general use of this memory would be entirely up to the application. Although this method is not as problematic as technique 1, it suffers from interoperability problems. For example, all modules using the per-thread pointer would have to agree on a common usage protocol.

3. Key/Value Mechanism

This method associates an opaque key (for example, stored in a variable of type *pthread_key_t*) with each per-thread datum. These keys play the role of identifiers for per-thread data. This technique is the most generic and avoids the problems noted above, albeit at the cost of some complexity.

The primary advantage of the third model is its information hiding properties. Modules using this model are free to create and use their own key(s) independent of all other such usage, whereas the other models require that all modules that use thread-specific context explicitly cooperate with all other such modules. The data-independence provided by the third model is worth the additional interface.

• Requirements

It is important that it be possible to implement the thread-specific data interface without the use of thread private memory. To do otherwise would increase the weight of each thread, thereby limiting the range of applications for which the threads interfaces provided by IEEE Std 1003.1-2001 is appropriate.

The values that one binds to the key via *pthread_setspecific()* may, in fact, be pointers to shared storage locations available to all threads. It is only the key/value bindings that are maintained on a per-thread basis, and these can be kept in any portion of the address space that is reserved for use by the calling thread (for example, on the stack). Thus, no per-thread MMU state is required to implement the interface. On the other hand, there is nothing in the interface specification to preclude the use of a per-thread MMU state if it is available (for example, the key values returned by *pthread_key_create()* could be thread private memory addresses).

• Standardization Issues

Thread-specific data is a requirement for a usable thread interface. The binding described in this section provides a portable thread-specific data mechanism for languages that do not directly support a thread-specific storage class. A binding to IEEE Std 1003.1-2001 for a
language that does include such a storage class need not provide this specific interface.

If a language were to include the notion of thread-specific storage, it would be desirable (but not required) to provide an implementation of the pthreads thread-specific data interface based on the language feature. For example, assume that a compiler for a C-like language supports a private storage class that provides thread-specific storage. Something similar to the following macros might be used to effect a compatible implementation:

```
#define pthread_key_t private void *
#define pthread_key_create(key) /* no-op */
#define pthread_setspecific(key,value) (key)=(value)
#define pthread_getspecific(key)
```

Note: For the sake of clarity, this example ignores destructor functions. A correct implementation would have to support them.

### Barriers

- **Background**

  Barriers are typically used in parallel DO/FOR loops to ensure that all threads have reached a particular stage in a parallel computation before allowing any to proceed to the next stage. Highly efficient implementation is possible on machines which support a "Fetch and Add" operation as described in the referenced Almasi and Gottlieb (1989).

  The use of return value PTHREAD_BARRIER_SERIAL_THREAD is shown in the following example:

  ```c
  if ( (status=pthread_barrier_wait(&barrier)) ==
      PTHREAD_BARRIER_SERIAL_THREAD) {
      ...serial section
  } else if (status != 0) {
      ...error processing
  }
  status=pthread_barrier_wait(&barrier);
  ...
  ```

  This behavior allows a serial section of code to be executed by one thread as soon as all threads reach the first barrier. The second barrier prevents the other threads from proceeding until the serial section being executed by the one thread has completed.

  Although barriers can be implemented with mutexes and condition variables, the referenced Almasi and Gottlieb (1989) provides ample illustration that such implementations are significantly less efficient than is possible. While the relative efficiency of barriers may well vary by implementation, it is important that they be recognized in the IEEE Std 1003.1-2001 to facilitate applications portability while providing the necessary freedom to implementors.

- **Lack of Timeout Feature**

  Alternate versions of most blocking routines have been provided to support watchdog timeouts. No alternate interface of this sort has been provided for barrier waits for the following reasons:

  - Multiple threads may use different timeout values, some of which may be indefinite. It is not clear which threads should break through the barrier with a timeout error if and when these timeouts expire.
• The barrier may become unusable once a thread breaks out of a `pthread_barrier_wait()` with a timeout error. There is, in general, no way to guarantee the consistency of a barrier's internal data structures once a thread has timed out of a `pthread_barrier_wait()`.

Even the inclusion of a special barrier reinitialization function would not help much since it is not clear how this function would affect the behavior of threads that reach the barrier between the original timeout and the call to the reinitialization function.

Spin Locks

• Background

Spin locks represent an extremely low-level synchronization mechanism suitable primarily for use on shared memory multi-processors. It is typically an atomically modified Boolean value that is set to one when the lock is held and to zero when the lock is freed.

When a caller requests a spin lock that is already held, it typically spins in a loop testing whether the lock has become available. Such spinning wastes processor cycles so the lock should only be held for short durations and not across sleep/block operations. Callers should unlock spin locks before calling sleep operations.

Spin locks are available on a variety of systems. The functions included in IEEE Std 1003.1-2001 are an attempt to standardize that existing practice.

• Lack of Timeout Feature

Alternate versions of most blocking routines have been provided to support watchdog timeouts. No alternate interface of this sort has been provided for spin locks for the following reasons:

• It is impossible to determine appropriate timeout intervals for spin locks in a portable manner. The amount of time one can expect to spend spin-waiting is inversely proportional to the degree of parallelism provided by the system.

It can vary from a few cycles when each competing thread is running on its own processor, to an indefinite amount of time when all threads are multiplexed on a single processor (which is why spin locking is not advisable on unprocessors).

• When used properly, the amount of time the calling thread spends waiting on a spin lock should be considerably less than the time required to set up a corresponding watchdog timer. Since the primary purpose of spin locks is to provide a low-overhead synchronization mechanism for multi-processors, the overhead of a timeout mechanism was deemed unacceptable.

It was also suggested that an additional `count` argument be provided (on the `pthread_spin_lock()` call) in lieu of a true timeout so that a spin lock call could fail gracefully if it was unable to apply the lock after `count` attempts. This idea was rejected because it is not existing practice. Furthermore, the same effect can be obtained with `pthread_spin_trilock()`, as illustrated below:
int n = MAX_SPIN;

while ( --n >= 0 )
{
    if ( !pthread_spin_try_lock(...) )
        break;
}

if ( n >= 0 )
{
    /* Successfully acquired the lock */
}
else
{
    /* Unable to acquire the lock */
}

• process-shared Attribute

The initialization functions associated with most POSIX synchronization objects (for example, mutexes, barriers, and read-write locks) take an attributes object with a process-shared attribute that specifies whether or not the object is to be shared across processes. In the draft corresponding to the first balloting round, two separate initialization functions are provided for spin locks, however: one for spin locks that were to be shared across processes (spin_init()), and one for locks that were only used by multiple threads within a single process (pthread_spin_init()). This was done so as to keep the overhead associated with spin waiting to an absolute minimum. However, the balloting group requested that, since the overhead associated to a bit check was small, spin locks should be consistent with the rest of the synchronization primitives, and thus the process-shared attribute was introduced for spin locks.

• Spin Locks versus Mutexes

It has been suggested that mutexes are an adequate synchronization mechanism and spin locks are not necessary. Locking mechanisms typically must trade off the processor resources consumed while setting up to block the thread and the processor resources consumed by the thread while it is blocked. Spin locks require very little resources to set up the blocking of a thread. Existing practice is to simply loop, repeating the atomic locking operation until the lock is available. While the resources consumed to set up blocking of the thread are low, the thread continues to consume processor resources while it is waiting.

On the other hand, mutexes may be implemented such that the processor resources consumed to block the thread are large relative to a spin lock. After detecting that the mutex lock is not available, the thread must alter its scheduling state, add itself to a set of waiting threads, and, when the lock becomes available again, undo all of this before taking over ownership of the mutex. However, while a thread is blocked by a mutex, no processor resources are consumed.

Therefore, spin locks and mutexes may be implemented to have different characteristics. Spin locks may have lower overall overhead for very short-term blocking, and mutexes may have lower overall overhead when a thread will be blocked for longer periods of time. The presence of both interfaces allows implementations with these two different characteristics, both of which may be useful to a particular application.

It has also been suggested that applications can build their own spin locks from the pthread_mutex_trylock() function:
while (pthread_mutex_trylock(&mutex));

The apparent simplicity of this construct is somewhat deceiving, however. While the actual
wait is quite efficient, various guarantees on the integrity of mutex objects (for example,
priority inheritance rules) may add overhead to the successful path of the trylock operation
that is not required of spin locks. One could, of course, add an attribute to the mutex to
bypass such overhead, but the very act of finding and testing this attribute represents more
overhead than is found in the typical spin lock.

The need to hold spin lock overhead to an absolute minimum also makes it impossible to
provide guarantees against starvation similar to those provided for mutexes or read-write
locks. The overhead required to implement such guarantees (for example, disabling
preemption before spinning) may well exceed the overhead of the spin wait itself by many
orders of magnitude. If a "safe" spin wait seems desirable, it can always be provided (albeit
at some performance cost) via appropriate mutex attributes.

XSI Supported Functions

On XSI-conformant systems, the following symbolic constants are always defined:

```
_POSIX_READER_WRITER_LOCKS
_POSIX_THREAD_ATTR_STACKADDR
_POSIX_THREAD_ATTR_STACKSIZE
_POSIX_THREAD_PROCESS_SHARED
_POSIX_THREADS
```

Therefore, the following threads functions are always supported:

```
 pthread_atfork()      pthread_key_create()
 pthread_attr_destroy()      pthread_key_delete()
 pthread_attr_getdetachstate()      pthread_kill()
 pthread_attr_getguardsize()      pthread_mutex_destroy()
 pthread_attr_getschedparam()      pthread_mutex_init()
 pthread_attr_getstack()      pthread_mutex_lock()
 pthread_attr_getstackaddr()      pthread_mutex_trylock()
 pthread_attr_getstacksize()      pthread_mutex_unlock()
 pthread_attr_init()      pthread_mutexattr_destroy()
 pthread_attr_setdetachstate()      pthread_mutexattr_getpshared()
 pthread_attr_setguardsize()      pthread_mutexattr_gettype()
 pthread_attr_setschedparam()      pthread_mutexattr_init()
 pthread_attr_setstack()      pthread_mutexattr_setpshared() pthread_attr_setstacksize()      pthread_mutexattr_settype() pthread_attr_setstackaddr()      pthread_mutexattr_getpshared()
 pthread_attr_setstacksize()      pthread_attribute()
 pthread_cancel()      pthread_rwlock_destroy()
 pthread_cleanup_pop()      pthread_rwlock_init()
 pthread_cleanup_push()      pthread_rwlock_rdlock()
 pthread_cond_broadcast()      pthread_rwlock_tryrdlock()
 pthread_cond_destroy()      pthread_rwlock_trywrlock()
 pthread_cond_init()      pthread_rwlock_unlock()
 pthread_cond_signal()      pthread_rwlock_rwlock()
 pthread_cond_timedwait()      pthread_rwlockattr_destroy()
 pthread_cond_wait()      pthread_rwlockattr_getpshared()
 pthread_condattr_destroy()      pthread_rwlockattr_init()```
General Information

Rationale for System Interfaces

6620  pthread_condattr_getpshared()  pthread_rwlockattr_setpshared()
6621  pthread_condattr_init()  pthread_self()
6622  pthread_condattr_setpshared()  pthread_setcancelstate()
6623  pthread_create()  pthread_setcanceltype()
6624  pthread_detach()  pthread_setconcurrency()
6625  pthread_equal()  pthread_setspecific()
6626  pthread_exit()  pthread_sigmask()
6627  pthread_getconcurrency()  pthread_testcancel()
6628  pthread_getspecific()  sigwait()
6629  pthread_join()

6630 On XSI-conformant systems, the symbolic constant _POSIX_THREAD_SAFE_FUNCTIONS is always defined. Therefore, the following functions are always supported:

6632  asctime_r()  getpwuid_r()
6633  ctime_r()  gmtime_r()
6634  flockfile()  localtime_r()
6635  ftrylockfile()  putc_unlocked()
6636  funlockfile()  putchar_unlocked()
6637  getc_unlocked()  rand_r()
6638  getchar_unlocked()  readdir_r()
6639  getgrgid_r()  strerror_r()
6640  getgrnam_r()  strtok_r()
6641  getpwnam_r()

6642 The following threads functions are only supported on XSI-conformant systems if the Realtime Threads Option Group is supported:

6644  pthread_attr_getinheritsched()  pthread_mutex_getprioceiling()
6645  pthread_attr_getschedpolicy()  pthread_mutex_setprioceiling()
6646  pthread_attr_getscope()  pthread_mutexattr_getprioceiling()
6647  pthread_attr_setinheritsched()  pthread_mutexattr_getprotocol()
6648  pthread_attr_setschedpolicy()  pthread_mutexattr_setprioceiling()
6649  pthread_attr_setscope()  pthread_mutexattr_setprotocol()
6650  pthread_getschedparam()  pthread_setschedparam()

XSI Threads Extensions

6651 The following XSI extensions to POSIX.1c are now supported in IEEE Std 1003.1-2001 as part of the alignment with the Single UNIX Specification:

6654  • Extended mutex attribute types
6655  • Read-write locks and attributes (also introduced by the IEEE Std 1003.1j-2000 amendment)
6656  • Thread concurrency level
6657  • Thread stack guard size
6658  • Parallel I/O

6659 A total of 19 new functions were added.

6660 These extensions carefully follow the threads programming model specified in POSIX.1c. As with POSIX.1c, all the new functions return zero if successful; otherwise, an error number is
The concept of attribute objects was introduced in POSIX.1c to allow implementations to extend IEEE Std 1003.1-2001 without changing the existing interfaces. Attribute objects were defined for threads, mutexes, and condition variables. Attributes objects are defined as implementation-defined opaque types to aid extensibility, and functions are defined to allow attributes to be set or retrieved. This model has been followed when adding the new type attribute of \texttt{pthread_mutexattr_t} or the new read-write lock attributes object \texttt{pthread_rwlockattr_t}.

- Extended Mutex Attributes

POSIX.1c defines a mutex attributes object as an implementation-defined opaque object of type \texttt{pthread_mutexattr_t}, and specifies a number of attributes which this object must have and a number of functions which manipulate these attributes. These attributes include \texttt{detachstate}, \texttt{inheritsched}, \texttt{schedparm}, \texttt{schedpolicy}, \texttt{contentionscope}, \texttt{stackaddr}, and \texttt{stacksize}.

The System Interfaces volume of IEEE Std 1003.1-2001 specifies another mutex attribute called \texttt{type}. The \texttt{type} attribute allows applications to specify the behavior of mutex locking operations in situations where POSIX.1c behavior is undefined. The OSF DCE threads implementation, based on Draft 4 of POSIX.1c, specified a similar attribute. Note that the names of the attributes have changed somewhat from the OSF DCE threads implementation.

The System Interfaces volume of IEEE Std 1003.1-2001 also extends the specification of the following POSIX.1c functions which manipulate mutexes:

\begin{verbatim}
    pthread_mutex_lock()
    pthread_mutex_trylock()
    pthread_mutex_unlock()
\end{verbatim}

to take account of the new mutex attribute type and to specify behavior which was declared as undefined in POSIX.1c. How a calling thread acquires or releases a mutex now depends upon the mutex \texttt{type} attribute.

The \texttt{type} attribute can have the following values:

- \texttt{PTHREAD_MUTEX_NORMAL}
  - Basic mutex with no specific error checking built in. Does not report a deadlock error.

- \texttt{PTHREAD_MUTEX_RECURSIVE}
  - Allows any thread to recursively lock a mutex. The mutex must be unlocked an equal number of times to release the mutex.

- \texttt{PTHREAD_MUTEX_ERRORCHECK}
  - Detects and reports simple usage errors; that is, an attempt to unlock a mutex that is not locked by the calling thread or that is not locked at all, or an attempt to relock a mutex the thread already owns.

- \texttt{PTHREAD_MUTEX_DEFAULT}
  - The default mutex type. May be mapped to any of the above mutex types or may be an implementation-defined type.

\textit{Normal} mutexes do not detect deadlock conditions; for example, a thread will hang if it tries to relock a normal mutex that it already owns. Attempting to unlock a mutex locked by another thread, or unlocking an unlocked mutex, results in undefined behavior. Normal mutexes will usually be the fastest type of mutex available on a platform but provide the least error checking.

\textit{Recursive} mutexes are useful for converting old code where it is difficult to establish clear boundaries of synchronization. A thread can relock a recursive mutex without first unlocking...
The relocking deadlock which can occur with normal mutexes cannot occur with this type of mutex. However, multiple locks of a recursive mutex require the same number of unlocks to release the mutex before another thread can acquire the mutex. Furthermore, this type of mutex maintains the concept of an owner. Thus, a thread attempting to unlock a recursive mutex which another thread has locked returns with an error. A thread attempting to unlock a recursive mutex that is not locked returns with an error. Never use a recursive mutex with condition variables because the implicit unlock performed by `pthread_cond_wait()` or `pthread_cond_timedwait()` will not actually release the mutex if it had been locked multiple times.

**Errorcheck** mutexes provide error checking and are useful primarily as a debugging aid. A thread attempting to relock an errorcheck mutex without first unlocking it returns with an error. Again, this type of mutex maintains the concept of an owner. Thus, a thread attempting to unlock an errorcheck mutex which another thread has locked returns with an error. A thread attempting to unlock an errorcheck mutex that is not locked also returns with an error. It should be noted that errorcheck mutexes will almost always be much slower than normal mutexes due to the extra state checks performed.

The default mutex type provides implementation-defined error checking. The default mutex may be mapped to one of the other defined types or may be something entirely different. This enables each vendor to provide the mutex semantics which the vendor feels will be most useful to their target users. Most vendors will probably choose to make normal mutexes the default so as to give applications the benefit of the fastest type of mutexes available on their platform. Check your implementation's documentation.

An application developer can use any of the mutex types almost interchangeably as long as the application does not depend upon the implementation detecting (or failing to detect) any particular errors. Note that a recursive mutex can be used with condition variable waits as long as the application never recursively locks the mutex.

Two functions are provided for manipulating the `type` attribute of a mutex attributes object. This attribute is set or returned in the `type` parameter of these functions. The `pthread_mutexattr_settype()` function is used to set a specific type value while `pthread_mutexattr_gettype()` is used to return the type of the mutex. Setting the `type` attribute of a mutex attributes object affects only mutexes initialized using that mutex attributes object. Changing the `type` attribute does not affect mutexes previously initialized using that mutex attributes object.

**Read-Write Locks and Attributes**

The read-write locks introduced have been harmonized with those in IEEE Std 1003.1j-2000; see also Section B.2.9.6 (on page 175).

Read-write locks (also known as reader-writer locks) allow a thread to exclusively lock some shared data while updating that data, or allow any number of threads to have simultaneous read-only access to the data.

Unlike a mutex, a read-write lock distinguishes between reading data and writing data. A mutex excludes all other threads. A read-write lock allows other threads access to the data, providing no thread is modifying the data. Thus, a read-write lock is less primitive than either a mutex-condition variable pair or a semaphore.

Application developers should consider using a read-write lock rather than a mutex to protect data that is frequently referenced but seldom modified. Most threads (readers) will be able to read the data without waiting and will only have to block when some other thread (a writer) is in the process of modifying the data. Conversely a thread that wants to change the data is forced to wait until there are no readers. This type of lock is often used to facilitate
parallel access to data on multi-processor platforms or to avoid context switches on single
processor platforms where multiple threads access the same data.

If a read-write lock becomes unlocked and there are multiple threads waiting to acquire the
write lock, the implementation's scheduling policy determines which thread acquires the
read-write lock for writing. If there are multiple threads blocked on a read-write lock for both
read locks and write locks, it is unspecified whether the readers or a writer acquire the lock
first. However, for performance reasons, implementations often favor writers over readers to
avoid potential writer starvation.

A read-write lock object is an implementation-defined opaque object of type
`pthread_rwlock_t` as defined in `<pthread.h>`. There are two different sorts of locks
associated with a read-write lock: a read lock and a write lock.

The `pthread_rwlockattr_init()` function initializes a read-write lock attributes object with the
default value for all the attributes defined in the implementation. After a read-write lock
attributes object has been used to initialize one or more read-write locks, changes to the
read-write lock attributes object, including destruction, do not affect previously initialized
read-write locks.

Implementations must provide at least the read-write lock attribute `process-shared`. This
attribute can have the following values:

PTHREAD_PROCESS_SHARED

Any thread of any process that has access to the memory where the read-write lock
resides can manipulate the read-write lock.

PTHREAD_PROCESS_PRIVATE

Only threads created within the same process as the thread that initialized the read-
write lock can manipulate the read-write lock. This is the default value.

The `pthread_rwlockattr_setpshared()` function is used to set the `process-shared` attribute of an
initialized read-write lock attributes object while the function `pthread_rwlockattr_getpshared()`
obtains the current value of the `process-shared` attribute.

A read-write lock attributes object is destroyed using the `pthread_rwlockattr_destroy()`
function. The effect of subsequent use of the read-write lock attributes object is undefined.

A thread creates a read-write lock using the `pthread_rwlock_init()` function. The attributes of
the read-write lock can be specified by the application developer; otherwise, the default
implementation-defined read-write lock attributes are used if the pointer to the read-write
lock attributes object is NULL. In cases where the default attributes are appropriate, the
PTHREAD_RWLOCK_INITIALIZER macro can be used to initialize statically allocated
read-write locks.

A thread which wants to apply a read lock to the read-write lock can use either
`pthread_rwlock_rdlock()` or `pthread_rwlock_tryrdlock()`. If `pthread_rwlock_rdlock()` is used, the
thread acquires a read lock if a writer does not hold the write lock and there are no writers
blocked on the write lock. If a read lock is not acquired, the calling thread blocks until it can
acquire a lock. However, if `pthread_rwlock_tryrdlock()` is used, the function returns
immediately with the error [EBUSY] if any thread holds a write lock or there are blocked
writers waiting for the write lock.

A thread which wants to apply a write lock to the read-write lock can use either of two
functions: `pthread_rwlock_wrlock()` or `pthread_rwlock_trywrlock()`. If `pthread_rwlock_wrlock()`
is used, the thread acquires the write lock if no other reader or writer threads hold the read-
write lock. If the write lock is not acquired, the thread blocks until it can acquire the write
lock. However, if `pthread_rwlock_trywrlock()` is used, the function returns immediately with
the error [EBUSY] if any thread is holding either a read or a write lock.

The `pthread_rwlock_unlock()` function is used to unlock a read-write lock object held by the calling thread. Results are undefined if the read-write lock is not held by the calling thread. If there are other read locks currently held on the read-write lock object, the read-write lock object remains in the read locked state but without the current thread as one of its owners. If this function releases the last read lock for this read-write lock object, the read-write lock object is put in the unlocked read state. If this function is called to release a write lock for this read-write lock object, the read-write lock object is put in the unlocked state.

- **Thread Concurrency Level**

On threads implementations that multiplex user threads onto a smaller set of kernel execution entities, the system attempts to create a reasonable number of kernel execution entities for the application upon application startup.

On some implementations, these kernel entities are retained by user threads that block in the kernel. Other implementations do not *timeslice* user threads so that multiple compute-bound user threads can share a kernel thread. On such implementations, some applications may use up all the available kernel execution entities before their user-space threads are used up. The process may be left with user threads capable of doing work for the application but with no way to schedule them.

The `pthread_setconcurrency()` function enables an application to request more kernel entities; that is, specify a desired concurrency level. However, this function merely provides a hint to the implementation. The implementation is free to ignore this request or to provide some other number of kernel entities. If an implementation does not multiplex user threads onto a smaller number of kernel execution entities, the `pthread_setconcurrency()` function has no effect.

The `pthread_setconcurrency()` function may also have an effect on implementations where the kernel mode and user mode schedulers cooperate to ensure that ready user threads are not prevented from running by other threads blocked in the kernel.

The `pthread_getconcurrency()` function always returns the value set by a previous call to `pthread_setconcurrency()`. However, if `pthread_setconcurrency()` was not previously called, this function returns zero to indicate that the threads implementation is maintaining the concurrency level.

- **Thread Stack Guard Size**

DCE threads introduced the concept of a “thread stack guard size”. Most thread implementations add a region of protected memory to a thread’s stack, commonly known as a “guard region”, as a safety measure to prevent stack pointer overflow in one thread from corrupting the contents of another thread’s stack. The default size of the guard regions attribute is `PAGESIZE` bytes and is implementation-defined.

Some application developers may wish to change the stack guard size. When an application creates a large number of threads, the extra page allocated for each stack may strain system resources. In addition to the extra page of memory, the kernel’s memory manager has to keep track of the different protections on adjoining pages. When this is a problem, the application developer may request a guard size of 0 bytes to conserve system resources by eliminating stack overflow protection.

Conversely an application that allocates large data structures such as arrays on the stack may wish to increase the default guard size in order to detect stack overflow. If a thread allocates two pages for a data array, a single guard page provides little protection against thread stack overflows since the thread can corrupt adjoining memory beyond the guard page.
The System Interfaces volume of IEEE Std 1003.1-2001 defines a new attribute of a thread attributes object; that is, the \textit{guardsize} attribute which allows applications to specify the size of the guard region of a thread’s stack.

Two functions are provided for manipulating a thread’s stack guard size. The \texttt{pthread_attr_setguardsize()} function sets the thread \textit{guardsize} attribute, and the \texttt{pthread_attr_getguardsize()} function retrieves the current value.

An implementation may round up the requested guard size to a multiple of the configurable system variable \texttt{PAGESIZE}. In this case, \texttt{pthread_attr_getguardsize()} returns the guard size specified by the previous \texttt{pthread_attr_setguardsize()} function call and not the rounded up value.

If an application is managing its own thread stacks using the \textit{stackaddr} attribute, the \textit{guardsize} attribute is ignored and no stack overflow protection is provided. In this case, it is the responsibility of the application to manage stack overflow along with stack allocation.

\begin{itemize}
  \item Parallel I/O
\end{itemize}

Suppose two or more threads independently issue read requests on the same file. To read specific data from a file, a thread must first call \texttt{lseek()} to seek to the proper offset in the file, and then call \texttt{read()} to retrieve the required data. If more than one thread does this at the same time, the first thread may complete its seek call, but before it gets a chance to issue its read call a second thread may complete its seek call, resulting in the first thread accessing incorrect data when it issues its read call. One workaround is to lock the file descriptor while seeking and reading or writing, but this reduces parallelism and adds overhead.

Instead, the System Interfaces volume of IEEE Std 1003.1-2001 provides two functions to make seek/read and seek/write operations atomic. The file descriptor’s current offset is unchanged, thus allowing multiple read and write operations to proceed in parallel. This improves the I/O performance of threaded applications. The \texttt{pread()} function is used to do an atomic read of data from a file into a buffer. Conversely, the \texttt{pwrite()} function does an atomic write of data from a buffer to a file.

\subsection{B.2.9.1 Thread-Safety}

All functions required by IEEE Std 1003.1-2001 need to be thread-safe. Implementations have to provide internal synchronization when necessary in order to achieve this goal. In certain cases—for example, most floating-point implementations—context switch code may have to manage the writable shared state.

While a read from a pipe of \texttt{PIPE_MAX}*2 bytes may not generate a single atomic and thread-safe stream of bytes, it should generate “several” (individually atomic) thread-safe streams of bytes. Similarly, while reading from a terminal device may not generate a single atomic and thread-safe stream of bytes, it should generate some finite number of (individually atomic) and thread-safe streams of bytes. That is, concurrent calls to read for a pipe, FIFO, or terminal device are not allowed to result in corrupting the stream of bytes or other internal data. However, \texttt{read()}, in these cases, is not required to return a single contiguous and atomic stream of bytes.

It is not required that all functions provided by IEEE Std 1003.1-2001 be either async-cancel-safe or async-signal-safe.

As it turns out, some functions are inherently not thread-safe; that is, their interface specifications preclude reentrancy. For example, some functions (such as \texttt{asctime()}) return a pointer to a result stored in memory space allocated by the function on a per-process basis. Such a function is not thread-safe, because its result can be overwritten by successive invocations. Other functions, while not inherently non-thread-safe, may be implemented in ways that lead to
them not being thread-safe. For example, some functions (such as `rand()`) store state information (such as a seed value, which survives multiple function invocations) in memory space allocated by the function on a per-process basis. The implementation of such a function is not thread-safe if the implementation fails to synchronize invocations of the function and thus fails to protect the state information. The problem is that when the state information is not protected, concurrent invocations can interfere with one another (for example, applications using `rand()` may see the same seed value).

Thread-Safety and Locking of Existing Functions

Originally, POSIX.1 was not designed to work in a multi-threaded environment, and some implementations of some existing functions will not work properly when executed concurrently. To provide routines that will work correctly in an environment with threads (“thread-safe”), two problems need to be solved:

1. Routines that maintain or return pointers to static areas internal to the routine (which may now be shared) need to be modified. The routines `ttyname()` and `localtime()` are examples.
2. Routines that access data space shared by more than one thread need to be modified. The `malloc()` function and the `stdio` family routines are examples.

There are a variety of constraints on these changes. The first is compatibility with the existing versions of these functions—non-thread-safe functions will continue to be in use for some time, as the original interfaces are used by existing code. Another is that the new thread-safe versions of these functions represent as small a change as possible over the familiar interfaces provided by the existing non-thread-safe versions. The new interfaces should be independent of any particular threads implementation. In particular, they should be thread-safe without depending on explicit thread-specific memory. Finally, there should be minimal performance penalty due to the changes made to the functions.

It is intended that the list of functions from POSIX.1 that cannot be made thread-safe and for which corrected versions are provided be complete.

Thread-Safety and Locking Solutions

Many of the POSIX.1 functions were thread-safe and did not change at all. However, some functions (for example, the math functions typically found in `libm`) are not thread-safe because of writable shared global state. For instance, in IEEE Std 754-1985 floating-point implementations, the computation modes and flags are global and shared.

Some functions are not thread-safe because a particular implementation is not reentrant, typically because of a non-essential use of static storage. These require only a new implementation.

Thread-safe libraries are useful in a wide range of parallel (and asynchronous) programming environments, not just within pthreads. In order to be used outside the context of pthreads, however, such libraries still have to use some synchronization method. These could either be independent of the pthread synchronization operations, or they could be a subset of the pthread interfaces. Either method results in thread-safe library implementations that can be used without the rest of pthreads.

Some functions, such as the `stdio` family interface and dynamic memory allocation functions such as `malloc()`, are inter-dependent routines that share resources (for example, buffers) across related calls. These require synchronization to work correctly, but they do not require any change to their external (user-visible) interfaces.

In some cases, such as `getc()` and `putc()`, adding synchronization is likely to create an unacceptable performance impact. In this case, slower thread-safe synchronized functions are to...
be provided, but the original, faster (but unsafe) functions (which may be implemented as
macros) are retained under new names. Some additional special-purpose synchronization
facilities are necessary for these macros to be usable in multi-threaded programs. This also
requires changes in `<stdio.h>`.

The other common reason that functions are unsafe is that they return a pointer to static storage,
making the functions non-thread-safe. This has to be changed, and there are three natural
choices:

1. Return a pointer to thread-specific storage

   This could incur a severe performance penalty on those architectures with a costly
implementation of the thread-specific data interface.

   A variation on this technique is to use `malloc()` to allocate storage for the function output
and return a pointer to this storage. This technique may also have an undesirable
performance impact, however, and a simplistic implementation requires that the user
program explicitly free the storage object when it is no longer needed. This technique is
used by some existing POSIX.1 functions. With careful implementation for infrequently
used functions, there may be little or no performance or storage penalty, and the
maintenance of already-standardized interfaces is a significant benefit.

2. Return the actual value computed by the function

   This technique can only be used with functions that return pointers to structures—routines
that return character strings would have to wrap their output in an enclosing structure in
order to return the output on the stack. There is also a negative performance impact
inherent in this solution in that the output value has to be copied twice before it can be
used by the calling function: once from the called routine's local buffers to the top of the
stack, then from the top of the stack to the assignment target. Finally, many older
compilers cannot support this technique due to a historical tendency to use internal static
buffers to deliver the results of structure-valued functions.

3. Have the caller pass the address of a buffer to contain the computed value

   The only disadvantage of this approach is that extra arguments have to be provided by the
calling program. It represents the most efficient solution to the problem, however, and,
unlike the `malloc()` technique, it is semantically clear.

There are some routines (often groups of related routines) whose interfaces are inherently non-
thread-safe because they communicate across multiple function invocations by means of static
memory locations. The solution is to redesign the calls so that they are thread-safe, typically by
passing the needed data as extra parameters. Unfortunately, this may require major changes to
the interface as well.

A floating-point implementation using IEEE Std 754-1985 is a case in point. A less problematic
example is the `rand48` family of pseudo-random number generators. The functions
`getgrgid()`,
`getgrnam()`, `getpwnam()`, and `getpwuid()` are another such case.

The problems with `errno` are discussed in Alternative Solutions for Per-Thread `errno` (on page
92).

Some functions can be thread-safe or not, depending on their arguments. These include the
tmpnam() and `ctermid()` functions. These functions have pointers to character strings as
arguments. If the pointers are NOT NULL, the functions store their results in the character string;
however, if the pointers are NULL, the functions store their results in an area that may be static
and thus subject to overwriting by successive calls. These should only be called by multi-thread
applications when their arguments are non-NULL.
Asynchronous Safety and Thread-Safety

A floating-point implementation has many modes that effect rounding and other aspects of computation. Functions in some math library implementations may change the computation modes for the duration of a function call. If such a function call is interrupted by a signal or cancellation, the floating-point state is not required to be protected.

There is a significant cost to make floating-point operations async-cancel-safe or async-signal-safe; accordingly, neither form of async safety is required.

Functions Returning Pointers to Static Storage

For those functions that are not thread-safe because they return values in fixed size statically allocated structures, alternate "_r" forms are provided that pass a pointer to an explicit result structure. Those that return pointers into library-allocated buffers have forms provided with explicit buffer and length parameters.

For functions that return pointers to library-allocated buffers, it makes sense to provide "_r" versions that allow the application control over allocation of the storage in which results are returned. This allows the state used by these functions to be managed on an application-specific basis, supporting per-thread, per-process, or other application-specific sharing relationships.

Early proposals had provided "_r" versions for functions that returned pointers to variable-size buffers without providing a means for determining the required buffer size. This would have made using such functions exceedingly clumsy, potentially requiring iteratively calling them with increasingly larger guesses for the amount of storage required. Hence, sysconf() variables have been provided for such functions that return the maximum required buffer size.

Thus, the rule that has been followed by IEEE Std 1003.1-2001 when adapting single-threaded non-thread-safe functions is as follows: all functions returning pointers to library-allocated storage should have "_r" versions provided, allowing the application control over the storage allocation. Those with variable-sized return values accept both a buffer address and a length parameter. The sysconf() variables are provided to supply the appropriate buffer sizes when required. Implementors are encouraged to apply the same rule when adapting their own existing functions to a pthreads environment.

B.2.9.2 Thread IDs

Separate applications should communicate through well-defined interfaces and should not depend on each other’s implementation. For example, if a programmer decides to rewrite the sort utility using multiple threads, it should be easy to do this so that the interface to the sort utility does not change. Consider that if the user causes SIGINT to be generated while the sort utility is running, keeping the same interface means that the entire sort utility is killed, not just one of its threads. As another example, consider a realtime application that manages a reactor. Such an application may wish to allow other applications to control the priority at which it watches the control rods. One technique to accomplish this is to write the ID of the thread watching the control rods into a file and allow other programs to change the priority of that thread as they see fit. A simpler technique is to have the reactor process accept IPCs (Interprocess Communication messages) from other processes, telling it at a semantic level what priority the program should assign to watching the control rods. This allows the programmer greater flexibility in the implementation. For example, the programmer can change the implementation from having one thread per rod to having one thread watching all of the rods without changing the interface.

Having threads live inside the process means that the implementation of a process is invisible to outside processes (excepting debuggers and system management tools).

Threads do not provide a protection boundary. Every thread model allows threads to share memory with other threads and encourages this sharing to be widespread. This means that one
thread can wipe out memory that is needed for the correct functioning of other threads that are sharing its memory. Consequently, providing each thread with its own user and/or group IDs would not provide a protection boundary between threads sharing memory.

B.2.9.3 Thread Mutexes

There is no additional rationale provided for this section.

B.2.9.4 Thread Scheduling

• Scheduling Implementation Models

The following scheduling implementation models are presented in terms of threads and “kernel entities”. This is to simplify exposition of the models, and it does not imply that an implementation actually has an identifiable “kernel entity”.

A kernel entity is not defined beyond the fact that it has scheduling attributes that are used to resolve contention with other kernel entities for execution resources. A kernel entity may be thought of as an envelope that holds a thread or a separate kernel thread. It is not a conventional process, although it shares with the process the attribute that it has a single thread of control; it does not necessarily imply an address space, open files, and so on. It is better thought of as a primitive facility upon which conventional processes and threads may be constructed.

— System Thread Scheduling Model

This model consists of one thread per kernel entity. The kernel entity is solely responsible for scheduling thread execution on one or more processors. This model schedules all threads against all other threads in the system using the scheduling attributes of the thread.

— Process Scheduling Model

A generalized process scheduling model consists of two levels of scheduling. A threads library creates a pool of kernel entities, as required, and schedules threads to run on them using the scheduling attributes of the threads. Typically, the size of the pool is a function of the simultaneously runnable threads, not the total number of threads. The kernel then schedules the kernel entities onto processors according to their scheduling attributes, which are managed by the threads library. This set model potentially allows a wide range of mappings between threads and kernel entities.

• System and Process Scheduling Model Performance

There are a number of important implications on the performance of applications using these scheduling models. The process scheduling model potentially provides lower overhead for making scheduling decisions, since there is no need to access kernel-level information or functions and the set of schedulable entities is smaller (only the threads within the process).

On the other hand, since the kernel is also making scheduling decisions regarding the system resources under its control (for example, CPU(s), I/O devices, memory), decisions that do not take thread scheduling parameters into account can result in unspecified delays for realtime application threads, causing them to miss maximum response time limits.

• Rate Monotonic Scheduling

Rate monotonic scheduling was considered, but rejected for standardization in the context of pthreads. A sporadic server policy is included.
• Scheduling Options

In IEEE Std 1003.1-2001, the basic thread scheduling functions are defined under the Threads option, so that they are required of all threads implementations. However, there are no specific scheduling policies required by this option to allow for conforming thread implementations that are not targeted to realtime applications.

Specific standard scheduling policies are defined to be under the Thread Execution Scheduling option, and they are specifically designed to support realtime applications by providing predictable resource-sharing sequences. The name of this option was chosen to emphasize that this functionality is defined as appropriate for realtime applications that require simple priority-based scheduling.

It is recognized that these policies are not necessarily satisfactory for some multi-processor implementations, and work is ongoing to address a wider range of scheduling behaviors. The interfaces have been chosen to create abundant opportunity for future scheduling policies to be implemented and standardized based on this interface. In order to standardize a new scheduling policy, all that is required (from the standpoint of thread scheduling attributes) is to define a new policy name, new members of the thread attributes object, and functions to set these members when the scheduling policy is equal to the new value.

Scheduling Contention Scope

In order to accommodate the requirement for realtime response, each thread has a scheduling contention scope attribute. Threads with a system scheduling contention scope have to be scheduled with respect to all other threads in the system. These threads are usually bound to a single kernel entity that reflects their scheduling attributes and are directly scheduled by the kernel.

Threads with a process scheduling contention scope need be scheduled only with respect to the other threads in the process. These threads may be scheduled within the process onto a pool of kernel entities. The implementation is also free to bind these threads directly to kernel entities and let them be scheduled by the kernel. Process scheduling contention scope allows the implementation the most flexibility and is the default if both contention scopes are supported and none is specified.

Thus, the choice by implementors to provide one or the other (or both) of these scheduling models is driven by the need of their supported application domains for worst-case (that is, realtime) response, or average-case (non-realtime) response.

Scheduling Allocation Domain

The SCHED_FIFO and SCHED_RR scheduling policies take on different characteristics on a multi-processor. Other scheduling policies are also subject to changed behavior when executed on a multi-processor. The concept of scheduling allocation domain determines the set of processors on which the threads of an application may run. By considering the application's processor scheduling allocation domain for its threads, scheduling policies can be defined in terms of their behavior for varying processor scheduling allocation domain values. It is conceivable that not all scheduling allocation domain sizes make sense for all scheduling policies on all implementations. The concept of scheduling allocation domain, however, is a useful tool for the description of multi-processor scheduling policies.

The “process control” approach to scheduling obtains significant performance advantages from dynamic scheduling allocation domain sizes when it is applicable.

Non-Uniform Memory Access (NUMA) multi-processors may use a system scheduling structure that involves reassignment of threads among scheduling allocation domains. In NUMA
machines, a natural model of scheduling is to match scheduling allocation domains to clusters of processors. Load balancing in such an environment requires changing the scheduling allocation domain to which a thread is assigned.

Scheduling Documentation

Implementation-provided scheduling policies need to be completely documented in order to be useful. This documentation includes a description of the attributes required for the policy, the scheduling interaction of threads running under this policy and all other supported policies, and the effects of all possible values for processor scheduling allocation domain. Note that for the implementor wishing to be minimally-compliant, it is (minimally) acceptable to define the behavior as undefined.

Scheduling Contention Scope Attribute

The scheduling contention scope defines how threads compete for resources. Within IEEE Std 1003.1-2001, scheduling contention scope is used to describe only how threads are scheduled in relation to one another in the system. That is, either they are scheduled against all other threads in the system ("system scope") or only against those threads in the process ("process scope"). In fact, scheduling contention scope may apply to additional resources, including virtual timers and profiling, which are not currently considered by IEEE Std 1003.1-2001.

Mixed Scopes

If only one scheduling contention scope is supported, the scheduling decision is straightforward. To perform the processor scheduling decision in a mixed scope environment, it is necessary to map the scheduling attributes of the thread with process-wide contention scope to the same attribute space as the thread with system-wide contention scope.

Since a conforming implementation has to support one and may support both scopes, it is useful to discuss the effects of such choices with respect to example applications. If an implementation supports both scopes, mixing scopes provides a means of better managing system-level (that is, kernel-level) and library-level resources. In general, threads with system scope will require the resources of a separate kernel entity in order to guarantee the scheduling semantics. On the other hand, threads with process scope can share the resources of a kernel entity while maintaining the scheduling semantics.

The application is free to create threads with dedicated kernel resources, and other threads that multiplex kernel resources. Consider the example of a window server. The server allocates two threads per widget: one thread manages the widget user interface (including drawing), while the other thread takes any required application action. This allows the widget to be "active" while the application is computing. A screen image may be built from thousands of widgets. If each of these threads had been created with system scope, then most of the kernel-level resources might be wasted, since only a few widgets are active at any one time. In addition, mixed scope is particularly useful in a window server where one thread with high priority and system scope handles the mouse so that it tracks well. As another example, consider a database server. For each of the hundreds or thousands of clients supported by a large server, an equivalent number of threads will have to be created. If each of these threads were system scope, the consequences would be the same as for the window server example above. However, the server could be constructed so that actual retrieval of data is done by several dedicated threads. Dedicated threads that do work for all clients frequently justify the added expense of system scope. If it were not permissible to mix system and process threads in the same process, this type of solution would not be possible.
Dynamic Thread Scheduling Parameters Access

In many time-constrained applications, there is no need to change the scheduling attributes dynamically during thread or process execution, since the general use of these attributes is to reflect directly the time constraints of the application. Since these time constraints are generally imposed to meet higher-level system requirements, such as accuracy or availability, they frequently should remain unchanged during application execution.

However, there are important situations in which the scheduling attributes should be changed. Generally, this will occur when external environmental conditions exist in which the time constraints change. Consider, for example, a space vehicle major mode change, such as the change from ascent to descent mode, or the change from the space environment to the atmospheric environment. In such cases, the frequency with which many of the sensors or actuators need to be read or written will change, which will necessitate a priority change. In other cases, even the existence of a time constraint might be temporary, necessitating not just a priority change, but also a policy change for ongoing threads or processes. For this reason, it is critical that the interface should provide functions to change the scheduling parameters dynamically, but, as with many of the other realtime functions, it is important that applications use them properly to avoid the possibility of unnecessarily degrading performance.

In providing functions for dynamically changing the scheduling behavior of threads, there were two options: provide functions to get and set the individual scheduling parameters of threads, or provide a single interface to get and set all the scheduling parameters for a given thread simultaneously. Both approaches have merit. Access functions for individual parameters allow simpler control of thread scheduling for simple thread scheduling parameters. However, a single function for setting all the parameters for a given scheduling policy is required when first setting that scheduling policy. Since the single all-encompassing functions are required, it was decided to leave the interface as minimal as possible. Note that simpler functions (such as \texttt{pthread_setprio()} for threads running under the priority-based schedulers) can be easily defined in terms of the all-encompassing functions.

If the \texttt{pthread_setschedparam()} function executes successfully, it will have set all of the scheduling parameter values indicated in \texttt{param}; otherwise, none of the scheduling parameters will have been modified. This is necessary to ensure that the scheduling of this and all other threads continues to be consistent in the presence of an erroneous scheduling parameter.

The [EPERM] error value is included in the list of possible \texttt{pthread_setschedparam()} error returns as a reflection of the fact that the ability to change scheduling parameters increases risks to the implementation and application performance if the scheduling parameters are changed improperly. For this reason, and based on some existing practice, it was felt that some implementations would probably choose to define specific permissions for changing either a thread’s own or another thread’s scheduling parameters. IEEE Std 1003.1-2001 does not include portable methods for setting or retrieving permissions, so any such use of permissions is completely unspecified.

Mutex Initialization Scheduling Attributes

In a priority-driven environment, a direct use of traditional primitives like mutexes and condition variables can lead to unbounded priority inversion, where a higher priority thread can be blocked by a lower priority thread, or set of threads, for an unbounded duration of time. As a result, it becomes impossible to guarantee thread deadlines. Priority inversion can be bounded and minimized by the use of priority inheritance protocols. This allows thread deadlines to be guaranteed even in the presence of synchronization requirements.

Two useful but simple members of the family of priority inheritance protocols are the basic priority inheritance protocol and the priority ceiling protocol emulation. Under the Basic Priority...
Inheritance protocol (governed by the Thread Priority Inheritance option), a thread that is blocking higher priority threads executes at the priority of the highest priority thread that it blocks. This simple mechanism allows priority inversion to be bounded by the duration of critical sections and makes timing analysis possible.

Under the Priority Ceiling Protocol Emulation protocol (governed by the Thread Priority Protection option), each mutex has a priority ceiling, usually defined as the priority of the highest priority thread that can lock the mutex. When a thread is executing inside critical sections, its priority is unconditionally increased to the highest of the priority ceilings of all the mutexes owned by the thread. This protocol has two very desirable properties in uni-processor systems. First, a thread can be blocked by a lower priority thread for at most the duration of one single critical section. Furthermore, when the protocol is correctly used in a single processor, and if threads do not become blocked while owning mutexes, mutual deadlocks are prevented.

The priority ceiling emulation can be extended to multiple processor environments, in which case the values of the priority ceilings will be assigned depending on the kind of mutex that is being used: local to only one processor, or global, shared by several processors. Local priority ceilings will be assigned the usual way, equal to the priority of the highest priority thread that may lock that mutex. Global priority ceilings will usually be assigned a priority level higher than all the priorities assigned to any of the threads that reside in the involved processors to avoid the effect called remote blocking.

Change the Priority Ceiling of a Mutex

In order for the priority protect protocol to exhibit its desired properties of bounding priority inversion and avoidance of deadlock, it is critical that the ceiling priority of a mutex be the same as the priority of the highest thread that can ever hold it, or higher. Thus, if the priorities of the threads using such mutexes never change dynamically, there is no need ever to change the priority ceiling of a mutex.

However, if a major system mode change results in an altered response time requirement for one or more application threads, their priority has to change to reflect it. It will occasionally be the case that the priority ceilings of mutexes held also need to change. While changing priority ceilings should generally be avoided, it is important that IEEE Std 1003.1-2001 provide these interfaces for those cases in which it is necessary.

B.2.9.5 Thread Cancellation

Many existing threads packages have facilities for canceling an operation or canceling a thread. These facilities are used for implementing user requests (such as the CANCEL button in a window-based application), for implementing OR parallelism (for example, telling the other threads to stop working once one thread has found a forced mate in a parallel chess program), or for implementing the ABORT mechanism in Ada.

POSIX programs traditionally have used the signal mechanism combined with either longjmp or polling to cancel operations. Many POSIX programmers have trouble using these facilities to solve their problems efficiently in a single-threaded process. With the introduction of threads, these solutions become even more difficult to use.

The main issues with implementing a cancellation facility are specifying the operation to be canceled, cleanly releasing any resources allocated to that operation, controlling when the target notices that it has been canceled, and defining the interaction between asynchronous signals and cancellation.
General Information  

Specifying the Operation to Cancel

Consider a thread that calls through five distinct levels of program abstraction and then, inside the lowest-level abstraction, calls a function that suspends the thread. (An abstraction boundary is a layer at which the client of the abstraction sees only the service being provided and can remain ignorant of the implementation. Abstractions are often layered, each level of abstraction being a client of the lower-level abstraction and implementing a higher-level abstraction.) Depending on the semantics of each abstraction, one could imagine wanting to cancel only the call that causes suspension, only the bottom two levels, or the operation being done by the entire thread. Canceling operations at a finer grain than the entire thread is difficult because threads are active and they may be run in parallel on a multi-processor. By the time one thread can make a request to cancel an operation, the thread performing the operation may have completed that operation and gone on to start another operation whose cancellation is not desired. Canceling at a finer grain than the entire thread is difficult because threads are active and they may be run in parallel on a multi-processor. By the time one thread can make a request to cancel an operation, the thread performing the operation may have completed that operation and gone on to start another operation whose cancellation is not desired. Thread IDs are not reused until the thread has exited, and either it was created with the `Attr detachstate` attribute set to PTHREAD_CREATE_DETACHED or the `pthread_join()` or `pthread_detach()` function has been called for that thread. Consequently, a thread cancellation will never be misdirected when the thread terminates. For these reasons, the canceling of operations is done at the granularity of the thread. Threads are designed to be inexpensive enough so that a separate thread may be created to perform each separately cancelable operation; for example, each possibly long running user request.

For cancellation to be used in existing code, cancellation scopes and handlers will have to be established for code that needs to release resources upon cancellation, so that it follows the programming discipline described in the text.

A Special Signal Versus a Special Interface

Two different mechanisms were considered for providing the cancellation interfaces. The first was to provide an interface to direct signals at a thread and then to define a special signal that had the required semantics. The other alternative was to use a special interface that delivered the correct semantics to the target thread. The solution using signals produced a number of problems. It required the implementation to provide cancellation in terms of signals whereas a perfectly valid (and possibly more efficient) implementation could have both layered on a low-level set of primitives. There were so many exceptions to the special signal (it cannot be used with `kill()`), no POSIX.1 interfaces can be used with it) that it was clearly not a valid signal. Its semantics on delivery were also completely different from any existing POSIX.1 signal. As such, a special interface that did not mandate the implementation and did not confuse the semantics of signals and cancellation was felt to be the better solution.

Races Between Cancellation and Resuming Execution

Due to the nature of cancellation, there is generally no synchronization between the thread requesting the cancellation of a blocked thread and events that may cause that thread to resume execution. For this reason, and because excess serialization hurts performance, when both an event that a thread is waiting for has occurred and a cancellation request has been made and cancellation is enabled, IEEE Std 1003.1-2001 explicitly allows the implementation to choose between returning from the blocking call or acting on the cancellation request.
Interaction of Cancellation with Asynchronous Signals

A typical use of cancellation is to acquire a lock on some resource and to establish a cancellation cleanup handler for releasing the resource when and if the thread is canceled.

A correct and complete implementation of cancellation in the presence of asynchronous signals requires considerable care. An implementation has to push a cancellation cleanup handler on the cancellation cleanup stack while maintaining the integrity of the stack data structure. If an asynchronously-generated signal is posted to the thread during a stack operation, the signal handler cannot manipulate the cancellation cleanup stack. As a consequence, asynchronous signal handlers may not cancel threads or otherwise manipulate the cancellation state of a thread. Threads may, of course, be canceled by another thread that used a `sigwait()` function to wait synchronously for an asynchronous signal.

In order for cancellation to function correctly, it is required that asynchronous signal handlers not change the cancellation state. This requires that some elements of existing practice, such as using `longjmp()` to exit from an asynchronous signal handler implicitly, be prohibited in cases where the integrity of the cancellation state of the interrupt thread cannot be ensured.

Thread Cancellation Overview

- **Cancelability States**

  The three possible cancelability states (disabled, deferred, and asynchronous) are encoded into two separate bits ((disable, enable) and (deferred, asynchronous)) to allow them to be changed and restored independently. For instance, short code sequences that will not block sometimes disable cancelability on entry and restore the previous state upon exit. Likewise, long or unbounded code sequences containing no convenient explicit cancellation points will sometimes set the cancelability type to asynchronous on entry and restore the previous value upon exit.

- **Cancellation Points**

  Cancellation points are points inside of certain functions where a thread has to act on any pending cancellation request when cancelability is enabled, if the function would block. As with checking for signals, operations need only check for pending cancellation requests when the operation is about to block indefinitely.

  The idea was considered of allowing implementations to define whether blocking calls such as `read()` should be cancellation points. It was decided that it would adversely affect the design of conforming applications if blocking calls were not cancellation points because threads could be left blocked in an uncancellable state.

  There are several important blocking routines that are specifically not made cancellation points:

  - `pthread_mutex_lock()`

    If `pthread_mutex_lock()` were a cancellation point, every routine that called it would also become a cancellation point (that is, any routine that touched shared state would automatically become a cancellation point). For example, `malloc()`, `free()`, and `rand()` would become cancellation points under this scheme. Having too many cancellation points makes programming very difficult, leading to either much disabling and restoring of cancelability or much difficulty in trying to arrange for reliable cleanup at every possible place.

    Since `pthread_mutex_lock()` is not a cancellation point, threads could result in being blocked uninterruptibly for long periods of time if mutexes were used as a general
synchronization mechanism. As this is normally not acceptable, mutexes should only be
used to protect resources that are held for small fixed lengths of time where not being
able to be canceled will not be a problem. Resources that need to be held exclusively for
long periods of time should be protected with condition variables.

— pthread_barrier_wait()

Canceling a barrier wait will render a barrier unusable. Similar to a barrier timeout (which
the standard developers rejected), there is no way to guarantee the consistency of a
barrier’s internal data structures if a barrier wait is canceled.

— pthread_spin_lock()

As with mutexes, spin locks should only be used to protect resources that are held for
small fixed lengths of time where not being cancelable will not be a problem.

Every library routine should specify whether or not it includes any cancellation points.
Typically, only those routines that may block or compute indefinitely need to include
cancellation points.

Correctly coded routines only reach cancellation points after having set up a cancellation
cleanup handler to restore invariants if the thread is canceled at that point. Being cancelable
only at specified cancellation points allows programmers to keep track of actions needed in a
cancellation cleanup handler more easily. A thread should only be made asynchronously
cancelable when it is not in the process of acquiring or releasing resources or otherwise in a
state from which it would be difficult or impossible to recover.

• Thread Cancellation Cleanup Handlers

The cancellation cleanup handlers provide a portable mechanism, easy to implement, for
releasing resources and restoring invariants. They are easier to use than signal handlers
because they provide a stack of cancellation cleanup handlers rather than a single handler,
and because they have an argument that can be used to pass context information to the
handler.

The alternative to providing these simple cancellation cleanup handlers (whose only use is
for cleaning up when a thread is canceled) is to define a general exception package that could
be used for handling and cleaning up after hardware traps and software-detected errors. This
was too far removed from the charter of providing threads to handle asynchrony. However,
it is an explicit goal of IEEE Std 1003.1-2001 to be compatible with existing exception facilities
and languages having exceptions.

The interaction of this facility and other procedure-based or language-level exception
facilities is unspecified in this version of IEEE Std 1003.1-2001. However, it is intended that it
be possible for an implementation to define the relationship between these cancellation
cleanup handlers and Ada, C++, or other language-level exception handling facilities.

It was suggested that the cancellation cleanup handlers should also be called when the
process exits or calls the exec function. This was rejected partly due to the performance
problem caused by having to call the cancellation cleanup handlers of every thread before the
operation could continue. The other reason was that the only state expected to be cleaned up
by the cancellation cleanup handlers would be the intraprocess state. Any handlers that are
to clean up the interprocess state would be registered with atexit(). There is the orthogonal
problem that the exec functions do not honor the atexit() handlers, but resolving this is
• Async-Cancel Safety

A function is said to be async-cancel-safe if it is written in such a way that entering the function with asynchronous cancelability enabled will not cause any invariants to be violated, even if a cancellation request is delivered at any arbitrary instruction. Functions that are async-cancel-safe are often written in such a way that they need to acquire no resources for their operation and the visible variables that they may write are strictly limited.

Any routine that gets a resource as a side effect cannot be made async-cancel-safe (for example, malloc()). If such a routine were called with asynchronous cancelability enabled, it might acquire the resource successfully, but as it was returning to the client, it could act on a cancellation request. In such a case, the application would have no way of knowing whether the resource was acquired or not.

Indeed, because many interesting routines cannot be made async-cancel-safe, most library routines in general are not async-cancel-safe. Every library routine should specify whether or not it is async-cancel safe so that programmers know which routines can be called from code that is asynchronously cancelable.

IEEE Std 1003.1-2001/Cor 1-2002, item XSH/TC1/D6/8 is applied, adding the pselect() function to the list of functions with cancellation points.

B.2.9.6 Thread Read-Write Locks

Background

Read-write locks are often used to allow parallel access to data on multi-processors, to avoid context switches on uni-processors when multiple threads access the same data, and to protect data structures that are frequently accessed (that is, read) but rarely updated (that is, written). The in-core representation of a file system directory is a good example of such a data structure. One would like to achieve as much concurrency as possible when searching directories, but limit concurrent access when adding or deleting files.

Although read-write locks can be implemented with mutexes and condition variables, such implementations are significantly less efficient than is possible. Therefore, this synchronization primitive is included in IEEE Std 1003.1-2001 for the purpose of allowing more efficient implementations in multi-processor systems.

Queuing of Waiting Threads

The pthread_rwlock_unlock() function description states that one writer or one or more readers must acquire the lock if it is no longer held by any thread as a result of the call. However, the function does not specify which thread(s) acquire the lock, unless the Thread Execution Scheduling option is supported.

The standard developers considered the issue of scheduling with respect to the queuing of threads blocked on a read-write lock. The question turned out to be whether IEEE Std 1003.1-2001 should require priority scheduling of read-write locks for threads whose execution scheduling policy is priority-based (for example, SCHED_FIFO or SCHED_RR). There are tradeoffs between priority scheduling, the amount of concurrency achievable among readers, and the prevention of writer and/or reader starvation.

For example, suppose one or more readers hold a read-write lock and the following threads request the lock in the listed order:

Part B: System Interfaces — Copyright © 2001-2003, IEEE and The Open Group. All rights reserved. 175
 pthread_rwlock_wrlock() - Low priority thread writer_a
 pthread_rwlock_rdlock() - High priority thread reader_a
 pthread_rwlock_rdlock() - High priority thread reader_b
 pthread_rwlock_rdlock() - High priority thread reader_c

 When the lock becomes available, should writer_a block the high priority readers? Or, suppose a read-write lock becomes available and the following are queued:

 pthread_rwlock_rdlock() - Low priority thread reader_a
 pthread_rwlock_rdlock() - Low priority thread reader_b
 pthread_rwlock_rdlock() - Low priority thread reader_c
 pthread_rwlock_wrlock() - Medium priority thread writer_a
 pthread_rwlock_rdlock() - High priority thread reader_d

 If priority scheduling is applied then reader_d would acquire the lock and writer_a would block the remaining readers. But should the remaining readers also acquire the lock to increase concurrency? The solution adopted takes into account that when the Thread Execution Scheduling option is supported, high priority threads may in fact starve low priority threads (the application developer is responsible in this case for designing the system in such a way that this starvation is avoided). Therefore, IEEE Std 1003.1-2001 specifies that high priority readers take precedence over lower priority writers. However, to prevent writer starvation from threads of the same or lower priority, writers take precedence over readers of the same or lower priority.

 Priority inheritance mechanisms are non-trivial in the context of read-write locks. When a high priority writer is forced to wait for multiple readers, for example, it is not clear which subset of the readers should inherit the writer's priority. Furthermore, the internal data structures that record the inheritance must be accessible to all readers, and this implies some sort of serialization that could negate any gain in parallelism achieved through the use of multiple readers in the first place. Finally, existing practice does not support the use of priority inheritance for read-write locks. Therefore, no specification of priority inheritance or priority ceiling is attempted. If reliable priority-scheduled synchronization is absolutely required, it can always be obtained through the use of mutexes.

 Comparison to fcntl() Locks

 The read-write locks and the fcntl() locks in IEEE Std 1003.1-2001 share a common goal: increasing concurrency among readers, thus increasing throughput and decreasing delay.

 However, the read-write locks have two features not present in the fcntl() locks. First, under priority scheduling, read-write locks are granted in priority order. Second, also under priority scheduling, writer starvation is prevented by giving writers preference over readers of equal or lower priority.

 Also, read-write locks can be used in systems lacking a file system, such as those conforming to the minimal realtime system profile of IEEE Std 1003.13-1998.

 History of Resolution Issues

 Based upon some balloting objections, early drafts specified the behavior of threads waiting on a read-write lock during the execution of a signal handler, as if the thread had not called the lock operation. However, this specified behavior would require implementations to establish internal signal handlers even though this situation would be rare, or never happen for many programs. This would introduce an unacceptable performance hit in comparison to the little additional functionality gained. Therefore, the behavior of read-write locks and signals was reverted back to its previous mutex-like specification.
B.2.9.7 Thread Interactions with Regular File Operations

There is no additional rationale provided for this section.

B.2.10 Sockets

The base document for the sockets interfaces in IEEE Std 1003.1-2001 is the XNS, Issue 5.2 specification. This was primarily chosen as it aligns with IPv6. Additional material has been added from IEEE Std 1003.1g-2000, notably socket concepts, raw sockets, the pselect() function, the sockatmark() function, and the <sys/select.h> header.

B.2.10.1 Address Families

There is no additional rationale provided for this section.

B.2.10.2 Addressing

There is no additional rationale provided for this section.

B.2.10.3 Protocols

There is no additional rationale provided for this section.

B.2.10.4 Routing

There is no additional rationale provided for this section.

B.2.10.5 Interfaces

There is no additional rationale provided for this section.

B.2.10.6 Socket Types

The type socklen_t was invented to cover the range of implementations seen in the field. The intent of socklen_t is to be the type for all lengths that are naturally bounded in size; that is, that they are the length of a buffer which cannot sensibly become of massive size: network addresses, host names, string representations of these, ancillary data, control messages, and socket options are examples. Truly boundless sizes are represented by size_t as in read(), write(), and so on.

All socklen_t types were originally (in BSD UNIX) of type int. During the development of IEEE Std 1003.1-2001, it was decided to change all buffer lengths to size_t, which appears at face value to make sense. When dual mode 32/64-bit systems came along, this choice unnecessarily complicated system interfaces because size_t (with long) was a different size under ILP32 and LP64 models. Reverting to int would have happened except that some implementations had already shipped 64-bit-only interfaces. The compromise was a type which could be defined to be any size by the implementation: socklen_t.

B.2.10.7 Socket I/O Mode

There is no additional rationale provided for this section.
B.2.10.8 Socket Owner
There is no additional rationale provided for this section.

B.2.10.9 Socket Queue Limits
There is no additional rationale provided for this section.

B.2.10.10 Pending Error
There is no additional rationale provided for this section.

B.2.10.11 Socket Receive Queue
There is no additional rationale provided for this section.

B.2.10.12 Socket Out-of-Band Data State
There is no additional rationale provided for this section.

B.2.10.13 Connection Indication Queue
There is no additional rationale provided for this section.

B.2.10.14 Signals
There is no additional rationale provided for this section.

B.2.10.15 Asynchronous Errors
There is no additional rationale provided for this section.

B.2.10.16 Use of Options
There is no additional rationale provided for this section.

B.2.10.17 Use of Sockets for Local UNIX Connections
There is no additional rationale provided for this section.

B.2.10.18 Use of Sockets over Internet Protocols
A raw socket allows privileged users direct access to a protocol; for example, raw access to the IP and ICMP protocols is possible through raw sockets. Raw sockets are intended for knowledgeable applications that wish to take advantage of some protocol feature not directly accessible through the other sockets interfaces.

B.2.10.19 Use of Sockets over Internet Protocols Based on IPv4
There is no additional rationale provided for this section.

B.2.10.20 Use of Sockets over Internet Protocols Based on IPv6
The Open Group Base Resolution bwg2001-012 is applied, clarifying that IPv6 implementations are required to support use of AF_INET6 sockets over IPv4.
B.2.11 Tracing

The organization of the tracing rationale differs from the traditional rationale in that this tracing rationale text is written against the trace interface as a whole, rather than against the individual components of the trace interface or the normative section in which those components are defined. Therefore the sections below do not parallel the sections of normative text in IEEE Std 1003.1-2001.

B.2.11.1 Objectives

The intended uses of tracing are application-system debugging during system development, as a ‘‘flight recorder’’ for maintenance of fielded systems, and as a performance measurement tool. In all of these intended uses, the vendor-supplied computer system and its software are, for this discussion, assumed error-free; the intent being to debug the user-written and/or third-party application code, and their interactions. Clearly, problems with the vendor-supplied system and its software will be uncovered from time to time, but this is a byproduct of the primary activity, debugging user code.

Another need for defining a trace interface in POSIX stems from the objective to provide an efficient portable way to perform benchmarks. Existing practice shows that such interfaces are commonly used in a variety of systems but with little commonality. As part of the benchmarking needs, two aspects within the trace interface must be considered.

The first, and perhaps more important one, is the qualitative aspect.

The second is the quantitative aspect.

• Qualitative Aspect

To better understand this aspect, let us consider an example. Suppose that you want to organize a number of actions to be performed during the day. Some of these actions are known at the beginning of the day. Some others, which may be more or less important, will be triggered by reading your mail. During the day you will make some phone calls and synchronously receive some more information. Finally you will receive asynchronous phone calls that also will trigger actions. If you, or somebody else, examines your day at work, you, or he, can discover that you have not efficiently organized your work. For instance, relative to the phone calls you made, would it be preferable to make some of these early in the morning? Or to delay some others until the end of the day? Relative to the phone calls you have received, you might find that somebody you called in the morning has called you 10 times while you were performing some important work. To examine, afterwards, your day at work, you record in sequence all the trace events relative to your work. This should give you a chance of organizing your next day at work.

This is the qualitative aspect of the trace interface. The user of a system needs to keep a trace of particular points the application passes through, so that he can eventually make some changes in the application and/or system configuration, to give the application a chance of running more efficiently.

• Quantitative Aspect

This aspect concerns primarily realtime applications, where missed deadlines can be undesirable. Although there are, in IEEE Std 1003.1-2001, some interfaces useful for such applications (timeouts, execution time monitoring, and so on), there are no APIs to aid in the tuning of a realtime application’s behavior (timespec in timeouts, length of message queues, duration of driver interrupt service routine, and so on). The tuning of an application needs a means of recording timestamped important trace events during execution in order to analyze offline, and eventually, to tune some realtime features (redesign the system with less
Detailed Objectives

Objectives were defined to build the trace interface and are kept for historical interest. Although some objectives are not fully respected in this trace interface, the concept of the POSIX trace interface assumes the following points:

1. It must be possible to trace both system and user trace events concurrently.
2. It must be possible to trace per-process trace events and also to trace system trace events which are unrelated to any particular process. A per-process trace event is either user-initiated or system-initiated.
3. It must be possible to control tracing on a per-process basis from either inside or outside the process.
4. It must be possible to control tracing on a per-thread basis from inside the enclosing process.
5. Trace points must be controllable by trace event type ID from inside and outside of the process. Multiple trace points can have the same trace event type ID, and will be controlled jointly.
6. Recording of trace events is dependent on both trace event type ID and the process/thread. Both must be enabled in order to record trace events. System trace events may or may not be handled differently.
7. The API must not mandate the ability to control tracing for more than one process at the same time.
8. There is no objective for trace control on anything bigger than a process; for example, group or session.
9. Trace propagation and control:
   a. Trace propagation across fork() is optional; the default is to not trace a child process.
   b. Trace control must span pthread_create() operations; that is, if a process is being traced, any thread will be traced as well if this thread allows tracing. The default is to allow tracing.
10. Trace control must not span exec or posix_spawn() operations.
11. A triggering API is not required. The triggering API is the ability to command or stop tracing based on the occurrence of a specific trace event other than a POSIX_TRACE_START trace event or a POSIX_TRACE_STOP trace event.
12. Trace log entries must have timestamps of implementation-defined resolution. Implementations are exhorted to support at least microsecond resolution. When a trace log entry is retrieved, it must have timestamp, PC address, PID, and TID of the entity that generated the trace event.
13. Independently developed code should be able to use trace facilities without coordination and without conflict.
14. Even if the trace points in the trace calls are not unique, the trace log entries (after any processing) must be uniquely identified as to trace point.
15. There must be a standard API to read the trace stream.
16. The format of the trace stream and the trace log is opaque and unspecified.

17. It must be possible to read a completed trace, if recorded on some suitable non-volatile storage, even subsequent to a power cycle or subsequent cold boot of the system.

18. Support of analysis of a trace log while it is being formed is implementation-defined.

19. The API must allow the application to write trace stream identification information into the trace stream and to be able to retrieve it, without it being overwritten by trace entries, even if the trace stream is full.

20. It must be possible to specify the destination of trace data produced by trace events.

21. It must be possible to have different trace streams, and for the tracing enabled by one trace stream to be completely independent of the tracing of another trace stream.

22. It must be possible to trace events from threads in different CPUs.

23. The API must support one or more trace streams per-system, and one or more trace streams per-process, up to an implementation-defined set of per-system and per-process maximums.

24. It must be possible to determine the order in which the trace events happened, without necessarily depending on the clock, up to an implementation-defined time resolution.

25. For performance reasons, the trace event point call(s) must be implementable as a macro (see the ISO POSIX-1:1996 standard, 1.3.4, Statement 2).

26. IEEE Std 1003.1-2001 must not define the trace points which a conforming system must implement, except for trace points used in the control of tracing.

27. The APIs must be thread-safe, and trace points should be lock-free (that is, not require a lock to gain exclusive access to some resource).

28. The user-provided information associated with a trace event is variable-sized, up to some maximum size.

29. Bounds on record and trace stream sizes:
   a. The API must permit the application to declare the upper bounds on the length of an application data record. The system must return the limit it used. The limit used may be smaller than requested.
   b. The API must permit the application to declare the upper bounds on the size of trace streams. The system must return the limit it used. The limit used may be different, either larger or smaller, than requested.

30. The API must be able to pass any fundamental data type, and a structured data type composed only of fundamental types. The API must be able to pass data by reference, given only as an address and a length. Fundamental types are the POSIX.1 types (see the <sys/types.h> header) plus those defined in the ISO C standard.

31. The API must apply the POSIX notions of ownership and permission to recorded trace data, corresponding to the sources of that data.
Comments on Objectives

Note: In the following comments, numbers in square brackets refer to the above objectives.

It is necessary to be able to obtain a trace stream for a complete activity. Thus there is a requirement to be able to trace both application and system trace events. A per-process trace event is either user-initiated, like the `write()` function, or system-initiated, like a timer expiration. There is also a need to be able to trace an entire process' activity even when it has threads in multiple CPUs. To avoid excess trace activity, it is necessary to be able to control tracing on a trace event type basis.

[Objectives 1,2,5,22]

There is a need to be able to control tracing on a per-process basis, both from inside and outside the process; that is, a process can start a trace activity on itself or any other process. There is also the perceived need to allow the definition of a maximum number of trace streams per system.

[Objectives 3,23]

From within a process, it is necessary to be able to control tracing on a per-thread basis. This provides an additional filtering capability to keep the amount of traced data to a minimum. It also allows for less ambiguity as to the origin of trace events. It is recognized that thread-level control is only valid from within the process itself. It is also desirable to know the maximum number of trace streams per process that can be started. The API should not require thread synchronization or mandate priority inversions that would cause the thread to block. However, the API must be thread-safe.

[Objectives 4,23,24,27]

There was no perceived objective to control tracing on anything larger than a process; for example, a group or session. Also, the ability to start or stop a trace activity on multiple processes atomically may be very difficult or cumbersome in some implementations.

[Objectives 6,8]

It is also necessary to be able to control tracing by trace event type identifier, sometimes called a trace hook ID. However, there is no mandated set of system trace events, since such trace points are implementation-defined. The API must not require from the operating system facilities that are not standard.

[Objectives 6,26]

Trace control must span `fork()` and `pthread_create()`. If not, there will be no way to ensure that an application's activity is entirely traced. The newly forked child would not be able to turn on its tracing until after it obtained control after the fork, and trace control externally would be even more problematic.

[Objective 9]

Since `exec` and `posix_spawn()` represent a complete change in the execution of a task (a new program), trace control need not persist over an `exec` or `posix_spawn()`.

[Objective 10]

Where trace activities are started on multiple processes, these trace activities should not interfere with each other.

[Objective 21]

There is no need for a triggering objective, primarily for performance reasons; see also Section B.2.11.8 (on page 202), rationale on triggering.

[Objective 11]

It must be possible to determine the origin of each traced event. The process and thread identifiers for each trace event are needed. Also there was a perceived need for a user-specifiable origin, but it was felt that this would create too much overhead.
An allowance must be made for trace points to come embedded in software components from several different sources and vendors without requiring coordination.

There is a requirement to be able to uniquely identify trace points that may have the same trace stream identifier. This is only necessary when a trace report is produced.

Tracing is a very performance-sensitive activity, and will therefore likely be implemented at a low level within the system. Hence the interface must not mandate any particular buffering or storage method. Therefore, a standard API is needed to read a trace stream. Also the interface must not mandate the format of the trace data, and the interface must not assume a trace storage method. Due to the possibility of a monolithic kernel and the possible presence of multiple processes capable of running trace activities, the two kinds of trace events may be stored in two separate streams for performance reasons. A mandatory dump mechanism, common in some existing practice, has been avoided to allow the implementation of this set of functions on small realtime profiles for which the concept of a file system is not defined. The trace API calls should be implemented as macros.

Since a trace facility is a valuable service tool, the output (or log) of a completed trace stream that is written to permanent storage must be readable on other systems of the type that produced the trace log. Note that there is no objective to be able to interpret a trace log that was not successfully completed.

For trace streams written to permanent storage, a way to specify the destination of the trace stream is needed.

There is a requirement to be able to depend on the ordering of trace events up to some implementation-defined time interval. For example, there is a need to know the time period during which, if trace events are closer together, their ordering is unspecified. Events that occur within an interval smaller than this resolution may or may not be read back in the correct order.

The application should be able to know how much data can be traced. When trace event types can be filtered, the application should be able to specify the approximate maximum amount of data that will be traced in a trace event so resources can be more efficiently allocated.

Users should not be able to trace data to which they would not normally have access. System trace events corresponding to a process/thread should be associated with the ownership of that process/thread.
Introduction

The model is based on two base entities: the "Trace Stream" and the "Trace Log", and a recorded unit called the "Trace Event". The possibility of using Trace Streams and Trace Logs separately gives two use dimensions and solves both the performance issue and the full-information system issue. In the case of a trace stream without log, specific information, although reduced in quantity, is required to be registered, in a possibly small realtime system, with as little overhead as possible. The Trace Log option has been added for small realtime systems. In the case of a trace stream with log, considerable complex application-specific information needs to be collected.

Trace Model Description

The trace model can be examined for three different subfunctions: Application Instrumentation, Trace Operation Control, and Trace Analysis.

Each of these subfunctions requires specific characteristics of the trace mechanism API.

- Application Instrumentation

When instrumenting an application, the programmer is not concerned about the future use of the trace events in the trace stream or the trace log, the full policy of the trace stream, or the eventual pre-filtering of trace events. But he is concerned about the correct determination of the specific trace event type identifier, regardless of how many independent libraries are used in the same user application; see Figure B-2 and Figure B-3 (on page 185).

This trace API provides the necessary operations to accomplish this subfunction. This is done by providing functions to associate a programmer-defined name with an implementation-defined trace event type identifier (see the posix_trace_eventid_open() function), and to send this trace event into a potential trace stream (see the posix_trace_event() function).
• Trace Operation Control

When controlling the recording of trace events in a trace stream, the programmer is concerned with the correct initialization of the trace mechanism (that is, the sizing of the trace stream), the correct retention of trace events in a permanent storage, the correct dynamic recording of trace events, and so on.

This trace API provides the necessary material to permit this efficiently. This is done by providing functions to initialize a new trace stream, and optionally a trace log:

— Trace Stream Attributes Object Initialization (see `posix_trace_attr_init()`)

— Functions to Retrieve or Set Information About a Trace Stream (see `posix_trace_attr_getgenversion()`)

— Functions to Retrieve or Set the Behavior of a Trace Stream (see `posix_trace_attr_getinherited()`)

— Functions to Retrieve or Set Trace Stream Size Attributes (see `posix_trace_attr_getmaxusereventsize()`)

— Trace Stream Initialization, Flush, and Shutdown from a Process (see `posix_trace_create()`)

— Clear Trace Stream and Trace Log (see `posix_trace_clear()`)

To select the trace event types that are to be traced:

— Manipulate Trace Event Type Identifier (see `posix_trace_trid_eventid_open()`)

— Iterate over a Mapping of Trace Event Type (see `posix_trace_eventtypelist_getnext_id()`)

— Manipulate Trace Event Type Sets (see `posix_trace_eventset_empty()`)

— Set Filter of an Initialized Trace Stream (see `posix_trace_set_filter()`)

To control the execution of an active trace stream:

— Trace Start and Stop (see `posix_trace_start()`)

— Functions to Retrieve the Trace Attributes or Trace Statuses (see `posix_trace_get_attr()`)

---

**Figure B-3** Trace System Overview: for Online Analysis
General Information  

Rationale for System Interfaces

- Trace Analysis

Once correctly recorded, on permanent storage or not, an ultimate activity consists of the analysis of the recorded information. If the recorded data is on permanent storage, a specific open operation is required to associate a trace stream to a trace log.

The first intent of the group was to request the presence of a system identification structure in the trace stream attribute. This was, for the application, to allow some portable way to process the recorded information. However, there is no requirement that the `utsname` structure, on which this system identification was based, be portable from one machine to another, so the contents of the attribute cannot be interpreted correctly by an application conforming to IEEE Std 1003.1-2001.

This modification has been incorporated and requests that some unspecified information be recorded in the trace log in order to fail opening it if the analysis process and the controller process were running in different types of machine, but does not request that this information be accessible to the application. This modification has implied a modification in the `posix_trace_open()` function error code returns.

This trace API provides functions to:

- Extract trace stream identification attributes (see `posix_trace_attr_getgenversion()`)
- Extract trace stream behavior attributes (see `posix_trace_attr_getinherited()`)
- Extract trace event, stream, and log size attributes (see `posix_trace_attr_getmaxusereventsize()`)
- Look up trace event type names (see `posix_trace_eventid_get_name()`)
- Iterate over trace event type identifiers (see `posix_trace_eventtypelist_getnext_id()`)
- Open, rewind, and close a trace log (see `posix_trace_open()`)
- Read trace stream attributes and status (see `posix_trace_get_attr()`)
- Read trace events (see `posix_trace_getnext_event()`)

Due to the following two reasons:

1. The requirement that the trace system must not add unacceptable overhead to the traced process and so that the trace event point execution must be fast

2. The traced application does not care about tracing errors

the trace system cannot return any internal error to the application. Internal error conditions can range from unrecoverable errors that will force the active trace stream to abort, to small errors that can affect the quality of tracing without aborting the trace stream. The group decided to define a system trace event to report to the analysis process such internal errors. It is not the intention of IEEE Std 1003.1-2001 to require an implementation to report an internal error that corrupts or terminates tracing operation. The implementor is free to decide which internal documented errors, if any, the trace system is able to report.
States of a Trace Stream

Figure B-4 shows the different states an active trace stream passes through. After the
posix_trace_create() function call, a trace stream becomes CREATED and a trace stream is
associated for the future collection of trace events. The status of the trace stream is
POSIX_TRACE_SUSPENDED. The state becomes STARTED after a call to the posix_trace_start()
function, and the status becomes POSIX_TRACE_RUNNING. In this state, all trace events that
are not filtered out will be stored into the trace stream. After a call to posix_trace_stop(), the trace
stream becomes STOPPED (and the status POSIX_TRACE_SUSPENDED). In this state, no new
trace events will be recorded in the trace stream, but previously recorded trace events may
continue to be read.

After a call to posix_trace_shutdown(), the trace stream is in the state COMPLETED. The trace
stream no longer exists but, if the Trace Log option is supported, all the information contained in
it has been logged. If a log object has not been associated with the trace stream at the creation, it
is the responsibility of the trace controller process to not shut the trace stream down while trace
events remain to be read in the stream.

Tracing All Processes

Some implementations have a tracing subsystem with the ability to trace all processes. This is
useful to debug some types of device drivers such as those for ATM or X25 adapters. These types
of adapters are used by several independent processes, that are not issued from the same
process.

The POSIX trace interface does not define any constant or option to create a trace stream tracing
all processes. POSIX.1 does not prevent this type of implementation and an implementor is free
to add this capability. Nevertheless, the trace interface allows tracing of all the system trace
events and all the processes issued from the same process.
If such a tracing system capability has to be implemented, when a trace stream is created, it is recommended that a constant named POSIX_TRACE_ALLPROC be used instead of the process identifier in the argument of the `posix_trace_create()` or `posix_trace_create_withlog()` function. A possible value for POSIX_TRACE_ALLPROC may be −1 instead of a real process identifier.

The implementor has to be aware that there is some impact on the tracing behavior as defined in the POSIX trace interface. For example:

- If the default value for the inheritance attribute is set to `POSIX_TRACE_CLOSE_FOR_CHILD`, the implementation has to stop tracing for the child process.
- The trace controller which is creating this type of trace stream must have the appropriate privilege to trace all the processes.

**Trace Storage**

The model is based on two types of trace events: system trace events and user-defined trace events. The internal representation of trace events is implementation-defined, and so the implementor is free to choose the more suitable, practical, and efficient way to design the internal management of trace events. For the timestamping operation, the model does not impose the CLOCK_REALTIME or any other clock. The buffering allocation and operation follow the same principle. The implementor is free to use one or more buffers to record trace events; the interface assumes only a logical trace stream of sequentially recorded trace events.

Regarding flushing of trace events, the interface allows the definition of a trace log object which typically can be a file. But the group was also aware of defining functions to permit the use of this interface in small real-time systems, which may not have general file system capabilities. For instance, the three functions `posix_trace_getnext_event()` (blocking), `posix_trace_timedgetnext_event()` (blocking with timeout), and `posix_trace_trygetnext_event()` (non-blocking) are proposed to read the recorded trace events.

The policy to be used when the trace stream becomes full also relies on common practice:

- For an active trace stream, the POSIX_TRACE_LOOP trace stream policy permits automatic overrun (overwrite of oldest trace events) while waiting for some user-defined condition to cause tracing to stop. By contrast, the POSIX_TRACE_UNTIL_FULL trace stream policy requires the system to stop tracing when the trace stream is full. However, if the trace stream that is full is at least partially emptied by a call to the `posix_trace_flush()` function or by calls to the `posix_trace_getnext_event()` function, the trace system will automatically resume tracing.

If the Trace Log option is supported, the operation of the POSIX_TRACE_FLUSH policy is an extension of the POSIX_TRACE_UNTIL_FULL policy. The automatic free operation (by flushing to the associated trace log) is added.

- If a log is associated with the trace stream and this log is a regular file, these policies also apply for the log. One more policy, POSIX_TRACE_APPEND, is defined to allow indefinite extension of the log. Since the log destination can be any device or pseudo-device, the implementation may not be able to manipulate the destination as required by IEEE Std 1003.1-2001. For this reason, the behavior of the log full policy may be unspecified depending on the trace log type.

The current trace interface does not define a service to preallocate space for a trace log file, because this space can be preallocated by means of a call to the `posix_fallocate()` function. This function could be called after the file has been opened, but before the trace stream is created. The `posix_fallocate()` function ensures that any required storage for regular file data is allocated on the file system storage media. If `posix_fallocate()` returns successfully,
subsequent writes to the specified file data will not fail due to the lack of free space on the file system storage media. Besides trace events, a trace stream also includes trace attributes and the mapping from trace event names to trace event type identifiers. The implementor is free to choose how to store the trace attributes and the trace event type map, but must ensure that this information is not lost when a trace stream overrun occurs.

B.2.11.3 Trace Programming Examples

Several programming examples are presented to show the code of the different possible subfunctions using a trace subsystem. All these programs need to include the `<trace.h>` header. In the examples shown, error checking is omitted for more simplicity.

Trace Operation Control

These examples show the creation of a trace stream for another process; one which is already trace instrumented. All the default trace stream attributes are used to simplify programming in the first example. The second example shows more possibilities.

First Example

```c
/* Caution. Error checks omitted */
{
    trace_attr_t attr;
    pid_t pid = traced_process_pid;
    int fd;
    trace_id_t trid;
    ------
    /* Initialize trace stream attributes */
   posix_trace_attr_init(&attr);
    /* Open a trace log */
    fd=open("/tmp/mytracelog",...);
    /*
    * Create a new trace associated with a log
    * and with default attributes
    */
    posix_trace_create_withlog(pid, &attr, fd, &trid);
    /* Trace attribute structure can now be destroyed */
    posix_trace_attr_destroy(&attr);
    /* Start of trace event recording */
    posix_trace_start(trid);
    ------
    ------
    /* Duration of tracing */
    ------
    ------
    /* Stop and shutdown of trace activity */
    posix_trace_shutdown(trid);
    ------
}
```
Second Example

Between the initialization of the trace stream attributes and the creation of the trace stream, these trace stream attributes may be modified; see Trace Stream Attribute Manipulation (on page 194) for a specific programming example. Between the creation and the start of the trace stream, the event filter may be set; after the trace stream is started, the event filter may be changed. The setting of an event set and the change of a filter is shown in Create a Trace Event Type Set and Change the Trace Event Type Filter (on page 194).

/* Caution. Error checks omitted */
{
    trace_attr_t attr;
    pid_t pid = traced_process_pid;
    int fd;
    trace_id_t trid;
    ---
    /* Initialize trace stream attributes */
    posix_trace_attr_init(&attr);
    /* Attr default may be changed at this place; see example */
    ---
    /* Create and open a trace log with R/W user access */
    fd=open("/tmp/mytracelog",O_WRONLY|O_CREAT,S_IRUSR|S_IWUSR);
    /* Create a new trace associated with a log */
    posix_trace_create_withlog(pid, &attr, fd, &trid);
    /*
    * If the Trace Filter option is supported
    * trace event type filter default may be changed at this place;
    * see example about changing the trace event type filter
    */
    posix_trace_start(trid);
    ---
    /*
    * If you have an uninteresting part of the application
    * you can stop temporarily.
    * *
    * posix_trace_stop(trid);
    * ---
    * posix_trace_start(trid);
    */
    ---
    /*
    * If the Trace Filter option is supported
    * the current trace event type filter can be changed
    * at any time (see example about how to set
    * a trace event type filter)
    */
    ---
    /* Stop the recording of trace events */
    posix_trace_stop(trid);
    /* Shutdown the trace stream */
    posix_trace_shutdown(trid);
}

Application Instrumentation

This example shows an instrumented application. The code is included in a block of instructions, perhaps a function from a library. Possibly in an initialization part of the instrumented application, two user trace events names are mapped to two trace event type identifiers (function \texttt{posix_trace_eventid_open}()). Then two trace points are programmed.

```
/* Caution. Error checks omitted */
{
trace_event_id_t eventid1, eventid2;
   - - - - - -
/* Initialization of two trace event type ids */
posix_trace_eventid_open("my_first_event", &eventid1);
posix_trace_eventid_open("my_second_event", &eventid2);
   - - - - - -
/* Trace point */
posix_trace_event(eventid1, NULL, 0);
   - - - - - -
/* Trace point */
posix_trace_event(eventid2, NULL, 0);
   - - - - - -
}
```

Trace Analyzer

This example shows the manipulation of a trace log resulting from the dumping of a completed trace stream. All the default attributes are used to simplify programming, and data associated with a trace event is not shown in the first example. The second example shows more possibilities.

First Example

```
/* Caution. Error checks omitted */
{
int fd;
trace_id_t trid;
posix_trace_event_info trace_event;
char trace_event_name[TRACE_EVENT_NAME_MAX];
int return_value;
size_t returndatasize;
int lost_event_number;
   - - - - - -
```
/* Open an existing trace log */
fd=open("/tmp/tracelog", O_RDONLY);
/* Open a trace stream on the open log */
posix_trace_open(fd, &trid);
/* Read a trace event */
posix_trace_getnext_event(trid, &trace_event,
    NULL, 0, &returndatasize,&return_value);
/* Read and print all trace event names out in a loop */
while (return_value == NULL)
{
    /* Get the name of the trace event associated 
     * with trid trace ID 
     */
    posix_trace_eventid_get_name(trid, trace_event.event_id,
        trace_event_name);
    /* Print the trace event name out */
    printf("%s\n",trace_event_name);
    /* Read a trace event */
    posix_trace_getnext_event(trid, &trace_event,
        NULL, 0, &returndatasize,&return_value);
}
/* Close the trace stream */
posix_trace_close(trid);
/* Close the trace log */
close(fd);

Second Example

The complete example includes the two other examples in Retrieve Information from a Trace Log (on page 195) and in Retrieve the List of Trace Event Types Used in a Trace Log (on page 196). For example, the maxdatasize variable is set in Retrieve the List of Trace Event Types Used in a Trace Log (on page 196).

/* Caution. Error checks omitted */
{
    int fd;
    trace_id_t trid;
    posix_trace_event_info trace_event;
    char trace_event_name[TRACE_EVENT_NAME_MAX];
    char * data;
    size_t maxdatasize=1024, returndatasize;
    int return_value;
    - - - - - -
    /* Open an existing trace log */
    fd=open("/tmp/tracelog", O_RDONLY);
    /* Open a trace stream on the open log */
    posix_trace_open( fd, &trid);
    /* Retrieve information about the trace stream which
Several Programming Manipulations

The following examples show some typical sets of operations needed in some contexts.
Trace Stream Attribute Manipulation

This example shows the manipulation of a trace stream attribute object in order to change the default value provided by a previous `posix_trace_attr_init()` call.

```c
/* Caution. Error checks omitted */
{
    trace_attr_t attr;
    size_t logsize=100000;
    /* Initialize trace stream attributes */
    posix_trace_attr_init(&attr);
    /* Set the trace name in the attributes structure */
    posix_trace_attr_setname(&attr, "my_trace");
    /* Set the trace full policy */
    posix_trace_attr_setstreamfullpolicy(&attr, POSIX_TRACE_LOOP);
    /* Set the trace log size */
    posix_trace_attr_setlogsize(&attr, logsize);
    - - - - - -
}
```

Create a Trace Event Type Set and Change the Trace Event Type Filter

This example is valid only if the Trace Event Filter option is supported. This example shows the manipulation of a trace event type set in order to change the trace event type filter for an existing active trace stream, which may be just-created, running, or suspended. Some sets of trace event types are well-known, such as the set of trace event types not associated with a process, some trace event types are just-built trace event types for this trace stream; one trace event type is the predefined trace event error type which is deleted from the trace event type set.

```c
/* Caution. Error checks omitted */
{
    trace_id_t trid = existing_trace;
    trace_event_set_t set;
    trace_event_id_t trace_event1, trace_event2;
    - - - - - -
    /* Initialize to an empty set of trace event types */
    /* (not strictly required because posix_trace_event_set_fill() */
    /* will ignore the prior contents of the event set.) */
    posix_trace_eventset_emptyset(&set);
    /* * Fill the set with all system trace events
    * not associated with a process
    */
    posix_trace_eventset_fill(&set, POSIX_TRACE_WOPID_EVENTS);
    /* * Get the trace event type identifier of the known trace event name
    * my_first_event for the trid trace stream
    */
    posix_trace_trid_eventid_open(trid, "my_first_event", &trace_event1);
    /* * Add the set with this trace event type identifier */
    posix_trace_eventset_add_event(trace_event1, &set);
    /*
```

8186  * Get the trace event type identifier of the known trace event name
8187  * my_second_event for the trid trace stream
8188  */
8189
8190  posix_trace_trid_eventid_open(trid, "my_second_event", &trace_event2);
8191  /* Add the set with this trace event type identifier */
8192  posix_trace_eventset_add_event(trace_event2, &set);
8193  - - - - - - -
8194  /* Delete the system trace event POSIX_TRACE_ERROR from the set */
8195  posix_trace_eventset_del_event(POSIX_TRACE_ERROR, &set);
8196  - - - - - -
8197  /* Modify the trace stream filter making it equal to the new set */
8198  posix_trace_set_filter(trid, &set, POSIX_TRACE_SET_EVENTSET);
8199  - - - - -
8200  /* Now trace_event1, trace_event2, and all system trace event types
8201  * not associated with a process, except for the POSIX_TRACE_ERROR
8202  * system trace event type, are filtered out of (not recorded in) the
8203  * existing trace stream.
8204  */
8205

Retrieve Information from a Trace Log

This example shows how to extract information from a trace log, the dump of a trace stream. This code:

- Asks if the trace stream has lost trace events
- Extracts the information about the version of the trace subsystem which generated this trace log
- Retrieves the maximum size of trace event data; this may be used to dynamically allocate an array for extracting trace event data from the trace log without overflow

/* Caution. Error checks omitted */
{
  struct posix_trace_status_info statusinfo;
  trace_attr_t attr;
  trace_id_t trid = existing_trace;
  size_t maxdatasize;
  char genversion[TRACE_NAME_MAX];
  - - - - - - -
  /* Get the trace stream status */
  posix_trace_get_status(trid, &statusinfo);
  /* Detect an overrun condition */
  if (statusinfo.posix_stream_overrun_status == POSIX_TRACE_OVERRUN)
    printf("trace events have been lost\n");
  /* Get attributes from the trid trace stream */
  posix_trace_get_attr(trid, &attr);
  /* Get the trace generation version from the attributes */
  posix_trace_attr_getgenversion(&attr, genversion);
  /* Print the trace generation version out */
  printf("Information about Trace Generator:%s\n", genversion);
/* Get the trace event max data size from the attributes */
posix_trace_attr_getmaxdatasize(&attr, &maxdatasize);
/* Print the trace event max data size out */
printf("Maximum size of associated data:%d\n",maxdatasize);
/* Destroy the trace stream attributes */
posix_trace_attr_destroy(&attr);
}

Retrieve the List of Trace Event Types Used in a Trace Log

This example shows the retrieval of a trace stream's trace event type list. This operation may be very useful if you are interested only in tracking the type of trace events in a trace log.

/* Caution. Error checks omitted */
{
  trace_id_t trid = existing_trace;
  trace_event_id_t event_id;
  char event_name[TRACE_EVENT_NAME_MAX];
  int return_value;
  ------
  /*
   * In a loop print all existing trace event names out
   * for the trid trace stream
   */
  while (1)
  {
    posix_trace_eventtypelist_getnext_id(trid, &event_id
      &return_value);
    if (return_value != NULL) break;
    /*
     * Get the name of the trace event associated
     * with trid trace ID
     */
    posix_trace_eventid_get_name(trid, event_id, event_name);
    /* Print the name out */
    printf("%s\n", event_name);
  }
}
Among the different possibilities offered by the trace interface defined in IEEE Std 1003.1-2001, the debugging of an application is the most interesting one. Typical operations in the controlling debugger process are to filter trace event types, to get trace events from the trace stream, to stop the trace stream when the debugged process is executing uninteresting code, to start the trace stream when some interesting point is reached, and so on. The interface defined in IEEE Std 1003.1-2001 should define all the necessary base functions to allow this dynamic debug handling.

Figure B-5 shows an example in which the trace stream is created after the call to the `fork()` function. If the user does not want to lose trace events, some synchronization mechanism (represented in the figure) may be needed before calling the `exec` function, to give the parent a chance to create the trace stream before the child begins the execution of its trace points.

At first, the working group was in favor of the representation of a trace event type by an integer `event_name`. It seems that existing practice shows the weakness of such a representation. The collision of trace event types is the main problem that cannot be simply resolved using this sort of representation. Suppose, for example, that a third party designs an instrumented library. The user does not have the source of this library and wants to trace his application which uses in some part the third-party library. There is no means for him to know what are the trace event types used in the instrumented library so he has some chance of duplicating some of them and thus to obtain a contaminated tracing of his application.
There are requirements to allow program images containing pieces from various vendors to be traced without also requiring those of any other vendors to coordinate their uses of the trace facility, and especially the naming of their various trace event types and trace point IDs. The chosen solution is to provide a very large name space, large enough so that the individual vendors can give their trace types and tracepoint IDs sufficiently long and descriptive names making the occurrence of collisions quite unlikely. The probability of collision is thus made sufficiently low so that the problem may, as a practical matter, be ignored. By requirement, the consequence of collisions will be a slight ambiguity in the trace streams; tracing will continue in spite of collisions and ambiguities. “The show must go on”. The `posix_prog_address` member of the `posix_trace_event_info` structure is used to allow trace streams to be unambiguously interpreted, despite the fact that trace event types and trace event names need not be unique.

The `posix_trace_eventid_open()` function is required to allow the instrumented third-party library to get a valid trace event type identifier for its trace event names. This operation is, somehow, an allocation, and the group was aware of proposing some deallocation mechanism which the instrumented application could use to recover the resources used by a trace event type identifier. This would have given the instrumented application the benefit of being capable of reusing a possible minimum set of trace event type identifiers, but also the inconvenience to have, possibly in the same trace stream, one trace event type identifier identifying two different trace event types. After some discussions the group decided to not define such a function which would make this API thicker for little benefit, the user having always the possibility of adding identification information in the `data` member of the trace event structure.

The set of the trace event type identifiers the controlling process wants to filter out is initialized in the trace mechanism using the function `posix_trace_set_filter()`, setting the arguments according to the definitions explained in `posix_trace_set_filter()`. This operation can be done statically (when the trace is in the STOPPED state) or dynamically (when the trace is in the STARTED state). The preparation of the filter is normally done using the function defined in `posix_trace_eventtypelist_getnext_id()` and eventually the function `posix_trace_eventtypelist_rewind()` in order to know (before the recording) the list of the potential
set of trace event types that can be recorded. In the case of an active trace stream, this list may
not be exhaustive. Actually, the target process may not have yet called the function
posix_trace_eventid_open(). But it is a common practice, for a controlling process, to prepare the
filtering of a future trace stream before its start. Therefore the user must have a way to get the
trace event type identifier corresponding to a well-known trace event name before its future
association by the pre-cited function. This is done by calling the posix_trace_trid_eventid_open()
function, given the trace stream identifier and the trace name, and described hereafter. Because
this trace event type identifier is associated with a trace stream identifier, where a unique
process has initialized two or more traces, the implementation is expected to return the same
trace event type identifier for successive calls to posix_trace_trid_eventid_open() with different
trace stream identifiers. The posix_trace_eventid_get_name() function is used by the controller
process to identify, by the name, the trace event type returned by a call to the
posix_trace_eventtypelist_getnext_id() function.

Afterwards, the set of trace event types is constructed using the functions defined in
posix_trace_eventset_empty(), posix_trace_eventset_fill(), posix_trace_eventset_add(), and
posix_trace_eventset_del().

A set of functions is provided devoted to the manipulation of the trace event type identifier and
names for an active trace stream. All these functions require the trace stream identifier argument
as the first parameter. The opacity of the trace event type identifier implies that the user cannot
associate directly its well-known trace event name with the system-associated trace event type
identifier.

The posix_trace_trid_eventid_open() function allows the application to get the system trace event
type identifier back from the system, given its well-known trace event name. This function is
useful only when a controlling process needs to specify specific events to be filtered.

The posix_trace_eventid_get_name() function allows the application to obtain a trace event name
given its trace event type identifier. One possible use of this function is to identify the type of a
trace event retrieved from the trace stream, and print it. The easiest way to implement this
requirement, is to use a single trace event type map for all the processes whose maps are
required to be identical. A more difficult way is to attempt to keep multiple maps identical at
every call to posix_trace_eventid_open() and posix_trace_trid_eventid_open().

B.2.11.6 Rationale on Trace Events Type Filtering

The most basic rationale for runtime and pre-registration filtering (selection/rejection) of trace
event types is to prevent choking of the trace collection facility, and/or overloading of the
computer system. Any worthwhile trace facility can bring even the largest computer to its
knees. Otherwise, everything would be recorded and filtered after the fact; it would be much
simpler, but impractical.

To achieve debugging, measurement, or whatever the purpose of tracing, the filtering of trace
event types is an important part of trace analysis. Due to the fact that the trace events are put
into a trace stream and probably logged afterwards into a file, different levels of filtering—that
is, rejection of trace event types—are possible.
Filtering of Trace Event Types Before Tracing

This function, represented by the `posix_trace_set_filter()` function in IEEE Std 1003.1-2001 (see `posix_trace_set_filter()`), selects, before or during tracing, the set of trace event types to be filtered out. It should be possible also (as OSF suggested in their ETAP trace specifications) to select the kernel trace event types to be traced in a system-wide fashion. These two functionalities are called the pre-filtering of trace event types.

The restriction on the actual type used for the `trace_event_set_t` type is intended to guarantee that these objects can always be assigned, have their address taken, and be passed by value as parameters. It is not intended that this type be a structure including pointers to other data structures, as that could impact the portability of applications performing such operations. A reasonable implementation could be a structure containing an array of integer types.

Filtering of Trace Event Types at Runtime

It is possible to build this functionality using the `posix_trace_set_filter()` function. A privileged process or a privileged thread can get trace events from the trace stream of another process or thread, and thus specify the type of trace events to record into a file, using implementation-defined methods and interfaces. This functionality, called inline filtering of trace event types, is used for runtime analysis of trace streams.

Post-Mortem Filtering of Trace Event Types

The word “post-mortem” is used here to indicate that some unanticipated situation occurs during execution that does not permit a pre or inline filtering of trace events and that it is necessary to record all trace event types to have a chance to discover the problem afterwards. When the program stops, all the trace events recorded previously can be analyzed in order to find the solution. This functionality could be named the post-filtering of trace event types.

Discussions about Trace Event Type-Filtering

After long discussions with the parties involved in the process of defining the trace interface, it seems that the sensitivity to the filtering problem is different, but everybody agrees that the level of the overhead introduced during the tracing operation depends on the filtering method elected. If the time that it takes the trace event to be recorded can be neglected, the overhead introduced by the filtering process can be classified as follows:

Pre-filtering	System and process/thread-level overhead
Inline-filtering	Process/thread-level overhead
Post-filtering	No overhead; done offline

The pre-filtering could be named “critical realtime” filtering in the sense that the filtering of trace event type is manageable at the user level so the user can lower to a minimum the filtering overhead at some user selected level of priority for the inline filtering, or delay the filtering to after execution for the post-filtering. The counterpart of this solution is that the size of the trace stream must be sufficient to record all the trace events. The advantage of the pre-filtering is that the utilization of the trace stream is optimized.

Only pre-filtering is defined by IEEE Std 1003.1-2001. However, great care must be taken in specifying pre-filtering, so that it does not impose unacceptable overhead. Moreover, it is necessary to isolate all the functionality relative to the pre-filtering.

The result of this rationale is to define a new option, the Trace Event Filter option, not necessarily implemented in small realtime systems, where system overhead is minimized to the extent possible.
The objective to be able to control tracing for individual threads may be in conflict with the efficiency expected in threads with a contentionscope attribute of PTHREAD_SCOPE_PROCESS. For these threads, context switches from one thread that has tracing enabled to another thread that has tracing disabled may require a kernel call to inform the kernel whether it has to trace system events executed by that thread or not. For this reason, it was proposed that the ability to enable or disable tracing for PTHREAD_SCOPE_PROCESS threads be made optional, through the introduction of a Trace Scope Process option. A trace implementation which did not implement the Trace Scope Process option would not honor the tracing-state attribute of a thread with PTHREAD_SCOPE_PROCESS; it would, however, honor the tracing-state attribute of a thread with PTHREAD_SCOPE_SYSTEM. This proposal was rejected as:

1. Removing desired functionality (per-thread trace control)
2. Introducing counter-intuitive behavior for the tracing-state attribute
3. Mixing logically orthogonal ideas (thread scheduling and thread tracing)

Finally, to solve this complex issue, this API does not provide pthread_gettracingstate(), pthread_settracingstate(), pthread_attr_gettracingstate(), and pthread_attr_settracingstate() interfaces. These interfaces force the thread implementation to add to the weight of the thread and cause a revision of the threads libraries, just to support tracing. Worse yet, posix_trace_event() must always test this per-thread variable even in the common case where it is not used at all. Per-thread tracing is easy to implement using existing interfaces where necessary; see the following example.

Example

```c
/* Caution. Error checks omitted */
static pthread_key_t my_key;
static trace_event_id_t my_event_id;
static pthread_once_t my_once = PTHREAD_ONCE_INIT;
void my_init(void)
{
    (void) pthread_key_create(&my_key, NULL);
    (void) posix_trace_eventid_open("my", &my_event_id);
}
int get_trace_flag(void)
{
    pthread_once(&my_once, my_init);
    return (pthread_getspecific(my_key) != NULL);
}
void set_trace_flag(int f)
{
    pthread_once(&my_once, my_init);
    pthread_setspecific(my_key, f? &my_event_id: NULL);
}
fn()
{
    if (get_trace_flag())
        posix_trace_event(my_event_id, ...)
```
The above example does not implement third-party state setting.

Lastly, per-thread tracing works poorly for threads with `PTHREAD_SCOPE_PROCESS` contention scope. These “library” threads have minimal interaction with the kernel and would have to explicitly set the attributes whenever they are context switched to a new kernel thread in order to trace system events. Such state was explicitly avoided in POSIX threads to keep `PTHREAD_SCOPE_PROCESS` threads lightweight.

The reason that keeping `PTHREAD_SCOPE_PROCESS` threads lightweight is important is that such threads can be used not just for simple multi-processors but also for co-routine style programming (such as discrete event simulation) without inventing a new threads paradigm. Adding extra runtime cost to thread context switches will make using POSIX threads less attractive in these situations.

**B.2.11.8 Rationale on Triggering**

The ability to start or stop tracing based on the occurrence of specific trace event types has been proposed as a parallel to similar functionality appearing in logic analyzers. Such triggering, in order to be very useful, should be based not only on the trace event type, but on trace event-specific data, including tests of user-specified fields for matching or threshold values.

Such a facility is unnecessary where the buffering of the stream is not a constraint, since such checks can be performed offline during post-mortem analysis.

For example, a large system could incorporate a daemon utility to collect the trace records from memory buffers and spool them to secondary storage for later analysis. In the instances where resources are truly limited, such as embedded applications, the application incorporation of application code to test the circumstances of a trace event and call the trace point only if needed is usually straightforward.

For performance reasons, the `posix_trace_event()` function should be implemented using a macro, so if the trace is inactive, the trace event point calls are latent code and must cost no more than a scalar test.

The API proposed in IEEE Std 1003.1-2001 does not include any triggering functionality.

**B.2.11.9 Rationale on Timestamp Clock**

It has been suggested that the tracing mechanism should include the possibility of specifying the clock to be used in timestamping the trace events. When application trace events must be correlated to remote trace events, such a facility could provide a global time reference not available from a local clock. Further, the application may be driven by timers based on a clock different from that used for the timestamp, and the correlation of the trace to those untraced timer activities could be an important part of the analysis of the application.

However, the tracing mechanism needs to be fast and just the provision of such an option can materially affect its performance. Leaving aside the performance costs of reading some clocks, this notion is also ill-defined when kernel trace events are to be traced by two applications making use of different tracing clocks. This can even happen within a single application where different parts of the application are served by different clocks. Another complication can occur when a clock is maintained strictly at the user level and is unavailable at the kernel level.

It is felt that the benefits of a selectable trace clock do not match its costs. Applications that wish to correlate clocks other than the default tracing clock can include trace events with sample values of those other clocks, allowing correlation of timestamps from the various independent clocks. In any case, such a technique would be required when applications are sensitive to
multiple clocks.

**B.2.11.10 Rationale on Different Overrun Conditions**

The analysis of the dynamic behavior of the trace mechanism shows that different overrun conditions may occur. The API must provide a means to manage such conditions in a portable way.

**Overrun in Trace Streams Initialized with POSIX_TRACE_LOOP Policy**

In this case, the user of the trace mechanism is interested in using the trace stream with POSIX_TRACE_LOOP policy to record trace events continuously, but ideally without losing any trace events. The online analyzer process must get the trace events at a mean speed equivalent to the recording speed. Should the trace stream become full, a trace stream overrun occurs. This condition is detected by getting the status of the active trace stream (function `posix_trace_get_status()` and looking at the member `posix_stream_overrun_status` of the read `posix_stream_status` structure. In addition, two predefined trace event types are defined:

1. The beginning of a trace overflow, to locate the beginning of an overflow when reading a trace stream
2. The end of a trace overflow, to locate the end of an overflow, when reading a trace stream

As a timestamp is associated with these predefined trace events, it is possible to know the duration of the overflow.

**Overrun in Dumping Trace Streams into Trace Logs**

The user lets the trace mechanism dump the trace stream initialized with POSIX_TRACE_FLUSH policy automatically into a trace log. If the dump operation is slower than the recording of trace events, the trace stream can overrun. This condition is detected by getting the status of the active trace stream (function `posix_trace_get_status()` and looking at the member `posix_log_overrun_status` of the read `posix_stream_status` structure. This overrun indicates that the trace mechanism is not able to operate in this mode at this speed. It is the responsibility of the user to modify one of the trace parameters (the stream size or the trace event type filter, for instance) to avoid such overrun conditions, if overruns are to be prevented. The same already predefined trace event types (see **Overrun in Trace Streams Initialized with POSIX_TRACE_LOOP Policy**) are used to detect and to know the duration of an overflow.

**Reading an Active Trace Stream**

Although this trace API allows one to read an active trace stream with log while it is tracing, this feature can lead to false overflow origin interpretation: the trace log or the reader of the trace stream. Reading from an active trace stream with log is thus non-portable, and has been left unspecified.

**B.2.12 Data Types**

The requirement that additional types defined in this section end in “_t” was prompted by the problem of name space pollution. It is difficult to define a type (where that type is not one defined by IEEE Std 1003.1-2001) in one header file and use it in another without adding symbols to the name space of the program. To allow implementors to provide their own types, all conforming applications are required to avoid symbols ending in “_t”, which permits the implementor to provide additional types. Because a major use of types is in the definition of structure members, which can (and in many cases must) be added to the structures defined in IEEE Std 1003.1-2001, the need for additional types is compelling.
The types, such as `ushort` and `ulong`, which are in common usage, are not defined in
IEEE Std 1003.1-2001 (although `ushort_t` would be permitted as an extension). They can be
added to `<sys/types.h>` using a feature test macro (see Section B.2.2.1 (on page 85)). A suggested
symbol for these is `_SYSIII`. Similarly, the types like `u_short` would probably be best controlled
by `_BSD`.

Some of these symbols may appear in other headers; see Section B.2.2.2 (on page 86).

**dev_t**
This type may be made large enough to accommodate host-locality considerations
of networked systems.

This type must be arithmetic. Earlier proposals allowed this to be non-arithmetic
(such as a structure) and provided a `samefile()` function for comparison.

**gid_t**
Some implementations had separated `gid_t` from `uid_t` before POSIX.1 was
completed. It would be difficult for them to coalesce them when it was
unnecessary. Additionally, it is quite possible that user IDs might be different from
group IDs because the user ID might wish to span a heterogeneous network,
where the group ID might not.

For current implementations, the cost of having a separate `gid_t` will be only
lexical.

**mode_t**
This type was chosen so that implementations could choose the appropriate
integer type, and for compatibility with the ISO C standard. 4.3 BSD uses
`unsigned short` and the SVID uses `ushort`, which is the same. Historically, only the
low-order sixteen bits are significant.

**nlink_t**
This type was introduced in place of `short` for `st_nlink` (see the `<sys/stat.h>` header)
in response to an objection that `short` was too small.

**off_t**
This type is used only in `lseek()`, `fcntl()`, and `<sys/stat.h>`. Many implementations
would have difficulties if it were defined as anything other than `long`. Requiring
an integer type limits the capabilities of `lseek()` to four gigabytes. The ISO C
standard supplies routines that use larger types; see `fgetpos()` and `fsetpos()`. XSI-
conformant systems provide the `fseeko()` and `ftello()` functions that use larger
types.

**pid_t**
The inclusion of this symbol was controversial because it is tied to the issue of the
representation of a process ID as a number. From the point of view of a
conforming application, process IDs should be “magic cookies”\(^1\) that are produced
by calls such as `fork()`, used by calls such as `waitpid()` or `kill()`, and not otherwise
analyzed (except that the sign is used as a flag for certain operations).

The concept of a [PID_MAX] value interacted with this in early proposals. Treating
process IDs as an opaque type both removes the requirement for [PID_MAX] and
allows systems to be more flexible in providing process IDs that span a large range
of values, or a small one.

Since the values in `uid_t`, `gid_t`, and `pid_t` will be numbers generally, and
potentially both large in magnitude and sparse, applications that are based on

---

\(^1\) An historical term meaning: “An opaque object, or token, of determinate size, whose significance is known only to the entity
which created it. An entity receiving such a token from the generating entity may only make such use of the `cookie` as is defined
and permitted by the supplying entity.”
arrays of objects of this type are unlikely to be fully portable in any case. Solutions
that treat them as magic cookies will be portable.

{CHILD_MAX} precludes the possibility of a “toy implementation”, where there
would only be one process.

**ssize_t**

This is intended to be a signed analog of **size_t**. The wording is such that an
implementation may either choose to use a longer type or simply to use the signed
version of the type that underlies **size_t**. All functions that return **ssize_t** (read() and
write()) describe as “implementation-defined” the result of an input exceeding
**SSIZE_MAX**. It is recognized that some implementations might have **ints** that
are smaller than **size_t**. A conforming application would be constrained not to
perform I/O in pieces larger than **SSIZE_MAX**, but a conforming application
using extensions would be able to use the full range if the implementation
provided an extended range, while still having a single type-compatible interface.

The symbols **size_t** and **ssize_t** are also required in <unistd.h> to minimize the
changes needed for calls to read() and write(). Implementors are reminded that it
must be possible to include both <sys/types.h> and <unistd.h> in the same
program (in either order) without error.

**uid_t**

Before the addition of this type, the data types used to represent these values
varied throughout early proposals. The <sys/stat.h> header defined these values as
type **short**, the <passwd.h> file (now <pwd.h> and <grp.h>) used an **int**, and
getuid() returned an **int**. In response to a strong objection to the inconsistent
definitions, all the types were switched to **uid_t**.

In practice, those historical implementations that use varying types of this sort can
typedef **uid_t** to **short** with no serious consequences.

The problem associated with this change concerns object compatibility after
structure size changes. Since most implementations will define **uid_t** as a short, the
only substantive change will be a reduction in the size of the passwd structure.
Consequently, implementations with an overriding concern for object
compatibility can pad the structure back to its current size. For that reason, this
problem was not considered critical enough to warrant the addition of a separate
type to POSIX.1.

The types **uid_t** and **gid_t** are magic cookies. There is no **{UID_MAX}** defined by
POSIX.1, and no structure imposed on **uid_t** and **gid_t** other than that they be
positive arithmetic types. (In fact, they could be **unsigned char**.) There is no
maximum or minimum specified for the number of distinct user or group IDs.
B.3 System Interfaces

See the RATIONALE sections on the individual reference pages.

B.3.1 Examples for Spawn

The following long examples are provided in the Rationale (Informative) volume of IEEE Std 1003.1-2001 as a supplement to the reference page for `posix_spawn()`.

Example Library Implementation of Spawn

The `posix_spawn()` or `posix_spawnp()` functions provide the following:

- Simply start a process executing a process image. This is the simplest application for process creation, and it may cover most executions of `fork()`.
- Support I/O redirection, including pipes.
- Run the child under a user and group ID in the domain of the parent.
- Run the child at any priority in the domain of the parent.

The `posix_spawn()` or `posix_spawnp()` functions do not cover every possible use of the `fork()` function, but they do span the common applications: typical use by a shell and a login utility.

The price for an application is that before it calls `posix_spawn()` or `posix_spawnp()`, the parent must adjust to a state that `posix_spawn()` or `posix_spawnp()` can map to the desired state for the child. Environment changes require the parent to save some of its state and restore it afterwards. The effective behavior of a successful invocation of `posix_spawn()` is as if the operation were implemented with POSIX operations as follows:

```c
#include <sys/types.h>
#include <stdlib.h>
#include <stdio.h>
#include <unistd.h>
#include <sched.h>
#include <fcntl.h>
#include <signal.h>
#include <errno.h>
#include <string.h>

/* #include <spawn.h> */
/*******************************************/
/* Things that could be defined in spawn.h */
/*******************************************/
typedef struct
{
    short posix_attr_flags;

}  

I/O Redirection with Spawn

I/O redirection with posix_spawn() or posix_spawnp() is accomplished by crafting a file_actions argument to effect the desired redirection. Such a redirection follows the general outline of the following example:

/* To redirect new standard output (fd 1) to a file, */  
/* and redirect new standard input (fd 0) from my fd socket_pair[1], */  
/* and close my fd socket_pair[0] in the new process. */  
posix_spawn_file_actions_t file_actions;  
posix_spawn_file_actions_init(&file_actions);  
posix_spawn_file_actions_addopen(&file_actions, 1, "newout", ...);  
posix_spawn_file_actions_dup2(&file_actions, socket_pair[1], 0);  
posix_spawn_file_actions_close(&file_actions, socket_pair[0]);  
posix_spawn_file_actions_close(&file_actions, socket_pair[1]);  
posix_spawn(..., &file_actions, ...);  
posix_spawn_file_actions_destroy(&file_actions);
Spawning a Process Under a New User ID

Spawning a process under a new user ID follows the outline shown in the following example:

```c
Save = getuid();
setuid(newid);
posix_spawn(...);
setuid(Save);
```

Appendix C

Rationale for Shell and Utilities

C.1 Introduction

C.1.1 Scope

Refer to Section A.1.1 (on page 3).

C.1.2 Conformance

Refer to Section A.2 (on page 9).

C.1.3 Normative References

There is no additional rationale provided for this section.

C.1.4 Change History

The change history is provided as an informative section, to track changes from previous issues of IEEE Std 1003.1-2001.

The following sections describe changes made to the Shell and Utilities volume of IEEE Std 1003.1-2001 since Issue 5 of the base document. The CHANGE HISTORY section for each utility describes technical changes made to that utility from Issue 5. Changes between earlier issues of the base document and Issue 5 are not included.

The change history between Issue 5 and Issue 6 also lists the changes since the ISO POSIX-2: 1993 standard.

Changes from Issue 5 to Issue 6 (IEEE Std 1003.1-2001)

The following list summarizes the major changes that were made in the Shell and Utilities volume of IEEE Std 1003.1-2001 from Issue 5 to Issue 6:

- This volume of IEEE Std 1003.1-2001 is extensively revised so that it can be both an IEEE POSIX Standard and an Open Group Technical Standard.

- The terminology has been reworked to meet the style requirements.

- Shading notation and margin codes are introduced for identification of options within the volume.

- This volume of IEEE Std 1003.1-2001 is updated to mandate support of FIPS 151-2. The following changes were made:
  - Support is mandated for the capabilities associated with the following symbolic constants:
    - _POSIX_CHOWN_RESTRICTED
    - _POSIX_JOB_CONTROL
    - _POSIX_SAVED_IDS
  - In the environment for the login shell, the environment variables LOGNAME and HOME shall be defined and have the properties described in the Base Definitions volume of
Introduction

This volume of IEEE Std 1003.1-2001 is updated to align with some features of the Single UNIX Specification.

A new section on Utility Limits is added.

A section on the Relationships to Other Documents is added.

Concepts and definitions have been moved to a separate volume.

A RATIONALE section is added to each reference page.

The \texttt{c99} utility is added as a replacement for \texttt{c89}, which is withdrawn in this issue.

IEEE Std 1003.2d-1994 is incorporated, adding the \texttt{qalter}, \texttt{qdel}, \texttt{qhold}, \texttt{qmove}, \texttt{qmsg}, \texttt{qrerun}, \texttt{qrls}, \texttt{qselect}, \texttt{qsig}, \texttt{qstat}, and \texttt{qsub} utilities.

IEEE P1003.2b draft standard is incorporated, making extensive updates and adding the \texttt{iconv} utility.

IEEE PASC Interpretations are applied.

The Open Group's corrigenda and resolutions are applied.

New Features in Issue 6

The following table lists the new utilities introduced since the ISO POSIX-2: 1993 standard (as modified by IEEE Std 1003.2d-1994). Apart from the \texttt{c99} and \texttt{iconv} utilities, these are all part of the XSI extension.

C.1.5 Terminology

Refer to Section A.1.4 (on page 5).

C.1.6 Definitions

Refer to Section A.3 (on page 13).

C.1.7 Relationship to Other Documents

C.1.7.1 System Interfaces

It has been pointed out that the Shell and Utilities volume of IEEE Std 1003.1-2001 assumes that a great deal of functionality from the System Interfaces volume of IEEE Std 1003.1-2001 is present, but never states exactly how much (and strictly does not need to since both are mandated on a conforming system). This section is an attempt to clarify the assumptions.
File Removal

This is intended to be a summary of the `unlink()` and `rmdir()` requirements. Note that it is possible using the `unlink()` function for item 4. to occur.

C.1.7.2 Concepts Derived from the ISO C Standard

This section was introduced to address the issue that there was insufficient detail presented by such utilities as `awk` or `sh` about their procedural control statements and their methods of performing arithmetic functions.

The ISO C standard was selected as a model because most historical implementations of the standard utilities were written in C. Thus, it was more likely that they would act in the desired manner without modification.

Using the ISO C standard is primarily a notational convenience so that the many procedural languages in the Shell and Utilities volume of IEEE Std 1003.1-2001 would not have to be rigorously described in every aspect. Its selection does not require that the standard utilities be written in Standard C; they could be written in Common Usage C, Ada, Pascal, assembler language, or anything else.

The sizes of the various numeric values refer to C-language data types that are allowed to be different sizes by the ISO C standard. Thus, like a C-language application, a shell application cannot rely on their exact size. However, it can rely on their minimum sizes expressed in the ISO C standard, such as `{LONG_MAX}` for a `long` type.

The behavior on overflow is undefined for ISO C standard arithmetic. Therefore, the standard utilities can use “bignum” representation for integers so that there is no fixed maximum unless otherwise stated in the utility description. Similarly, standard utilities can use infinite-precision representations for floating-point arithmetic, as long as these representations exceed the ISO C standard requirements.

This section addresses only the issue of semantics; it is not intended to specify syntax. For example, the ISO C standard requires that 0L be recognized as an integer constant equal to zero, but utilities such as `awk` and `sh` are not required to recognize 0L (though they are allowed to, as an extension).

The ISO C standard requires that a C compiler must issue a diagnostic for constants that are too large to represent. Most standard utilities are not required to issue these diagnostics; for example, the command:

```
diff -C 2147483648 file1 file2
```

has undefined behavior, and the `diff` utility is not required to issue a diagnostic even if the number 2147483648 cannot be represented.

C.1.8 Portability

Refer to Section A.1.5 (on page 8).

C.1.8.1 Codes

Refer to Section A.1.5.1 (on page 8).

C.1.9 Utility Limits

This section grew out of an idea that originated with the original POSIX.1, in the tables of system limits for the `sysconf()` and `pathconf()` functions. The idea being that a conforming application can be written to use the most restrictive values that a minimal system can provide, but it should not have to. The values provided represent compromises so that some vendors can use historically limited versions of UNIX system utilities. They are the highest values that a strictly conforming application can assume, given no other information.

However, by using the `getconf` utility or the `sysconf()` function, the elegant application can be tailored to more liberal values on some of the specific instances of specific implementations.

There is no explicitly stated requirement that an implementation provide finite limits for any of these numeric values; the implementation is free to provide essentially unbounded capabilities (where it makes sense), stopping only at reasonable points such as `{ULONG_MAX}` (from the ISO C standard). Therefore, applications desiring to tailor themselves to the values on a particular implementation need to be ready for possibly huge values; it may not be a good idea to allocate blindly a buffer for an input line based on the value of `{LINE_MAX}`, for instance. However, unlike the System Interfaces volume of IEEE Std 1003.1-2001, there is no set of limits that return a special indication meaning “unbounded”. The implementation should always return an actual number, even if the number is very large.

The statement:

“It is not guaranteed that the application ...”

is an indication that many of these limits are designed to ensure that implementors design their utilities without arbitrary constraints related to unimaginative programming. There are certainly conditions under which combinations of options can cause failures that would not render an implementation non-conforming. For example, `{EXPR_NEST_MAX}` and `{ARG_MAX}` could collide when expressions are large; combinations of `{BC_SCALE_MAX}` and `{BC_DIM_MAX}` could exceed virtual memory.

In the Shell and Utilities volume of IEEE Std 1003.1-2001, the notion of a limit being guaranteed for the process lifetime, as it is in the System Interfaces volume of IEEE Std 1003.1-2001, is not as useful to a shell script. The `getconf` utility is probably a process itself, so the guarantee would be without value. Therefore, the Shell and Utilities volume of IEEE Std 1003.1-2001 requires the guarantee to be for the session lifetime. This will mean that many vendors will either return very conservative values or possibly implement `getconf` as a built-in.

It may seem confusing to have limits that apply only to a single utility grouped into one global section. However, the alternative, which would be to disperse them out into their utility description sections, would cause great difficulty when `sysconf()` and `getconf` were described. Therefore, the standard developers chose the global approach.

Each language binding could provide symbol names that are slightly different from those shown here. For example, the C-Language Binding option adds a leading underscore to the symbols as a prefix.

The following comments describe selection criteria for the symbols and their values:

 `{ARG_MAX}`

This is defined by the System Interfaces volume of IEEE Std 1003.1-2001. Unfortunately, it is very difficult for a conforming application to deal with this value, as it does not know how much of its argument space is being consumed by the environment variables of the user.
These were originally one value, \{BC\_SCALE\_MAX\}, but it was unreasonable to link all three concepts into one limit.

\{CHILD\_MAX\}

This is defined by the System Interfaces volume of IEEE Std 1003.1-2001.

\{COLL\_WEIGHTS\_MAX\}

The weights assigned to \texttt{order} can be considered as "passes" through the collation algorithm.

\{EXPR\_NEST\_MAX\}

The value for expression nesting was borrowed from the ISO C standard.

\{LINE\_MAX\}

This is a global limit that affects all utilities, unless otherwise noted. The \{MAX\_CANON\} value from the System Interfaces volume of IEEE Std 1003.1-2001 may further limit input lines from terminals. The \{LINE\_MAX\} value was the subject of much debate and is a compromise between those who wished to have unlimited lines and those who understood that many historical utilities were written with fixed buffers. Frequently, utility writers selected the UNIX system constant \texttt{BUFSIZ} to allocate these buffers; therefore, some utilities were limited to 512 bytes for I/O lines, while others achieved 4,096 bytes or greater.

It should be noted that \{LINE\_MAX\} applies only to input line length; there is no requirement in IEEE Std 1003.1-2001 that limits the length of output lines. Utilities such as \texttt{awk}, \texttt{sed}, and \texttt{paste} could theoretically construct lines longer than any of the input lines they received, depending on the options used or the instructions from the application. They are not required to truncate their output to \{LINE\_MAX\}. It is the responsibility of the application to deal with this. If the output of one of those utilities is to be piped into another of the standard utilities, line length restrictions will have to be considered; the \texttt{fold} utility, among others, could be used to ensure that only reasonable line lengths reach utilities or applications.

\{LINK\_MAX\}

This is defined by the System Interfaces volume of IEEE Std 1003.1-2001.

\{MAX\_CANON\}
\{MAX\_INPUT\}
\{NAME\_MAX\}
\{NGROUPS\_MAX\}
\{OPEN\_MAX\}
\{PATH\_MAX\}
\{PIPE\_BUF\}

These limits are defined by the System Interfaces volume of IEEE Std 1003.1-2001. Note that the byte lengths described by some of these values continue to represent bytes, even if the applicable character set uses a multi-byte encoding.

\{RE\_DUP\_MAX\}

The value selected is consistent with historical practice. Although the name implies that it applies to all REs, only BREs use the interval notation \{\textit{m},n\} addressed by this limit.

\{POSIX2\_SYMLINKS\}

The \{POSIX2\_SYMLINKS\} variable indicates that the underlying operating system supports the creation of symbolic links in specific directories. Many of the utilities defined in IEEE Std 1003.1-2001 that deal with symbolic links do not depend on this value. For
example, a utility that follows symbolic links (or does not, as the case may be) will only be
affected by a symbolic link if it encounters one. Presumably, a file system that does not
support symbolic links will not contain any. This variable does affect such utilities as ln −s
and pax that attempt to create symbolic links.

{POSIX2_SYMLINKS} was developed even though there is no comparable configuration
value for the system interfaces.

There are different limits associated with command lines and input to utilities, depending on the
method of invocation. In the case of a C program exec-ing a utility, {ARG_MAX} is the
underlying limit. In the case of the shell reading a script and exec-ing a utility, {LINE_MAX}
limits the length of lines the shell is required to process, and {ARG_MAX} will still be a limit. If a
user is entering a command on a terminal to the shell, requesting that it invoke the utility,
{MAX_INPUT} may restrict the length of the line that can be given to the shell to a value below
{LINE_MAX}.

When an option is supported, getconf returns a value of 1. For example, when C development is
supported:

```bash
if [ "$(getconf POSIX2_C_DEV)" = 1 ]; then
    echo C supported
fi
```

The sysconf() function in the C-Language Binding option would return 1.

The following comments describe selection criteria for the symbols and their values:

- POSIX2_C_BIND
- POSIX2_C_DEV
- POSIX2_FORT_DEV
- POSIX2_FORT_RUN
- POSIX2_SW_DEV
- POSIX2_UPE

It is possible for some (usually privileged) operations to remove utilities that support these
options or otherwise to render these options unsupported. The header files, the sysconf() function, or the getconf utility will not necessarily detect such actions, in which case they
should not be considered as rendering the implementation non-conforming. A test suite
should not attempt tests such as:

```bash
rm /usr/bin/c99
getconf POSIX2_C_DEV
```

POSIX2_LOCALEDEF

This symbol was introduced to allow implementations to restrict supported locales to only
those supplied by the implementation.

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/2 is applied, deleting the entry for
{POSIX2_VERSION} since it is not a utility limit minimum value.

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/3 is applied, changing the text in Utility
Limits from: “utility (see getconf) through the sysconf() function defined in the System Interfaces
volume of IEEE Std 1003.1-2001. The literal names shown in Table 1-3 apply only to the getconf
utility; the high-level language binding describes the exact form of each name to be used by the
interfaces in that binding.” to: “utility (see getconf).”
C.1.10 Grammar Conventions

There is no additional rationale provided for this section.

C.1.11 Utility Description Defaults

This section is arranged with headings in the same order as all the utility descriptions. It is a collection of related and unrelated information concerning:

1. The default actions of utilities
2. The meanings of notations used in IEEE Std 1003.1-2001 that are specific to individual utility sections

Although this material may seem out of place here, it is important that this information appear before any of the utilities to be described later.

NAME

There is no additional rationale provided for this section.

SYNOPSIS

There is no additional rationale provided for this section.

DESCRIPTION

There is no additional rationale provided for this section.

OPTIONS

Although it has not always been possible, the standard developers tried to avoid repeating information to reduce the risk that duplicate explanations could each be modified differently.

The need to recognize -- is required because conforming applications need to shield their operands from any arbitrary options that the implementation may provide as an extension. For example, if the standard utility foo is listed as taking no options, and the application needed to give it a pathname with a leading hyphen, it could safely do it as:

```
foo -- myfile
```

and avoid any problems with -m used as an extension.

OPERANDS

The usage of – is never shown in the SYNOPSIS. Similarly, the usage of -- is never shown.

The requirement for processing operands in command-line order is to avoid a “WeirdNIX” utility that might choose to sort the input files alphabetically, by size, or by directory order.

Although this might be acceptable for some utilities, in general the programmer has a right to know exactly what order will be chosen.

Some of the standard utilities take multiple file operands and act as if they were processing the concatenation of those files. For example:

```
asa file1 file2
```

and:

```
cat file1 file2 | asa
```
have similar results when questions of file access, errors, and performance are ignored. Other
utilities such as `grep` or `wc` have completely different results in these two cases. This latter type of
utility is always identified in its DESCRIPTION or OPERANDS sections, whereas the former is
not. Although it might be possible to create a general assertion about the former case, the
following points must be addressed:

- Access times for the files might be different in the operand case versus the `cat` case.
- The utility may have error messages that are cognizant of the input filename, and this added
  value should not be suppressed. (As an example, `awk` sets a variable with the filename at
each file boundary.)

**STDIN**

There is no additional rationale provided for this section.

**INPUT FILES**

A conforming application cannot assume the following three commands are equivalent:

```bash
tail -n +2 file
(sed -n 1q; cat) < file
cat file | (sed -n 1q; cat)
```

The second command is equivalent to the first only when the file is seekable. In the third
command, if the file offset in the open file description were not unspecified, `sed` would have to be
implemented so that it read from the pipe 1 byte at a time or it would have to employ some
method to seek backwards on the pipe. Such functionality is not defined currently in POSIX.1
and does not exist on all historical systems. Other utilities, such as `head`, `read`, and `sh`, have similar
properties, so the restriction is described globally in this section.

The definition of “text file” is strictly enforced for input to the standard utilities; very few of
them list exceptions to the undefined results called for here. (Of course, “undefined” here does
not mean that historical implementations necessarily have to change to start indicating error
conditions. Conforming applications cannot rely on implementations succeeding or failing when
non-text files are used.)

The utilities that allow line continuation are generally those that accept input languages, rather
than pure data. It would be unusual for an input line of this type to exceed `{LINE_MAX}` bytes
and unreasonable to require that the implementation allow unlimited accumulation of multiple
lines, each of which could reach `{LINE_MAX}`. Thus, for a conforming application the total of all
the continued lines in a set cannot exceed `{LINE_MAX}`.

The format description is intended to be sufficiently rigorous to allow other applications to
generate these input files. However, since `<blank>`s can legitimately be included in some of the
fields described by the standard utilities, particularly in locales other than the POSIX locale, this
intent is not always realized.

**ENVIRONMENT VARIABLES**

There is no additional rationale provided for this section.
ASYNCHRONOUS EVENTS

Because there is no language prohibiting it, a utility is permitted to catch a signal, perform some additional processing (such as deleting temporary files), restore the default signal action (or action inherited from the parent process), and resignal itself.

STDOUT

The format description is intended to be sufficiently rigorous to allow post-processing of output by other programs, particularly by an *awk* or *lex* parser.

STDERR

This section does not describe error messages that refer to incorrect operation of the utility. Consider a utility that processes program source code as its input. This section is used to describe messages produced by a correctly operating utility that encounters an error in the program source code on which it is processing. However, a message indicating that the utility had insufficient memory in which to operate would not be described.

Some utilities have traditionally produced warning messages without returning a non-zero exit status; these are specifically noted in their sections. Other utilities shall not write to standard error if they complete successfully, unless the implementation provides some sort of extension to increase the verbosity or debugging level.

The format descriptions are intended to be sufficiently rigorous to allow post-processing of output by other programs.

OUTPUT FILES

The format description is intended to be sufficiently rigorous to allow post-processing of output by other programs, particularly by an *awk* or *lex* parser.

Receipt of the SIGQUIT signal should generally cause termination (unless in some debugging mode) that would bypass any attempted recovery actions.

EXTENDED DESCRIPTION

There is no additional rationale provided for this section.

EXIT STATUS

Note the additional discussion of exit values in *Exit Status for Commands* in the *sh* utility. It describes requirements for returning exit values greater than 125.

A utility may list zero as a successful return, 1 as a failure for a specific reason, and greater than 1 as “an error occurred”. In this case, unspecified conditions may cause a 2 or 3, or other value, to be returned. A strictly conforming application should be written so that it tests for successful exit status values (zero in this case), rather than relying upon the single specific error value listed in IEEE Std 1003.1-2001. In that way, it will have maximum portability, even on implementations with extensions.

The standard developers are aware that the general non-enumeration of errors makes it difficult to write test suites that test the incorrect operation of utilities. There are some historical implementations that have expended effort to provide detailed status messages and a helpful environment to bypass or explain errors, such as prompting, retrying, or ignoring unimportant syntax errors; other implementations have not. Since there is no realistic way to mandate system behavior in cases of undefined application actions or system problems—in a manner acceptable to all cultures and environments—attention has been limited to the correct operation of utilities.
by the conforming application. Furthermore, the conforming application does not need detailed
information concerning errors that it caused through incorrect usage or that it cannot correct.

There is no description of defaults for this section because all of the standard utilities specify
something (or explicitly state “Unspecified”) for exit status.

CONSEQUENCES OF ERRORS

Several actions are possible when a utility encounters an error condition, depending on the
severity of the error and the state of the utility. Included in the possible actions of various
utilities are: deletion of temporary or intermediate work files; deletion of incomplete files; and
validity checking of the file system or directory.

The text about recursive traversing is meant to ensure that utilities such as find process as many
files in the hierarchy as they can. They should not abandon all of the hierarchy at the first error
and resume with the next command-line operand, but should attempt to keep going.

APPLICATION USAGE

This section provides additional caveats, issues, and recommendations to the developer.

EXAMPLES

This section provides sample usage.

RATIONALE

There is no additional rationale provided for this section.

FUTURE DIRECTIONS

FUTURE DIRECTIONS sections act as pointers to related work that may impact the interface in
the future, and often cautions the developer to architect the code to account for a change in this
area. Note that a future directions statement should not be taken as a commitment to adopt a
feature or interface in the future.

SEE ALSO

CHANGE HISTORY

There is no additional rationale provided for this section.

C.1.12 Considerations for Utilities in Support of Files of Arbitrary Size

This section is intended to clarify the requirements for utilities in support of large files.

The utilities listed in this section are utilities which are used to perform administrative tasks
such as to create, move, copy, remove, change the permissions, or measure the resources of a
file. They are useful both as end-user tools and as utilities invoked by applications during
software installation and operation.

The chgrp, chmod, chown, ln, and rm utilities probably require use of large file-capable versions of
stat(), lstat(), ftw(), and the stat structure.

The cat, cksum, cmp, cp, dd, mv, sum, and touch utilities probably require use of large file-capable
versions of creat(), open(), and fopen().
The cat, cksum, cmp, dd, df, du, ls, and sum utilities may require writing large integer values. For example:

- The cat utility might have a \texttt{-n} option which counts <newline>s.
- The cksum and ls utilities report file sizes.
- The cmp utility reports the line number at which the first difference occurs, and also has a \texttt{-l} option which reports file offsets.
- The dd, df, du, ls, and sum utilities report block counts.

The \texttt{dd}, \texttt{find}, and test utilities may need to interpret command arguments that contain 64-bit values. For \texttt{dd}, the arguments include \texttt{skip=n}, \texttt{seek=n}, and \texttt{count=n}. For \texttt{find}, the arguments include \texttt{-size}. For \texttt{test}, the arguments are those associated with algebraic comparisons.

The df utility might need to access large file systems with \texttt{statvfs( )}.

The ulimit utility will need to use large file-capable versions of \texttt{getrlimit( )} and \texttt{setrlimit( )} and be able to read and write large integer values.

\section*{C.1.13 Built-In Utilities}

All of these utilities can be \texttt{exec}-ed. There is no requirement that these utilities are actually built into the shell itself, but many shells need the capability to do so because the Shell and Utilities volume of IEEE Std 1003.1-2001, Section 2.9.1.1, Command Search and Execution requires that they be found prior to the \texttt{PATH} search. The shell could satisfy its requirements by keeping a list of the names and directly accessing the file-system versions regardless of \texttt{PATH}. Providing all of the required functionality for those such as \texttt{cd} or \texttt{read} would be more difficult.

There were originally three justifications for allowing the omission of \texttt{exec}-able versions:

1. It would require wasting space in the file system, at the expense of very small systems. However, it has been pointed out that all 16 utilities in the table can be provided with 16 links to a single-line shell script:

\begin{verbatim}
$0 "$@"
\end{verbatim}

2. It is not logical to require invocation of utilities such as \texttt{cd} because they have no value outside the shell environment or cannot be useful in a child process. However, counter-examples always seemed to be available for even the most unusual cases:

\begin{verbatim}
find . -type d -exec cd {} \; -exec foo {} \;
\end{verbatim}

(which invokes ‘‘foo’’ on accessible directories)

\begin{verbatim}
ps ... | sed ... | xargs kill
\end{verbatim}

\begin{verbatim}
find . -exec true \; -a ...
\end{verbatim}

(where ‘‘true’’ is used for temporary debugging)

3. It is confusing to have a utility such as \texttt{kill} that can easily be in the file system in the base standard, but that requires built-in status for the User Portability Utilities option (for the \$ job control job ID notation). It was decided that it was more appropriate to describe the required functionality (rather than the implementation) to the system implementors and let them decide how to satisfy it.

On the other hand, it was realized that any distinction like this between utilities was not useful to applications, and that the cost to correct it was small. These arguments were ultimately the most effective.
There were varying reasons for including utilities in the table of built-ins:

- **alias, fc, unalias**
  The functionality of these utilities is performed more simply within the shell itself and that is the model most historical implementations have used.

- **bg, fg, jobs**
  All of the job control-related utilities are eligible for built-in status because that is the model most historical implementations have used.

- **cd, getopts, newgrp, read, umask, wait**
  The functionality of these utilities is performed more simply within the context of the current process. An example can be taken from the usage of the *cd* utility. The purpose of the cd utility is to change the working directory for subsequent operations. The actions of cd affect the process in which cd is executed and all subsequent child processes of that process. Based on the POSIX standard process model, changes in the process environment of a child process have no effect on the parent process. If the *cd* utility were executed from a child process, the working directory change would be effective only in the child process. Child processes initiated subsequent to the child process that executed the *cd* utility would not have a changed working directory relative to the parent process.

- **command**
  This utility was placed in the table primarily to protect scripts that are concerned about their PATH being manipulated. The "secure" shell script example in the *command* utility in the Shell and Utilities volume of IEEE Std 1003.1-2001 would not be possible if a PATH change retrieved an alien version of *command*. (An alternative would have been to implement *getconf* as a built-in, but the standard developers considered that it carried too many changing configuration strings to require in the shell.)

- **kill**
  Since *kill* provides optional job control functionality using shell notation (%1, %2, and so on), some implementations would find it extremely difficult to provide this outside the shell.

- **true, false**
  These are in the table as a courtesy to programmers who wish to use the "while true" shell construct without protecting *true* from PATH searches. (It is acknowledged that "while :") also works, but the idiom with *true* is historically pervasive.)

All utilities, including those in the table, are accessible via the *system()* and *popen()* functions in the System Interfaces volume of IEEE Std 1003.1-2001. There are situations where the return functionality of *system()* and *popen()* is not desirable. Applications that require the exit status of the invoked utility will not be able to use *system()* or *popen()* since the exit status returned is that of the command language interpreter rather than that of the invoked utility. The alternative for such applications is the use of the *exec* family.
C.2 Shell Command Language

C.2.1 Shell Introduction

The System V shell was selected as the starting point for the Shell and Utilities volume of IEEE Std 1003.1-2001. The BSD C shell was excluded from consideration for the following reasons:

- Most historically portable shell scripts assume the Version 7 Bourne shell, from which the System V shell is derived.
- The majority of tutorial materials on shell programming assume the System V shell.

The construct "#!" is reserved for implementations wishing to provide that extension. If it were not reserved, the Shell and Utilities volume of IEEE Std 1003.1-2001 would disallow it by forcing it to be a comment. As it stands, a strictly conforming application must not use "#!" as the first two characters of the file.

C.2.2 Quoting

There is no additional rationale provided for this section.

C.2.2.1 Escape Character (Backslash)

There is no additional rationale provided for this section.

C.2.2.2 Single-Quotes

A backslash cannot be used to escape a single-quote in a single-quoted string. An embedded quote can be created by writing, for example: "'a\'b'", which yields "a'b". (See the Shell and Utilities volume of IEEE Std 1003.1-2001, Section 2.6.5, Field Splitting for a better understanding of how portions of words are either split into fields or remain concatenated.) A single token can be made up of concatenated partial strings containing all three kinds of quoting or escaping, thus permitting any combination of characters.

C.2.2.3 Double-Quotes

The escaped <newline> used for line continuation is removed entirely from the input and is not replaced by any white space. Therefore, it cannot serve as a token separator.

In double-quoting, if a backslash is immediately followed by a character that would be interpreted as having a special meaning, the backslash is deleted and the subsequent character is taken literally. If a backslash does not precede a character that would have a special meaning, it is left in place unmodified and the character immediately following it is also left unmodified. Thus, for example:

\"$\" \rightarrow $\n\"a\" \rightarrow \a

It would be desirable to include the statement ‘The characters from an enclosed "$\{" to the matching '}" shall not be affected by the double quotes”, similar to the one for "$()". However, historical practice in the System V shell prevents this.

The requirement that double-quotes be matched inside "$\{\ldots\}" within double-quotes and the rule for finding the matching ‘}’ in the Shell and Utilities volume of IEEE Std 1003.1-2001, Section 2.6.2, Parameter Expansion eliminate several subtle inconsistencies in expansion for historical shells in rare cases; for example:
"${foo-bar}"

yields bar when foo is not defined, and is an invalid substitution when foo is defined, in many historical shells. The differences in processing the "${...}" form have led to inconsistencies between historical systems. A consequence of this rule is that single-quotes cannot be used to quote the ‘}’ within "${...}"; for example:

    unset bar
    foo="${bar-'}'}"

is invalid because the "${...}" substitution contains an unpaired unescaped single-quote. The backslash can be used to escape the ‘}’ in this example to achieve the desired result:

    unset bar
    foo="${bar-\}"

The differences in processing the "${...}" form have led to inconsistencies between the historical System V shell, BSD, and KornShells, and the text in the Shell and Utilities volume of IEEE Std 1003.1-2001 is an attempt to converge them without breaking too many applications. The only alternative to this compromise between shells would be to make the behavior unspecified whenever the literal characters ‘’, ‘{’, ‘}’, and ‘”’ appear within "${...}". To write a portable script that uses these values, a user would have to assign variables; for example:

    squote=\' dquote=" lbrace=' \rbrace=' \'
    ${foo-$squote$rbrace$squote}

rather than:

    ${foo-'""

Some implementations have allowed the end of the word to terminate the backquoted command substitution, such as in:

    "'echo hello"

This usage is undefined; the matching backquote is required by the Shell and Utilities volume of IEEE Std 1003.1-2001. The other undefined usage can be illustrated by the example:

    sh -c "' echo "foo'"

The description of the recursive actions involving command substitution can be illustrated with an example. Upon recognizing the introduction of command substitution, the shell parses input (in a new context), gathering the source for the command substitution until an unbalanced ‘)’ or ‘}’ is located. For example, in the following:

    echo "${(date; echo "
          one" )}"

the double-quote following the echo does not terminate the first double-quote; it is part of the command substitution script. Similarly, in:

    echo "$ (echo *)"

the asterisk is not quoted since it is inside command substitution; however:

    echo "$ (echo **)"

is quoted (and represents the asterisk character itself).
C.2.3 Token Recognition

The "((" and "))" symbols are control operators in the KornShell, used for an alternative syntax of an arithmetic expression command. A conforming application cannot use "((" as a single token (with the exception of the "$((" form for shell arithmetic).

On some implementations, the symbol "((" is a control operator; its use produces unspecified results. Applications that wish to have nested subshells, such as:

```
((echo Hello);(echo World))
```

must separate the "((" characters into two tokens by including white space between them. Some systems may treat these as invalid arithmetic expressions instead of subshells.

Certain combinations of characters are invalid in portable scripts, as shown in the grammar. Implementations may use these combinations (such as "|&") as valid control operators. Portable scripts cannot rely on receiving errors in all cases where this volume of IEEE Std 1003.1-2001 indicates that a syntax is invalid.

The (3) rule about combining characters to form operators is not meant to preclude systems from extending the shell language when characters are combined in otherwise invalid ways. Conforming applications cannot use invalid combinations, and test suites should not penalize systems that take advantage of this fact. For example, the unquoted combination "|&" is not valid in a POSIX script, but has a specific KornShell meaning.

The (10) rule about '#' as the current character is the first in the sequence in which a new token is being assembled. The '#' starts a comment only when it is at the beginning of a token. This rule is also written to indicate that the search for the end-of-comment does not consider escaped <newline> specially, so that a comment cannot be continued to the next line.

C.2.3.1 Alias Substitution

The alias capability was added in the User Portability Utilities option because it is widely used in historical implementations by interactive users.

The definition of “alias name” precludes an alias name containing a slash character. Since the text applies to the command words of simple commands, reserved words (in their proper places) cannot be confused with aliases.

The placement of alias substitution in token recognition makes it clear that it precedes all of the word expansion steps.

An example concerning trailing <blank>s and reserved words follows. If the user types:

```
$ alias foo="/bin/ls "
$ alias while="/"
```

The effect of executing:
```
$ while true
   > do
   >   echo "Hello, World"
   > done
```

is a never-ending sequence of "Hello, World" strings to the screen. However, if the user types:
```
$ foo while
```

the result is an ls listing of /. Since the alias substitution for foo ends in a <space>, the next word is checked for alias substitution. The next word, while, has also been aliased, so it is substituted
as well. Since it is not in the proper position as a command word, it is not recognized as a
reserved word.

If the user types:

```sh
$ foo; while
```

while retains its normal reserved-word properties.

### C.2.4 Reserved Words

All reserved words are recognized syntactically as such in the contexts described. However, note
that `in` is the only meaningful reserved word after a `case` or `for`; similarly, `in` is not meaningful as
the first word of a simple command.

Reserved words are recognized only when they are delimited (that is, meet the definition of the
Base Definitions volume of IEEE Std 1003.1-2001, Section 3.435, Word), whereas operators are
themselves delimiters. For instance, `(` and `)` are control operators, so that no `<space>` is
needed in `(list)`. However, `{` and `}` are reserved words in `{list}`, so that in this case the
leading `<space>` and semicolon are required.

The list of unspecified reserved words is from the KornShell, so conforming applications cannot
use them in places a reserved word would be recognized. This list contained `time` in early
proposals, but it was removed when the `time` utility was selected for the Shell and Utilities

There was a strong argument for promoting braces to operators (instead of reserved words), so
they would be syntactically equivalent to subshell operators. Concerns about compatibility
outweighed the advantages of this approach. Nevertheless, conforming applications should
consider quoting `{` and `}` when they represent themselves.

The restriction on ending a name with a colon is to allow future implementations that support
named labels for flow control; see the RATIONALE for the `break` built-in utility.

It is possible that a future version of the Shell and Utilities volume of IEEE Std 1003.1-2001 may
require that `{` and `}` be treated individually as control operators, although the token `"{}"`
will probably be a special-case exemption from this because of the often-used `find{}` construct.

### C.2.5 Parameters and Variables

#### C.2.5.1 Positional Parameters

There is no additional rationale provided for this section.

#### C.2.5.2 Special Parameters

Most historical implementations implement subshells by forking; thus, the special parameter
`$` does not necessarily represent the process ID of the shell process executing the commands
since the subshell execution environment preserves the value of `$`.

If a subshell were to execute a background command, the value of `"$!"` for the parent would
not change. For example:

```sh
( date &
 echo $!
)
 echo $!
```
would echo two different values for "$!".

The "$−" special parameter can be used to save and restore set options:

```bash
Save=$(echo $− | sed 's/[ics]//g')
... 
set +aCefnuvx
if [ −n "$Save" ]; then
  set −$Save
fi
```

The three options are removed using sed in the example because they may appear in the value of "$−" (from the sh command line), but are not valid options to set.

The descriptions of parameters ‘*’ and ‘@’ assume the reader is familiar with the field splitting discussion in the Shell and Utilities volume of IEEE Std 1003.1-2001, Section 2.6.5, Field Splitting and understands that portions of the word remain concatenated unless there is some reason to split them into separate fields.

Some examples of the ‘*’ and ‘@’ properties, including the concatenation aspects:

```bash
set "abc" "def ghi" "jkl"
```

```bash
echo $* => "abc" "def" "ghi" "jkl"
```

```bash
echo "$*" => "abc def ghi jkl"
```

```bash
echo $@ => "abc" "def" "ghi" "jkl"
```

but:

```bash
echo "$@" => "abc" "def ghi" "jkl"
```

```bash
echo "xx$@yy" => "xxabc" "def ghi" "jklyy"
```

```bash
echo "$@$@" => "abc" "def ghi" "jklabc" "def ghi" "jkl"
```

In the preceding examples, the double-quote characters that appear after the "=>" do not appear in the output and are used only to illustrate word boundaries.

The following example illustrates the effect of setting IFS to a null string:

```bash
$ IFS=''
$ set foo bar bam
$ echo "$@"
```

```bash
foo bar bam
```

```bash
$ echo "$*"
```

```bash
foo bar bam
```

```bash
$ unset IFS
$ echo "$*
```

```bash
foo bar bam
```

### C.2.5.3 Shell Variables

See the discussion of IFS in Section C.2.6.5 (on page 241) and the RATIONALE for the sh utility.

The prohibition on LC_CTYPE changes affecting lexical processing protects the shell implementor (and the shell programmer) from the ill effects of changing the definition of <blank> or the set of alphabetic characters in the current environment. It would probably not be feasible to write a compiled version of a shell script without this rule. The rule applies only to the current invocation of the shell and its subshells—invoking a shell script or performing exec sh would subject the new shell to the changes in LC_CTYPE.
Other common environment variables used by historical shells are not specified by the Shell and Utilities volume of IEEE Std 1003.1-2001, but they should be reserved for the historical uses.

Tilde expansion for components of PATH in an assignment such as:

```
PATH=`~hlj/bin:~dwc/bin:$PATH`
```

is a feature of some historical shells and is allowed by the wording of the Shell and Utilities volume of IEEE Std 1003.1-2001, Section 2.6.1, Tilde Expansion. Note that the tildes are expanded during the assignment to PATH, not when PATH is accessed during command search.

The following entries represent additional information about variables included in the Shell and Utilities volume of IEEE Std 1003.1-2001, or rationale for common variables in use by shells that have been excluded:

- (Underscore.) While underscore is historical practice, its overloaded usage in the KornShell is confusing, and it has been omitted from the Shell and Utilities volume of IEEE Std 1003.1-2001.

  ENV

  This variable can be used to set aliases and other items local to the invocation of a shell. The file referred to by \texttt{ENV} differs from \texttt{HOME/.profile} in that \texttt{.profile} is typically executed at session start-up, whereas the \texttt{ENV} file is executed at the beginning of each shell invocation. The \texttt{ENV} value is interpreted in a manner similar to a dot script, in that the commands are executed in the current environment and the file needs to be readable, but not executable. However, unlike dot scripts, no \texttt{PATH} searching is performed. This is used as a guard against Trojan Horse security breaches.

  ERRNO

  This variable was omitted from the Shell and Utilities volume of IEEE Std 1003.1-2001 because the values of error numbers are not defined in IEEE Std 1003.1-2001 in a portable manner.

  FCEDIT

  Since this variable affects only the \texttt{fc} utility, it has been omitted from this more global place. The value of \texttt{FCEDIT} does not affect the command-line editing mode in the shell; see the description of \texttt{set -o vi} in the \texttt{set} built-in utility.

  PS1

  This variable is used for interactive prompts. Historically, the “superuser” has had a prompt of \texttt{’ #’}. Since privileges are not required to be monolithic, it is difficult to define which privileges should cause the alternate prompt. However, a sufficiently powerful user should be reminded of that power by having an alternate prompt.

  PS3

  This variable is used by the KornShell for the \texttt{select} command. Since the POSIX shell does not include \texttt{select}, \texttt{PS3} was omitted.

  PS4

  This variable is used for shell debugging. For example, the following script:

  ```
  PS4='[\${LINENO}]+ '+
  set -x
  echo Hello
  ```

  writes the following to standard error:

  ```
  [3]+ echo Hello
  ```

  RANDOM

  This pseudo-random number generator was not seen as being useful to interactive users.

  SECONDS

  Although this variable is sometimes used with \texttt{PS1} to allow the display of the current time in the prompt of the user, it is not one that would be manipulated
frequently enough by an interactive user to include in the Shell and Utilities volume of IEEE Std 1003.1-2001.

C.2.6 Word Expansions

Step (2) refers to the ‘‘portions of fields generated by step (1)’’. For example, if the word being expanded were "$x+$y" and $IFS=+, the word would be split only if "$x" or "$y" contained ‘‘+’’; the ‘‘+’’ in the original word was not generated by step (1).

$IFS is used for performing field splitting on the results of parameter and command substitution; it is not used for splitting all fields. Previous versions of the shell used it for splitting all fields during field splitting, but this has severe problems because the shell can no longer parse its own script. There are also important security implications caused by this behavior. All useful applications of $IFS use it for parsing input of the read utility and for splitting the results of parameter and command substitution.

The rule concerning expansion to a single field requires that if foo=abc and bar=def, that:

"$foo""$bar"

expands to the single field:

abcdef

The rule concerning empty fields can be illustrated by:

$ unset foo
$ set $foo bar '' xyz "$foo" abc
$ for i
  > do
  >   echo "−$i−"
  > done
  −bar−
−
−xyz−
−
−abc−

Step (1) indicates that parameter expansion, command substitution, and arithmetic expansion are all processed simultaneously as they are scanned. For example, the following is valid arithmetic:

x=1
echo $(( $(echo 3)+$x ))

An early proposal stated that tilde expansion preceded the other steps, but this is not the case in known historical implementations; if it were, and if a referenced home directory contained a ’ $’ character, expansions would result within the directory name.

C.2.6.1 Tilde Expansion

Tilde expansion generally occurs only at the beginning of words, but an exception based on historical practice has been included:

PATH=/posix/bin:~dgk/bin

This is eligible for tilde expansion because tilde follows a colon and none of the relevant characters is quoted. Consideration was given to prohibiting this behavior because any of the following are reasonable substitutes:
PATH=$(printf %s ~karels/bin : ~bostic/bin)
for Dir in ~maart/bin ~srb/bin ...
  do
    PATH=${PATH:+$PATH:}$Dir
  done

In the first command, explicit colons are used for each directory. In all cases, the shell performs tilde expansion on each directory because all are separate words to the shell.

Note that expressions in operands such as:

make -k mumble LIBDIR=~-chet/lib

do not qualify as shell variable assignments, and tilde expansion is not performed (unless the command does so itself, which make does not).

Because of the requirement that the word is not quoted, the following are not equivalent; only the last causes tilde expansion:

\`hlj/ -hlj/ ~"hlj"/ -hlj/ ~hlj/

In an early proposal, tilde expansion occurred following any unquoted equals sign or colon, but this was removed because of its complexity and to avoid breaking commands such as:

cp hostname:~marc/.profile .

A suggestion was made that the special sequence "$~" should be allowed to force tilde expansion anywhere. Since this is not historical practice, it has been left for future implementations to evaluate. (The description in the Shell and Utilities volume of IEEE Std 1003.1-2001, Section 2.2, Quoting requires that a dollar sign be quoted to represent itself, so the "$~" combination is already unspecified.)

The results of giving tilde with an unknown login name are undefined because the KornShell "~+" and "~-" constructs make use of this condition, but in general it is an error to give an incorrect login name with tilde. The results of having HOME unset are unspecified because some historical shells treat this as an error.

C.2.6.2 Parameter Expansion

The rule for finding the closing ’}‘ in "${...}" is the one used in the KornShell and is upwardly-compatible with the Bourne shell, which does not determine the closing ’}‘ until the word is expanded. The advantage of this is that incomplete expansions, such as:

${foo

can be determined during tokenization, rather than during expansion.

The string length and substring capabilities were included because of the demonstrated need for them, based on their usage in other shells, such as C shell and KornShell.

Historical versions of the KornShell have not performed tilde expansion on the word part of parameter expansion; however, it is more consistent to do so.
C.2.6.3 Command Substitution

The "$( )" form of command substitution solves a problem of inconsistent behavior when using backquotes. For example:

<table>
<thead>
<tr>
<th>Command</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>echo '$x'</td>
<td>$x</td>
</tr>
<tr>
<td>echo 'echo $x'</td>
<td>$x</td>
</tr>
<tr>
<td>echo $(echo $x)</td>
<td>$x</td>
</tr>
</tbody>
</table>

Additionally, the backquoted syntax has historical restrictions on the contents of the embedded command. While the newer "$( )" form can process any kind of valid embedded script, the backquoted form cannot handle some valid scripts that include backquotes. For example, these otherwise valid embedded scripts do not work in the left column, but do work on the right:

```bash
echo 'cat <<\eof
a here-doc with '
eof
'$(echo abc # a comment with ')

'$(echo '')'
```

Because of these inconsistent behaviors, the backquoted variety of command substitution is not recommended for new applications that nest command substitutions or attempt to embed complex scripts.

The KornShell feature:

If `command` is of the form `<word, word` is expanded to generate a pathname, and the value of the command substitution is the contents of this file with any trailing <newline>s deleted.

was omitted from the Shell and Utilities volume of IEEE Std 1003.1-2001 because $(cat word) is an appropriate substitute. However, to prevent breaking numerous scripts relying on this feature, it is unspecified to have a script within "$( )" that has only redirections.

The requirement to separate "$( " and ' ' when a single subshell is command-substituted is to avoid any ambiguities with arithmetic expansion.

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/4 is applied, changing the text from: “If a command substitution occurs inside double-quotes, it shall not be performed on the results of the substitution.” to: “If a command substitution occurs inside double-quotes, field splitting and pathname expansion shall not be performed on the results of the substitution.”. The replacement text taken from the ISO POSIX-2:1993 standard is clearer about the items that are not performed.
The "$()" form of KornShell arithmetic in early proposals was omitted. The standard developers concluded that there was a strong desire for some kind of arithmetic evaluator to replace expr, and that relating it to '$' makes it work well with the standard shell language, and it provides access to arithmetic evaluation in places where accessing a utility would be inconvenient.

The syntax and semantics for arithmetic were changed for the ISO/IEC 9945-2:1993 standard. The language is essentially a pure arithmetic evaluator of constants and operators (excluding assignment) and represents a simple subset of the previous arithmetic language (which was derived from the KornShell "(()") construct). The syntax was changed from that of a command denoted by ((expression)) to an expansion denoted by $(expression)). The new form is a dollar expansion ('$') that evaluates the expression and substitutes the resulting value. Objections to the previous style of arithmetic included that it was too complicated, did not fit in well with the use of variables in the shell, and its syntax conflicted with subshells. The justification for the new syntax is that the shell is traditionally a macro language, and if a new feature is to be added, it should be accomplished by extending the capabilities presented by the current model of the shell, rather than by inventing a new one outside the model; adding a new dollar expansion was perceived to be the most intuitive and least destructive way to add such a new capability.

In early proposals, a form $[expression] was used. It was functionally equivalent to the "$(())" of the current text, but objections were lodged that the 1988 KornShell had already implemented "$()") and there was no compelling reason to invent yet another syntax. Furthermore, the "$[[]"] syntax had a minor incompatibility involving the patterns in case statements.

The portion of the ISO C standard arithmetic operations selected corresponds to the operations historically supported in the KornShell.

It was concluded that the test command (l) was sufficient for the majority of relational arithmetic tests, and that tests involving complicated relational expressions within the shell are rare, yet could still be accommodated by testing the value of "$(()") itself. For example:

# a complicated relational expression
while [ $(( ((($x + $y)/(a * $b)) < ($foo*$bar) )) -ne 0 ]

or better yet, the rare script that has many complex relational expressions could define a function like this:

val() {
  return $((!$1))
}

and complicated tests would be less intimidating:

while val $(( ($(x + y)/(a * $b)) < ($foo*$bar) ))
do
  # some calculations
done

A suggestion that was not adopted was to modify true and false to take an optional argument, and true would exit true only if the argument was non-zero, and false would exit false only if the argument was non-zero:

while true $((x > 5 && y <= 25))

There is a minor portability concern with the new syntax. The example "$((2+2))" could have been intended to mean a command substitution of a utility named "2+2" in a subshell. The
standard developers considered this to be obscure and isolated to some KornShell scripts (because "$(())" command substitution existed previously only in the KornShell). The text on command substitution requires that the "$(" and ")" be separate tokens if this usage is needed.

An example such as:

```
echo $( (echo hi); (echo there))
```

should not be misinterpreted by the shell as arithmetic because attempts to balance the parentheses pairs would indicate that they are subshells. However, as indicated by the Base Definitions volume of IEEE Std 1003.1-2001, Section 3.112, Control Operator, a conforming application must separate two adjacent parentheses with white space to indicate nested subshells.

Although the ISO/IEC 9899:1999 standard now requires support for `long long` and allows extended integer types with higher ranks, IEEE Std 1003.1-2001 only requires arithmetic expansions to support `signed long` integer arithmetic. Implementations are encouraged to support signed integer values at least as large as the size of the largest file allowed on the implementation.

Implementations are also allowed to perform floating-point evaluations as long as an application won't see different results for expressions that would not overflow `signed long` integer expression evaluation. (This includes appropriate truncation of results to integer values.)

Changes made in response to IEEE PASC Interpretation 1003.2 #208 removed the requirement that the integer constant suffixes `l` and `L` had to be recognized. The ISO POSIX-2:1993 standard did not require the `u`, `ul`, `UL`, `u1`, `UL`, `lu`, `LU`, `lu`, and `LU` suffixes since only signed integer arithmetic was required. Since all arithmetic expressions were treated as handling `signed long` integer types anyway, the `l` and `L` suffixes were redundant. No known scripts used them and some historic shells did not support them. When the ISO/IEC 9899:1999 standard was used as the basis for the description of arithmetic processing, the `ll` and `LL` suffixes and combinations were also not required. Implementations are still free to accept any or all of these suffixes, but are not required to do so.

There was also some confusion as to whether the shell was required to recognize character constants. Syntactically, character constants were required to be recognized, but the requirements for the handling of backslash (`\`) and quote (`''`) characters (needed to specify character constants) within an arithmetic expansion were ambiguous. Furthermore, no known shells supported them. Changes made in response to IEEE PASC Interpretation 1003.2 #208 removed the requirement to support them (if they were indeed required before).

IEEE Std 1003.1-2001 clearly does not require support for character constants.

### C.2.6.5 Field Splitting

The operation of field splitting using `IFS`, as described in early proposals, was based on the way the KornShell splits words, but it is incompatible with other common versions of the shell. However, each has merit, and so a decision was made to allow both. If the `IFS` variable is unset or is `<space><tab><newline>`, the operation is equivalent to the way the System V shell splits words. Using characters outside the `<space><tab><newline>` set yields the KornShell behavior, where each of the non-`<space><tab><newline>`s is significant. This behavior, which affords the most flexibility, was taken from the way the original `awk` handled field splitting.

Rule (3) can be summarized as a pseudo-ERE:

```
(s*ns* | s+)
```

where `s` is an `IFS` white space character and `n` is a character in the `IFS` that is not white space. Any string matching that ERE delimits a field, except that the `s+` form does not delimit fields at
the beginning or the end of a line. For example, if IFS is `<space>/<comma>/<tab>`, the string:

```
<space><space>red<space><space>,<space>white<space>blue
```

yields the three colors as the delimited fields.

**C.2.6.6 Pathname Expansion**

There is no additional rationale provided for this section.

**C.2.6.7 Quote Removal**

There is no additional rationale provided for this section.

**C.2.7 Redirection**

In the System Interfaces volume of IEEE Std 1003.1-2001, file descriptors are integers in the range `0−{OPEN_MAX}−1`. The file descriptors discussed in the Shell and Utilities volume of IEEE Std 1003.1-2001, Section 2.7, Redirection are that same set of small integers.

Having multi-digit file descriptor numbers for I/O redirection can cause some obscure compatibility problems. Specifically, scripts that depend on an example command:

```
echo 22>/dev/null
```

echoing "2" to standard error or "22" to standard output are no longer portable. However, the file descriptor number must still be delimited from the preceding text. For example:

```
cat file2>foo
```

writes the contents of `file2`, not the contents of `file`.

The ">|" format of output redirection was adopted from the KornShell. Along with the `noclobber` option, `set −C`, it provides a safety feature to prevent inadvertent overwriting of existing files. (See the RATIONALE for the `pathchk` utility for why this step was taken.) The restriction on regular files is historical practice.

The System V shell and the KornShell have differed historically on pathname expansion of `word`; the former never performed it, the latter only when the result was a single field (file). As a compromise, it was decided that the KornShell functionality was useful, but only as a shorthand device for interactive users. No reasonable shell script would be written with a command such as:

```
cat foo > a*
```

Thus, shell scripts are prohibited from doing it, while interactive users can select the shell with which they are most comfortable.

The construct "2>&1" is often used to redirect standard error to the same file as standard output. Since the redirections take place beginning to end, the order of redirections is significant. For example:

```
ls > foo 2>&1
```

directs both standard output and standard error to file `foo`. However:

```
ls 2>&1 > foo
```

only directs standard output to file `foo` because standard error was duplicated as standard output before standard output was directed to file `foo`. 
Rationale for Shell and Utilities

10032 The "<>" operator could be useful in writing an application that worked with several terminals, and occasionally wanted to start up a shell. That shell would in turn be unable to run applications that run from an ordinary controlling terminal unless it could make use of "<>": redirection. The specific example is a historical version of the pager more, which reads from standard error to get its commands, so standard input and standard output are both available for their usual usage. There is no way of saying the following in the shell without "<>":

\[
\text{cat food | more } \rightarrow /dev/tty03 2<>/dev/tty03
\]

Another example of "<>" is one that opens /dev/tty on file descriptor 3 for reading and writing:

\[
\text{exec 3<> /dev/tty}
\]

An example of creating a lock file for a critical code region:

\[
\text{set -C}
\]
\[
\text{until 2> /dev/null > lockfile}
\]
\[
\text{do sleep 30}
\]
\[
\text{done}
\]
\[
\text{set +C}
\]
\[
\text{perform critical function}
\]
\[
\text{rm lockfile}
\]

Since /dev/null is not a regular file, no error is generated by redirecting to it in noclobber mode.

Tilde expansion is not performed on a here-document because the data is treated as if it were enclosed in double quotes.

10052 C.2.7.1 Redirecting Input

There is no additional rationale provided for this section.

10054 C.2.7.2 Redirecting Output

There is no additional rationale provided for this section.

10056 C.2.7.3 Appending Redirected Output

Note that when a file is opened (even with the O_APPEND flag set), the initial file offset for that file is set to the beginning of the file. Some historic shells set the file offset to the current end-of-file when append mode shell redirection was used, but this is not allowed by IEEE Std 1003.1-2001.

10061 C.2.7.4 Here-Document

There is no additional rationale provided for this section.

10063 C.2.7.5 Duplicating an Input File Descriptor

There is no additional rationale provided for this section.
C.2.7.7  Open File Descriptors for Reading and Writing

There is no additional rationale provided for this section.

C.2.8  Exit Status and Errors

C.2.8.1  Consequences of Shell Errors

There is no additional rationale provided for this section.

C.2.8.2  Exit Status for Commands

There is a historical difference in \texttt{sh} and \texttt{ksh} non-interactive error behavior. When a command named in a script is not found, some implementations of \texttt{sh} exit immediately, but \texttt{ksh} continues with the next command. Thus, the Shell and Utilities volume of IEEE Std 1003.1-2001 says that the shell “may” exit in this case. This puts a small burden on the programmer, who has to test for successful completion following a command if it is important that the next command not be executed if the previous command was not found. If it is important for the command to have been found, it was probably also important for it to complete successfully. The test for successful completion would not need to change.

Historically, shells have returned an exit status of $128+n$, where $n$ represents the signal number. Since signal numbers are not standardized, there is no portable way to determine which signal caused the termination. Also, it is possible for a command to exit with a status in the same range of numbers that the shell would use to report that the command was terminated by a signal.

Implementations are encouraged to choose exit values greater than 256 to indicate programs that terminate by a signal so that the exit status cannot be confused with an exit status generated by a normal termination.

Historical shells make the distinction between “utility not found” and “utility found but cannot execute” in their error messages. By specifying two seldomly used exit status values for these cases, 127 and 126 respectively, this gives an application the opportunity to make use of this distinction without having to parse an error message that would probably change from locale to locale. The \texttt{command}, \texttt{env}, \texttt{nohup}, and \texttt{xargs} utilities in the Shell and Utilities volume of IEEE Std 1003.1-2001 have also been specified to use this convention.

When a command fails during word expansion or redirection, most historical implementations exit with a status of 1. However, there was some sentiment that this value should probably be much higher so that an application could distinguish this case from the more normal exit status values. Thus, the language “greater than zero” was selected to allow either method to be implemented.

C.2.9  Shell Commands

A description of an “empty command” was removed from an early proposal because it is only relevant in the cases of \texttt{sh \(-c "", system(""), or an empty shell-script file (such as the implementation of \texttt{true} on some historical systems). Since it is no longer mentioned in the Shell and Utilities volume of IEEE Std 1003.1-2001, it falls into the silently unspecified category of behavior where implementations can continue to operate as they have historically, but conforming applications do not construct empty commands. (However, note that \texttt{sh} does explicitly state an exit status for an empty string or file.) In an interactive session or a script with other commands, extra <newline>s or semicolons, such as:
would not qualify as the empty command described here because they would be consumed by other parts of the grammar.

C.2.9.1 Simple Commands

The enumerated list is used only when the command is actually going to be executed. For example, in:

```
ture || $foo *
```

no expansions are performed.

The following example illustrates both how a variable assignment without a command name affects the current execution environment, and how an assignment with a command name only affects the execution environment of the command:

```
$ x=red
$ echo $x
red
$ export x
$ sh -c 'echo $x'
red
$ x=blue sh -c 'echo $x'
blue
$ echo $x
red
```

This next example illustrates that redirections without a command name are still performed:

```
$ ls foo
ls: foo: no such file or directory
$ > foo
$ ls foo
foo
```

A command without a command name, but one that includes a command substitution, has an exit status of the last command substitution that the shell performed. For example:

```
if x=${(command)
then ...
fi
```

An example of redirections without a command name being performed in a subshell shows that the here-document does not disrupt the standard input of the `while` loop:

```
IFS=:
while read a b
do echo $a
<<-eof
Hello
eof
done </etc/passwd
```
Following are examples of commands without command names in AND-OR lists:

```bash
> foo || {
    echo "error: foo cannot be created" >&2
    exit 1
}
```

```bash
# set saved if /vmunix.save exists

test -f /vmunix.save && saved=1
```

Command substitution and redirections without command names both occur in subshells, but they are not necessarily the same ones. For example, in:

```bash
exec 3> file
var=$(echo foo >&3) 3>&1
```

it is unspecified whether `foo` is echoed to the file or to standard output.

## Command Search and Execution

This description requires that the shell can execute shell scripts directly, even if the underlying system does not support the common "#!" interpreter convention. That is, if file `foo` contains shell commands and is executable, the following executes `foo`:

```bash
./foo
```

The command search shown here does not match all historical implementations. A more typical sequence has been:

- Any built-in (special or regular)
- Functions
- Path search for executable files

But there are problems with this sequence. Since the programmer has no idea in advance which utilities might have been built into the shell, a function cannot be used to override portably a utility of the same name. (For example, a function named `cd` cannot be written for many historical systems.) Furthermore, the `PATH` variable is partially ineffective in this case, and only a pathname with a slash can be used to ensure a specific executable file is invoked.

After the `execve()` failure described, the shell normally executes the file as a shell script. Some implementations, however, attempt to detect whether the file is actually a script and not an executable from some other architecture. The method used by the KornShell is allowed by the text that indicates non-text files may be bypassed.

The sequence selected for the Shell and Utilities volume of IEEE Std 1003.1-2001 acknowledges that special built-ins cannot be overridden, but gives the programmer full control over which versions of other utilities are executed. It provides a means of suppressing function lookup (via the `command` utility) for the user's own functions and ensures that any regular built-ins or functions provided by the implementation are under the control of the path search. The mechanisms for associating built-ins or functions with executable files in the path are not specified by the Shell and Utilities volume of IEEE Std 1003.1-2001, but the wording requires that if either is implemented, the application is not able to distinguish a function or built-in from an executable (other than in terms of performance, presumably). The implementation ensures that all effects specified by the Shell and Utilities volume of IEEE Std 1003.1-2001 resulting from the invocation of the regular built-in or function (interaction with the environment, variables, traps, and so on) are identical to those resulting from the invocation of an executable file.
Examples

Consider three versions of the `ls` utility:

1. The application includes a shell function named `ls`.
2. The user writes a utility named `ls` and puts it in `/fred/bin`.
3. The example implementation provides `ls` as a regular shell built-in that is invoked (either by the shell or directly by `exec`) when the path search reaches the directory `/posix/bin`.

If `PATH=/posix/bin`, various invocations yield different versions of `ls`:

<table>
<thead>
<tr>
<th>Invocation</th>
<th>Version of <code>ls</code></th>
</tr>
</thead>
<tbody>
<tr>
<td><code>ls</code> (from within application script)</td>
<td>(1) function</td>
</tr>
<tr>
<td><code>command ls</code> (from within application script)</td>
<td>(3) built-in</td>
</tr>
<tr>
<td><code>ls</code> (from within makefile called by application)</td>
<td>(3) built-in</td>
</tr>
<tr>
<td><code>system(&quot;ls&quot;)</code></td>
<td>(3) built-in</td>
</tr>
<tr>
<td><code>PATH=&quot;/fred/bin:$PATH&quot; ls</code></td>
<td>(2) user’s version</td>
</tr>
</tbody>
</table>

C.2.9.2 Pipelines

Because pipeline assignment of standard input or standard output or both takes place before redirection, it can be modified by redirection. For example:

```
$ command1 2>&1 | command2
```

sends both the standard output and standard error of `command1` to the standard input of `command2`.

The reserved word `!` allows more flexible testing using AND and OR lists.

It was suggested that it would be better to return a non-zero value if any command in the pipeline terminates with non-zero status (perhaps the bitwise-inclusive OR of all return values). However, the choice of the last-specified command semantics are historical practice and would cause applications to break if changed. An example of historical behavior:

```
$ sleep 5 | (exit 4)
$ echo $?
4
$ (exit 4) | sleep 5
$ echo $?
0
```

C.2.9.3 Lists

The equal precedence of `&&` and `||` is historical practice. The standard developers evaluated the model used more frequently in high-level programming languages, such as C, to allow the shell logical operators to be used for complex expressions in an unambiguous way, but they could not allow historical scripts to break in the subtle way unequal precedence might cause. Some arguments were posed concerning the `{ }` or `()` groupings that are required historically. There are some disadvantages to these groupings:

- The `()` can be expensive, as they spawn other processes on some implementations. This performance concern is primarily an implementation issue.
- The `{ }` braces are not operators (they are reserved words) and require a trailing space after each `,` and a semicolon before each `}`. Most programmers (and certainly...
interactive users) have avoided braces as grouping constructs because of the problematic syntax required. Braces were not changed to operators because that would generate compatibility issues even greater than the precedence question; braces appear outside the context of a keyword in many shell scripts.

IEEE PASC Interpretation 1003.2 #204 is applied, clarifying that the operators "&&" and "||" are evaluated with left associativity.

Asynchronous Lists
The grammar treats a construct such as:

    foo & bar & bam &

as one “asynchronous list”, but since the status of each element is tracked by the shell, the term “element of an asynchronous list” was introduced to identify just one of the foo, bar, or bam portions of the overall list.

Unless the implementation has an internal limit, such as [CHILD_MAX], on the retained process IDs, it would require unbounded memory for the following example:

    while true
        do    foo & echo $!
    done

The treatment of the signals SIGINT and SIGQUIT with asynchronous lists is described in the Shell and Utilities volume of IEEE Std 1003.1-2001, Section 2.11, Signals and Error Handling.

Since the connection of the input to the equivalent of /dev/null is considered to occur before redirections, the following script would produce no output:

    exec < /etc/passwd
cat <&0 &
wait

Sequential Lists
There is no additional rationale provided for this section.

AND Lists
There is no additional rationale provided for this section.

OR Lists
There is no additional rationale provided for this section.
C.2.9.4 Compound Commands

Grouping Commands

The semicolon shown in \( \{ \text{compound-list}; \} \) is an example of a control operator delimiting the \} reserved word. Other delimiters are possible, as shown in the Shell and Utilities volume of IEEE Std 1003.1-2001, Section 2.10, Shell Grammar; <newline> is frequently used.

A proposal was made to use the \texttt{<do-done>} construct in all cases where command grouping in the current process environment is performed, identifying it as a construct for the grouping commands, as well as for shell functions. This was not included because the shell already has a grouping construct for this purpose ("\{ \}"), and changing it would have been counter-productive.

For Loop

The format is shown with generous usage of <newline>s. See the grammar in the Shell and Utilities volume of IEEE Std 1003.1-2001, Section 2.10, Shell Grammar for a precise description of where <newline>s and semicolons can be interchanged.

Some historical implementations support ‘\{ ‘ and ‘\} ‘ as substitutes for \texttt{do} and \texttt{done}. The standard developers chose to omit them, even as an obsolescent feature. (Note that these substitutes were only for the \texttt{for} command; the \texttt{while} and \texttt{until} commands could not use them historically because they are followed by compound-lists that may contain "\{ . . . \}" grouping commands themselves.)

The reserved word pair \texttt{do ... done} was selected rather than \texttt{do ... od} (which would have matched the spirit of \texttt{if ... fi} and \texttt{case ... esac} because \texttt{od} is already the name of a standard utility.

PASC Interpretation 1003.2 #169 has been applied changing the grammar.

Case Conditional Construct

An optional left parenthesis before \texttt{pattern} was added to allow numerous historical KornShell scripts to conform. At one time, using the leading parenthesis was required if the \texttt{case} statement was to be embedded within a "$()" command substitution; this is no longer the case with the POSIX shell. Nevertheless, many historical scripts use the left parenthesis, if only because it makes matching-parenthesis searching easier in \texttt{vi} and other editors. This is a relatively simple implementation change that is upwards-compatible for all scripts.

Consideration was given to requiring \texttt{break} inside the \texttt{compound-list} to prevent falling through to the next pattern action list. This was rejected as being nonexisting practice. An interesting undocumented feature of the KornShell is that using ";\&" instead of ";;\" as a terminator causes the exact opposite behavior—the flow of control continues with the next \texttt{compound-list}.

The pattern ‘\*\’, given as the last pattern in a \texttt{case} construct, is equivalent to the default case in a C-language \texttt{switch} statement.

The grammar shows that reserved words can be used as patterns, even if one is the first word on a line. Obviously, the reserved word \texttt{esac} cannot be used in this manner.
If Conditional Construct

The precise format for the command syntax is described in the Shell and Utilities volume of IEEE Std 1003.1-2001, Section 2.10, Shell Grammar.

While Loop

The precise format for the command syntax is described in the Shell and Utilities volume of IEEE Std 1003.1-2001, Section 2.10, Shell Grammar.

Until Loop

The precise format for the command syntax is described in the Shell and Utilities volume of IEEE Std 1003.1-2001, Section 2.10, Shell Grammar.

C.2.9.5 Function Definition Command

The description of functions in an early proposal was based on the notion that functions should behave like miniature shell scripts; that is, except for sharing variables, most elements of an execution environment should behave as if they were a new execution environment, and changes to these should be local to the function. For example, traps and options should be reset on entry to the function, and any changes to them do not affect the traps or options of the caller. There were numerous objections to this basic idea, and the opponents asserted that functions were intended to be a convenient mechanism for grouping common commands that were to be executed in the current execution environment, similar to the execution of the dot special built-in.

It was also pointed out that the functions described in that early proposal did not provide a local scope for everything a new shell script would, such as the current working directory, or umask, but instead provided a local scope for only a few select properties. The basic argument was that if a local scope is needed for the execution environment, the mechanism already existed: the application can put the commands in a new shell script and call that script. All historical shells that implemented functions, other than the KornShell, have implemented functions that operate in the current execution environment. Because of this, traps and options have a global scope within a shell script. Local variables within a function were considered and included in another early proposal (controlled by the special built-in local), but were removed because they do not fit the simple model developed for functions and because there was some opposition to adding yet another new special built-in that was not part of historical practice. Implementations should reserve the identifier local (as well as typeset, as used in the KornShell) in case this local variable mechanism is adopted in a future version of IEEE Std 1003.1-2001.

A separate issue from the execution environment of a function is the availability of that function to child shells. A few objectors maintained that just as a variable can be shared with child shells by exporting it, so should a function. In early proposals, the export command therefore had a −f flag for exporting functions. Functions that were exported were to be put into the environment as name=value pairs, and upon invocation, the shell would scan the environment for these and automatically define these functions. This facility was strongly opposed and was omitted. Some of the arguments against exportable functions were as follows:

- There was little historical practice. The Ninth Edition shell provided them, but there was controversy over how well it worked.
- There are numerous security problems associated with functions appearing in the environment of a user and overriding standard utilities or the utilities owned by the application.
There was controversy over requiring `make` to import functions, where it has historically used an `exec` function for many of its command line executions.

Functions can be big and the environment is of a limited size. (The counter-argument was that functions are no different from variables in terms of size: there can be big ones, and there can be small ones—and just as one does not export huge variables, one does not export huge functions. However, this might not apply to the average shell-function writer, who typically writes much larger functions than variables.)

As far as can be determined, the functions in the Shell and Utilities volume of IEEE Std 1003.1-2001 match those in System V. Earlier versions of the KornShell had two methods of defining functions:

```bash
function fname { compound-list }
```

and:

```bash
fname() { compound-list }
```

The latter used the same definition as the Shell and Utilities volume of IEEE Std 1003.1-2001, but differed in semantics, as described previously. The current edition of the KornShell aligns the latter syntax with the Shell and Utilities volume of IEEE Std 1003.1-2001 and keeps the former as is.

The name space for functions is limited to that of a `name` because of historical practice. Complications in defining the syntactic rules for the function definition command and in dealing with known extensions such as the `@()` usage in the KornShell prevented the name space from being widened to a `word`. Using functions to support synonyms such as the `!!` and `%` usage in the C shell is thus disallowed to conforming applications, but acceptable as an extension. For interactive users, the aliasing facilities in the Shell and Utilities volume of IEEE Std 1003.1-2001 should be adequate for this purpose. It is recognized that the name space for utilities in the file system is wider than that currently supported for functions, if the portable filename character set guidelines are ignored, but it did not seem useful to mandate extensions in systems for so little benefit to conforming applications.

The `@()` in the function definition command consists of two operators. Therefore, intermixing `<blank>`s with the `fname`, `'(', and ')'` is allowed, but unnecessary.

An example of how a function definition can be used wherever a simple command is allowed:

```bash
# If variable i is equal to "yes",
# define function foo to be ls -l
#
[ "$i" = yes ] && foo() {
  ls -l
}
```

### C.2.10 Shell Grammar

There are several subtle aspects of this grammar where conventional usage implies rules about the grammar that in fact are not true.

For `compound_list`, only the forms that end in a `separator` allow a reserved word to be recognized, so usually only a `separator` can be used where a compound list precedes a reserved word (such as `Then`, `Else`, `Do`, and `Rbrace`). Explicitly requiring a separator would disallow such valid (if rare) statements as:

```bash
if (false) then (echo x) else (echo y) fi
```
See the Note under special grammar rule (1).

Concerning the third sentence of rule (1) ("Also, if the parser ..."):

- This sentence applies rather narrowly: when a compound list is terminated by some clear
delimiter (such as the closing fi of an inner if_clause) then it would apply; where the
compound list might continue (as in after a ‘;’), rule (7a) (and consequently the first
sentence of rule (1)) would apply. In many instances the two conditions are identical, but this
part of rule (1) does not give license to treating a WORD as a reserved word unless it is in a
place where a reserved word has to appear.

- The statement is equivalent to requiring that when the LR(1) lookahead set contains exactly
one reserved word, it must be recognized if it is present. (Here "LR(1)" refers to the
theoretical concepts, not to any real parser generator.)

For example, in the construct below, and when the parser is at the point marked with ‘ˆ’,
the only next legal token is then (this follows directly from the grammar rules):

```
if if...fi then ... fi
```

At that point, the then must be recognized as a reserved word.

(Depending on the parser generator actually used, “extra” reserved words may be in some
lookahead sets. It does not really matter if they are recognized, or even if any possible
reserved word is recognized in that state, because if it is recognized and is not in the
(theoretical) LR(1) lookahead set, an error is ultimately detected. In the example above, if
some other reserved word (for example, while) is also recognized, an error occurs later.

This is approximately equivalent to saying that reserved words are recognized after other
reserved words (because it is after a reserved word that this condition occurs), but avoids the
“except for ...” list that would be required for case, for, and so on. (Reserved words are of
course recognized anywhere a simple_command can appear, as well. Other rules take care of
the special cases of non-recognition, such as rule (4) for case statements.)

Note that the body of here-documents are handled by token recognition (see the Shell and
Utilities volume of IEEE Std 1003.1-2001, Section 2.3, Token Recognition) and do not appear in
the grammar directly. (However, the here-document I/O redirection operator is handled as part
of the grammar.)

The start symbol of the grammar (complete_command) represents either input from the
command line or a shell script. It is repeatedly applied by the interpreter to its input and
represents a single “chunk” of that input as seen by the interpreter.

C.2.10.1 Shell Grammar Lexical Conventions

There is no additional rationale provided for this section.

C.2.10.2 Shell Grammar Rules

There is no additional rationale provided for this section.
C.2.11 Signals and Error Handling

There is no additional rationale provided for this section.

C.2.12 Shell Execution Environment

Some implementations have implemented the last stage of a pipeline in the current environment so that commands such as:

```
command | read foo
```

set variable `foo` in the current environment. This extension is allowed, but not required; therefore, a shell programmer should consider a pipeline to be in a subshell environment, but not depend on it.

In early proposals, the description of execution environment failed to mention that each command in a multiple command pipeline could be in a subshell execution environment. For compatibility with some historical shells, the wording was phrased to allow an implementation to place any or all commands of a pipeline in the current environment. However, this means that a POSIX application must assume each command is in a subshell environment, but not depend on it.

The wording about shell scripts is meant to convey the fact that describing "trap actions" can only be understood in the context of the shell command language. Outside of this context, such as in a C-language program, signals are the operative condition, not traps.

C.2.13 Pattern Matching Notation

Pattern matching is a simpler concept and has a simpler syntax than REs, as the former is generally used for the manipulation of filenames, which are relatively simple collections of characters, while the latter is generally used to manipulate arbitrary text strings of potentially greater complexity. However, some of the basic concepts are the same, so this section points liberally to the detailed descriptions in the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 9, Regular Expressions.

C.2.13.1 Patterns Matching a Single Character

Both quoting and escaping are described here because pattern matching must work in three separate circumstances:

1. Calling directly upon the shell, such as in pathname expansion or in a `case` statement. All of the following match the string or file `abc`:

```
  abc "abc" a"b"c a\bc a\[b\]c a[\"b\"]c a\[\"b\"]c a?c a*c
```

   The following do not:

```
  "a?c" a\*c a\[\[b\]\c
```

2. Calling a utility or function without going through a shell, as described for `find` and the `fnmatch()` function defined in the System Interfaces volume of IEEE Std 1003.1-2001.

3. Calling utilities such as `find`, `cpio`, `tar`, or `pax` through the shell command line. In this case, shell quote removal is performed before the utility sees the argument. For example, in:

```
find /bin -name "e\c[\h]o" -print
```

after quote removal, the backslashes are presented to `find` and it treats them as escape characters. Both precede ordinary characters, so the `c` and `h` represent themselves and `echo` would be found on many historical systems (that have it in `/bin`). To find a filename that
contained shell special characters or pattern characters, both quoting and escaping are required, such as:

```
pax \-r \*a\(\?\)
```

to extract a filename ending with "a (?".

Conforming applications are required to quote or escape the shell special characters (sometimes called metacharacters). If used without this protection, syntax errors can result or implementation extensions can be triggered. For example, the KornShell supports a series of extensions based on parentheses in patterns.

The restriction on a circumflex in a bracket expression is to allow implementations that support pattern matching using the circumflex as the negation character in addition to the exclamation mark. A conforming application must use something like "] \^ !]" to match either character.

C.2.13.2 Patterns Matching Multiple Characters

Since each asterisk matches zero or more occurrences, the patterns "a*b" and "a**b" have identical functionality.

**Examples**

- `a [bc]`         Matches the strings "ab" and "ac".
- `a*d`            Matches the strings "ad", "abd", and "abcd", but not the string "abc".
- `a*d*`           Matches the strings "ad", "abcd", "abcdef", "aaaaad", and "adddd".
- `*a*d`           Matches the strings "ad", "abcd", "efabcd", "aaaaad", and "adddd".

C.2.13.3 Patterns Used for Filename Expansion

The caveat about a slash within a bracket expression is derived from historical practice. The pattern "a [b/c] d" does not match such pathnames as abd or a/d. On some implementations (including those conforming to the Single UNIX Specification), it matched a pathname of literally "a [b/c] d". On other systems, it produced an undefined condition (an unescaped ‘ ’ used outside a bracket expression). In this version, the XSI behavior is now required.

Filenames beginning with a period historically have been specially protected from view on UNIX systems. A proposal to allow an explicit period in a bracket expression to match a leading period was considered; it is allowed as an implementation extension, but a conforming application cannot make use of it. If this extension becomes popular in the future, it will be considered for a future version of the Shell and Utilities volume of IEEE Std 1003.1-2001.

Historical systems have varied in their permissions requirements. To match f*/bar has required read permissions on the f* directories in the System V shell, but the Shell and Utilities volume of IEEE Std 1003.1-2001, the C shell, and KornShell require only search permissions.
C.2.14 Special Built-In Utilities

See the RATIONALE sections on the individual reference pages.

C.3 Batch Environment Services and Utilities

Scope of the Batch Environment Services and Utilities Option

This section summarizes the deliberations of the IEEE P1003.15 (Batch Environment) working group in the development of the Batch Environment Services and Utilities option, which covers a set of services and utilities defining a batch processing system.

This informative section contains historical information concerning the contents of the amendment and describes why features were included or discarded by the working group.

History of Batch Systems

The supercomputing technical committee began as a “Birds Of a Feather” (BOF) at the January 1987 Usenix meeting. There was enough general interest to form a supercomputing attachment to the /usr/group working groups. Several subgroups rapidly formed. Of those subgroups, the batch group was the most ambitious. The first early meetings were spent evaluating user needs and existing batch implementations.

To evaluate user needs, individuals from the supercomputing community came and presented their needs. Common requests were flexibility, interoperability, control of resources, and ease-of-use. Backward-compatibility was not an issue. The working group then evaluated some existing systems. The following different systems were evaluated:

- PROD
- Convex Distributed Batch
- NQS
- CTSS
- MDQS from Ballistics Research Laboratory (BRL)

Finally, NQS was chosen as a model because it satisfied not only the most user requirements, but because it was public domain, already implemented on a variety of hardware platforms, and network-based.

Historical Implementations of Batch Systems

Deferred processing of work under the control of a scheduler has been a feature of most proprietary operating systems from the earliest days of multi-user systems in order to maximize utilization of the computer.

The arrival of UNIX systems proved to be a dilemma to many hardware providers and users because it did not include the sophisticated batch facilities offered by the proprietary systems. This omission was rectified in 1986 by NASA Ames Research Center who developed the Network Queuing System (NQS) as a portable UNIX application that allowed the routing and processing of batch “jobs” in a network. To encourage its usage, the product was later put into the public domain. It was promptly picked up by UNIX hardware providers, and ported and developed for their respective hardware and UNIX implementations.
Many major vendors, who traditionally offer a batch-dominated environment, ported the public-domain product to their systems, customized it to support the capabilities of their systems, and added many customer-requested features.

Due to the strong hardware provider and customer acceptance of NQS, it was decided to use NQS as the basis for the POSIX Batch Environment amendment in 1987. Other batch systems considered at the time included CTSS, MDQS (a forerunner of NQS from the Ballistics Research Laboratory), and PROD (a Los Alamos Labs development). None were thought to have both the functionality and acceptability of NQS.

**NQS Differences from the at utility**

The base standard at and batch utilities are not sufficient to meet the batch processing needs in a supercomputing environment and additional functionality in the areas of resource management, job scheduling, system management, and control of output is required.

**Batch Environment Services and Utilities Option Definitions**

The concept of a batch job is closely related to a session with a session leader. The main difference is that a batch job does not have a controlling terminal. There has been much debate over whether to use the term “request” or “job”. Job was the final choice because of the historical use of this term in the batch environment.

The current definition for job identifiers is not sufficient with the model of destinations. The current definition is:

```
sequence_number.originating_host
```

Using the model of destination, a host may include multiple batch nodes, the location of which is identified uniquely by a name or directory service. If the current definition is used, batch nodes running on the same host would have to coordinate their use of sequence numbers, as sequence numbers are assigned by the originating host. The alternative is to use the originating batch node name instead of the originating host name.

The reasons for wishing to run more than one batch system per host could be the following.

A test and production batch system are maintained on a single host. This is most likely in a development facility, but could also arise when a site is moving from one version to another. The new batch system could be installed as a test version that is completely separate from the production batch system, so that problems can be isolated to the test system. Requiring the batch nodes to coordinate their use of sequence numbers creates a dependency between the two nodes, and that defeats the purpose of running two nodes.

A site has multiple departments using a single host, with different management policies. An example of contention might be in job selection algorithms. One group might want a FIFO type of selection, while another group wishes to use a more complex algorithm based on resource availability. Again, requiring the batch nodes to coordinate is an unnecessary binding.

The proposal eventually accepted was to replace originating host with originating batch node. This supplies sufficient granularity to ensure unique job identifiers. If more than one batch node is on a particular host, they each have their own unique name.

The queue portion of a destination is not part of the job identifier as these are not required to be unique between batch nodes. For instance, two batch nodes may both have queues called small, medium, and large. It is only the batch node name that is uniquely identifiable throughout the batch system. The queue name has no additional function in this context.
Assume there are three batch nodes, each of which has its own name server. On batch node one, there are no queues. On batch node two, there are fifty queues. On batch node three, there are forty queues. The system administrator for batch node one does not have to configure queues, because there are none implemented. However, if a user wishes to send a job to either batch node two or three, the system administrator for batch node one must configure a destination that maps to the appropriate batch node and queue. If every queue is to be made accessible from batch node one, the system administrator has to configure ninety destinations.

To avoid requiring this, there should be a mechanism to allow a user to separate the destination into a batch node name and a queue name. Then, an implementation that is configured to get to all the batch nodes does not need any more configuration to allow a user to get to all of the queues on all of the batch nodes. The node name is used to locate the batch node, while the queue name is sent unchanged to that batch node.

The following are requirements that a destination identifier must be capable of providing:

- The ability to direct a job to a queue in a particular batch node.
- The ability to direct a job to a particular batch node.
- The ability to group at a higher level than just one queue. This includes grouping similar queues across multiple batch nodes (this is a pipe queue).
- The ability to group batch nodes. This allows a user to submit a job to a group name with no knowledge of the batch node configuration. This also provides aliasing as a special case. Aliasing is a group containing only one batch node name. The group name is the alias.

In addition, the administrator has the following requirements:

- The ability to control access to the queues.
- The ability to control access to the batch nodes.
- The ability to control access to groups of queues (pipe queues).
- The ability to configure retry time intervals and durations.

The requirements of the user are met by destination as explained in the following.

The user has the ability to specify a queue name, which is known only to the batch node specified. There is no configuration of these queues required on the submitting node.

The user has the ability to specify a batch node whose name is network-unique. The configuration required is that the batch node be defined as an application, just as other applications such as FTP are configured.

Once a job reaches a queue, it can again become a user of the batch system. The batch node can choose to send the job to another batch node or queue or both. In other words, the routing is at an application level, and it is up to the batch system to choose where the job will be sent. Configuration is up to the batch node where the queue resides. This provides grouping of queues across batch nodes or within a batch node. The user submits the job to a queue, which by definition routes the job to other queues or nodes or both.

A node name may be given to a naming service, which returns multiple addresses as opposed to just one. This provides grouping at a batch node level. This is a local issue, meaning that the batch node must choose only one of these addresses. The list of addresses is not sent with the job, and once the job is accepted on another node, there is no connection between the list and the job. The requirements of the administrator are met by destination as explained in the following.

The control of queues is a batch system issue, and will be done using the batch administrative utilities.
The control of nodes is a network issue, and will be done through whatever network facilities are available.

The control of access to groups of queues (pipe queues) is covered by the control of any other queue. The fact that the job may then be sent to another destination is not relevant.

The propagation of a job across more than one point-to-point connection was dropped because of its complexity and because all of the issues arising from this capability could not be resolved. It could be provided as additional functionality at some time in the future.

The addition of network as a defined term was done to clarify the difference between a network of batch nodes as opposed to a network of hosts. A network of batch nodes is referred to as a batch system. The network refers to the actual host configuration. A single host may have multiple batch nodes.

In the absence of a standard network naming convention, this option establishes its own convention for the sake of consistency and expediency. This is subject to change, should a future working group develop a standard naming convention for network pathnames.

### C.3.1 Batch General Concepts

During the development of the Batch Environment Services and Utilities option, a number of topics were discussed at length which influenced the wording of the normative text but could not be included in the final text. The following items are some of the most significant terms and concepts of those discussed:

- **Small and Consistent Command Set**

  Often, conventional utilities from UNIX systems have a very complicated utility syntax and usage. This can often result in confusion and errors when trying to use them. The Batch Environment Services and Utilities option utility set, on the other hand, has been paired to a small set of robust utilities with an orthogonal calling sequence.

- **Checkpoint/Restart**

  This feature permits an already executing process to checkpoint or save its contents. Some implementations permit this at both the batch utility level (for example, checkpointing this job upon its abnormal termination) or from within the job itself via a system call. Support of checkpoint/restart is optional. A conscious, careful effort was made to make the qsub utility consistently refer to checkpoint/restart as optional functionality.

- **Rerunability**

  When a user submits a job for batch processing, they can designate it “rerunnable” in that it will automatically resume execution from the start of the job if the machine on which it was executing crashes for some reason. The decision on whether the job will be rerun or not is entirely up to the submitter of the job and no decisions will be made within the batch system. A job that is rerunnable and has been submitted with the proper checkpoint/restart switch will first be checkpointed and execution begun from that point. Furthermore, use of the implementation-defined checkpoint/restart feature will not be defined in this context.

- **Error Codes**

  All utilities exit with error status zero (0) if successful, one (1) if a user error occurred, and two (2) for an internal Batch Environment Services and Utilities option error.

- **Level of Portability**

  Portability is specified at both the user, operator, and administrator levels. A conforming batch implementation prevents identical functionality and behavior at all these levels.
Additionally, portable batch shell scripts with embedded Batch Environment Services and Utilities option utilities add an additional level of portability.

- Resource Specification

A small set of globally understood resources, such as memory and CPU time, is specified. All conforming batch implementations are able to process them in a manner consistent with the yet-to-be-developed resource management model. Resources not in this amendment set are ignored and passed along as part of the argument stream of the utility.

- Queue Position

Queue position is the place a job occupies in a queue. It is dependent on a variety of factors such as submission time and priority. Since priority may be affected by the implementation of fair share scheduling, the definition of queue position is implementation-defined.

- Queue ID

A numerical queue ID is an external requirement for purposes of accounting. The identification number was chosen over queue name for processing convenience.

- Job ID

A common notion of “jobs” is a collection of processes whose process group cannot be altered and is used for resource management and accounting. This concept is implementation-defined and, as such, has been omitted from the batch amendment.

- Bytes versus Words

Except for one case, bytes are used as the standard unit for memory size. Furthermore, the definition of a word varies from machine to machine. Therefore, bytes will be the default unit of memory size.

- Regular Expressions

The standard definition of regular expressions is much too broad to be used in the batch utility syntax. All that is needed is a simple concept of “all”; for example, delete all my jobs from the named queue. For this reason, regular expressions have been eliminated from the batch amendment.

- Display Privacy

How much data should be displayed locally through functions? Local policy dictates the amount of privacy. Library functions must be used to create and enforce local policy. Network and local qstats must reflect the policy of the server machine.

- Remote Host Naming Convention

It was decided that host names would be a maximum of 255 characters in length, with at most 15 characters being shown in displays. The 255 character limit was chosen because it is consistent with BSD. The 15-character limit was an arbitrary decision.

- Network Administration

Network administration is important, but is outside the scope of the batch amendment. Network administration could be done with rsh. However, authentication becomes two-sided.

- Network Administration Philosophy

Keep it simple. Centralized management should be possible. For example, Los Alamos needs a dumb set of CPUs to be managed by a central system versus several independently-
Batch Environment Services and Utilities

Rationale for Shell and Utilities

managed systems as is the general case for the Batch Environment Services and Utilities option.

• Operator Utility Defaults (that is, Default Host, User, Account, and so on)

   It was decided that usability would override orthogonality and syntactic consistency.

• The Batch System Manager and Operator Distinction

   The distinction between manager and operator is that operators can only control the flow of jobs. A manager can alter the batch system configuration in addition to job flow. POSIX makes a distinction between user and system administrator but goes no further. The concepts of manager and operator privileges fall under local policy. The distinction between manager and operator is historical in batch environments, and the Batch Environment Services and Utilities option has continued that distinction.

• The Batch System Administrator

   An administrator is equivalent to a batch system manager.

C.3.2 Batch Services

This rationale is provided as informative rather than normative text, to avoid placing requirements on implementors regarding the use of symbolic constants, but at the same time to give implementors a preferred practice for assigning values to these constants to promote interoperability.

The Checkpoint and Minimum_Cpu_Interval attributes induce a variety of behavior depending upon their values. Some jobs cannot or should not be checkpointed. Other users will simply need to ensure job continuation across planned downtimes; for example, scheduled preventive maintenance. For users consuming expensive resources, or for jobs that run longer than the mean time between failures, however, periodic checkpointing may be essential. However, system administrators must be able to set minimum checkpoint intervals on a queue-by-queue basis to guard against, for example, naive users specifying interval values too small on memory-intensive jobs. Otherwise, system overhead would adversely affect performance.

The use of symbolic constants, such as NO_CHECKPOINT, was introduced to lend a degree of formalism and portability to this option.

Support for checkpointing is optional for servers. However, clients must provide for the −c option, since in a distributed environment the job may run on a server that does provide such support, even if the host of the client does not support the checkpoint feature.

If the user does not specify the −c option, the default action is left unspecified by this option. Some implementations may wish to do checkpointing by default; others may wish to checkpoint only under an explicit request from the user.

The Priority attribute has been made non-optional. All clients already had been required to support the −p option. The concept of prioritization is common in historical implementations. The default priority is left to the server to establish.

The Hold_Types attribute has been modified to allow for implementation-defined hold types to be passed to a batch server.

It was the intent of the IEEE P1003.15 working group to mandate the support for the Resource_List attribute in this option by referring to another amendment, specifically the IEEE P1003.1a draft standard. However, during the development of the IEEE P1003.1a draft standard this was excluded. As such this requirement has been removed from the normative text.
The Shell_Path attribute has been modified to accept a list of shell paths that are associated with a host. The name of the attribute has been changed to Shell_Path_List.

### C.3.3 Common Behavior for Batch Environment Utilities

This section was defined to meet the goal of a “Small and Consistent Command Set” for this option.

### C.4 Utilities

For the utilities included in IEEE Std 1003.1-2001, see the RATIONALE sections on the individual reference pages.

#### Exclusion of Utilities

The set of utilities contained in IEEE Std 1003.1-2001 is drawn from the base documents, with one addition: the c99 utility. This section contains rationale for some of the deliberations that led to this set of utilities, and why certain utilities were excluded.

Many utilities were evaluated by the standard developers; more historical utilities were excluded from the base documents than included. The following list contains many common UNIX system utilities that were not included as mandatory utilities, in the User Portability Utilities option, in the XSI extension, or in one of the software development groups. It is logistically difficult for this rationale to distribute correctly the reasons for not including a utility among the various utility options. Therefore, this section covers the reasons for all utilities not included in IEEE Std 1003.1-2001.

This rationale is limited to a discussion of only those utilities actively or indirectly evaluated by the standard developers of the base documents, rather than the list of all known UNIX utilities from all its variants.

- **adb**
  
  The intent of the various software development utilities was to assist in the installation (rather than the actual development and debugging) of applications. This utility is primarily a debugging tool. Furthermore, many useful aspects of adb are very hardware-specific.

- **as**
  
  Assemblers are hardware-specific and are included implicitly as part of the compilers in IEEE Std 1003.1-2001.

- **banner**
  
  The only known use of this command is as part of the lp printer header pages. It was decided that the format of the header is implementation-defined, so this utility is superfluous to application portability.

- **calendar**
  
  This reminder service program is not useful to conforming applications.

- **cancel**
  
  The lp (line printer spooling) system specified is the most basic possible and did not need this level of application control.

- **chroot**
  
  This is primarily of administrative use, requiring superuser privileges.

- **col**
  
  No utilities defined in IEEE Std 1003.1-2001 produce output requiring such a filter. The nroff text formatter is present on many historical systems and will continue to remain as an extension; col is expected to be shipped by all the systems that ship nroff.

- **cpio**
  
  This has been replaced by pax, for reasons explained in the rationale for that utility.
Utilities

This is subsumed by c99.

This utility is terminal-oriented and is not useful from shell scripts or typical application programs.

The functionality of this utility can be provided by the bc utility; bc was selected because it was easier to use and had superior functionality. Although the historical versions of bc are implemented using dc as a base, IEEE Std 1003.1-2001 prescribes the interface and not the underlying mechanism used to implement it.

Although a useful concept, the historical output of this directory comparison program is not suitable for processing in application programs. Also, the diff --r command gives equivalent functionality.

Disassemblers are hardware-specific.

The community of emacs editing enthusiasts was adamant that the full emacs editor not be included in the base documents because they were concerned that an attempt to standardize this very powerful environment would encourage vendors to ship versions conforming strictly to the standard, but lacking the extensibility required by the community. The author of the original emacs program also expressed his desire to omit the program. Furthermore, there were a number of historical UNIX systems that did not include emacs, or included it without supporting it, but there were very few that did not include and support vi.

This is subsumed by c99.

The functionality of line can be provided with read.

This technology is partially subsumed by c99. It is also hard to specify the degree of checking for possible error conditions in programs in any compiler, and specifying what lint would do in these cases is equally difficult.

It is fairly easy to specify what a compiler does. It requires specifying the language, what it does with that language, and stating that the interpretation of any incorrect program is unspecified. Unfortunately, any description of lint is required to specify what to do with erroneous programs. Since the number of possible errors and questionable programming practices is infinite, one cannot require lint to detect all errors of any given class.

Additionally, some vendors complained that since many compilers are distributed in a binary form without a lint facility (because the ISO C standard does not require one), implementing the standard as a stand-alone product will be much harder. Rather than being able to build upon a standard compiler component (simply by providing c99 as an interface), source to that compiler would most likely need to be modified to provide the lint functionality. This was considered a major burden on system providers for a very small gain to developers (users).

This utility is terminal-oriented and is not useful from shell scripts or typical application programs.

This utility is an aid in creating an implementation-defined detail of object libraries that the standard developers did not feel required standardization.

The lp system specified is the most basic possible and did not need this level of application control.

This utility was omitted in favor of mailx because there was a considerable functionality overlap between the two.
10844  
mknod  
This was omitted in favor of mkfifo, as mknod has too many implementation-defined functions.

10846  
news  
This utility is terminal-oriented and is not useful from shell scripts or typical application programs.

10848  
pack  
This compression program was considered inferior to compress.

10849  
passwd  
This utility was proposed in a historical draft of the base documents but met with too many objections to be included. There were various reasons:

10850  
• Changing a password should not be viewed as a command, but as part of the login sequence. Changing a password should only be done while a trusted path is in effect.

10854  
• Even though the text in early drafts was intended to allow a variety of implementations to conform, the security policy for one site may differ from another site running with identical hardware and software. One site might use password authentication while the other did not. Vendors could not supply a passwd utility that would conform to IEEE Std 1003.1-2001 for all sites using their system.

10860  
• This is really a subject for a system administration working group or a security working group.

10862  
pcat  
This compression program was considered inferior to zcat.

10863  
ping  
This duplicated many of the features of the more pager, which was preferred by the standard developers.

10865  
prof  
The intent of the various software development utilities was to assist in the installation (rather than the actual development and debugging) of applications.

10867  
RCS  
This utility is primarily a debugging tool.

10868  
RCS  
RCS was originally considered as part of a version control utilities portion of the scope. However, this aspect was abandoned by the standard developers. SCCS is now included as an optional part of the XSI extension.

10871  
red  
Restricted editor. This was not considered by the standard developers because it never provided the level of security restriction required.

10873  
rsh  
Restricted shell. This was not considered by the standard developers because it does not provide the level of security restriction that is implied by historical documentation.

10876  
sdb  
The intent of the various software development utilities was to assist in the installation (rather than the actual development and debugging) of applications.

10878  
This utility is primarily a debugging tool. Furthermore, some useful aspects of sdb are very hardware-specific.

10880  
sdiff  
The "side-by-side diff" utility from System V was omitted because it is used infrequently, and even less so by conforming applications. Despite being in System V, it is not in the SVID or XPG.

10883  
shar  
Any of the numerous "shell archivers" were excluded because they did not meet the requirement of existing practice.

10885  
shl  
This utility is terminal-oriented and is not useful from shell scripts or typical application programs. The job control aspects of the shell command language are generally more useful.
The intent of the various software development utilities was to assist in the installation (rather than the actual development and debugging) of applications. This utility is primarily a debugging tool.

This utility is not useful from shell scripts or typical application programs. The spell utility was considered, but was omitted because there is no known technology that can be used to make it recognize general language for user-specified input without providing a complete dictionary along with the input file.

This utility is not useful from shell scripts or typical application programs. (There was also sentiment to avoid security-related utilities.)

This utility was renamed cksum.

This has been replaced by pax, for reasons explained in the rationale for that utility.

This compression program was considered inferior to uncompress.

This utility is terminal-oriented and is not useful in shell scripts or typical applications. It is generally used only by system administrators.
Rationale (Informative)

Part D:

Portability Considerations

The Open Group
The Institute of Electrical and Electronics Engineers, Inc.
Appendix D

Portability Considerations (Informative)

This section contains information to satisfy various international requirements:

- Section D.1 describes perceived user requirements.
- Section D.2 (on page 270) indicates how the facilities of IEEE Std 1003.1-2001 satisfy those requirements.
- Section D.3 (on page 277) offers guidance to writers of profiles on how the configurable options, limits, and optional behavior of IEEE Std 1003.1-2001 should be cited in profiles.

D.1 User Requirements

This section describes the user requirements that were perceived by the developers of IEEE Std 1003.1-2001. The primary source for these requirements was an analysis of historical practice in widespread use, as typified by the base documents listed in Section A.1.1 (on page 3).

IEEE Std 1003.1-2001 addresses the needs of users requiring open systems solutions for source code portability of applications. It currently addresses users requiring open systems solutions for source-code portability of applications involving multi-programming and process management (creating processes, signaling, and so on); access to files and directories in a hierarchy of file systems (opening, reading, writing, deleting files, and so on); access to asynchronous communications ports and other special devices; access to information about other users of the system; facilities supporting applications requiring bounded (realtime) response.

The following users are identified for IEEE Std 1003.1-2001:

- Those employing applications written in high-level languages, such as C, Ada, or FORTRAN.
- Users who desire conforming applications that do not necessarily require the characteristics of high-level languages (for example, the speed of execution of compiled languages or the relative security of source code intellectual property inherent in the compilation process).
- Users who desire conforming applications that can be developed quickly and can be modified readily without the use of compilers and other system components that may be unavailable on small systems or those without special application development capabilities.
- Users who interact with a system to achieve general-purpose time-sharing capabilities common to most business or government offices or academic environments: editing, filing, inter-user communications, printing, and so on.
- Users who develop applications for POSIX-conformant systems.
- Users who develop applications for UNIX systems.

An acknowledged restriction on applicable users is that they are limited to the group of individuals who are familiar with the style of interaction characteristic of historically-derived systems based on one of the UNIX operating systems (as opposed to other historical systems with different models, such as MS/DOS, Macintosh, VMS, MVS, and so on). Typical users would include program developers, engineers, or general-purpose time-sharing users.

The requirements of users of IEEE Std 1003.1-2001 can be summarized as a single goal: application source portability. The requirements of the user are stated in terms of the requirements
of portability of applications. This in turn becomes a requirement for a standardized set of syntax and semantics for operations commonly found on many operating systems.

The following sections list the perceived requirements for application portability.

D.1.1 Configuration Interrogation
An application must be able to determine whether and how certain optional features are provided and to identify the system upon which it is running, so that it may appropriately adapt to its environment.
Applications must have sufficient information to adapt to varying behaviors of the system.

D.1.2 Process Management
An application must be able to manage itself, either as a single process or as multiple processes. Applications must be able to manage other processes when appropriate.
Applications must be able to identify, control, create, and delete processes, and there must be communication of information between processes and to and from the system.
Applications must be able to use multiple flows of control with a process (threads) and synchronize operations between these flows of control.

D.1.3 Access to Data
Applications must be able to operate on the data stored on the system, access it, and transmit it to other applications. Information must have protection from unauthorized or accidental access or modification.

D.1.4 Access to the Environment
Applications must be able to access the external environment to communicate their input and results.

D.1.5 Access to Determinism and Performance Enhancements
Applications must have sufficient control of resource allocation to ensure the timeliness of interactions with external objects.

D.1.6 Operating System-Dependent Profile
The capabilities of the operating system may make certain optional characteristics of the base language in effect no longer optional, and this should be specified.

D.1.7 I/O Interaction
The interaction between the C language I/O subsystem (stdio) and the I/O subsystem of IEEE Std 1003.1-2001 must be specified.
D.1.8 Internationalization Interaction

The effects of the environment of IEEE Std 1003.1-2001 on the internationalization facilities of the C language must be specified.

D.1.9 C-Language Extensions

Certain functions in the C language must be extended to support the additional capabilities provided by IEEE Std 1003.1-2001.

D.1.10 Command Language

Users should be able to define procedures that combine simple tools and/or applications into higher-level components that perform to the specific needs of the user. The user should be able to store, recall, use, and modify these procedures. These procedures should employ a powerful command language that is used for recurring tasks in conforming applications (scripts) in the same way that it is used interactively to accomplish one-time tasks. The language and the utilities that it uses must be consistent between systems to reduce errors and retraining.

D.1.11 Interactive Facilities

Use the system to accomplish individual tasks at an interactive terminal. The interface should be consistent, intuitive, and offer usability enhancements to increase the productivity of terminal users, reduce errors, and minimize retraining costs. Online documentation or usage assistance should be available.

D.1.12 Accomplish Multiple Tasks Simultaneously

Access applications and interactive facilities from a single terminal without requiring serial execution: switch between multiple interactive tasks; schedule one-time or periodic background work; display the status of all work in progress or scheduled; influence the priority scheduling of work, when authorized.

D.1.13 Complex Data Manipulation

Manipulate data in files in complex ways: sort, merge, compare, translate, edit, format, pattern match, select subsets (strings, columns, fields, rows, and so on). These facilities should be available to both conforming applications and interactive users.

D.1.14 File Hierarchy Manipulation

Create, delete, move/rename, copy, backup/archive, and display files and directories. These facilities should be available to both conforming applications and interactive users.

D.1.15 Locale Configuration

Customize applications and interactive sessions for the cultural and language conventions of the user. Employ a wide variety of standard character encodings. These facilities should be available to both conforming applications and interactive users.
D.1.16 Inter-User Communication

Send messages or transfer files to other users on the same system or other systems on a network. These facilities should be available to both conforming applications and interactive users.

D.1.17 System Environment

Display information about the status of the system (activities of users and their interactive and background work, file system utilization, system time, configuration, and presence of optional facilities) and the environment of the user (terminal characteristics, and so on). Inform the system operator/administrator of problems. Control access to user files and other resources.

D.1.18 Printing

Output files on a variety of output device classes, accessing devices on local or network-connected systems. Control (or influence) the formatting, priority scheduling, and output distribution of work. These facilities should be available to both conforming applications and interactive users.

D.1.19 Software Development

Develop (create and manage source files, compile/interpret, debug) portable open systems applications and package them for distribution to, and updating of, other systems.

D.2 Portability Capabilities

This section describes the significant portability capabilities of IEEE Std 1003.1-2001 and indicates how the user requirements listed in Section D.1 (on page 267) are addressed. The capabilities are listed in the same format as the preceding user requirements; they are summarized below:

- Configuration Interrogation
- Process Management
- Access to Data
- Access to the Environment
- Access to Determinism and Performance Enhancements
- Operating System-Dependent Profile
- I/O Interaction
- Internationalization Interaction
- C-Language Extensions
- Command Language
- Interactive Facilities
- Accomplish Multiple Tasks Simultaneously
- Complex Data Manipulation
- File Hierarchy Manipulation
Portability Considerations (Informative)  

Part D: Portability Considerations

11047 • Locale Configuration
11048 • Inter-User Communication
11049 • System Environment
11050 • Printing
11051 • Software Development

11052 D.2.1 Configuration Interrogation

11053 The *uname*() operation provides basic identification of the system. The *sysconf*(), *pathconf*(), and *fpathconf*() functions and the *getconf* utility provide means to interrogate the implementation to determine how to adapt to the environment in which it is running. These values can be either static (indicating that all instances of the implementation have the same value) or dynamic (indicating that different instances of the implementation have the different values, or that the value may vary for other reasons, such as reconfiguration).

11059 Unsatisfied Requirements

11060 None directly. However, as new areas are added, there will be a need for additional capability in this area.

11062 D.2.2 Process Management

11063 The *fork*(), *exec* family, *posix_spawn*(), and *posix_spawnp*() functions provide for the creation of new processes or the insertion of new applications into existing processes. The *_Exit*(), *_exit*(), *exit*(), and *abort*() functions allow for the termination of a process by itself. The *wait*() and *waitpid*() functions allow one process to deal with the termination of another.

11067 The *times*() function allows for basic measurement of times used by a process. Various functions, including *fstat*(), *getegid*(), *geteuid*(), *getgid*(), *getgrgid*(), *getgrnam*(), *getlogin*(), *getpid*(), *getppid*(), *getpwnam*(), *getpwuid*(), *getuid*(), *lstat*(), and *stat*(), provide for access to the identifiers of processes and the identifiers and names of owners of processes (and files).

11071 The various functions operating on environment variables provide for communication of information (primarily user-configurable defaults) from a parent to child processes.

11073 The operations on the current working directory control and interrogate the directory from which relative filename searches start. The *umask*() function controls the default protections applied to files created by the process.

11076 The *alarm*(), *pause*(), *sleep*(), *ualarm*(), and *usleep*() operations allow the process to suspend until a timer has expired or to be notified when a period of time has elapsed. The *time*() operation interrogates the current time and date.

11078 The signal mechanism provides for communication of events either from other processes or from the environment to the application, and the means for the application to control the effect of these events. The mechanism provides for external termination of a process and for a process to suspend until an event occurs. The mechanism also provides for a value to be associated with an event.

11084 Job control provides a means to group processes and control them as groups, and to control their access to the function between the user and the system (the “controlling terminal”). It also provides the means to suspend and resume processes.

11087 The Process Scheduling option provides control of the scheduling and priority of a process.
The Message Passing option provides a means for interprocess communication involving small amounts of data.

The Memory Management facilities provide control of memory resources and for the sharing of memory. This functionality is mandatory on XSI-conformant systems.

The Threads facilities provide multiple flows of control with a process (threads), synchronization between threads, association of data with threads, and controlled cancellation of threads.

The XSI interprocess communications functionality provide an alternate set of facilities to manipulate semaphores, message queues, and shared memory. These are provided on XSI-conformant systems to support conforming applications developed to run on UNIX systems.

### D.2.3 Access to Data

The `open()`, `close()`, `fclose()`, `fopen()`, and `pipe()` functions provide for access to files and data. Such files may be regular files, interprocess data channels (pipes), or devices. Additional types of objects in the file system are permitted and are being contemplated for standardization.

The `access()`, `chmod()`, `chown()`, `dup()`, `dup2()`, `fchown()`, `fchmod()`, `fstat()`, `ftruncate()`, `lstat()`, `realpath()`, `stat()`, and `utime()` functions allow for control and interrogation of file and file-related objects (including symbolic links), and their ownership, protections, and timestamps.

The `fgetc()`, `fputc()`, `fread()`, `fseek()`, `fsetpos()`, `fstat()`, `ftruncate()`, `getchar()`, `lseek()`, `putchar()`, `putc()`, `read()`, and `write()` functions provide for data transfer from the application to files (in all their forms).

The `closedir()`, `link()`, `mkdir()`, `opendir()`, `readdir()`, `rename()`, `rmdir()`, `rewinddir()`, and `unlink()` functions provide for a complete set of operations on directories. Directories can arbitrarily contain other directories, and a single file can be mentioned in more than one directory.

The file-locking mechanism provides for advisory locking (protection during transactions) of ranges of bytes (in effect, records) in a file.

The `confstr()`, `fpathconf()`, `pathconf()`, and `sysconf()` functions provide for enquiry as to the behavior of the system where variability is permitted.

The Synchronized Input and Output option provides for assured commitment of data to media.

The Asynchronous Input and Output option provides for initiation and control of asynchronous data transfers.

### D.2.4 Access to the Environment

The operations and types in the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 11, General Terminal Interface are provided for access to asynchronous serial devices. The primary intended use for these is the controlling terminal for the application (the interaction point between the user and the system). They are general enough to be used to control any asynchronous serial device. The functions are also general enough to be used with many other device types as a user interface when some emulation is provided.

Less detailed access is provided for other device types, but in many instances an application need not know whether an object in the file system is a device or a regular file to operate correctly.
D.2.5 **Bounded (Realtime) Response**

The Realtime Signals Extension provides queued signals and the prioritization of the handling of signals. The SCHED_FIFO, SCHED_SPORADIC, and SCHED_RR scheduling policies provide control over processor allocation. The Semaphores option provides high-performance synchronization. The Memory Management functions provide memory locking for control of memory allocation, file mapping for high-performance, and shared memory for high-performance interprocess communication. The Message Passing option provides for interprocess communication without being dependent on shared memory.

The Timers option provides a high resolution function called `nanosleep()` with a finer resolution than the `sleep()` function.

The Typed Memory Objects option, the Monotonic Clock option, and the Timeouts option provide further facilities for applications to use to obtain predictable bounded response.

D.2.6 **Operating System-Dependent Profile**

IEEE Std 1003.1-2001 makes no distinction between text and binary files. The values of `EXIT_SUCCESS` and `EXIT_FAILURE` are further defined.

Unsatisfied Requirements

None known, but the ISO C standard may contain some additional options that could be specified.

D.2.7 **I/O Interaction**

IEEE Std 1003.1-2001 defines how each of the ISO C standard `stdio` functions interact with the POSIX.1 operations, typically specifying the behavior in terms of POSIX.1 operations.

Unsatisfied Requirements

None.

D.2.8 **Internationalization Interaction**

The IEEE Std 1003.1-2001 environment operations provide a means to define the environment for `setlocale()` and time functions such as `ctime()`. The `tzset()` function is provided to set time conversion information.

The `nl_langinfo()` function is provided as an XSI extension to query locale-specific cultural settings.

Unsatisfied Requirements

None.
D.2.9 C-Language Extensions

The setjmp() and longjmp() functions are not defined to be cognizant of the signal masks defined for POSIX.1. The sigsetjmp() and siglongjmp() functions are provided to fill this gap.

The _setjmp() and _longjmp() functions are provided as XSI extensions to support historic practice.

Unsatisfied Requirements

None.

D.2.10 Command Language

The shell command language, as described in the Shell and Utilities volume of IEEE Std 1003.1-2001, Chapter 2, Shell Command Language, is a common language useful in batch scripts, through an API to high-level languages (for the C-Language Binding option, system() and popen()) and through an interactive terminal (see the sh utility). The shell language has many of the characteristics of a high-level language, but it has been designed to be more suitable for user terminal entry and includes interactive debugging facilities. Through the use of pipelining, many complex commands can be constructed from combinations of data filters and other common components. Shell scripts can be created, stored, recalled, and modified by the user with simple editors.

In addition to the basic shell language, the following utilities offer features that simplify and enhance programmatic access to the utilities and provide features normally found only in high-level languages: basename, bc, command, dirname, echo, env, expr, false, printf, read, sleep, tee, test, time*, true, wait, xargs, and all of the special built-in utilities in the Shell and Utilities volume of IEEE Std 1003.1-2001, Section 2.14, Special Built-In Utilities.

Unsatisfied Requirements

None.

D.2.11 Interactive Facilities

The utilities offer a common style of command-line interface through conformance to the Utility Syntax Guidelines (see the Base Definitions volume of IEEE Std 1003.1-2001, Section 12.2, Utility Syntax Guidelines) and the common utility defaults (see the Shell and Utilities volume of IEEE Std 1003.1-2001, Section 1.11, Utility Description Defaults). The sh utility offers an interactive command-line history and editing facility. The following utilities in the User Portability Utilities option have been customized for interactive use: alias, ex, fc, mailx, more, talk, vi, unalias, and write; the man utility offers online access to system documentation.
Unsatisfied Requirements

The command line interface to individual utilities is as intuitive and consistent as historical practice allows. Work underway based on graphical user interfaces may be more suitable for novice or occasional users of the system.

D.2.12 Accomplish Multiple Tasks Simultaneously

The shell command language offers background processing through the asynchronous list command form; see the Shell and Utilities volume of IEEE Std 1003.1-2001, Section 2.9, Shell Commands. The nohup utility makes background processing more robust and usable. The kill utility can terminate background jobs. When the User Portability Utilities option is supported, the following utilities allow manipulation of jobs: bg, fg, and jobs. Also, if the User Portability Utilities option is supported, the following can support periodic job scheduling, control, and display: at, batch, crontab, nice, ps, and renice.

Unsatisfied Requirements

Terminals with multiple windows may be more suitable for some multi-tasking interactive uses than the job control approach in IEEE Std 1003.1-2001. See the comments on graphical user interfaces in Section D.2.11 (on page 274). The nice and renice utilities do not necessarily take advantage of complex system scheduling algorithms that are supported by the realtime options within IEEE Std 1003.1-2001.

D.2.13 Complex Data Manipulation

The following utilities address user requirements in this area: asa, awk, bc, cmp, comm, csplit*, cut, dd, diff, ed, ex*, expand*, expr, find, fold, grep, head, join, od, paste, pr, printf, sed, sort, split*, tabs*, tail, tr, unexpand*, uniq, uudecode*, uuencode*, and wc.

Unsatisfied Requirements

Sophisticated text formatting utilities, such as troff or TeX, are not included. Standards work in the area of SGML may satisfy this.

D.2.14 File Hierarchy Manipulation

The following utilities address user requirements in this area: basename, cd, chgrp, chmod, chown, cksum, cp, dd, df*, diff, dirname, du*, find, ls, ln, mkdir, mkfifo, mv, patch*, pathchk, pax, pwd, rm, rmdir, test, and touch.

Unsatisfied Requirements

Some graphical user interfaces offer more intuitive file manager components that allow file manipulation through the use of icons for novice users.
D.2.15 Locale Configuration

The standard utilities are affected by the various \texttt{LC_} variables to achieve locale-dependent operation: character classification, collation sequences, regular expressions and shell pattern matching, date and time formats, numeric formatting, and monetary formatting. When the \texttt{POSIX2_LOCALEDEF} option is supported, applications can provide their own locale definition files. The following utilities address user requirements in this area: \texttt{date}, \texttt{ed}, \texttt{ex*}, \texttt{find}, \texttt{grep}, \texttt{locale}, \texttt{localedef}, \texttt{more*}, \texttt{sed}, \texttt{sh}, \texttt{sort}, \texttt{tr}, \texttt{uniq}, and \texttt{vi*}.

The \texttt{iconv()}, \texttt{iconv_close()}, and \texttt{iconv_open()} functions are available to allow an application to convert character data between supported character sets.

The \texttt{gencat} utility and the \texttt{catopen()}, \texttt{catclose()}, and \texttt{catgets()} functions for message catalog manipulation are available on XSI-conformant systems.

Unsatisfied Requirements

Some aspects of multi-byte character and state-encoded character encodings have not yet been addressed. The C-language functions, such as \texttt{getopt()}, are generally limited to single-byte characters. The effect of the \texttt{LC_MESSAGES} variable on message formats is only suggested at this time.

D.2.16 Inter-User Communication

The following utilities address user requirements in this area: \texttt{cksum}, \texttt{mailx*}, \texttt{mesg*}, \texttt{patch*}, \texttt{pax}, \texttt{talk*}, \texttt{uudecode*}, \texttt{uuencode*}, \texttt{who*}, and \texttt{write*}.

The historical UUCP utilities are included on XSI-conformant systems.

Unsatisfied Requirements

None.

D.2.17 System Environment

The following utilities address user requirements in this area: \texttt{chgrp}, \texttt{chmod}, \texttt{chown}, \texttt{df*}, \texttt{du*}, \texttt{env}, \texttt{getconf}, \texttt{id}, \texttt{logger}, \texttt{logname}, \texttt{mesg*}, \texttt{newgrp*}, \texttt{ps*}, \texttt{stty}, \texttt{tput*}, \texttt{tty}, \texttt{umask}, \texttt{uname}, and \texttt{who*}.

The \texttt{closelog()}, \texttt{openlog()}, \texttt{setlogmask()}, and \texttt{syslog()} functions provide System Logging facilities on XSI-conformant systems; these are analogous to the \texttt{logger} utility.

Unsatisfied Requirements

None.

D.2.18 Printing

The following utilities address user requirements in this area: \texttt{pr} and \texttt{lpr}.

Unsatisfied Requirements

There are no features to control the formatting or scheduling of the print jobs.
D.2.19 Software Development

The following utilities address user requirements in this area: ar, asa, awk, c99, ctags*, fort77, getconf, getopts, lex, localedef, make, nm*, od, patch*, pax, strings*, strip, time*, and yacc.

The system(), popen(), pclose(), regcomp(), regexec(), regerror(), regfree(), fnmatch(), getopt(), glob(), globfree(), wordexp(), and wordfree() functions allow C-language programmers to access some of the interfaces used by the utilities, such as argument processing, regular expressions, and pattern matching.

The SCCS source-code control system utilities are available on systems supporting the XSI Development option.

Unsatisfied Requirements

There are no language-specific development tools related to languages other than C and FORTRAN. The C tools are more complete and varied than the FORTRAN tools. There is no data dictionary or other CASE-like development tools.

D.2.20 Future Growth

It is arguable whether or not all functionality to support applications is potentially within the scope of IEEE Std 1003.1-2001. As a simple matter of practicality, it cannot be. Areas such as graphics, application domain-specific functionality, windowing, and so on, should be in unique standards. As such, they are properly “Unsatisfied Requirements” in terms of providing fully conforming applications, but ones which are outside the scope of IEEE Std 1003.1-2001.

However, as the standards evolve, certain functionality once considered “exotic” enough to be part of a separate standard become common enough to be included in a core standard such as this. Realtime and networking, for example, have both moved from separate standards (with much difficult cross-referencing) into IEEE Std 1003.1 over time, and although no specific areas have been identified for inclusion in future revisions, such inclusions seem likely.

D.3 Profiling Considerations

This section offers guidance to writers of profiles on how the configurable options, limits, and optional behavior of IEEE Std 1003.1-2001 should be cited in profiles. Profile writers should consult the general guidance in POSIX.0 when writing POSIX Standardized Profiles.

The information in this section is an inclusive list of features that should be considered by profile writers. Subsetting of IEEE Std 1003.1-2001 should follow the Base Definitions volume of IEEE Std 1003.1-2001, Section 2.1.5.1, Subprofiling Considerations. A set of profiling options is described in Appendix E (on page 291).

D.3.1 Configuration Options

There are two set of options suggested by IEEE Std 1003.1-2001: those for POSIX-conforming systems and those for X/Open System Interface (XSI) conformance. The requirements for XSI conformance are documented in the Base Definitions volume of IEEE Std 1003.1-2001 and not discussed further here, as they superset the POSIX conformance requirements.
D.3.2 Configuration Options (Shell and Utilities)

There are three broad optional configurations for the Shell and Utilities volume of IEEE Std 1003.1-2001: basic execution system, development system, and user portability interactive system. The options to support these, and other minor configuration options, are listed in the Base Definitions volume of IEEE Std 1003.1-2001, Chapter 2, Conformance. Profile writers should consult the following list and the comments concerning user requirements addressed by various components in Section D.2 (on page 270).

POSIX2_UPE
The system supports the User Portability Utilities option.

This option is a requirement for a user portability interactive system. It is required frequently except for those systems, such as embedded realtime or dedicated application systems, that support little or no interactive time-sharing work by users or operators. XSI-conformant systems support this option.

POSIX2_SW_DEV
The system supports the Software Development Utilities option.

This option is required by many systems, even those in which actual software development does not occur. The `make` utility, in particular, is required by many application software packages as they are installed onto the system. If POSIX2_C_DEV is supported, POSIX2_SW_DEV is almost a mandatory requirement because of `ar` and `make`.

POSIX2_C_BIND
The system supports the C-Language Bindings option.

This option is required on some implementations developing complex C applications or on any system installing C applications in source form that require the functions in this option. The `system()` and `popen()` functions, in particular, are widely used by applications; the others are rather more specialized.

POSIX2_C_DEV
The system supports the C-Language Development Utilities option.

This option is required by many systems, even those in which actual C-language software development does not occur. The `c99` utility, in particular, is required by many application software packages as they are installed onto the system. The `lex` and `yacc` utilities are used less frequently.

POSIX2_FORT_DEV
The system supports the FORTRAN Development Utilities option.

As with C, this option is needed on any system developing or installing FORTRAN applications in source form.

POSIX2_FORT_RUN
The system supports the FORTRAN Runtime Utilities option.

This option is required for some FORTRAN applications that need the `asa` utility to convert Hollerith printing statement output. It is unknown how frequently this occurs.

POSIX2_LOCALEDEF
The system supports the creation of locales.

This option is needed if applications require their own customized locale definitions to operate. It is presently unknown whether many applications are dependent on this. However, the option is virtually mandatory for systems in which internationalized applications are developed.
XSI-conformant systems support this option.

POSIX2_PBS
The system supports the Batch Environment Services and Utilities option.

POSIX2_PBS_ACCOUNTING
The system supports the optional feature of accounting within the Batch Environment Services and Utilities option. It will be required in servers that implement the optional feature of accounting.

POSIX2_PBS_CHECKPOINT
The system supports the optional feature of checkpoint/restart within the Batch Environment Services and Utilities option.

POSIX2_PBS_LOCATE
The system supports the optional feature of locating batch jobs within the Batch Environment Services and Utilities option.

POSIX2_PBS_MESSAGE
The system supports the optional feature of sending messages to batch jobs within the Batch Environment Services and Utilities option.

POSIX2_PBS_TRACK
The system supports the optional feature of tracking batch jobs within the Batch Environment Services and Utilities option.

POSIX2_CHAR_TERM
The system supports at least one terminal type capable of all operations described in IEEE Std 1003.1-2001.

On systems with POSIX2_UPE, this option is almost always required. It was developed solely to allow certain specialized vendors and user applications to bypass the requirement for general-purpose asynchronous terminal support. For example, an application and system that was suitable for block-mode terminals, such as IBM 3270s, would not need this option.

XSI-conformant systems support this option.

D.3.3 Configurable Limits

Very few of the limits need to be increased for profiles. No profile can cite lower values.

POSIX2_BC_BASE_MAX
POSIX2_BC_DIM_MAX
POSIX2_BC_SCALE_MAX
POSIX2_BC_STRING_MAX
No increase is anticipated for any of these *bc* values, except for very specialized applications involving huge numbers.

POSIX2_COLL_WEIGHTS_MAX
Some natural languages with complex collation requirements require an increase from the default 2 to 4; no higher numbers are anticipated.

POSIX2_EXPR_NEST_MAX
No increase is anticipated.

POSIX2_LINE_MAX
This number is much larger than most historical applications have been able to use. At some future time, applications may be rewritten to take advantage of even larger values.
[POSIX2_RE_DUP_MAX]
No increase is anticipated.

[POSIX2_VERSION]
This is actually not a limit, but a standard version stamp. Generally, a profile should specify the Shell and Utilities volume of IEEE Std 1003.1-2001, Chapter 2, Shell Command Language by name in the normative references section, not this value.

D.3.4 Configuration Options (System Interfaces)

[NGROUPS_MAX]
A non-zero value indicates that the implementation supports supplementary groups.

This option is needed where there is a large amount of shared use of files, but where a certain amount of protection is needed. Many profiles\(^3\) are known to require this option; it should only be required if needed, but it should never be prohibited.

_POSIX_ADVISORY_INFO
The system provides advisory information for file management.

This option allows the application to specify advisory information that can be used to achieve better or even deterministic response time in file manager or input and output operations.

_POSIXASYNCHRONOUS_IO
The system provides concurrent process execution and input and output transfers.

This option was created to support historical systems that did not provide the feature. It should only be required if needed, but it should never be prohibited.

_POSIX_BARRIERS
The system supports barrier synchronization.

This option was created to allow efficient synchronization of multiple parallel threads in multi-processor systems in which the operation is supported in part by the hardware architecture.

_POSIX_CHOWN_RESTRICTED
The system restricts the right to “give away” files to other users.

This option should be carefully investigated before it is required. Some applications expect that they can change the ownership of files in this way. It is provided where either security or system account requirements cause this ability to be a problem. It is also known to be specified in many profiles.

_POSIX_CLOCK_SELECTION
The system supports the Clock Selection option.

This option allows applications to request a high resolution sleep in order to suspend a thread during a relative time interval, or until an absolute time value, using the desired clock. It also allows the application to select the clock used in a `pthread_cond_timedwait()` function call.

\(^3\) There are no formally approved profiles of IEEE Std 1003.1-2001 at the time of publication; the reference here is to various profiles generated by private bodies or governments.
Portability Considerations (Informative)

Profiling Considerations

11429 _POSIX_CPUTIME
The system supports the Process CPU-Time Clocks option.
11430 This option allows applications to use a new clock that measures the execution times of
11431 processes or threads, and the possibility to create timers based upon these clocks, for
11432 runtime detection (and treatment) of execution time overruns.

11434 _POSIX_FSYNC
The system supports file synchronization requests.
11435 This option was created to support historical systems that did not provide the feature.
11436 Applications that are expecting guaranteed completion of their input and output operations
11437 should require the _POSIX_SYNC_IO option. This option should never be prohibited.
11438 XSI-conformant systems support this option.

11440 _POSIX_IPV6
The system supports facilities related to Internet Protocol Version 6 (IPv6).
11441 This option was created to allow systems to transition to IPv6.

11443 _POSIX_JOB_CONTROL
Job control facilities are mandatory in IEEE Std 1003.1-2001.
11445 The option was created primarily to support historical systems that did not provide the
11446 feature. Many existing profiles now require it; it should only be required if needed, but it
11447 should never be prohibited. Most applications that use it can run when it is not present,
11448 although with a degraded level of user convenience.

11450 _POSIX_MAPPED_FILES
The system supports the mapping of regular files into the process address space.
11451 XSI-conformant systems support this option.
11452 Both this option and the Shared Memory Objects option provide shared access to memory
11453 objects in the process address space. The functions defined under this option provide the
11454 functionality of existing practice for mapping regular files. This functionality was deemed
11455 unnecessary, if not inappropriate, for embedded systems applications and, hence, is
11456 provided under this option. It should only be required if needed, but it should never be
11457 prohibited.

11458 _POSIX_MEMLOCK
The system supports the locking of the address space.
11459 This option was created to support historical systems that did not provide the feature. It
11460 should only be required if needed, but it should never be prohibited.

11462 _POSIX_MEMLOCK_RANGE
The system supports the locking of specific ranges of the address space.
11463 For applications that have well-defined sections that need to be locked and others that do
11464 not, IEEE Std 1003.1-2001 supports an optional set of functions to lock or unlock a range of
11465 process addresses. The following are two reasons for having a means to lock down a
11466 specific range:
11467 1. An asynchronous event handler function that must respond to external events in a
deterministic manner such that page faults cannot be tolerated
11468 2. An input/output “buffer” area that is the target for direct-to-process I/O, and the
overhead of implicit locking and unlocking for each I/O call cannot be tolerated
It should only be required if needed, but it should never be prohibited.

_POSIX_MEMORY_PROTECTION
The system supports memory protection.
XSI-conformant systems support this option.
The provision of this option typically imposes additional hardware requirements. It should never be prohibited.

_POSIX_PRIORITIZED_IO
The system provides prioritization for input and output operations.
The use of this option may interfere with the ability of the system to optimize input and output throughput. It should only be required if needed, but it should never be prohibited.

_POSIX_MESSAGE_PASSING
The system supports the passing of messages between processes.
This option was created to support historical systems that did not provide the feature. The functionality adds a high-performance XSI interprocess communication facility for local communication. It should only be required if needed, but it should never be prohibited.

_POSIX_MONOTONIC_CLOCK
The system supports the Monotonic Clock option.
This option allows real-time applications to rely on a monotonically increasing clock that does not jump backwards, and whose value does not change except for the regular ticking of the clock.

_POSIX_PRIORITY_SCHEDULING
The system provides priority-based process scheduling.
Support of this option provides predictable scheduling behavior, allowing applications to determine the order in which processes that are ready to run are granted access to a processor. It should only be required if needed, but it should never be prohibited.

_POSIX_REALTIME_SIGNALS
The system provides prioritized, queued signals with associated data values.
This option was created to support historical systems that did not provide the features. It should only be required if needed, but it should never be prohibited.

_POSIX_REGEXP

_POSIX_SAVED_IDS
Support for this feature is mandatory in IEEE Std 1003.1-2001.
Certain classes of applications rely on it for proper operation, and there is no alternative short of giving the application root privileges on most implementations that did not provide _POSIX_SAVED_IDS.

_POSIX_SEMAPHORES
The system provides counting semaphores.
This option was created to support historical systems that did not provide the feature. It should only be required if needed, but it should never be prohibited.

_POSIX_SHARED_MEMORY_OBJECTS
The system supports the mapping of shared memory objects into the process address space.
Both this option and the Memory Mapped Files option provide shared access to memory objects in the process address space. The functions defined under this option provide the functionality of existing practice for shared memory objects. This functionality was deemed appropriate for embedded systems applications and, hence, is provided under this option. It should only be required if needed, but it should never be prohibited.

_POSIX_SHELL
Support for the *sh* utility command line interpreter is mandatory in IEEE Std 1003.1-2001.

_POSIX_SPAWN
The system supports the spawn option.
This option provides applications with an efficient mechanism to spawn execution of a new process.

_POSIX_SPINLOCKS
The system supports spin locks.
This option was created to support a simple and efficient synchronization mechanism for threads executing in multi-processor systems.

_POSIX_SPORADIC_SERVER
The system supports the sporadic server scheduling policy.
This option provides applications with a new scheduling policy for scheduling aperiodic processes or threads in hard realtime applications.

_POSIX_SYNCHRONIZED_IO
The system supports guaranteed file synchronization.
This option was created to support historical systems that did not provide the feature. Applications that are expecting guaranteed completion of their input and output operations should require this option, rather than the File Synchronization option. It should only be required if needed, but it should never be prohibited.

_POSIX_THREADS
The system supports multiple threads of control within a single process.
This option was created to support historical systems that did not provide the feature. Applications written assuming a multi-threaded environment would be expected to require this option. It should only be required if needed, but it should never be prohibited.
XSI-conformant systems support this option.

_POSIX_THREAD_ATTR_STACKADDR
The system supports specification of the stack address for a created thread.
Applications may take advantage of support of this option for performance benefits, but dependence on this feature should be minimized. This option should never be prohibited.
XSI-conformant systems support this option.

_POSIX_THREAD_ATTR_STACKSIZE
The system supports specification of the stack size for a created thread.
Applications may require this option in order to ensure proper execution, but such usage limits portability and dependence on this feature should be minimized. It should only be required if needed, but it should never be prohibited.
XSI-conformant systems support this option.
Profiling Considerations  
Portability Considerations (Informative)

_POSIX_THREAD_PRIORITY_SCHEDULING
The system provides priority-based thread scheduling.
Support of this option provides predictable scheduling behavior, allowing applications to
determine the order in which threads that are ready to run are granted access to a processor.
It should only be required if needed, but it should never be prohibited.

_POSIX_THREAD_PRIO_INHERIT
The system provides mutual-exclusion operations with priority inheritance.
Support of this option provides predictable scheduling behavior, allowing applications to
determine the order in which threads that are ready to run are granted access to a processor.
It should only be required if needed, but it should never be prohibited.

_POSIX_THREAD_PRIO_PROTECT
The system supports a priority ceiling emulation protocol for mutual-exclusion operations.
Support of this option provides predictable scheduling behavior, allowing applications to
determine the order in which threads that are ready to run are granted access to a processor.
It should only be required if needed, but it should never be prohibited.

_POSIX_THREAD_PROCESS_SHARED
The system provides shared access among multiple processes to synchronization objects.
This option was created to support historical systems that did not provide the feature. It
should only be required if needed, but it should never be prohibited.
XSI-conformant systems support this option.

_POSIX_THREAD_SAFE_FUNCTIONS
The system provides thread-safe versions of all of the POSIX.1 functions.
This option is required if the Threads option is supported. This is a separate option because
thread-safe functions are useful in implementations providing other mechanisms for
concurrency. It should only be required if needed, but it should never be prohibited.
XSI-conformant systems support this option.

_POSIX_THREAD_SPORADIC_SERVER
The system supports the thread sporadic server scheduling policy.
Support for this option provides applications with a new scheduling policy for scheduling
aperiodic threads in hard realtime applications.

_POSIX_TIMEOUTS
The system provides timeouts for some blocking services.
This option was created to provide a timeout capability to system services, thus allowing
applications to include better error detection, and recovery capabilities.

_POSIX_TIMERS
The system provides higher resolution clocks with multiple timers per process.
This option was created to support historical systems that did not provide the features. This
option is appropriate for applications requiring higher resolution timestamps or needing to
control the timing of multiple activities. It should only be required if needed, but it should
never be prohibited.

_POSIX_TRACE
The system supports the Trace option.
This option was created to allow applications to perform tracing.

POSIX_TRACE_EVENT_FILTER
The system supports the Trace Event Filter option.
This option is dependent on support of the Trace option.

POSIX_TRACE_INHERIT
The system supports the Trace Inherit option.
This option is dependent on support of the Trace option.

POSIX_TRACE_LOG
The system supports the Trace Log option.
This option is dependent on support of the Trace option.

POSIX_TYPED_MEMORY_OBJECTS
The system supports the Typed Memory Objects option.
This option was created to allow realtime applications to access different kinds of physical memory, and allow processes in these applications to share portions of this memory.

D.3.5 Configurable Limits
In general, the configurable limits in the `<limits.h>` header defined in the Base Definitions volume of IEEE Std 1003.1-2001 have been set to minimal values; many applications or implementations may require larger values. No profile can cite lower values.

AIO_LISTIO_MAX
The current minimum is likely to be inadequate for most applications. It is expected that this value will be increased by profiles requiring support for list input and output operations.

AIO_MAX
The current minimum is likely to be inadequate for most applications. It is expected that this value will be increased by profiles requiring support for asynchronous input and output operations.

AIO_PRIO_DELTA_MAX
The functionality associated with this limit is needed only by sophisticated applications. It is not expected that this limit would need to be increased under a general-purpose profile.

ARG_MAX
The current minimum is likely to need to be increased for profiles, particularly as larger amounts of information are passed through the environment. Many implementations are believed to support larger values.

CHILD_MAX
The current minimum is suitable only for systems where a single user is not running applications in parallel. It is significantly too low for any system also requiring windows, and if _POSIX_JOB_CONTROL is specified, it should be raised.

CLOCKRES_MIN
It is expected that profiles will require a finer granularity clock, perhaps as fine as 1 μs, represented by a value of 1 000 for this limit.

DELAYTIMER_MAX
It is believed that most implementations will provide larger values.
For most applications and usage, the current minimum is adequate. Many implementations have a much larger value, but this should not be used as a basis for raising the value unless the applications to be used require it.

This is not actually a limit, but an implementation parameter. No profile should impose a requirement on this value.

For most purposes, the current minimum is adequate. Unless high-speed burst serial devices are used, it should be left as is.

See [MAX_CANON].

The current minimum should be adequate for most profiles.

The current minimum corresponds to the required number of process scheduling priorities. Many realtime practitioners believe that the number of message priority levels ought to be the same as the number of execution scheduling priorities.

Many implementations now support larger values, and many applications and users assume that larger names can be used. Many existing profiles also specify a larger value. Specifying this value will reduce the number of conforming implementations, although this might not be a significant consideration over time. Values greater than 255 should not be required.

The value selected will typically be 8 or larger.

The historically common value for this has been 20. Many implementations support larger values. If applications that use larger values are anticipated, an appropriate value should be specified.

This is not actually a limit, but an implementation parameter. No profile should impose a requirement on this value.

Historically, the minimum has been either 1024 or indefinite, depending on the implementation. Few applications actually require values larger than 256, but some users may create file hierarchies that must be accessed with longer paths. This value should only be changed if there is a clear requirement.

The current minimum is adequate for most applications. Historically, it has been larger. If applications that write single transactions larger than this are anticipated, it should be increased. Applications that write lines of text larger than this probably do not need it increased, as the text line is delimited by a <newline>.

This is actually not a limit, but a standard version stamp. Generally, a profile should specify IEEE Std 1003.1-2001 by a name in the normative references section, not this value.
Portability Considerations (Informative)  Profiling Considerations

[PTHREAD_DESTRUCTOR_ITERATIONS]
It is unlikely that applications will need larger values to avoid loss of memory resources.

[PTHREAD_KEYS_MAX]
The current value should be adequate for most profiles.

[PTHREAD_STACK_MIN]
This should not be treated as an actual limit, but as an implementation parameter. No profile should impose a requirement on this value.

[PTHREAD_THREADS_MAX]
It is believed that most implementations will provide larger values.

[RTSIG_MAX]
The current limit was chosen so that the set of POSIX.1 signal numbers can fit within a 32-bit field. It is recognized that most existing implementations define many more signals than are specified in POSIX.1 and, in fact, many implementations have already exceeded 32 signals (including the "null signal"). Support of \_POSIX_RTSIG_MAX additional signals may push some implementations over the single 32-bit word line, but is unlikely to push any implementations that are already over that line beyond the 64 signal line.

[SEM_NSEMS_MAX]
The current value should be adequate for most profiles.

[SEM_VALUE_MAX]
The current value should be adequate for most profiles.

[SSIZE_MAX]
This limit reflects fundamental hardware characteristics (the size of an integer), and should not be specified unless it is clearly required. Extreme care should be taken to assure that any value that might be specified does not unnecessarily eliminate implementations because of accidents of hardware design.

[STREAM_MAX]
This limit is very closely related to \_OPEN_MAX. It should never be larger than \_OPEN_MAX, but could reasonably be smaller for application areas where most files are not accessed through \_stdio. Some implementations may limit \_STREAM_MAX to 20 but allow \_OPEN_MAX to be considerably larger. Such implementations should be allowed for if the applications permit.

[TIMER_MAX]
The current limit should be adequate for most profiles, but it may need to be larger for applications with a large number of asynchronous operations.

[TTY_NAME_MAX]
This is not actually a limit, but an implementation parameter. No profile should impose a requirement on this value.

[TZNAME_MAX]
The minimum has been historically adequate, but if longer timezone names are anticipated (particularly such values as UTC−1), this should be increased.
### D.3.6 Optional Behavior

In IEEE Std 1003.1-2001, there are no instances of the terms unspecified, undefined, implementation-defined, or with the verbs “may” or “need not”, that the developers of IEEE Std 1003.1-2001 anticipate or sanction as suitable for profile or test method citation. All of these are merely warnings to conforming applications to avoid certain areas that can vary from system to system, and even over time on the same system. In many cases, these terms are used explicitly to support extensions, but profiles should not anticipate and require such extensions; future versions of IEEE Std 1003.1 may do so.
Rationale (Informative)

Part E:
Subprofiling Considerations

The Open Group
The Institute of Electrical and Electronics Engineers, Inc.
This section contains further information to satisfy the requirement that the project scope enable subprofiling of IEEE Std 1003.1-2001. The original intent was to have included a set of options similar to the “Units of Functionality” contained in IEEE Std 1003.13-1998. However, as the development of IEEE Std 1003.1-2001 continued, the standard developers felt it premature to fix these in normative text. The approach instead has been to include a general requirement in normative text regarding subprofiling and to include an informative section (here) containing a proposed set of subprofiling options.

E.1 Subprofiling Option Groups

The following Option Groups are defined to support profiling. Systems claiming support to IEEE Std 1003.1-2001 need not implement these options apart from the requirements stated in the Base Definitions volume of IEEE Std 1003.1-2001, Section 2.1.3, POSIX Conformance. These Option Groups allow profiles to subset the System Interfaces volume of IEEE Std 1003.1-2001 by collecting sets of related functions.
